Cisco IOS Security Command Reference

CONTENTS

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

Introduction

The *Cisco IOS Security Command Reference* contains commands that are used to configure Cisco IOS security features for your Cisco networking devices; specifically, it contains commands used to perform the following functions:

- Configure authentication, authorization, and accounting (AAA).
- Configure security server protocols such as RADIUS, TACACS+, and Kerberos.

Note TACACS and Extended TACACS commands are included in Cisco IOS Release 12.2 software for backward compatibility with earlier Cisco IOS releases; however, these commands are no longer supported and are not documented for this release.

Cisco recommends using only the TACACS+ security protocol with Release 12.1 and later of Cisco IOS software.

Table 1 identifies Cisco IOS software commands available to the different versions of TACACS. Although TACACS+ is enabled through AAA and uses commands specific to AAA, there are some commands that are common to TACACS, Extended TACACS, and TACACS+. TACACS and Extended TACACS commands that are not common to TACACS+ are not documented in this release.

Table 1 TACACS Command Comparison

Cisco IOS Command	TACACS	Extended TACACS	TACACS+
aaa accounting	—	—	**yes**
aaa authentication arap	—	—	**yes**
aaa authentication enable default	—	—	**yes**
aaa authentication login	—	—	**yes**
aaa authentication ppp	—	—	**yes**
aaa authorization	—	—	**yes**
aaa group server tacacs+	—	—	**yes**
aaa new-model	—	—	**yes**
arap authentication	—	—	**yes**
arap use-tacacs	**yes**	**yes**	—
enable last-resort	**yes**	**yes**	—

Table 1 TACACS Command Comparison (continued)

Cisco IOS Command	TACACS	Extended TACACS	TACACS+
enable use-tacacs	**yes**	**yes**	—
ip tacacs source-interface	**yes**	**yes**	**yes**
login authentication	—	—	**yes**
login tacacs	**yes**	**yes**	—
ppp authentication	**yes**	**yes**	**yes**
ppp use-tacacs	**yes**	**yes**	no
server	—	—	**yes**
tacacs-server administration	**—**	—	**yes**
tacacs-server directed-request	**yes**	**yes**	**yes**
tacacs-server dns-alias-lookup	**—**	**—**	yes
tacacs-server host	**yes**	**yes**	**yes**
tacacs-server key	—	—	**yes**
tacacs-server packet	**—**	**—**	yes
tacacs-server timeout	**yes**	**yes**	yes

- Configure the following traffic filtering and firewall features:
  - Context-Based Access Control (CBAC)
  - Intrusion Detection System (IDS)
  - Port to application mapping (PAM)
  - Reflexive access lists
  - TCP Intercept
- Configure IP Security (IPSec) and encryption features such as public key infrastructure (PKI) and Internet Key Exchange (IKE).
- Configure additional security features such as passwords and privileges, IP Security Options (IPSO), Unicast Reverse Path Forwarding (uRPF), secure shell (SSH), and AutoSecure.

For information on how to configure Cisco IOS security features and configuration examples using the commands in this book, refer to the *Cisco IOS Security Configuration Guide*.

Security Commands

aaa accounting

To enable authentication, authorization, and accounting (AAA) accounting of requested services for billing or security purposes when you use RADIUS or TACACS+, use the **aaa accounting** command in global configuration mode or template configuration mode. To disable AAA accounting, use the **no** form of this command.

aaa accounting {**auth-proxy** | **system** | **network** | **exec** | **connection** | **commands** *level* | **dot1x**} {**default** | *list-name* | **guarantee-first**} [**vrf** *vrf-name*] {**start-stop** | **stop-only** | **none**} [**broadcast**] {**radius** | **group** *group-name*}

no aaa accounting {**auth-proxy** | **system** | **network** | **exec** | **connection** | **commands** *level* | **dot1x**} {**default** | *list-name* | **guarantee-first**} [**vrf** *vrf-name*] {**start-stop** | **stop-only** | **none**} [**broadcast**] {**radius** | **group** *group-name*}

Template Configuration Mode

aaa accounting {**delay-start** | **send stop-record authentication**} {**failure** | **success** **remote-server**}

no aaa accounting {**delay-start** | **send stop-record authentication**} {**failure** | **success** **remote-server**}

Syntax Description

auth-proxy	Provides information about all authenticated-proxy user events.
system	Performs accounting for all system-level events not associated with users, such as reloads. **Note** When system accounting is used and the accounting server is unreachable at system startup time, the system will not be accessible for approximately two minutes.
network	Runs accounting for all network-related service requests, including Serial Line Internet Protocol (SLIP), PPP, PPP Network Control Protocols (NCPs), and AppleTalk Remote Access Protocol (ARAP).
exec	Runs accounting for the EXEC shell session.
connection	Provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler and disassembler (PAD), and rlogin.
commands *level*	Runs accounting for all commands at the specified privilege level. Valid privilege level entries are integers from 0 through 15.
dot1x	Provides information about all IEEE 802.1x-related user events.
default	Uses the listed accounting methods that follow this keyword as the default list of methods for accounting services.

list-name	Character string used to name the list of at least one of the following accounting methods: • **group radius**—Uses the list of all RADIUS servers for authentication as defined by the **aaa group server radius** command. • **group tacacs+**—Uses the list of all TACACS+ servers for authentication as defined by the **aaa group server tacacs+** command. • **group** *group-name*—Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group *group-name* argument.
guarantee-first	Guarantees system accounting as the first record.
vrf *vrf-name*	(Optional) Specifies a virtual routing and forwarding (VRF) configuration. • VRF is used *only* with system accounting.
start-stop	Sends a “start” accounting notice at the beginning of a process and a “stop” accounting notice at the end of a process. The “start” accounting record is sent in the background. The requested user process begins regardless of whether the “start” accounting notice was received by the accounting server.
stop-only	Sends a “stop” accounting record for all cases including authentication failures regardless of whether the **aaa accounting send stop-record authentication failure** command is configured.
none	Disables accounting services on this line or interface.
broadcast	(Optional) Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.
radius	Runs the accounting service for RADIUS.

group *group-name*	Specifies the accounting method list. Enter at least one of the following keywords: • **auth-proxy**—Creates a method list to provide accounting information about all authenticated hosts that use the authentication proxy service. • **commands**—Creates a method list to provide accounting information about specific, individual EXEC commands associated with a specific privilege level. • **connection**—Creates a method list to provide accounting information about all outbound connections made from the network access server. • **exec**—Creates a method list to provide accounting records about user EXEC terminal sessions on the network access server, including username, date, and start and stop times. • **network**—Creates a method list to provide accounting information for SLIP, PPP, NCPs, and ARAP sessions. • **resource**—Creates a method list to provide accounting records for calls that have passed user authentication or calls that failed to be authenticated. • **tunnel**—Creates a method list to provide accounting records (Tunnel-Start, Tunnel-Stop, and Tunnel-Reject) for virtual private dialup network (VPDN) tunnel status changes. • **tunnel-link**—Creates a method list to provide accounting records (Tunnel-Link-Start, Tunnel-Link-Stop, and Tunnel-Link-Reject) for VPDN tunnel-link status changes.
delay-start	Delays PPP network start records until peer IP address is known.
send	Sends records to the accounting server.
stop-record	Generates stop records for a specified event.
authentication	Generates stop records for authentication.
failure	Generates stop records for authentication failures.
success	Generates stop records for authenticated users.
remote-server	Specifies that the users are successfully authenticated through access-accept, by a remote AAA server.

Defaults

AAA accounting is disabled.

Command Modes

Global configuration (config)
Template configuration (config-template)

Command History

Release	Modification
12.0(5)T	This command was modified. The Group server support was added.
12.1(1)T	This command was modified. The **broadcast** keyword was added on the Cisco AS5300 and Cisco AS5800 universal access servers.
12.1(5)T	This command was modified. The **auth-proxy** keyword was added.

Release	Modification
12.2(1)DX	This command was modified. The **vrf** keyword and *vrf-name* argument were added on the Cisco 7200 series and Cisco 7401ASR series routers.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(13)T	This command was modified. The **vrf** keyword and *vrf-name* argument were integrated into Cisco IOS Release 12.2(13)T.
12.2(15)B	This command was modified. The tunnel and tunnel-link accounting methods were introduced.
12.3(4)T	This command was modified. The tunnel and tunnel-link accounting methods were integrated into Cisco IOS Release 12.3(4)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11)T	The **dot1x** keyword was integrated into Cisco IOS Release 12.4(11)T.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6. The **radius** keyword was added.

Usage Guidelines

General Information

Use the **aaa accounting** command to enable accounting and to create named method lists that define specific accounting methods on a per-line or per-interface basis. You must enable AAA services using the **aaa new-model** global configuration command.

Table 1 contains descriptions of keywords for AAA accounting methods.

Table 1 aaa accounting Methods

Keyword	Description
group radius	Uses the list of all RADIUS servers for authentication as defined by the **aaa group server radius** command.
group tacacs+	Uses the list of all TACACS+ servers for authentication as defined by the **aaa group server tacacs+** command.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group *group-name* argument.

In Table 1, the **group radius** and **group tacacs+** methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs-server host** commands to configure the host servers. Use the **aaa group server radius** and **aaa group server tacacs+** commands to create a named group of servers.

Cisco IOS software supports the following two methods of accounting:

- RADIUS—The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.

- TACACS+—The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.

Method lists for accounting define the way accounting will be performed. Named accounting method lists enable you to designate a particular security protocol to be used on specific lines or interfaces for particular types of accounting services. Create a list by entering values for the *list-name* argument where *list-name* is any character string used to name this list (excluding the names of methods, such as RADIUS or TACACS+) and method list keywords to identify the methods to be tried in sequence as given.

If the **aaa accounting** command for a particular accounting type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines (where this accounting type applies) except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, then no accounting takes place.

Note System accounting does not use named accounting lists; you can define the default list only for system accounting.

For minimal accounting, include the **stop-only** keyword to send a "stop" accounting record for all cases including authentication failures. For more accounting, you can include the **start-stop** keyword, so that RADIUS or TACACS+ sends a "start" accounting notice at the beginning of the requested process and a "stop" accounting notice at the end of the process. Accounting is stored only on the RADIUS or TACACS+ server. The **none** keyword disables accounting services for the specified line or interface.

To specify an accounting configuration for a particular VRF, specify a default system accounting method list, and use the **vrf** keyword and *vrf-name* argument. System accounting does not have knowledge of VRF unless specified.

When AAA accounting is activated, the network access server monitors either RADIUS accounting attributes or TACACS+ AV pairs pertinent to the connection, depending on the security method you have implemented. The network access server reports these attributes as accounting records, which are then stored in an accounting log on the security server. For a list of supported RADIUS accounting attributes, see the appendix "RADIUS Attributes" in the*Cisco IOS Security Configuration Guide*. For a list of supported TACACS+ accounting AV pairs, see the appendix "TACACS+ Attribute-Value Pairs" in the *Cisco IOS Security Configuration Guide*.

Note The **aaa accounting** command cannot be used with TACACS or extended TACACS.

Cisco Service Selection Gateway Broadcast Accounting

To configure Cisco Service Selection Gateway (SSG) broadcast accounting, use ssg_broadcast_accounting for the *list-name* argument. For more information about configuring SSG, see the chapter "Configuring Accounting for SSG" in the *Cisco IOS Service Selection Gateway Configuration Guide*, Release 12.4.

Layer 2 LAN Switch Port

You must configure the RADIUS server to perform accounting tasks, such as logging start, stop, and interim-update messages and time stamps. To turn on these functions, enable logging of "Update/Watchdog packets from this AAA client" in your RADIUS server Network Configuration tab. Next, enable "CVS RADIUS Accounting" in your RADIUS server System Configuration tab.

You must enable AAA before you can enter the **aaa accounting** command. To enable AAA and 802.1X (port-based authentication), use the following global configuration mode commands:

- **aaa new-model**
- **aaa authentication dot1x default group radius**
- **dot1x system-auth-control**

Use the **show radius statistics** command to display the number of RADIUS messages that do not receive the accounting response message.

Use the **aaa accounting system default start-stop group radius** command to send "start" and "stop" accounting records after the router reboots. The "start" record is generated while the router is booted and the stop record is generated while the router is reloaded.

The router generates a "start" record to reach the AAA server. If the AAA server is not reachable, the router retries sending the packet four times. The retry mechanism is based on the exponential backoff algorithm. If there is no response from the AAA server, the request will be dropped.

Establishing a Session with a Router if the AAA Server is Unreachable

The **aaa accounting system guarantee-first** command guarantees system accounting as the first record, which is the default condition. In some situations, users may be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than three minutes.

To establish a console or telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

Note Entering the **no aaa accounting system guarantee-first** command is not the only condition by which the console or telnet session can be started. For example, if the privileged EXEC session is being authenticated by TACACS and the TACACS server is not reachable, then the session cannot start.

Examples

The following example shows how to define a default command accounting method list, where accounting services are provided by a TACACS+ security server, set for privilege level 15 commands with a stop-only restriction.

```
aaa accounting commands 15 default stop-only group tacacs+
```

The following example shows how to defines a default auth-proxy accounting method list, where accounting services are provided by a TACACS+ security server with a start-stop restriction. The **aaa accounting** command activates authentication proxy accounting.

```
aaa new-model
aaa authentication login default group tacacs+
aaa authorization auth-proxy default group tacacs+
aaa accounting auth-proxy default start-stop group tacacs+
```

The following example shows how to define a default system accounting method list, where accounting services are provided by RADIUS security server "server1" with a start-stop restriction. The **aaa accounting** command specifies accounting for VRF "vrf1."

```
aaa accounting system default vrf vrf1 start-stop group server1
```

The following example shows how to define a default IEEE 802.1x accounting method list, where accounting services are provided by a RADIUS server. The **aaa accounting** command activates IEEE 802.1x accounting.

```
aaa new model
aaa authentication dot1x default group radius
aaa authorization dot1x default group radius
aaa accounting dot1x default start-stop group radius
```

The following example shows how to enable network accounting and send tunnel and tunnel-link accounting records to the RADIUS server. (Tunnel-Reject and Tunnel-Link-Reject accounting records are automatically sent if either start or stop records are configured.)

```
aaa accounting network tunnel start-stop group radius
aaa accounting network session start-stop group radius
```

The following example shows how to delay PPP Network start record until peer IP address is known:

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# template name
Router(config-template)# aaa accounting delay-start
```

Related Commands

Command	Description
aaa authentication dot1x	Specifies one or more AAA methods for use on interfaces running IEEE 802.1X.
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict user access to a network.
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
aaa group server tacacs+	Groups different server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
auto command	Configures the system to automatically execute a specific EXEC command when it connects to a port.
dot1x system-auth-control	Enables port-based authentication.
radius-server host	Specifies a RADIUS server host.
show radius statistics	Displays the RADIUS statistics for accounting and authentication packets.
tacacs-server host	Specifies a TACACS+ server host.

aaa accounting (IKEv2 profile)

To enable AAA accounting for IPsec sessions, use the **aaa accounting** command in IKEv2 profile configuration mode. To disable AAA accounting, use the **no** form of this command.

aaa accounting [**psk** | **cert** | **eap**] *list-name*

no aaa accounting [**psk** | **cert** | **eap**] *list-name*

Syntax Description

psk	(Optional) Specifies a method list if the authentication method preshared key.
cert	(Optional) Specifies a method list if the authentication method is certificate based.
eap	(Optional) Specifies a method list if the authentication method is Extensible Authentication Protocol (EAP).
list-name	Name of the AAA list.

Command Default

AAA accounting is disabled.

Command Modes

IKEv2 profile configuration (config-ikev2-profile)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use the **aaa accounting** command to enable and specify the method list for AAA accounting for IPsec sessions. The **aaa accounting** command can be specific to an authentication method or common to all authentication methods, but not both at the same time. If no method list is specified, the list is common across authentication methods.

Examples

The following example defines an AAA accounting configuration common to all authentication methods:

```
Router(config-ikev2-profile)# aaa accounting common-list1
```

The following example configures an AAA accounting for each authentication method:

```
Router(config-ikev2-profile)# aaa accounting psk psk-list1
Router(config-ikev2-profile)# aaa accounting cert cert-list1
Router(config-ikev2-profile)# aaa accounting eap eap-list1
```

Related Commands

Command	Description
crypto ikev2 profile	Defines an IKEv2 profile.

aaa accounting connection h323

To define the accounting method list H.323 using RADIUS as a method with either **stop-only** or **start-stop** accounting options, use the **aaa accounting connection h323** command in global configuration mode. To disable the use of this accounting method list, use the **no** form of this command.

aaa accounting connection h323 {**stop-only** | **start-stop** | **none**} [**broadcast**] **group** *groupname*

no aaa accounting connection h323 {**stop-only** | **start-stop** | **none**} [**broadcast**] **group** *groupname*

Syntax Description

stop-only	Sends a "stop" accounting notice at the end of the requested user process.
start-stop	Sends a "start" accounting notice at the beginning of a process and a "stop" accounting notice at the end of a process. The "start" accounting record is sent in the background. The requested user process begins regardless of whether the "start" accounting notice was received by the accounting server.
none	Disables accounting services on this line or interface.
broadcast	(Optional) Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.
group *groupname*	Specifies the server group to be used for accounting services. The following are valid server group names: • *string*: Character string used to name a server group. • **radius**: Uses list of all RADIUS hosts. • **tacacs+**: Uses list of all TACACS+ hosts.

Defaults

No accounting method list is defined.

Command Modes

Global configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command creates a method list called h323 and is applied by default to all voice interfaces if the **gw-accounting h323** command is also activated.

Examples

The following example enables authentication, authorization, and accounting (AAA) services, gateway accounting services, and defines a connection accounting method list (h323). The h323 accounting method lists specifies that RADIUS is the security protocol that will provide the accounting services, and that the RADIUS service will track start-stop records.

```
aaa new model
gw-accounting h323
aaa accounting connection h323 start-stop group radius
```

Related Commands

Command	Description
gw-accounting	Enables the accounting method for collecting call detail records.

aaa accounting delay-start

To delay generation of accounting "start" records until the user IP address is established, use the **aaa accounting delay-start** command in global configuration mode. To disable this functionality, use the **no** form of this command.

aaa accounting delay-start [**all**] [**vrf** *vrf-name*]

no aaa accounting delay-start [**all**] [**vrf** *vrf-name*]

Syntax Description

all	(Optional) Extends the delay of accounting "start" records to all Virtual Route Forwarding (VRF) and non-VRF users.
vrf *vrf-name*	(Optional) Extends the delay of accounting "start" records to individual VRF users.

Defaults

Accounting records are not delayed.

Command Modes

Global configuration

Command History

Release	Modification
12.1	This command was introduced.
12.2(1)DX	The **vrf** keyword and *vrf-name* argument were introduced on the Cisco 7200 series and Cisco 7401ASR.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(13)T	The **vrf** keyword and *vrf-name* argument were integrated into Cisco IOS Release 12.2(13)T.
12.3(1)	The **all** keyword was added.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Use the **aaa accounting delay-start** command to delay generation of accounting "start" records until the IP address of the user has been established. Use the **vrf** *vrf-name* keyword and argument to delay accounting "start" records for individual Virtual Private Network (VPN) routing and forwarding (VRF) users or use the **all** keyword for all VRF and non-VRF users.

Note The **aaa accounting delay-start** command applies only to non-VRF users. If you have a mix of VRF and non-VRF users, configure either **aaa accounting delay-start** (for non-VRF users) or **aaa accounting delay-start vrf** {*vrf-name*} (for VRF users) or **aaa accounting delay-start all** (for all VRF and non-VRF users).

Examples

The following example shows how to delay accounting "start" records until the IP address of the user is established:

```
aaa new-model
aaa authentication ppp default radius
aaa accounting network default start-stop group radius
aaa accounting delay-start
radius-server host 172.16.0.0 non-standard
radius-server key rad123
```

The following example shows that accounting "start" records are to be delayed to all VRF and non-VRF users:

```
aaa new-model
aaa authentication ppp default radius
aaa accounting network default start-stop group radius
aaa accounting delay-start all
radius-server host 172.16.0.0 non-standard
radius-server key rad123
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict user access to a network.
aaa new-model	Enables the AAA access control model.
radius-server host	Specifies a RADIUS server host.
tacacs-server host	Specifies a TACACS+ server host.

aaa accounting gigawords

To enable authentication, authorization, and accounting (AAA) 64-bit, high-capacity counters, use the **aaa accounting gigawords** command in global configuration mode. To disable the counters, use the **no** form of this command. (Note that gigaword support is automatically configured unless you unconfigure it using the **no** form of the command.)

aaa accounting gigawords

no aaa accounting gigawords

Syntax Description

This command has no arguments or keywords.

Defaults

If this command is not configured, the 64-bit, high-capacity counters that support RADIUS attributes 52 and 53 are automatically enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13.7)T	This command was introduced.

Usage Guidelines

The AAA high-capacity counter process takes approximately 8 percent CPU memory for 24,000 (24 K) sessions running under steady state.

If you have entered the **no** form of this command to turn off the 64-bit counters and you want to reenable them, you will need to enter the **aaa accounting gigawords** command. Also, once you have entered the **no** form of the command, it takes a reload of the router to actually disable the use of the 64-bit counters.

Note The **aaa accounting gigawords** command does not show up in the running configuration unless the **no** form of the command is used in the configuration.

Examples

The following example shows that the AAA 64-bit counters have been disabled:

```
no aaa accounting gigawords
```

aaa accounting include auth-profile

To include authorization profile attributes for the AAA accounting records, use the **aaa accounting include auth-profile** command in global configuration mode. To disable the authorization profile, use the **no** form of this command.

aaa accounting include auth-profile {**delegated-ipv6-prefix** | **framed-ip-address** | **framed-ipv6-prefix**}

no aaa accounting include auth-profile {**delegated-ipv6-prefix** | **framed-ip-address** | **framed-ipv6-prefix**}

Syntax Description

delegated-ipv6-prefix	Includes the delegated-IPv6-Prefix profile in accounting records.
framed-ip-address	Includes the Framed-IP-Address profile in accounting records.
framed-ipv6-prefix	Includes the Framed-IPv6-Prefix profile in accounting records.

Command Default

authorization profile is included in the aaa accounting records.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced in a release earlier than Cisco IOS Release 15.1(1)T.

Usage Guidelines

The **aaa accounting include auth-profile** command can also be used for a dual-stack session if the negotiation between IPv4 and IPv6 is successful.

Examples

The following example shows how to include the delegated-IPv6-Prefix profile in the AAA accounting records:

```
Router(config)# aaa accounting include auth-profile delegated-ipv6-prefix
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.

aaa accounting-list

To enable authentication, authorization, and accounting (AAA) accounting when you are using RADIUS for Secure Socket Layer Virtual Private Network (SSL VPN) sessions, use the **aaa accounting-list** command in global configuration mode. To disable the AAA accounting, use the **no** form of this command.

aaa accounting-list *aaa-list*

no aaa accounting-list *aaa-list*

Syntax Description

aaa-list	Name of the AAA accounting list that has been configured under global configuration.

Defaults

AAA accounting is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Before configuring this command, ensure that the AAA accounting list has already been configured under global configuration.

Examples

The following example shows that AAA accounting has been configured for an SSL VPN session:

```
Router (config)# aaa accounting-list aaalist1
```

Related Commands

Command	Description
aaa accounting network SSLVPN start-stop group radius	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.

aaa accounting jitter maximum

To provide an interval of time between records so that the AAA server does not get overwhelmed by a constant stream of records, use the **aaa accounting jitter maximum** command in global configuration mode. To return to the default interval, use the **no** form of this command.

aaa accounting jitter maximum *max-value*

no aaa accounting jitter

Syntax Description

jitter-value	Allows the maximum jitter value from 0 to 2147483 seconds to be set in periodic accounting. The value 0 turns off jitter.

Defaults

Jitter is set to 300 seconds (5 minutes) by default.

Command Modes

Global configuration

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

If certain applications require that periodic records be sent at exact intervals, disable jitter by setting it to 0.

Examples

The following example sets the maximum jitter value to 20 seconds:

```
aaa accounting jitter maximum 20
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.

aaa accounting nested

To specify that NETWORK records be generated, or nested, within EXEC "start" and "stop" records for PPP users who start EXEC terminal sessions, use the **aaa accounting nested** command in global configuration mode. To allow the sending of records for users with a NULL username, use the **no** form of this command.

aaa accounting nested [**suppress stop**]

no aaa accounting nested [**suppress stop**]

Syntax Description

suppress stop	(Optional) Prevents sending a multiple set of records (one from EXEC and one from PPP) for the same client.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11)T	The **suppress** and **stop** keywords were added.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa accounting nested** command when you want to specify that NETWORK records be nested within EXEC "start" and "stop" records, such as for PPP users who start EXEC terminal sessions. In some cases, such as billing customers for specific services, is can be desirable to keep NETWORK "start" and "stop" records together, essentially nesting them within the framework of the EXEC "start" and "stop" messages. For example, if you dial in using PPP, you can create the following records: EXEC-start, NETWORK-start, EXEC-stop, and NETWORK-stop. By using the **aaa accounting nested** command to generate accounting records, NETWORK-stop records follow NETWORK-start messages: EXEC-start, NETWORK-start, NETWORK-stop, EXEC-stop.

Use the **aaa accounting nested suppress stop** command to suppress the sending of EXEC accounting records and to send only PPP accounting records.

Examples

The following example enables nesting of NETWORK accounting records for user sessions:

```
Router(config)# aaa accounting nested
```

The following example disables nesting of EXEC accounting records for user sessions:

```
Router(config)# aaa accounting nested suppress stop
```

aaa accounting redundancy

To set the Accounting, Authorization, and Authentication (AAA) platform redundancy accounting behavior, use the **aaa accounting redundancy** command in global configuration mode. To disable the accounting behavior, use the **no** form of this command.

aaa accounting redundancy {**best-effort-reuse** | **new-session**}

no aaa accounting redundancy{**best-effort-reuse** | **new-session**}

Cisco 1000 Series Router

aaa accounting redundancy {**best-effort-reuse** | **new-session** | **suppress system-records**}

no aaa accounting redundancy {**best-effort-reuse** | **new-session** | **suppress system-records**}

Syntax Description

best-effort-reuse	Specifies accounting redundant session as existing session on switchover.
new-session	Specifies accounting redundant session as a new session on switchover.
suppress	Suppresess specific records on switchover.
system-records	Generates system records on switchover

Command Default

By default, the redundant session is set as a new session on switchover.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0 (1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M
Cisco IOS XE Release 2.6	This command was integrated on Cisco IOS XE Release 2.6.

Usage Guidelines

Use the **aaa accounting redundancy** command to specify the AAA platform redundancy accounting behavior. This command also enables you to track and suppress the redundant sessions or existing sessions on switchover. You can use the no form of this command or use the **best-effort-use** or **new-session** keywords to set them to their respective accounting behaviors.

Examples

The following example shows how to set the AAA platform redundancy accounting behavior to track redundant session as existing session on switchover:

```
Router(config)# aaa accounting redundancy best-effort-reuse
```

Related Commands

Command	Description
aaa authentication dot1x	Specifies one or more authentication, authorization, and accounting (AAA) methods for use on interfaces running IEEE 802.1X
aaa accounting delay-start	Specifies delay generation of accounting "start" records until the user IP address is established.

aaa accounting resource start-stop group

To enable full resource accounting, which will generate both a "start" record at call setup and a "stop" record at call termination, use the **aaa accounting resource start-stop group** command in global configuration mode. To disable full resource accounting, use the **no** form of this command.

aaa accounting resource *method-list* **start-stop** [**broadcast**] **group** *groupname*

no aaa accounting resource *method-list* **start-stop** [**broadcast**] **group** *groupname*

Syntax Description

method-list	Method used for accounting services. Use one of the following options: • **default**: Uses the listed accounting methods that follow this argument as the default list of methods for accounting services. • *string*: Character string used to name the list of accounting methods.
broadcast	(Optional) Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.
groupname	Specifies the server group to be used for accounting services. The following are valid server group names: • *string*: Character string used to name a server group. • **radius**: Uses list of all RADIUS hosts. • **tacacs+**: Uses list of all TACACS+ hosts.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa accounting resource start-stop group** command to send a "start" record at each call setup followed with a corresponding "stop" record at the call disconnect. There is a separate "call setup-call disconnect "start-stop" accounting record tracking the progress of the resource connection to the device, and a separate "user authentication start-stop accounting" record tracking the user management progress. These two sets of accounting records are interlinked by using a unique session ID for the call.

You may want to use this command to manage and monitor wholesale customers from one source of data reporting, such as accounting records.

Note Sending "start-stop" records for resource allocation along with user "start-stop" records during user authentication can lead to serious performance issues and is discouraged unless absolutely required.

All existing AAA accounting method list and server group options are made available to this command.

Examples

The following example shows how to configure resource accounting for "start-stop" records:

```
aaa new-model
aaa authentication login AOL group radius local
aaa authentication ppp default group radius local
aaa authorization exec AOL group radius if-authenticated
aaa authorization network default group radius if-authenticated
aaa accounting exec default start-stop group radius
aaa accounting network default start-stop group radius
aaa accounting resource default start-stop group radius
```

Related Commands

Command	Description
aaa accounting start-stop failure	Enables resource failure stop accounting support, which will only generate a stop record at any point prior to user authentication if a call is terminated.

aaa accounting resource stop-failure group

To enable resource failure stop accounting support, which will generate a "stop" record at any point prior to user authentication only if a call is terminated, use the **aaa accounting resource stop-failure group** command in global configuration mode. To disable resource failure stop accounting, use the **no** form of this command.

aaa accounting resource *method-list* **stop-failure** [**broadcast**] **group** *groupname*

no aaa accounting resource *method-list* **stop-failure** [**broadcast**] **group** *groupname*

Syntax Description

method-list	Method used for accounting services. Use one of the following options: • **default**: Uses the listed accounting methods that follow this argument as the default list of methods for accounting services. • *string*: Character string used to name the list of accounting methods.
broadcast	(Optional) Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.
groupname	Group to be used for accounting services. Use one of the following options: • *string*: Character string used to name a server group. • **radius**: Uses list of all RADIUS hosts. • **tacacs+**: Uses list of all TACACS+ hosts.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa accounting resource stop-failure group** command to generate a "stop" record for any calls that do not reach user authentication; this function creates "stop" accounting records for the moment of call setup. All calls that pass user authentication will behave as before; that is, no additional accounting records will be seen.

All existing authentication, authorization, and accounting (AAA) accounting method list and server group options are made available to this command.

Examples

The following example shows how to configure "stop" accounting records from the moment of call setup:

```
aaa new-model
aaa authentication login AOL group radius local
aaa authentication ppp default group radius local
aaa authorization exec AOL group radius if-authenticated
aaa authorization network default group radius if-authenticated
aaa accounting exec default start-stop group radius
aaa accounting network default start-stop group radius
aaa accounting resource default stop-failure group radius
```

Related Commands

Command	Description
aaa accounting resource start-stop group	Enables full resource accounting, which will generate both a "start" record at call setup and a "stop" record at call termination.

aaa accounting send stop-record always

To generate authentication, authorization, and accounting (AAA) stop records regardless of whether a start record was sent earlier, use the **aaa accounting send stop-record always** command in global configuration mode. To stop generating the AAA stop records, use the **no** form of this command.

aaa accounting send stop-record always

no aaa accounting send stop-record always

Syntax Description

This command has no arguments or keywords.

Command Default

The stop records are not generated.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

If you configure the **aaa accounting send stop-record always** command on a AAA server and Network Control Protocol (NCP) timeout occurs, then the stop record will be sent to the AAA server regardless of whether a start record was sent earlier.

Examples

The following example shows how to generate AAA stop records constantly if a start record is not sent:

```
Router> enable
Router# configure terminal
Router(config)# aaa accounting send stop-record always
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict user access to a network.

aaa accounting send stop-record authentication

To refine generation of authentication, authorization, and accounting (AAA) accounting "stop" records, use the **aaa accounting send stop-record authentication** command in global configuration mode. To end generation of accounting stop records, use the **no** form of this command that is appropriate.

aaa accounting send stop-record authentication {**failure** | **success remote-server**} [**vrf** *vrf-name*]

Failed Calls: End Accounting Stop Record Generation

no aaa accounting send stop-record authentication failure [**vrf** *vrf-name*]

Successful Calls: End Accounting Stop Record Generation

no aaa accounting send stop-record authentication success remote-server [**vrf** *vrf-name*]

Syntax Description

failure	Used to generate accounting "stop" records for calls that fail to authenticate at login or during session negotiation.
success	• Used to generate accounting "stop" records for calls that have been authenticated by the remote AAA server. A "stop" record will be sent after the call is terminated. • Used to generate accounting "stop" records for calls that have *not* been authenticated by the remote AAA server. A"stop" record will be sent if one of the following states is true: – The start record has been sent. – The call is successfully established and is terminated with the "stop-only" configuration.
remote-server	Used to specify that the remote server is to be used.
vrf *vrf-name*	(Optional) Used to enable this feature for a particular Virtual Private Network (VPN) routing and forwarding configuration.

Command Default

Accounting "stop" records are sent only if one of the following is true:

- A start record has been sent.
- The call is successfully established with the "stop-only" configuration and is terminated.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(1)DX	The **vrf** keyword and *vrf-name* argument were introduced on the Cisco 7200 series and Cisco 7401ASR.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.

Release	Modification
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(13)T	The **vrf** keyword and *vrf-name* argument were added.
12.4(2)T	The **success** and **remote-server** keywords were added.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

When the **aaa accounting** command is activated, by default the Cisco IOS software does not generate accounting records for system users who fail login authentication or who succeed in login authentication but fail PPP negotiation for some reason. The **aaa accounting** command can be configured to sent a "stop" record using either the **start-stop** keyword or the **stop-only** keyword.

When the **aaa accounting** command is issued with either the **start-stop** keyword or the **stop-only** keyword, the "stop" records can be further configured with the **aaa accounting send stop-record authentication** command. The failure and success keywords are mutually exclusive. If you have the **aaa accounting send stop-record authentication** command enabled with the **failure** keyword and then enable the same command with the **success** keyword, accounting stop records will no longer be generated for failed calls. Accounting stop records are sent for successful calls only until you issue either of the following commands:

- **no aaa accounting send stop-record authentication success remote-server**
- **aaa accounting send stop-record authentication failure**

When using the **failure** keyword, a "stop" record will be sent for calls that are rejected during authentication.

When using the **success** keyword, a "stop" record will be sent for calls that meet one of the following criteria:

- Calls that are authenticated by a remote AAA server when the call is terminated.
- Calls that are not authenticated by a remote AAA server and the start record has been sent.
- Calls that are successfully established and then terminated with the "stop-only" **aaa accounting** configuration.

Use the **vrf** *vrf-name* keyword and argument to generate accounting "stop" records per VPN routing and forwarding configuration.

Note The **success** and **remote-server** keywords are not available in Cisco IOS Release 12.2SX.

Examples

The following example shows how to generate "stop" records for users who fail to authenticate at login or during session negotiation:

```
aaa accounting send stop-record authentication failure
```

The following example shows "start" and "stop" records being sent for a successful call when the **aaa accounting send stop-record authentication** command is issued with the **failure** keyword:

```
Router# show running-config | include aaa
.
.
.
aaa new-model
aaa authentication ppp default group radius
aaa authorization network default local
aaa accounting send stop-record authentication failure
aaa accounting network default start-stop group radius
.

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict user access to a network.

aaa accounting session-duration ntp-adjusted

To calculate RADIUS attribute 46, Acct-Sess-Time, on the basis of the Network Time Protocol (NTP) clock time, use the **aaa accounting session-duration ntp-adjusted** command in global configuration mode. To disable the calculation that was configured on the basis of the NTP clock time, use the **no** form of this command.

aaa accounting session-duration ntp-adjusted

no aaa accounting session-duration ntp-adjusted

Syntax Description

This command has no arguments or keywords.

Defaults

If this command is not configured, RADIUS attribute 46 is calculated on the basis of the 64-bit monotonically increasing counter, which is not NTP adjusted.

Command Modes

Global configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If this command is not configured, RADIUS attribute 46 can skew the session time by as much as 5 to 7 seconds for calls that have a duration of more than 24 hours. However, you may not want to configure the command for short-lived calls or if your device is up for only a short time because of the convergence time required if the session time is configured on the basis of the NTP clock time.

For RADIUS attribute 46 to reflect the NTP-adjusted time, you must configure the **ntp server** command as well as the **aaa accounting session-duration ntp-adjusted** command.

Examples

The following example shows that the attribute 46 session time is to be calculated on the basis of the NTP clock time:

```
aaa new-model
aaa authentication ppp default group radius
aaa accounting session-time ntp-adjusted
aaa accounting network default start-stop group radius
```

Related Commands

Command	Description
ntp server	Allows the software clock to be synchronized by a NTP time server.

aaa accounting suppress null-username

To prevent the Cisco IOS software from sending accounting records for users whose username string is NULL, use the **aaa accounting suppress null-username** command in global configuration mode. To allow sending records for users with a NULL username, use the **no** form of this command.

aaa accounting suppress null-username

no aaa accounting suppress null-username

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When **aaa accounting** is activated, the Cisco IOS software issues accounting records for all users on the system, including users whose username string, because of protocol translation, is NULL. This command prevents accounting records from being generated for those users who do not have usernames associated with them.

Examples

The following example suppresses accounting records for users who do not have usernames associated with them:

```
aaa accounting suppress null-username
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.

aaa accounting update

To enable periodic interim accounting records to be sent to the accounting server, use the **aaa accounting update** command in global configuration mode. To disable interim accounting updates, use the **no** form of this command.

aaa accounting update [**newinfo**] [**periodic** *number* [**jitter** {**maximum** *max-value*}]]

no aaa accounting update

Syntax Description

newinfo	(Optional) An interim accounting record is sent to the accounting server whenever there is new accounting information to report relating to the user in question.
periodic	(Optional) An interim accounting record is sent to the accounting server periodically, as defined by the *number*.
number	(Optional) Integer specifying number of minutes.
jitter	(Optional) Allows you to set the maximum jitter value in periodic accounting.
maximum *max-value*	The number of seconds to set for maximum jitter in periodic accounting. The value 0 turns off jitter. Jitter is set to 300 seconds (5 minutes) by default.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(13)T	Introduced support for generation of an additional updated interim accounting record that contains all available attributes when a call leg is connected.
12.2(15)T11	The **jitter** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

- When the **aaa accounting update** command is activated, the Cisco IOS software issues interim accounting records for all users on the system. If the **newinfo** keyword is used, interim accounting records will be sent to the accounting server every time there is new accounting information to report. An example would be when IP Control Protocol (IPCP) completes IP address negotiation with the remote peer. The interim accounting record will include the negotiated IP address used by the remote peer.

- When the **gw-accounting aaa** command and the **aaa accounting update newinfo** command and keyword are activated, Cisco IOS software generates and sends an additional updated interim accounting record to the accounting server when a call leg is connected. All attributes (for example, h323-connect-time and backward-call-indicators (BCI)) available at the time of call connection are sent through this interim updated accounting record.
- When used with the **periodic** keyword, interim accounting records are sent periodically as defined by the number. The interim accounting record contains all of the accounting information recorded for that user up to the time the accounting record is sent.
- When using both the **newinfo** and **periodic** keywords, interim accounting records are sent to the accounting server every time there is new accounting information to report, and accounting records are sent to the accounting server periodically as defined by the number. For example, if you configure the **aaa accounting update newinfo periodic** *number* command, all users currently logged in will continue to generate periodic interim accounting records while new users will generate accounting records based on the **newinfo** algorithm.
- Vendor-specific attributes (VSAs) such as h323-connect-time and backward-call-indicator (BCI) are transmitted in the interim update RADIUS message when the **aaa accounting update newinfo** command and keyword are enabled.
- Jitter is used to provide an interval of time between records so that the AAA server does not get overwhelmed by a constant stream of records. If certain applications require that periodic records be sent a exact intervals, you should disable jitter by setting it to 0.

Caution Using the **aaa accounting update periodic** command and keyword can cause heavy congestion when many users are logged into the network.

Examples

The following example sends PPP accounting records to a remote RADIUS server. When IPCP completes negotiation, this command sends an interim accounting record to the RADIUS server that includes the negotiated IP address for this user; it also sends periodic interim accounting records to the RADIUS server at 30-minute intervals.

```
aaa accounting network default start-stop group radius
aaa accounting update newinfo periodic 30
```

The following example sends periodic interim accounting records to the RADIUS server at 30-minute intervals and disables jitter:

```
aaa accounting update newinfo periodic 30 jitter maximum 0
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.
gw-accounting aaa	Enables VoIP gateway accounting through the AAA system.

aaa attribute

To add calling line identification (CLID) and dialed number identification service (DNIS) attribute values to a user profile, use the **aaa attribute** command in AAA-user configuration mode. To remove this command from your configuration, use the **no** form of this command.

aaa attribute {**clid** | **dnis**} *attribute-value*

no aaa attribute {**clid** | **dnis**} *attribute-value*

Syntax Description

clid	Adds CLID attribute values to the user profile.
dnis	Adds DNIS attribute values to the user profile.
attribute-value	Specifies a name for CLID or DNIS attribute values.

Command Default

If this command is not enabled, you will have an empty user profile.

Command Modes

AAA-user configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

Use the **aaa attribute** command to add CLID or DNIS attribute values to a named user profile, which is created by using the **aaa user profile** command. The CLID or DNIS attribute values can be associated with the record that is going out with the user profile (via the **test aaa group** command), thereby providing the RADIUS server with access to CLID or DNIS information when the server receives a RADIUS record.

Examples

The following example shows how to add CLID and DNIS attribute values to the user profile “cat”:

```
aaa user profile cat
 aaa attribute clid clidval
 aaa attribute dnis dnisval
```

Related Commands

Command	Description
aaa user profile	Creates a AAA user profile.
test aaa group	Associates a DNIS or CLID user profile with the record that is sent to the RADIUS server.

aaa attribute list

To define an authentication, authorization, and accounting (AAA) attribute list locally on a router, use the **aaa attribute list** command in global configuration mode. To remove the AAA attribute list, use the **no** form of this command.

aaa attribute list *list-name*

no aaa attribute list *list-name*

Syntax Description

list-name	Name of the local attribute list.

Command Default

A local attribute list is not defined.

Command Modes

Global configuration

Command History

Release	Modification
12.3(7)XI1	This command was introduced.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

There is no limit to the number of lists that can be defined (except for NVRAM storage limits).

Examples

The following example shows that the attribute list named “TEST” is to be added to the subscriber profile “cisco.com”:

```
aaa authentication ppp template1 local
aaa authorization network template1 local
!
aaa attribute list TEST
   attribute type interface-config "ip unnumbered FastEthernet0" service ppp protocol lcp
   attribute type interface-config "ip vrf forwarding blue" service ppp protocol lcp
!
ip vrf blue
 description vrf blue template1
 rd 1:1
 route-target export 1:1
 route-target import 1:1
!
subscriber authorization enable
!
```

```
subscriber profile cisco.com
 service local
 aaa attribute list TEST
!
bba-group pppoe grp1
 virtual-template 1
 service profile cisco.com
!
interface Virtual-Template1
 no ip address
 no snmp trap link-status
 no peer default ip address
 no keepalive
 ppp authentication pap template1
 ppp authorization template1
!
```

Related Commands

Command	Description
attribute type	Defines an attribute type that is to be added to an attribute list locally on a router.

aaa authentication (IKEv2 profile)

To specify the AAA authentication list for Extensible Authentication Protocol (EAP) authentication, use the **aaa authentication** command in IKEv2 profile configuration mode. To remove the AAA authentication for EAP, use the **no** form of this command.

aaa authentication eap *list-name*

no aaa authentication eap

Syntax Description

eap	Specifies the external EAP server for the authentication list.
list-name	Name of the AAA authentication list.

Command Default

AAA authentication for EAP is not specified.

Command Modes

IKEv2 profile configuration (config-ikev2-profile)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify the AAA authentication list for EAP authentication. The **crypto ikev2 profile** command must be enabled before this command is executed.

Examples

The following example shows how to configure the remote access server using the remote EAP authentication method with an external EAP server:

```
Router(config)# aaa new-model
Router(config)# aaa authentication login aaa-eap-list default group radius
Router(config)# crypto ikev2 profile profile2
Router(config-ikev2-profile)# authentication remote eap
Router(config-ikev2-profile)# aaa authentication eap aaa-eap-list
```

The following example shows how to configure the remote access server using the remote EAP authentication method with a local and external EAP server:

```
Router(config)# aaa new-model
Router(config)# aaa authentication login aaa-eap-list default group radius
Router(config)# aaa authentication login aaa-eap-local-list default group tacacs
Router(config)# crypto ikev2 profile profile2
Router(config-ikev2-profile)# authentication remote eap
Router(config-ikev2-profile)# authentication remote eap-local
Router(config-ikev2-profile)# aaa authentication eap aaa-eap-list
Router(config-ikev2-profile)# aaa authentication eap-local aaa-eap-local-list
```

Related Commands

Command	Description
crypt ikev2 profile	Defines an IKEv2 profile.

aaa authentication (WebVPN)

To configure authentication, authorization, and accounting (AAA) authentication for SSL VPN sessions, use the **aaa authentication** command in webvpn context configuration mode. To remove the AAA configuration from the SSL VPN context configuration, use the **no** form of this command.

aaa authentication {**domain** *name* | **list** *name*}

no aaa authentication {**domain** | **list**}

Syntax Description

domain *name*	Configures authentication using the specified domain name.
list *name*	Configures authentication using the specified list name.

Command Default

If this command is not configured or if the **no** form of this command is entered, the SSL VPN gateway will use global AAA parameters (if configured).

Command Modes

Webvpn context configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

The **aaa authentication** command is entered to specify an authentication list or server group under a SSL VPN context configuration. If this command is not configured and AAA is configured globally on the router, global authentication will be applied to the context configuration.

The database that is configured for remote-user authentication on the SSL VPN gateway can be a local database, or the database can be accessed through any RADIUS or TACACS+ AAA server.

We recommend that you use a separate AAA server, such as a Cisco Access Control Server (ACS). A separate AAA server provides a more robust security solution. It allows you to configure unique passwords for each remote user and accounting and logging for remote-user sessions.

Examples

Local AAA Example (Default to Global Configuration)

The following example configures local AAA for remote-user connections. Notice that the **aaa authentication** command is not configured in a context configuration.

```
Router (config)# aaa new-model
Router (config)# username USER1 secret 0 PsW2143
Router (config)# aaa authentication login default local
```

AAA Access Control Server Example

The following example configures a RADIUS server group and associates the AAA configuration under the SSL VPN context configuration.

```
Router (config)# aaa new-model
Router (config)# aaa group server radius myServer
Router (config-sg-radius)# server 10.1.1.20 auth-port 1645 acct-port 1646
Router (config-sg-radius)# exit
Router (config)# aaa authentication login default local group myServer
Router (config)# radius-server host 10.1.1.0 auth-port 1645 acct-port 1646
Router (config)# webvpn context context1
Router (config-webvpn-context)# aaa authentication list myServer
Router (config-webvpn-context)# exit
```

Related Commands

Command	Description
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.

aaa authentication arap

To enable an authentication, authorization, and accounting (AAA) authentication method for AppleTalk Remote Access (ARA), use the **aaa authentication arap** command in global configuration mode. To disable this authentication, use the **no** form of this command.

aaa authentication arap {**default** | *list-name*} *method1* [*method2*...]

no aaa authentication arap {**default** | *list-name*} *method1* [*method2*...]

Syntax Description

default	Uses the listed methods that follow this argument as the default list of methods when a user logs in.
list-name	Character string used to name the following list of authentication methods tried when a user logs in.
method1 [*method2*...]	At least one of the keywords described in Table 2.

Defaults

If the **default** list is not set, only the local user database is checked. This has the same effect as the following command:

```
aaa authentication arap default local
```

Command Modes

Global configuration

Command History

Release	Modification
10.3	This command was introduced.
12.0(5)T	Group server and local-case support were added as method keywords for this command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The list names and default that you set with the **aaa authentication arap** command are used with the **arap authentication** command. Note that ARAP guest logins are disabled by default when you enable AAA. To allow guest logins, you must use either the **guest** or **auth-guest** method listed in Table 2. You can only use one of these methods; they are mutually exclusive.

Create a list by entering the **aaa authentication arap** *list-name method* command, where *list-name* is any character string used to name this list (such as *MIS-access*). The *method* argument identifies the list of methods the authentication algorithm tries in the given sequence. See Table 2 for descriptions of method keywords.

To create a default list that is used if no list is specified in the **arap authentication** command, use the **default** keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails.

Use the **more system:running-config** command to view currently configured lists of authentication methods.

Note In Table 2, the **group radius**, **group tacacs+**, and **group** *group-name* methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs+-server host** commands to configure the host servers. Use the **aaa group server radius** and **aaa group server tacacs+** commands to create a named group of servers.

Table 2 aaa authentication arap Methods

Keyword	Description
guest	Allows guest logins. This method must be the first method listed, but it can be followed by other methods if it does not succeed.
auth-guest	Allows guest logins only if the user has already logged in to EXEC. This method must be the first method listed, but can be followed by other methods if it does not succeed.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the **aaa group server radius** or **aaa group server tacacs+** command.

Examples

The following example creates a list called *MIS-access*, which first tries TACACS+ authentication and then none:

```
aaa authentication arap MIS-access group tacacs+ none
```

The following example creates the same list, but sets it as the default list that is used for all ARA protocol authentications if no other list is specified:

```
aaa authentication arap default group tacacs+ none
```

Related Commands

Command	Description
aaa new-model	Enables the AAA access control model.

aaa authentication attempts login

To set the maximum number of login attempts that will be permitted before a session is dropped, use the **aaa authentication attempts login** command in global configuration mode. To reset the number of attempts to the default, use the **no** form of this command.

aaa authentication attempts login *number-of-attempts*

no aaa authentication attempts login

Syntax Description

number-of-attempts	Number of login attempts. Range is from 1 to 25. Default is 3.

Defaults

3 attempts

Command Modes

Global configuration

Command History

Release	Modification
12.2 T	This command was introduced.

Usage Guidelines

The **aaa authentication attempts login** command configures the number of times a router will prompt for username and password before a session is dropped.

The **aaa authentication attempts login** command can be used only if the **aaa new-model** command is configured.

Examples

The following example configures a maximum of 5 attempts at authentication for login:

```
aaa authentication attempts login 5
```

Related Commands

Command	Description
aaa new-model	Enables the AAA access control model.

aaa authentication auto (WebVPN)

To allow automatic authentication for Secure Socket Layer virtual private network (SSL VPN) users, use the **aaa authentication auto** command in webvpn context configuration mode. To disable automatic authentication, use the **no** form of this command.

aaa authentication auto

no aaa authentication auto

Syntax Description

This command has no arguments or keywords.

Command Default

Automatic authentication is not allowed.

Command Modes

Webvpn context (config-webvpn-context)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

Configuring this command allows users to provide their usernames and passwords via the gateway page URL. They do not have to enter the usernames and passwords again from the login page.

A user can embed his or her username and password in the URL using the following format:

```
http://<gateway-address>/<vw_context>/webvpnauth?username:password
```

Examples

The following example shows that automatic authentication has been configured for users:

```
Router (config)# webvpn context
Router (config-webvpn-context)# aaa authentication auto
```

aaa authentication banner

To configure a personalized banner that will be displayed at user login, use the **aaa authentication banner** command in global configuration mode. To remove the banner, use the **no** form of this command.

aaa authentication banner *dstringd*

no aaa authentication banner

Syntax Description

d	Any delimiting character at the beginning and end of the *string* that notifies the system that the *string* is to be displayed as the banner. The delimiting character can be any character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.
string	Any group of characters, excluding the one used as the delimiter. The maximum number of characters that you can display is 2996.

Defaults

Not enabled

Command Modes

Global configuration

Command History

Release	Modification
11.3(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa authentication banner** command to create a personalized message that appears when a user logs in to the system. This message or banner will replace the default message for user login.

To create a login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

Note The AAA authentication banner message is not displayed if TACACS+ is the first method in the method list.

Examples

The following example shows the default login message if **aaa authentication banner** is not configured. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication login default group radius
```

This configuration produces the following standard output:

```
User Verification Access
Username:
Password:
```

The following example configures a login banner (in this case, the phrase "Unauthorized use is prohibited.") that will be displayed when a user logs in to the system. In this case, the asterisk (*) symbol is used as the delimiter. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized use is prohibited.*
aaa authentication login default group radius
```

This configuration produces the following login banner:

```
Unauthorized use is prohibited.
Username:
```

Related Commands

Command	Description
aaa authentication fail-message	Configures a personalized banner that will be displayed when a user fails login.

aaa authentication dot1x

To specify one or more authentication, authorization, and accounting (AAA) methods for use on interfaces running IEEE 802.1X, use the **aaa authentication dot1x** command in global configuration mode. To disable authentication, use the **no** form of this command

aaa authentication dot1x {**default** | **listname**} *method1* [*method2...*]

no aaa authentication dot1x {**default** | **listname**} *method1* [*method2...*]

Syntax Description

default	Uses the listed authentication methods that follow this argument as the default list of methods when a user logs in.
listname	Character string used to name the list of authentication methods tried when a user logs in.
method1 [*method2...*]	At least one of these keywords: • **enable**—Uses the enable password for authentication. • **group radius**—Uses the list of all RADIUS servers for authentication. • **line**—Uses the line password for authentication. • **local**—Uses the local username database for authentication. • **local-case**—Uses the case-sensitive local username database for authentication. • **none**—Uses no authentication. The client is automatically authenticated by the switch without using the information supplied by the client.

Defaults

No authentication is performed.

Command Types

Global configuration

Command History

Release	Modification
12.1(6)EA2	This command was introduced for the Cisco Ethernet switch network module.
12.2(15)ZJ	This command was implemented on the following platforms for the Cisco Ethernet Switch Module: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series.
12.3(2)XA	This command was introduced on the following Cisco router platforms: Cisco 806, Cisco 831, Cisco 836, Cisco 837, Cisco 1701, Cisco 1710, Cisco 1721, Cisco 1751-V, and Cisco 1760.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T. Router support was added for the following platforms: Cisco 1751, Cisco 2610XM – Cisco 2611XM, Cisco 2620XM – Cisco 2621XM, Cisco 2650XM – Cisco 2651XM, Cisco 2691, Cisco 3640, Cisco 3640A, and Cisco 3660.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The *method* argument identifies the list of methods that the authentication algorithm tries in the given sequence to validate the password provided by the client. The only method that is truly 802.1X-compliant is the **group radius** method, in which the client data is validated against a RADIUS authentication server. The remaining methods enable AAA to authenticate the client by using locally configured data. For example, the **local** and **local-case** methods use the username and password that are saved in the Cisco IOS configuration file. The **enable** and **line** methods use the **enable** and **line** passwords for authentication.

If you specify **group radius**, you must configure the RADIUS server by entering the **radius-server host** global configuration command. If you are not using a RADIUS server, you can use the **local** or **local-case** methods, which access the local username database to perform authentication. By specifying the **enable** or **line** methods, you can supply the clients with a password to provide access to the switch.

Use the **show running-config** privileged EXEC command to display the configured lists of authentication methods.

Examples

The following example shows how to enable AAA and how to create an authentication list for 802.1X. This authentication first tries to contact a RADIUS server. If this action returns an error, the user is allowed access with no authentication:

```
Router(config)# aaa new model
Router(config)# aaa authentication dot1x default group radius none
```

Related Commands

Command	Description
debug dot1x	Displays 802.1X debugging information.
identity profile default	Creates an identity profile and enters dot1x profile configuration mode.
show dot1x	Displays details for an identity profile.
show dot1x (EtherSwitch)	Displays 802.1X statistics, administrative status, and operational status for the switch or for the specified interface.

aaa authentication enable default

To enable authentication, authorization, and accounting (AAA) authentication to determine whether a user can access the privileged command level, use the **aaa authentication enable default** command in global configuration mode. To disable this authorization method, use the **no** form of this command.

aaa authentication enable default *method1* [*method2*...]

no aaa authentication enable default *method1* [*method2*...]

Syntax Description

method1 [*method2*...]	At least one of the keywords described in Table 3.

Defaults

If the **default** list is not set, only the enable password is checked. This has the same effect as the following command:

```
aaa authentication enable default enable
```

On the console, the enable password is used if it exists. If no password is set, the process will succeed anyway.

Command Modes

Global configuration (config)

Command History

Release	Modification
10.3	This command was introduced.
12.0(5)T	Group server support was added as various method keywords for this command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa authentication enable default** command to create a series of authentication methods that are used to determine whether a user can access the privileged command level. Method keywords are described in Table 3. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

All **aaa authentication enable default** requests sent by the router to a RADIUS server include the username "$enab15$."

Note An enable authentication request for $enab{*x*}$ is sent only for RADIUS servers.

If a default authentication routine is not set for a function, the default is **none** and no authentication is performed. Use the **more system:running-config** command to view currently configured lists of authentication methods.

Note In Table 3, the **group radius**, **group tacacs+**, and **group** *group-name* methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs+-server host** commands to configure the host servers. Use the **aaa group server radius** and **aaa group server tacacs+** commands to create a named group of servers.

Table 3 aaa authentication enable default Methods

Keyword	Description
enable	Uses the enable password for authentication. **Note** An authentication request fails over to the next authentication method only if no enable password is configured on the router.
line	Uses the line password for authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication. **Note** The RADIUS method does not work on a per-username basis.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the **aaa group server radius** or **aaa group server tacacs+** command.

Examples

The following example shows how to create an authentication list that first tries to contact a TACACS+ server. If no server can be found, AAA tries to use the enable password. If this attempt also returns an error (because no enable password is configured on the server), the user is allowed access with no authentication.

```
aaa authentication enable default group tacacs+ enable none
```

Related Commands

Command	Description
aaa authorization	Sets parameters that restrict network access to a user.
aaa new-model	Enables the AAA access control model.
enable password	Sets a local password to control access to various privilege levels.

aaa authentication eou default enable group radius

To set authentication lists for Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP), use the **aaa authentication eou default enable group radius** command in global configuration mode. To remove the authentication lists, use the **no** form of this command.

aaa authentication eou default enable group radius

no aaa authentication eou default enable group radius

Syntax Description

This command has no arguments or keywords.

Defaults

Authentication lists for EAPoUDP are not set.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Examples

The following example shows that authentication lists have been set for EAPoUDP:

```
Router (config)# aaa new-model
Router (config)# aaa authentication eou default enable group radius
```

Related Commands

Command	Description
eou	Provides information about EAPoUDP.
ip admission	Creates a Layer 3 network admission control rule to be applied to the interface.

aaa authentication fail-message

To configure a personalized banner that will be displayed when a user fails login, use the **aaa authentication fail-message** command in global configuration mode. To remove the failed login message, use the **no** form of this command.

aaa authentication fail-message *dstringd*

no aaa authentication fail-message

Syntax Description

d	The delimiting character at the beginning and end of the *string* that notifies the system that the *string* is to be displayed as the banner. The delimiting character can be any character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.
string	Any group of characters, excluding the one used as the delimiter. The maximum number of characters that you can display is 2996.

Defaults

Not enabled

Command Modes

Global configuration

Command History

Release	Modification
11.3(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa authentication fail-message** command to create a personalized message that appears when a user fails login. This message will replace the default message for failed login.

To create a failed-login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

Examples

The following example shows the default login message and failed login message that is displayed if **aaa authentication banner** and **aaa authentication fail-message** are not configured. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication login default group radius
```

This configuration produces the following standard output:

```
User Verification Access
Username:
Password:

% Authentication failed.
```

The following example configures both a login banner (“Unauthorized use is prohibited.”) and a login-fail message (“Failed login. Try again.”). The login message will be displayed when a user logs in to the system. The failed-login message will display when a user tries to log in to the system and fails. (RADIUS is specified as the default login authentication method.) In this example, the asterisk (*) is used as the delimiting character.

```
aaa new-model
aaa authentication banner *Unauthorized use is prohibited.*
aaa authentication fail-message *Failed login. Try again.*
aaa authentication login default group radius
```

This configuration produces the following login and failed login banner:

```
Unauthorized use is prohibited.
Username:
Password:
Failed login. Try again.
```

Related Commands

Command	Description
aaa authentication banner	Configures a personalized banner that will be displayed at user login.

aaa authentication login

To set authentication, authorization, and accounting (AAA) authentication at login, use the **aaa authentication login** command in global configuration mode. To disable AAA authentication, use the **no** form of this command.

aaa authentication login {**default** | *list-name*} {[**passwd-expiry**] *method1* [*method2*...]}

no aaa authentication login {**default** | *list-name*} {[**passwd-expiry**] *method1* [*method2*...]}

Syntax Description

default	Uses the listed authentication methods that follow this keyword as the default list of methods when a user logs in.
list-name	Character string used to name the list of authentication methods activated when a user logs in. See the "Authentication Methods That Cannot Be Used for the list-name Argument" in the "Usage Guidelines" section for more information.
passwd-expiry	Enables password aging on a local authentication list. **Note** The **radius-server vsa send authentication** command is required to make the **passwd-expiry** keyword work.
method1 [*method2*...]	The list of methods that the authentication algorithm tries in the given sequence. You must enter at least one method; you may enter up to four methods. Method keywords are described in Table 4.

Command Default

AAA authentication at login is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
10.3	This command was introduced.
12.0(5)T	This command was modified. The **group radius**, **group tacacs+**, and **local-case** keywords were added as methods for authentication.
12.4(6)T	This command was modified. The **password-expiry** keyword was added.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB. The **cache** *group-name* keyword and argument were added as a method for authentication.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.
15.1(1)T	This command was modified. The **group ldap** keyword was added.

Release	Modification
Cisco IOS XE Release 3.1S	This command was integrated into Cisco IOS XE Release 3.1S and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.
15.0(1)S	This command was integrated into Cisco IOS Release 15.0(1)S.

Usage Guidelines

If the **default** keyword is not set, only the local user database is checked. This has the same effect as the following command:

```
aaa authentication login default local
```

Note On the console, login will succeed without any authentication checks if **default** keyword is not set.

The default and optional list names that you create with the **aaa authentication login** command are used with the **login authentication** command.

Create a list by entering the **aaa authentication login** *list-name method* command for a particular protocol. The *list-name* argument is the character string used to name the list of authentication methods activated when a user logs in. The *method* argument identifies the list of methods that the authentication algorithm tries, in the given sequence. The "Authentication Methods That Cannot Be Used for the list-name Argument" section lists authentication methods that cannot be used for the *list-name* argument and Table 4 describes the method keywords.

To create a default list that is used if no list is assigned to a line, use the **login authentication** command with the default argument followed by the methods you want to use in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To ensure that the authentication succeeds even if all methods return an error, specify **none** as the final method in the command line.

If authentication is not specifically set for a line, the default is to deny access and no authentication is performed. Use the **more system:running-config** command to display currently configured lists of authentication methods.

Authentication Methods That Cannot Be Used for the list-name Argument

The authentication methods that cannot be used for the *list-name* argument are as follows:

- **auth-guest**
- **enable**
- **guest**
- **if-authenticated**
- **if-needed**
- **krb5**
- **krb-instance**
- **krb-telnet**
- **line**
- **local**
- **none**
- **radius**

- **rcmd**
- **tacacs**
- **tacacsplus**

Note In Table 4, the **group radius**, **group tacacs+**, **group ldap**, and **group** *group-name* methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs-server host** commands to configure the host servers. Use the **aaa group server radius**, **aaa group server ldap**, and **aaa group server tacacs+** commands to create a named group of servers.

Table 4 describes the method keywords.

Table 4 aaa authentication login Methods Keywords

Keyword	Description
cache *group-name*	Uses a cache server group for authentication.
enable	Uses the enable password for authentication. This keyword cannot be used.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the **aaa group server radius** or **aaa group server tacacs+** command.
group ldap	Uses the list of all Lightweight Directory Access Protocol (LDAP) servers for authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
krb5	Uses Kerberos 5 for authentication.
krb5-telnet	Uses Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
passwd-expiry	Uses the login list to provide password aging support.

Examples

The following example shows how to create an AAA authentication list called *MIS-access*. This authentication first tries to contact a TACACS+ server. If no server is found, TACACS+ returns an error and AAA tries to use the enable password. If this attempt also returns an error (because no enable password is configured on the server), the user is allowed access with no authentication.

```
aaa authentication login MIS-access group tacacs+ enable none
```

The following example shows how to create the same list, but it sets it as the default list that is used for all login authentications if no other list is specified:

```
aaa authentication login default group tacacs+ enable none
```

The following example shows how to set authentication at login to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router:

```
aaa authentication login default krb5
```

The following example shows how to configure password aging by using AAA with a crypto client:

```
aaa authentication login userauthen passwd-expiry group radius
```

Related Commands

Command	Description
aaa new-model	Enables the AAA access control model.
login authentication	Enables AAA authentication for logins.

aaa authentication nasi

To specify authentication, authorization, and accounting (AAA) authentication for Netware Asynchronous Services Interface (NASI) clients connecting through the access server, use the **aaa authentication nasi** command in global configuration mode. To disable authentication for NASI clients, use the **no** form of this command.

aaa authentication nasi {**default** | *list-name*} *method1* [*method2*...]

no aaa authentication nasi {**default** | *list-name*} *method1* [*method2*...]

Syntax Description

default	Makes the listed authentication methods that follow this argument the default list of methods used when a user logs in.
list-name	Character string used to name the list of authentication methods activated when a user logs in.
method1 [*method2*...]	At least one of the methods described in Table 5.

Defaults

If the **default** list is not set, only the local user database is selected. This has the same effect as the following command:

```
aaa authentication nasi default local
```

Command Modes

Global configuration

Command History

Release	Modification
11.1	This command was introduced.
12.0(5)T	Group server support and **local-case** were added as method keywords for this command.
12.2(13)T	This command is no longer supported in Cisco IOS Mainline releases or in Technology-based (T-train) releases. It might continue to appear in 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The default and optional list names that you create with the **aaa authentication nasi** command are used with the **nasi authentication** command.

Create a list by entering the **aaa authentication nasi** command, where *list-name* is any character string that names the list (such as *MIS-access*). The *method* argument identifies the list of methods the authentication algorithm tries in the given sequence. Method keywords are described in Table 5.

To create a default list that is used if no list is assigned to a line with the **nasi authentication** command, use the default argument followed by the methods that you want to use in default situations.

The remaining methods of authentication are used only if the previous method returns an error, not if it fails. To ensure that the authentication succeeds even if all methods return an error, specify **none** as the final method in the command line.

If authentication is not specifically set for a line, the default is to deny access and no authentication is performed. Use the **more system:running-config** command to display currently configured lists of authentication methods.

Note In Table 5, the **group radius**, **group tacacs+**, and **group** *group-name* methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs+-server host** commands to configure the host servers. Use the **aaa group server radius** and **aaa group server tacacs+** commands to create a named group of servers.

Table 5 aaa authentication nasi Methods

Keyword	Description
enable	Uses the enable password for authentication.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the **aaa group server radius** or **aaa group server tacacs+** command.

Examples

The following example creates an AAA authentication list called *list1*. This authentication first tries to contact a TACACS+ server. If no server is found, TACACS+ returns an error and AAA tries to use the enable password. If this attempt also returns an error (because no enable password is configured on the server), the user is allowed access with no authentication.

```
aaa authentication nasi list1 group tacacs+ enable none
```

The following example creates the same list, but sets it as the default list that is used for all login authentications if no other list is specified:

```
aaa authentication nasi default group tacacs+ enable none
```

Related Commands

Command	Description
ip trigger-authentication (global)	Enables the automated part of double authentication at a device.
ipx nasi-server enable	Enables NASI clients to connect to asynchronous devices attached to a router.
nasi authentication	Enables AAA authentication for NASI clients connecting to a router.

Command	Description
show ipx nasi connections	Displays the status of NASI connections.
show ipx spx-protocol	Displays the status of the SPX protocol stack and related counters.

aaa authentication password-prompt

To change the text displayed when users are prompted for a password, use the **aaa authentication password-prompt** command in global configuration mode. To return to the default password prompt text, use the **no** form of this command.

aaa authentication password-prompt *text-string*

no aaa authentication password-prompt *text-string*

Syntax Description

text-string	String of text that will be displayed when the user is prompted to enter a password. If this text-string contains spaces or unusual characters, it must be enclosed in double-quotes (for example, “Enter your password:”).

Defaults

There is no user-defined *text-string*, and the password prompt appears as “Password.”

Command Modes

Global configuration

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa authentication password-prompt** command to change the default text that the Cisco IOS software displays when prompting a user to enter a password. This command changes the password prompt for the enable password as well as for login passwords that are not supplied by remote security servers. The **no** form of this command returns the password prompt to the default value:

```
Password:
```

The **aaa authentication password-prompt** command does not change any dialog that is supplied by a remote TACACS+ server.

The **aaa authentication password-prompt** command works when RADIUS is used as the login method. The password prompt that is defined in the command will be shown even when the RADIUS server is unreachable. The **aaa authentication password-prompt** command does not work with TACACS+. TACACS+ supplies the network access server (NAS) with the password prompt to display to the users. If the TACACS+ server is reachable, the NAS gets the password prompt from the server and uses that prompt instead of the one defined in the **aaa authentication password-prompt** command. If the TACACS+ server is not reachable, the password prompt that is defined in the **aaa authentication password-prompt** command may be used.

Examples

The following example changes the text for the password prompt:

```
aaa authentication password-prompt "Enter your password now:"
```

Related Commands

Command	Description
aaa authentication username-prompt	Changes the text displayed when users are prompted to enter a username.
aaa new-model	Enables the AAA access control model.
enable password	Sets a local password to control access to various privilege levels.

aaa authentication ppp

To specify one or more authentication, authorization, and accounting (AAA) methods for use on serial interfaces that are running PPP, use the **aaa authentication ppp** command in global configuration mode. To disable authentication, use the **no** form of this command.

aaa authentication ppp {**default** | *list-name*} *method1* [*method2*...]

no aaa authentication ppp {**default** | *list-name*} *method1* [*method2*...]

Syntax Description

default	Uses the listed authentication methods that follow this keyword as the default list of methods when a user logs in.
list-name	Character string used to name the list of authentication methods tried when a user logs in.
method1 [*method2*...]	Identifies the list of methods that the authentication algorithm tries in the given sequence. You must enter at least one method; you may enter up to four methods. Method keywords are described in Table 6.

Command Default

AAA authentication methods on serial interfaces running PPP are not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
10.3	This command was introduced.
12.0(5)T	Group server support and **local-case** were added as method keywords.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.
Cisco IOS XE Release 2.5	This command was integrated into Cisco IOS XE Release 2.5.

Usage Guidelines

If the **default** list is not set, only the local user database is checked. This has the same effect as that created by the following command:

```
aaa authentication ppp default local
```

The lists that you create with the **aaa authentication ppp** command are used with the **ppp authentication** command. These lists contain up to four authentication methods that are used when a user tries to log in to the serial interface.

Create a list by entering the **aaa authentication ppp** *list-name method* command, where *list-name* is any character string used to name this list MIS-access. The *method* argument identifies the list of methods that the authentication algorithm tries in the given sequence. You can enter up to four methods. Method keywords are described in Table 6.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. Specify **none** as the final method in the command line to have authentication succeed even if all methods return an error.

If authentication is not specifically set for a function, the default is **none** and no authentication is performed. Use the **more system:running-config** command to display currently configured lists of authentication methods.

Note In Table 6, the **group radius**, **group tacacs+**, and **group** *group-name* methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs-server host** commands to configure the host servers. Use the **aaa group server radius** and **aaa group server tacacs+** commands to create a named group of servers.

Table 6 aaa authentication ppp Methods

Keyword	Description
cache *group-name*	Uses a cache server group for authentication.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the **aaa group server radius** or **aaa group server tacacs+** command.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
if-needed	Does not authenticate if the user has already been authenticated on a tty line.
krb5	Uses Kerberos 5 for authentication (can be used only for Password Authentication Protocol [PAP] authentication).
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.

Cisco 10000 Series Router

The Cisco 10000 series router supports a maximum of 2,000 AAA method lists. If you configure more than 2,000 AAA method lists, traceback messages appear on the console.

Examples

The following example creates an AAA authentication list called MIS-access for serial lines that use PPP. This authentication first tries to contact a TACACS+ server. If this action returns an error, the user is allowed access with no authentication.

```
aaa authentication ppp MIS-access group tacacs+ none
```

Related Commands

Command	Description
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
aaa group server tacacs+	Groups different server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
more system:running-config	Displays the contents of the currently running configuration file, the configuration for a specific interface, or map class information.
ppp authentication	Enables CHAP or PAP or both and specifies the order in which CHAP and PAP authentication are selected on the interface.
radius-server host	Specifies a RADIUS server host.
tacacs-server host	Specifies a TACACS host.

aaa authentication sgbp

To specify one or more authentication, authorization, and accounting (AAA) authentication methods for Stack Group Bidding Protocol (SGBP), use the **aaa authentication sgbp** command in global configuration mode. To disable SGBP authentication and return to the default, use the **no** form of this command.

aaa authentication sgbp {**default** | *list-name*} *method1* [*method2...*]

no aaa authentication sgbp {**default** | *list-name*} *method1* [*method2...*]

Syntax Description

default	Uses the listed authentication methods that follow this keyword as the default list of methods when a user logs in.
list-name	Character string used to name the list of authentication methods tried when a user logs in.
method1 [*method2...*]	Identifies the list of methods that the authentication algorithm tries in the given sequence. You must enter at least one method; you may enter up to four methods. Method keywords are described in

Defaults

The **aaa authentication ppp default** command. If the **aaa authentication ppp default** command is not enabled, local authentication will be the default functionality.

Command Modes

Global configuration

Command History

Release	Modification
12.3(2)T	This command introduced.

Usage Guidelines

The lists that you create with the **aaa authentication sgbp** command are used with the **sgbp aaa authentication** command.

Create a list by entering the **aaa authentication sgbp** *list-name method* command, where the *list-name* argument is any character string used to name this list. The *method* argument identifies the list of methods that the authentication algorithm tries in the given sequence. You can enter up to four methods. Method keywords are described in Table 7.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. Specify **none** as the final method in the command line to have authentication succeed even if all methods return an error.

Use the **more system:running-config** command to display currently configured lists of authentication methods.

Table 7 aaa authentication sgbp Methods

Keyword	Description
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the **aaa group server radius** or **aaa group server tacacs+** command.

Examples

The following example shows how to create a AAA authentication list called SGBP. The user first tries to contact a RADIUS server for authentication. If this action returns an error, the user will try to access the local database.

```
Router(config)# aaa authentication sgbp SGBP group radius local
```

Related Commands

Command	Description
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces that are running PPP.
sgbp aaa authentication	Enables a SGBP authentication list.

aaa authentication suppress null-username

To configure Cisco IOS software to prevent an Access Request with a blank username from being sent to the RADIUS server, use the **aaa authentication suppress null-username** command in global configuration mode.

To configure Cisco IOS software to allow an Access Request with a blank username to be sent to the RADIUS server, use the **no** form of this command:

aaa authentication suppress null-username

no aaa authentication suppress null-username

SyntaxDescription

Enables the prevention of an Access Request with a blank username from being sent to the RADIUS server.

Command Default

The command-level default is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS Release 12.2(33)SRD	This command was introduced.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4

Usage Guidelines

This command ensures that unnecessary RADIUS server interaction is avoided, and RADIUS logs are kept short.

Examples

The following example shows how the **aaa authentication suppress null-username** is configured:

```
enable
configure terminal
aaa new-model
aaa authentication suppress null-username
```

Related Commands

Command	Description
aaa new-model	Enables AAA globally.

aaa authentication username-prompt

To change the text displayed when users are prompted to enter a username, use the **aaa authentication username-prompt** command in global configuration mode. To return to the default username prompt text, use the **no** form of this command.

aaa authentication username-prompt *text-string*

no aaa authentication username-prompt *text-string*

Syntax Description

text-string	String of text that will be displayed when the user is prompted to enter a username. If this text-string contains spaces or unusual characters, it must be enclosed in double-quotes (for example, “Enter your name:”).

Defaults

There is no user-defined *text-string*, and the username prompt appears as “Username.”

Command Modes

Global configuration

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa authentication username-prompt** command to change the default text that the Cisco IOS software displays when prompting a user to enter a username. The **no** form of this command returns the username prompt to the default value:

```
Username:
```

Some protocols (for example, TACACS+) have the ability to override the use of local username prompt information. Using the **aaa authentication username-prompt** command will not change the username prompt text in these instances.

Note The **aaa authentication username-prompt** command does not change any dialog that is supplied by a remote TACACS+ server.

Examples

The following example changes the text for the username prompt:

```
aaa authentication username-prompt “Enter your name here:”
```

Related Commands

Command	Description
aaa authentication password-prompt	Changes the text that is displayed when users are prompted for a password.
aaa new-model	Enables the AAA access control model.
enable password	Sets a local password to control access to various privilege levels.

aaa authorization

To set the parameters that restrict user access to a network, use the **aaa authorization** command in global configuration mode. To remove the parameters, use the **no** form of this command.

aaa authorization {**auth-proxy** | **cache** | **commands** *level* | **config-commands** | **configuration** | **console** | **exec** | **ipmobile** | **multicast** | **network** | **policy-if** | **prepaid** | **radius-proxy** | **reverse-access** | **subscriber-service** | **template**} {**default** | *list-name*} [*method1* [*method2*...]]

no aaa authorization {**auth-proxy** | **cache** | **commands** *level* | **config-commands** | **configuration** | **console** | **exec** | **ipmobile** | **multicast** | **network** | **policy-if** | **prepaid** | **radius-proxy** | **reverse-access** | **subscriber-service** | **template**} {**default** | *list-name*} [*method1* [*method2*...]]

Syntax Description

auth-proxy	Runs authorization for authentication proxy services.
cache	Configures the authentication, authorization, and accounting (AAA) server.
commands	Runs authorization for all commands at the specified privilege level.
level	Specific command level that should be authorized. Valid entries are 0 through 15.
config-commands	Runs authorization to determine whether commands entered in configuration mode are authorized.
configuration	Downloads the configuration from the AAA server.
console	Enables the console authorization for the AAA server.
exec	Runs authorization to determine if the user is allowed to run an EXEC shell. This facility returns user profile information such as the autocommand information.
ipmobile	Runs authorization for mobile IP services.
multicast	Downloads the multicast configuration from the AAA server.
network	Runs authorization for all network-related service requests, including Serial Line Internet Protocol (SLIP), PPP, PPP Network Control Programs (NCPs), and AppleTalk Remote Access (ARA).
policy-if	Runs authorization for the diameter policy interface application.
prepaid	Runs authorization for diameter prepaid services.
radius-proxy	Runs authorization for proxy services.
reverse-access	Runs authorization for reverse access connections, such as reverse Telnet.
subscriber-service	Runs authorization for iEdge subscriber services such as virtual private dialup network (VPDN).
template	Enables template authorization for the AAA server.
default	Uses the listed authorization methods that follow this keyword as the default list of methods for authorization.
list-name	Character string used to name the list of authorization methods.
method1 [*method2*...]	(Optional) Identifies an authorization method or multiple authorization methods to be used for authorization. A method may be any one of the keywords listed in Table 8.

Command Default

Authorization is disabled for all actions (equivalent to the method keyword **none**).

Command Modes Global configuration (config)

Command History

Release	Modification
10.0	This command was introduced.
12.0(5)T	This command was modified. The **group radius** and **group tacacs+** keywords were added as methods for authorization.
12.2(28)SB	This command was modified. The **cache** *group-name* keyword and argument were added as a method for authorization.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.
15.1(1)T	This command was modified. The **group ldap** keyword was added.

Usage Guidelines Use the **aaa authorization** command to enable authorization and to create named methods lists, which define authorization methods that can be used when a user accesses the specified function. Method lists for authorization define the ways in which authorization will be performed and the sequence in which these methods will be performed. A method list is a named list that describes the authorization methods (such as RADIUS or TACACS+) that must be used in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system in case the initial method fails. Cisco IOS software uses the first method listed to authorize users for specific network services; if that method fails to respond, the Cisco IOS software selects the next method listed in the method list. This process continues until there is successful communication with a listed authorization method, or until all the defined methods are exhausted.

Note The Cisco IOS software attempts authorization with the next listed method only when there is no response from the previous method. If authorization fails at any point in this cycle—meaning that the security server or the local username database responds by denying the user services—the authorization process stops and no other authorization methods are attempted.

If the **aaa authorization** command for a particular authorization type is issued without a specified named method list, the default method list is automatically applied to all interfaces or lines (where this authorization type applies) except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, then no authorization takes place. The default authorization method list must be used to perform outbound authorization, such as authorizing the download of IP pools from the RADIUS server.

Use the **aaa authorization** command to create a list by entering the values for the *list-name* and the *method* arguments, where *list-name* is any character string used to name this list (excluding all method names) and *method* identifies the list of authorization methods tried in the given sequence.

Note In Table 8, the **group** *group-name,* **group ldap, group radius**, and **group tacacs+** methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs-server host** commands to configure the host servers. Use the **aaa group server radius**, **aaa group server ldap**, and **aaa group server tacacs+** commands to create a named group of servers.

Table 8 describes the method keywords.

Table 8 aaa authorization Methods

Keyword	Description
cache *group-name*	Uses a cache server group for authorization.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the **server group** *group-name* command.
group ldap	Uses the list of all Lightweight Directory Access Protocol (LDAP) servers for authentication.
group radius	Uses the list of all RADIUS servers for authentication as defined by the **aaa group server radius** command.
group tacacs+	Uses the list of all TACACS+ servers for authentication as defined by the **aaa group server tacacs+** command.
if-authenticated	Allows the user to access the requested function if the user is authenticated. **Note** The **if-authenticated** method is a terminating method. Therefore, if it is listed as a method, any methods listed after it will never be evaluated.
local	Uses the local database for authorization.
none	Indicates that no authorization is performed.

Cisco IOS software supports the following methods for authorization:

- Cache Server Groups—The router consults its cache server groups to authorize specific rights for users.
- If-Authenticated—The user is allowed to access the requested function provided the user has been authenticated successfully.
- Local—The router or access server consults its local database, as defined by the **username** command, to authorize specific rights for users. Only a limited set of functions can be controlled through the local database.
- None—The network access server does not request authorization information; authorization is not performed over this line or interface.
- RADIUS—The network access server requests authorization information from the RADIUS security server group. RADIUS authorization defines specific rights for users by associating attributes, which are stored in a database on the RADIUS server, with the appropriate user.
- TACACS+—The network access server exchanges authorization information with the TACACS+ security daemon. TACACS+ authorization defines specific rights for users by associating attribute-value (AV) pairs, which are stored in a database on the TACACS+ security server, with the appropriate user.

Method lists are specific to the type of authorization being requested. AAA supports five different types of authorization:

- Commands—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- EXEC—Applies to the attributes associated with a user EXEC terminal session.

- Network—Applies to network connections. The network connections can include a PPP, SLIP, or ARA connection.

Note You must configure the **aaa authorization config-commands** command to authorize global configuration commands, including EXEC commands prepended by the **do** command.

- Reverse Access—Applies to reverse Telnet sessions.
- Configuration—Applies to the configuration downloaded from the AAA server.

When you create a named method list, you are defining a particular list of authorization methods for the indicated authorization type.

Once defined, the method lists must be applied to specific lines or interfaces before any of the defined methods are performed.

The authorization command causes a request packet containing a series of AV pairs to be sent to the RADIUS or TACACS daemon as part of the authorization process. The daemon can do one of the following:

- Accept the request as is.
- Make changes to the request.
- Refuse the request and authorization.

For a list of supported RADIUS attributes, see the module *RADIUS Attributes*. For a list of supported TACACS+ AV pairs, see the module *TACACS+ Attribute-Value Pairs*.

Note Five commands are associated with privilege level 0: **disable**, **enable**, **exit**, **help**, and **logout**. If you configure AAA authorization for a privilege level greater than 0, these five commands will not be included in the privilege level command set.

Examples

The following example shows how to define the network authorization method list named mygroup, which specifies that RADIUS authorization will be used on serial lines using PPP. If the RADIUS server fails to respond, local network authorization will be performed.

```
aaa authorization network mygroup group radius local
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
aaa group server tacacs+	Groups different TACACS+ server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
radius-server host	Specifies a RADIUS server host.
tacacs-server host	Specifies a TACACS+ host.
username	Establishes a username-based authentication system.

aaa authorization (IKEv2 profile)

To specify AAA authorization for a local or external group policy, use the **aaa authorization** command in IKEv2 profile configuration mode. To remove the AAA authorization, use the **no** form of this command.

aaa authorization {**group** | **user**}{**cert** | **eap** | **psk**}{*aaa-name aaa-username* | **name-mangler** *mangler-name*}

no aaa authorization {**group** | **user**}{**cert** | **eap** | **psk**} *aaa-name*

Syntax Description

group	Specifies AAA authorization for local or external group policy.
user	Specifies AAA authorization for each user policy
cert	Specifies the AAA method list that is used when the remote authentication method is certificate based.
eap	Specifies the AAA method list that is used when the remote authentication method is Extensible Authentication Protocol (EAP).
psk	Specifies the AAA method list that is used when the remote authentication method is preshared key.
aaa-name	The AAA list name.
aaa-username	The AAA username.
name-mangler *mangler-name*	Derives the name mangler from the **crypto ikev2 name-mangler** command.

Command Default

AAA authorization is not specified.

Command Modes

IKEv2 profile configuration (config-ikev2-profile)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify AAA authorization for local or external group policy. The **crypto ikev2 profile** command must be enabled before this command is executed.

Note If no AAA method list is specified, the list is common for all authentication methods. Local AAA is not supported for user authorization.

The following is the order of precedence among group and user policies:

- AAA user policy

- AAA group policy

Note The **user** keyword is not required and not recommended when RADIUS is the external AAA server as RADIUS combines authentication and authorization and returns authorization data with successful authentication. The user keyword can be used with AAA servers such as TACACS+ where authentication and authorization are decoupled.

Examples

The following example shows how to configure the AAA authorization for a local group policy. The aaa-group-list specifies that group authorization is local and the AAA username is abc. The authorization list name corresponds to the group policy defined in the **crypto ikev2 authorization policy** command.

```
Router(config)# aaa new-model
Router(config)# aaa authorization network aaa-group-list default local
Router(config)# crypto ikev2 authorization policy 123
Router(config-ikev2-client-config-group)# pool addr-pool1
Router(config-ikev2-client-config-group)# dns 198.51.100.1 198.51.100.100
Router(config-ikev2-client-config-group)# wins 203.0.113.1 203.0.113.115
Router(config-ikev2-client-config-group)# exit
Router(config)# crypto ikev2 profile profile1
Router(config-ikev2-profile)# wins 203.0.113.1 203.0.113.115 authentication remote eap
Router(config-ikev2-profile)# aaa authorization group aaa-group-list abc
```

The following example shows how to configure an external AAA-based group policy. The aaa-group-list specifies that the group authorization is RADIUS based. The name mangler derives the group name from the domain part of ID-FQDN, which is abc.'

```
Router(config)# aaa new-model
Router(config)# aaa authorization network aaa-group-list default group radius
Router(config)# crypto ikev2 name-mangler mangler1
Router(config-ikev2-name-mangler)# fqdn domain
Router(config-ikev2-name-mangler)# exit
Router(config)# crypto ikev2 profile profile1
Router(config-ikev2-profile)# identity remote fqdn host1.abc
Router(config-ikev2-profile)# authentication remote eap
Router(config-ikev2-profile)# aaa authorization group aaa-group-list name-mangler mangler1
```

The following example shows how to configure an external AAA-based group policy. The aaa-user-list specifies that user authorization is RADIUS based. The name mangler derives the username from hostname part of ID-FQDN, which is host1.

```
Router(config)# aaa new-model
Router(config)# aaa authorization network aaa-user-list default group radius
Router(config)# crypto ikev2 name-mangler mangler2
Router(config-ikev2-name-mangler)# fqdn hostname
Router(config-ikev2-name-mangler)# exit
Router(config-ikev2-profile)# crypto ikev2 profile profile1
Router(config-ikev2-profile)# match identity remote fqdn host1.abc
Router(config-ikev2-profile)# authentication remote eap
Router(config-ikev2-profile)# aaa authorization user aaa-user-list name-mangler mangler2
```

Related Commands

Command	Description
crypto ikev2 name-mangler	Defines a name mangler.
crypto ikev2 profile	Defines an IKEv2 profile.

aaa authorization cache filterserver

To enable authentication, authorization, and accounting (AAA) authorization caches and the downloading of access control list (ACL) configurations from a RADIUS filter server, use the **aaa authorization cache filterserver** command in global configuration mode. To disable AAA authorization caches, use the **no** form of this command.

aaa authorization cache filterserver default *methodlist* [*methodlist2...*]

no aaa authorization cache filterserver default

Syntax Description

default	Default authorization list.
methodlist [*methodlist2...*]	One of the keywords listed in Table 9.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

Use the **aaa authorization cache filterserver** command to enable the RADIUS ACL filter server.

Method keywords are described in Table 9.

Table 9 aaa authorization cache filterserver Methods

Keyword	Description
group *group-name*	Uses a subset of RADIUS servers for authentication as defined by the **aaa group server radius** command.
local	Uses the local database for authorization caches and ACL configuration downloading.
none	No authorization is performed.

This command functions similarly to the **aaa authorization** command with the following exceptions:

- Named method-lists cannot be configured.
- Only one instance of this command can be configured.
- TACACS+ groups cannot be configured.

Examples

The following example shows how to configure the default RADIUS server group as the desired filter. If the request is rejected or a reply is not returned, local configuration will be consulted. If the local filter does not respond, the call will be accepted but filtering will not occur.

```
aaa authorization cache filterserver group radius local none
```

Related Commands

Command	Description
aaa authorization	Sets parameters that restrict user access to a network.
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.

aaa authorization config-commands

To reestablish the default created when the **aaa authorization commands** command was issued, use the **aaa authorization config-commands** command in global configuration mode. To disable authentication, authorization, and accounting (AAA) configuration command authorization, use the **no** form of this command.

aaa authorization config-commands

no aaa authorization config-commands

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

Global configuration

Command History

Release	Modification
11.2	This command was introduced.
12.0(6.02)T	This command was changed from being enabled by default to being disabled by default.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If the **aaa authorization commands** *level method* command is enabled, all commands, including configuration commands, are authorized by authentication, authorization, and accounting (AAA) using the method specified. Because there are configuration commands that are identical to some EXEC-level commands, there can be some confusion in the authorization process. Using the **no aaa authorization config-commands** command stops the network access server from attempting configuration command authorization.

After the **no** form of this command has been entered, AAA authorization of configuration commands is completely disabled. Care should be taken before entering the **no** form of this command because it potentially reduces the amount of administrative control on configuration commands.

Use the **aaa authorization config-commands** command if, after using the **no** form of this command, you need to reestablish the default set by the **aaa authorization commands** *level method* command.

Note You will get the same result if you (1) do not configure this command, or (2) configure **no aaa authorization config-commands**.

Examples

The following example specifies that TACACS+ authorization is run for level 15 commands and that AAA authorization of configuration commands is disabled:

```
aaa new-model
aaa authorization command 15 group tacacs+ none
no aaa authorization config-commands
```

Related Commands

Command	Description
aaa authorization	Sets parameters that restrict user access to a network.

aaa authorization console

To apply authorization to a console, use the **aaa authorization console** command in global configuration mode. To disable the authorization, use the **no** form of this command.

aaa authorization console

no aaa authorization console

Syntax Description

This command has no arguments or keywords.

Defaults

Authentication, authorization, and accounting (AAA) authorization is disabled on the console.

Command Modes

Global configuration

Command History

Release	Modification
12.0(6)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If the **aaa new-model** command has been configured to enable the AAA access control model, the **no aaa authorization console** command is the default, and the authorization that is configured on the console line will always succeed. If you do not want the default, you need to configure the **aaa authorization console** command.

Note This command by itself does not turn on authorization of the console line. It needs to be used in conjunction with the **authorization** command under console line configurations.

If you are trying to enable authorization and the **no aaa authorization console** command is configured by default, you will see the following message:

```
%Authorization without the global command aaa authorization console is useless.
```

Examples

The following example shows that the default authorization that is configured on the console line is being disabled:

```
Router (config)# aaa authorization console
```

Related Commands

Command	Description
authorization	Enables AAA authorization for a specific line or group of lines.

aaa authorization list

To allow user attributes to get "pushed" during authentication, use the **aaa authorization list** command in webvpn context configuration mode. To disable the pushing of attributes, use the **no** form of this command.

aaa authorization list

no aaa authorization list

Syntax Description

name	Name of the list to be automatically authorized.

Command Default

User attributes are not pushed during authentication.

Command Modes

Webvpn context (config-webvpn-context)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

If this command is configured, a separate authorization step is no longer needed after authentication.

Examples

The following example shows that authorization is to be pushed during authentication for List 11:

```
Router (config)# webvpn context
Router (config-webvpn-context)# aaa authorization list 11
```

Related Commands

Command	Description
aaa authentication auto (WebVPN)	Allows automatic authentication for SSL VPN users.

aaa authorization reverse-access

To configure a network access server to request authorization information from a security server before allowing a user to establish a reverse Telnet session, use the **aaa authorization reverse-access** command in global configuration mode. To restore the default value for this command, use the **no** form of this command.

aaa authorization reverse-access {**group radius** | **group tacacs+**}

no aaa authorization reverse-access {**group radius** | **group tacacs+**}

Syntax Description

group radius	Specifies that the network access server will request authorization from a RADIUS security server before allowing a user to establish a reverse Telnet session.
group tacacs+	Specifies that the network access server will request authorization from a TACACS+ security server before allowing a user to establish a reverse Telnet session.

Defaults

This command is disabled by default, meaning that authorization for reverse Telnet is not requested.

Command Modes

Global configuration

Command History

Release	Modification
11.3	This command was introduced.
12.0(5)T	Group server support was added as various method keywords for this command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Telnet is a standard terminal emulation protocol used for remote terminal connection. Normally, you log in to a network access server (typically through a dialup connection) and then use Telnet to access other network devices from that network access server. There are times, however, when it is necessary to establish a reverse Telnet session. In reverse Telnet sessions, the Telnet connection is established in the opposite direction—from inside a network to a network access server on the network periphery to gain access to modems or other devices connected to that network access server. Reverse Telnet is used to provide users with dialout capability by allowing them to open Telnet sessions to modem ports attached to a network access server.

It is important to control access to ports accessible through reverse Telnet. Failure to do so could, for example, allow unauthorized users free access to modems where they can trap and divert incoming calls or make outgoing calls to unauthorized destinations.

Authentication during reverse Telnet is performed through the standard AAA login procedure for Telnet. Typically the user has to provide a username and password to establish either a Telnet or reverse Telnet session. This command provides an additional (optional) level of security by requiring authorization in

addition to authentication. When this command is enabled, reverse Telnet authorization can use RADIUS or TACACS+ to authorize whether or not this user is allowed reverse Telnet access to specific asynchronous ports, after the user successfully authenticates through the standard Telnet login procedure.

Examples

The following example causes the network access server to request authorization information from a TACACS+ security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
aaa authentication login default group tacacs+
aaa authorization reverse-access default group tacacs+
!
tacacs-server host 172.31.255.0
tacacs-server timeout 90
tacacs-server key goaway
```

The lines in this sample TACACS+ reverse Telnet authorization configuration are defined as follows:

- The **aaa new-model** command enables AAA.
- The **aaa authentication login default group tacacs+** command specifies TACACS+ as the default method for user authentication during login.
- The **aaa authorization reverse-access default group tacacs+** command specifies TACACS+ as the method for user authorization when trying to establish a reverse Telnet session.
- The **tacacs-server host** command identifies the TACACS+ server.
- The **tacacs-server timeout** command sets the interval of time that the network access server waits for the TACACS+ server to reply.
- The **tacacs-server key** command defines the encryption key used for all TACACS+ communications between the network access server and the TACACS+ daemon.

The following example configures a generic TACACS+ server to grant a user, “jim,” reverse Telnet access to port tty2 on the network access server named “site1” and to port tty5 on the network access server named site2:

```
user = jim
  login = cleartext lab
  service = raccess {
    port#1 = site1/tty2
    port#2 = site2/tty5
}
```

Note In this example, “site1” and “site2” are the configured host names of network access servers, not DNS names or alias.

The following example configures the TACACS+ server (CiscoSecure) to authorize a user named Jim for reverse Telnet:

```
user = jim
 profile_id = 90
 profile_cycle = 1
 member = Tacacs_Users
 service=shell {
 default cmd=permit
 }
 service=raccess {
 allow "c2511e0" "tty1" ".*"
 refuse ".*" ".*" ".*"
```

```
password = clear "goaway"
```

Note CiscoSecure only supports reverse Telnet using the command line interface in versions 2.1(*x*) through version 2.2(1).

An empty "service=raccess {}" clause permits a user to have unconditional access to network access server ports for reverse Telnet. If no "service=raccess" clause exists, the user is denied access to any port for reverse Telnet.

For more information about configuring TACACS+, refer to the chapter "Configuring TACACS+" in the *Cisco IOS Security Configuration Guide*. For more information about configuring CiscoSecure, refer to the *CiscoSecure Access Control Server User Guide*, version 2.1(2) or later.

The following example causes the network access server to request authorization from a RADIUS security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
aaa authentication login default group radius
aaa authorization reverse-access default group radius
!
radius-server host 172.31.255.0
radius-server key goaway
```

The lines in this sample RADIUS reverse Telnet authorization configuration are defined as follows:

- The **aaa new-model** command enables AAA.
- The **aaa authentication login default group radius** command specifies RADIUS as the default method for user authentication during login.
- The **aaa authorization reverse-access default group radius** command specifies RADIUS as the method for user authorization when trying to establish a reverse Telnet session.
- The **radius-server host** command identifies the RADIUS server.
- The **radius-server key** command defines the encryption key used for all RADIUS communications between the network access server and the RADIUS daemon.

The following example configures the RADIUS server to grant a user named "jim" reverse Telnet access at port tty2 on network access server site1:

```
Password = "goaway"
User-Service-Type = Shell-User
cisco-avpair = "raccess:port#1=site1/tty2"
```

The syntax "raccess:port=any/any" permits a user to have unconditional access to network access server ports for reverse Telnet. If no "raccess:port={*nasname*}/{*tty number*}" clause exists in the user profile, the user is denied access to reverse Telnet on all ports.

For more information about configuring RADIUS, refer to the chapter "Configuring RADIUS" in the *Cisco IOS Security Configuration Guide*.

aaa authorization template

To enable usage of a local or remote customer template on the basis of Virtual Private Network (VPN) routing and forwarding (VRF), use the **aaa authorization template** command in global configuration mode. To disable the new authorization, use the **no** form of this command.

aaa authorization template

no aaa authorization template

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Examples

The following example enables usage of a remote customer template:

```
aaa authorization template
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict user access to a network.
aaa new-model	Enables the AAA access control model.
radius-server host	Specifies a RADIUS server host.
tacacs-server host	Specifies a TACACS+ server host.
template	Accesses the template configuration mode for configuring a particular customer profile template.

aaa cache filter

To enable filter cache configuration, use the **aaa cache filter** command in global configuration mode. To disable this functionality, use the **no** form of this command.

aaa cache filter

no aaa cache filter

Syntax Description

This command has no arguments or keywords.

Defaults

Filter cache configuration is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

Use the **aaa cache filter** command to begin filter cache configuration and enter AAA filter configuration mode (config-aaa-filter).

After enabling this command, you can specify filter cache parameters with the following commands:

- **cache clear age**—Specifies, in minutes, when cache entries expire and the cache is cleared.
- **cache disable**—Disables the cache.
- **cache max**—Refreshes a cache entry when a new sessions begins.
- **cache refresh**—Limits the absolute number of entries the cache can maintain for a particular server.
- **password**—Specifies the optional password that is to be used for filter server authentication requests.

Note Each of these commands is optional; thus, the default value will be enabled for any command that is not specified.

Examples

The following example shows how to enable filter cache configuration and specify cache parameters.

```
aaa cache filter
 password mycisco
 no cache refresh
 cache max 100
```

Related Commands

Command	Description
aaa authorization cache filterserver	Enables AAA authorization caches and the downloading of ACL configurations from a RADIUS filter server.
cache clear age	Specifies when, in minutes, cache entries expire and the cache is cleared.
cache disable	Disables the cache.
cache max	Refreshes a cache entry when a new sessions begins.
cache refresh	Limits the absolute number of entries the cache can maintain for a particular server.
password	Specifies the optional password that is to be used for filter server authentication requests.

aaa cache filterserver

To enable Authentication, Authorization, and Accounting (AAA) filter server definitions, use the **aaa cache filterserver** command in global configuration mode. To disable AAA filter server definitions, use the **no** form of this command.

aaa cache filterserver

no aaa cache filterserver

Syntax Description

This command has no arguments or keywords.

Command Default

This command is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(31)SB2	This command was introduced.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.

Usage Guidelines

The **aaa cache filterserver** command is mainly used to define AAA cache filter server requirements for downloading access control lists (ACLs) commands but is also used for cache configurations, domain names, and passwords. To use this command, enable the **aaa authorization cache filterserver** command first.

Examples

The following example enables the **aaa cache filterserver** command:

```
Router> enable

Router# configure terminal

Router(config)# aaa new-model

Router (config)# aaa authorization cache filterserver default group radius

Router(config)# aaa cache filterserver

Router(config-filter)# cache max 100

Router(config-filter)# no cache refresh
```

Related Commands

Command	Description
show aaa cache filterserver	Displays the aaa cache filterserver status.

aaa cache profile

To create a named authentication and authorization cache profile group and enter profile map configuration mode, use the **aaa cache profile** command in global configuration mode. To disable a cache profile group, use the **no** form of this command.

aaa cache profile *group-name*

no aaa cache profile *group-name*

Syntax Description

group-name	Text string that specifies an authentication and authorization group. Group names cannot be duplicated.

Command Default

No cache profile groups are defined.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use this command to define or modify an authentication or authorization cache group and to specify cache profile parameters using the following commands:

- **all**—Specifies that all authentication and authorization requests are cached. Using the **all** command makes sense for certain service authorization requests, but it should be avoided when dealing with authentication requests.
- **profile**—Specifies an exact profile match to cache. The profile name must be an exact match to the username being queried by the service authentication or authorization request. This is the recommended format to enter profiles that users want to cache.
- **regexp**—Allows entries to match based on regular expressions. Matching on regular expressions is not recommended for most situations.

  The **any** keyword, which is available under the **regexp** submenu, allows any unique instance of a AAA server response that matches the regular expression to be saved in the cache. The **only** keyword allows for only one instance of a AAA server response that matches the regular expression to be saved in the cache.

Entering the **no** form of this command deletes the profile definition and all of its command definitions.

Examples

The following example creates the AAA cache profile group localusers:

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa cache profile localusers
```

Related Commands

Command	Description
all	Specifies that all authentication and authorization requests be cached.
profile	Defines or modifies an individual authentication and authorization cache profile.
regexp	Creates an entry in a cache profile group that allows authentication and authorization matches based on a regular expression.

aaa configuration

To configure the username and password that are to be used when downloading configuration requests, an IP pool, or static routes through RADIUS, use the **aaa configuration** command in global configuration mode. To disable this feature, use the **no** form of this command.

aaa configuration {**config-username** | **pool** | **route**} **username** *username* [**password** [**0** | **7**] *password*]

no aaa configuration {**config-username** | **pool** | **route**} **username** *username* [**password** [**0** | **7**] *password*]

Syntax Description

config-username	Configures the username and password used in configuration requests that can be downloaded.
pool	Configures the username and password used for downloading an IP pool. IP pools are used to define range of IP addresses that are used for Dynamic Host Configuration Protocol (DHCP) servers and point-to-point servers.
route	Configures the username and password used when downloading static routes through RADIUS.
username *username*	Defines a username to be used instead of the router's hostname.
password *password*	(Optional) Defines an alphanumeric password to be used instead of the default "cisco."
0 | **7**	(Optional) Defines whether the text immediately following is encrypted, and, if so, what type of encryption is used. • **0**—The text immediately following is not encrypted. **Note** Type 0 passwords are automatically converted to type 7 passwords by enabling the **service password-encryption** command. • **7**—The text is encrypted using a Cisco-defined encryption algorithm .

Defaults

The hostname of the router and the password "cisco" are used during the static route configuration download.

Command Modes

Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The **aaa configuration** command allows you to specify a username other than the router's hostname and a stronger password than the default "cisco."

Examples

The following example shows how to specify the username “MyUsername” and the password “MyPass” when downloading a static route configuration:

```
aaa new-model
aaa group server radius rad1
    server 10.1.1.1
    exit
aaa authorization configuration default group radius
aaa authorization configuration foo group rad1
aaa route download 1 authorization foo
aaa configuration route username MyUsername password 0 MyPass
radius-server host 10.2.2.2
radius-server key 0 RadKey
```

Related Commands

Command	Description
aaa route download	Enables the static route download feature and sets the amount of time between downloads.
service password-encryption	Enables 0 (non-encrypted) passwords to be automatically converted to type 7 (encrypted) passwords.

aaa dnis map accounting network

To map a Dialed Number Information Service (DNIS) number to a particular authentication, authorization, and accounting (AAA) server group that will be used for AAA accounting, use the **aaa dnis map accounting network** command in global configuration mode. To remove DNIS mapping from the named server group, use the **no** form of this command.

aaa dnis map *dnis-number* **accounting network** [**start-stop** | **stop-only** | **none**] [**broadcast**] **group** *groupname*

no aaa dnis map *dnis-number* **accounting network**

Syntax Description

dnis-number	Number of the DNIS.
start-stop	(Optional) Indicates that the defined security server group will send a "start accounting" notice at the beginning of a process and a "stop accounting" notice at the end of a process. The "start accounting" record is sent in the background. (The requested user process begins regardless of whether the "start accounting" notice was received by the accounting server.)
stop-only	(Optional) Indicates that the defined security server group will send a "stop accounting" notice at the end of the requested user process.
none	(Optional) Indicates that the defined security server group will not send accounting notices.
broadcast	(Optional) Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.
group *groupname*	At least one of the keywords described in Table 10.

Defaults

This command is disabled by default.

Command Modes

Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced.
12.1(1)T	• The optional **broadcast** keyword was added. • The ability to specify multiple server groups was added. • To accommodate multiple server groups, the name of the command was changed from **aaa dnis map accounting network group** to **aaa dnis map accounting network**.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command lets you assign a DNIS number to a particular AAA server group so that the server group can process accounting requests for users dialing in to the network using that particular DNIS. To use this command, you must first enable AAA, define an AAA server group, and enable DNIS mapping.

Table 10 contains descriptions of accounting method keywords.

Table 10 AAA Accounting Methods

Keyword	Description
group radius	Uses the list of all RADIUS servers for authentication as defined by the **aaa group server radius command.**
group tacacs+	Uses the list of all TACACS+ servers for authentication as defined by the **aaa group server tacacs+** command.
group *group-name*	Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group *group-name*.

In Table 10, the **group radius** and **group tacacs+** methods refer to a set of previously defined RADIUS or TACACS+ servers. Use the **radius-server host** and **tacacs+-server host** commands to configure the host servers. Use the **aaa group server radius** and **aaa group server tacacs+** commands to create a named group of servers.

Examples

The following example maps DNIS number 7777 to the RADIUS server group called group1. Server group group1 will use RADIUS server 172.30.0.0 for accounting requests for users dialing in with DNIS 7777.

```
aaa new-model
radius-server host 172.30.0.0 acct-port 1646 key cisco1
aaa group server radius group1
 server 172.30.0.0
aaa dnis map enable
aaa dnis map 7777 accounting network group group1
```

Related Commands

Command	Description
aaa dnis map authentication ppp group	Maps a DNIS number to a particular authentication server group.
aaa dnis map enable	Enables AAA server selection based on DNIS.
aaa group server	Groups different server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
radius-server host	Specifies a RADIUS server host.

aaa dnis map authentication group

To map a dialed number identification service (DNIS) number to a particular authentication server group (this server group will be used for authentication, authorization, and accounting [AAA] authentication), use the **aaa dnis map authentication group** command in AAA-server-group configuration mode. To remove the DNIS number from the defined server group, use the **no** form of this command.

aaa dnis map *dnis-number* **authentication** {**ppp** | **login**} **group** *server-group-name*

no aaa dnis map *dnis-number* **authentication** {**ppp** | **login**} **group** *server-group-name*

Syntax Description

dnis-number	Number of the DNIS.
ppp	Enables PPP authentication methods.
login	Enables character-mode authentication.
server-group-name	Character string used to name a group of security servers associated in a server group.

Command Default

A DNIS number is not mapped to a server group.

Command Modes

AAA-server-group configuration

Command History

Release	Modification
12.0(7)T	This command was introduced.
12.1(3)XL1	This command was modified with the addition of the **login** keyword to include character-mode authentication.
12.2(2)T	Support for the **login** keyword was added into Cisco IOS Release 12.2(2)T and this command was implemented for the Cisco 2600 series, Cisco 3600 series, and Cisco 7200 platforms.
12.2(8)T	This command was implemented on the Cisco 806, Cisco 828, Cisco 1710, Cisco SOHO 78, Cisco 3631, Cisco 3725, Cisco 3745, and Cisco URM for IGX8400 platforms.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5800 platforms.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa dnis map authentication group** command to assign a DNIS number to a particular AAA server group so that the server group can process authentication requests for users that are dialing in to the network using that particular DNIS. To use the **aaa dnis map authentication group** command, you must first enable AAA, define a AAA server group, and enable DNIS mapping.

Examples

The following example maps DNIS number 7777 to the RADIUS server group called group1. Server group group1 uses RADIUS server 172.30.0.0 for authentication requests for users dialing in with DNIS number 7777.

```
aaa new-model
radius-server host 172.30.0.0 auth-port 1645 key cisco1
aaa group server radius group1
 server 172.30.0.0
 aaa dnis map enable
 aaa dnis map 7777 authentication ppp group group1
 aaa dnis map 7777 authentication login group group1
```

Related Commands

Command	Description
aaa dnis map accounting network group	Maps a DNIS number to a particular accounting server group.
aaa dnis map enable	Enables AAA server selection based on DNIS.
aaa group server	Groups different server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
radius-server host	Specifies a RADIUS server host.

aaa dnis map authorization network group

To map a Dialed Number Identification Service (DNIS) number to a particular authentication, authorization, and accounting (AAA) server group (the server group that will be used for AAA authorization), use the **aaa dnis map authorization network group** command in global configuration mode. To unmap this DNIS number from the defined server group, use the **no** form of this command.

aaa dnis map *dnis-number* **authorization network group** *server-group-name*

no aaa dnis map *dnis-number* **authorization network group** *server-group-name*

Syntax Description

dnis-number	Number of the DNIS.
server-group-name	Character string used to name a group of security servers functioning within a server group.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command lets you assign a DNIS number to a particular AAA server group so that the server group can process authorization requests for users dialing in to the network using that particular DNIS number. To use this command, you must first enable AAA, define a AAA server group, and enable DNIS mapping.

Examples

The following example maps DNIS number 7777 to the RADIUS server group called group1. Server group group1 will use RADIUS server 172.30.0.0 for authorization requests for users dialing in with DNIS 7777:

```
aaa new-model
radius-server host 172.30.0.0 auth-port 1645 key cisco1
aaa group server radius group1
server 172.30.0.0
aaa dnis map enable
aaa dnis map 7777 authorization network group group1
```

Related Commands

Command	Description
aaa new-model	Enables the AAA access control model.
aaa dnis map accounting network group	Maps a DNIS number to a AAA server group used for accounting services.
aaa dnis map authentication ppp group	Maps a DNIS number to a AAA server used for authentication services.
aaa dnis map enable	Enables AAA server selection based on DNIS number.
aaa group server	Groups different server hosts into distinct lists and methods.
radius-server host	Specifies and defines the IP address of the RADIUS server host.

aaa group server diameter

To group different Diameter server hosts into distinct lists and distinct methods, enter the **aaa group server diameter** command in global configuration mode. To remove a group server from the configuration list, enter the **no** form of this command.

aaa group server diameter *group-name*

no aaa group server diameter *group-name*

Syntax Description

group-name	Character string used to name the group of servers.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

The **aaa group server diameter command** introduces a way to group existing server hosts. This command enables you to select a subset of the configured server hosts and use them for a particular service.

A group server is a list of server hosts of a particular type. Currently supported server host types are Diameter server hosts, RADIUS server hosts, and TACACS+ server hosts. A group server is used in conjunction with a global server host list. The group server lists the IP addresses of the selected server hosts.

Examples

The following example shows the configuration of a Diameter server group named dia_group_1 that comprises two member servers configured as Diameter peers:

```
aaa group server diameter dia_group_1
 server dia_peer_1
 server dia_peer_2
```

Note If a peer port is not specified, the default value for the peer port is 3868.

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.
aaa authentication login	Sets AAA authentication at login.

Command	Description
aaa authorization	Sets parameters that restrict user access to a network.
server	Associates a Diameter server with a Diameter server group.

aaa group server ldap

To group different Lightweight Directory Access Protocol (LDAP) servers into distinct lists and distinct methods, use the **aaa group server ldap** command in global configuration mode. To remove a group server from the configuration list, enter the **no** form of this command.

aaa group server ldap *group-name*

no aaa group server ldap *group-name*

Syntax Description

group-name	Name of the server groups.

Command Default

No LDAP servers are configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

The **aaa group server ldap** command enables you to group existing servers. This command allows you to select a subset of the configured server and use them for a particular service.

A group server is a list of servers of a particular type. A group server is used in conjunction with a global server host list. The group server lists the IP addresses of the selected server hosts.

Examples

The following example shows how to configure an LDAP server group named ldp_group_1:

```
Router> enable
Router(config)# aaa group server ldp_group_1
```

Related Commands

Command	Description
aaa authentication login	Sets AAA authentication at login.
aaa authorization	Sets parameters that restrict user access to a network.
ldap server	Defines an LDAP server and enters LDAP server configuration mode.

aaa group server radius

To group different RADIUS server hosts into distinct lists and distinct methods, enter the **aaa group server radius** command in global configuration mode. To remove a group server from the configuration list, enter the **no** form of this command.

aaa group server radius *group-name*

no aaa group server radius *group-name*

Syntax Description

group-name	Character string used to name the group of servers. See Table 11 for a list of words that cannot be used as the *group-name* argument.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The authentication, authorization, and accounting (AAA) server-group feature introduces a way to group existing server hosts. The feature enables you to select a subset of the configured server hosts and use them for a particular service.

A group server is a list of server hosts of a particular type. Currently supported server host types are RADIUS server hosts and TACACS+ server hosts. A group server is used in conjunction with a global server host list. The group server lists the IP addresses of the selected server hosts.

Table 11 lists words that cannot be used as the *group-name* argument.

tacacs-server host	Specifies a TACACS+ host.

aaa intercept

To enable lawful intercept on a router, use the **aaa intercept** command in global configuration mode. To disable lawful intercept, use the **no** form of this command.

aaa intercept

no aaa intercept

Syntax Description

This command has no arguments or keywords.

Command Default

Lawful intercept is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(28)SB	This command was introduced.
Cisco IOS XE Release 2.6	This command was integrated into CiscoIOS XE Release 2.6.

Usage Guidelines

Use the **aaa intercept** command to enable a RADIUS-Based Lawful Intercept solution on your router. Intercept requests are sent (via Access-Accept packets or CoA-Request packets) to the network access server (NAS) or the Layer 2 Tunnel Protocol (L2TP) access concentrator (LAC) from the RADIUS server. All data traffic going to or from a PPP or L2TP session is passed to a mediation device.

Configure this command with high administrative security so that unauthoried people cannot remove the command.

Examples

The following example shows the configuration of a RADIUS-Based Lawful Intercept solution on a router acting as NAS device employing a PPP over Ethernet (PPPoEo) link:

```
aaa new-model
!
aaa intercept
!
aaa group server radius SG

```

aaa local authentication attempts max-fail

To specify the maximum number of unsuccessful authentication attempts before a user is locked out, use the **aaa local authentication attempts max-fail** command in global configuration mode. To remove the setting for the number of unsuccessful attempts, use the **no** form of this command.

aaa local authentication attempts max-fail *number-of-unsuccessful-attempts*

no aaa local authentication attempts max-fail *number-of-unsuccessful-attempts*

Syntax Description

number-of-unsuccessful-attempts	Number of unsuccessful authentication attempts.

Defaults

The Login Password Retry Lockout feature is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRE	This command was modified. It was integrated into Cisco IOS Release 12.2(33)SRE.

Usage Guidelines

A system message is generated when a user is either locked by the system or unlocked by the system administrator:

```
%AAA-5-USER_LOCKED: User user1 locked out on authentication failure.
```

An administrator cannot be locked out.

Note No messages are displayed to users after authentication failures that are due to the locked status (that is, there is no distinction between a normal authentication failure and an authentication failure due to the locked status of the user).

Note Unconfiguring this command will maintain the status of the user with respect to locked-out or number-of-failed attempts. To clear the existing locked-out or number-of-failed attempts, the system administrator has to explicitly clear the status of the user using **clear** commands.

Examples

The following example illustrates that the maximum number of unsuccessful authentication attempts before a user is locked out has been set for 2:

```
username sysadmin
username sysad privilege 15 password 0 cisco
username user1 password 0 cisco
```

```
aaa new-model
aaa local authentication attempts max-fail 2
!
!
aaa authentication login default local
aaa dnis map enable
aaa session-id common
ip subnet-zero
```

Related Commands

Command	Description
clear aaa local user fail-attempts	Clears the unsuccessful login attempts of the user.
clear aaa local user lockout	Unlocks the locked-out user.
show aaa local user locked	Displays a list of all locked-out users.

aaa max-sessions

To set the maximum number of simultaneous authentication, authorization, and accounting (AAA) connections permitted for a user, use the **aaa max-sessions** command in global configuration mode. To disable the maximum number of sessions, use the **no** form of this command.

aaa max-sessions *maximum-number-of-sessions*

no aaa max-sessions

Syntax Description

maximum-number-of-sessions	Number of estimated AAA maximum sessions. The range is from 1024 to 64000.

Command Default

The default value for **aaa max-sessions** command is platform dependent.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.

Usage Guidelines

The **aaa max-sessions** command enables you to set the maximum number of simultaneous connections permitted for a user. The **aaa max-sessions** command can be used only if the **aaa new-model** command is configured.

Examples

The following example shows how to adjust the initial hash size for the maximum number of simultaneous AAA sessions:

```
Router# configure terminal
Router(config)# aaa max-sessions 1025
```

Related Commands

Command	Description
aaa new-model	Enables the AAA access control model.

aaa memory threshold

To set appropriate threshold values for the authentication, authorization, and accounting (AAA) memory parameters, use the **aaa memory threshold** command in global configuration mode. To remove threshold values for the AAA memory parameters, use the **no** form of this command.

aaa memory threshold {**accounting disable** *available-memory* | **authentication reject** *available-memory*}

no aaa memory threshold {**accounting disable | authentication reject**}

Syntax Description

accounting	Sets the AAA accounting low-memory threshold.
disable	Disables the accounting threshold, if the available memory falls below the specified percentage.
available-memory	Available memory threshold. The range is from 1 to 15.
authentication	Sets the AAA authentication low-memory threshold.
reject	Rejects the AAA authentication request, if the available memory falls below the specified percentage.
available-memory	Available memory threshold. The range is from 2 to 15.

Command Default

The default memory threshold value for authentication is 3, and the default memory threshold value for accounting is 2.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.

Usage Guidelines

You must use the **aaa new-model** command to enable AAA.

Examples

The following example shows how to set the threshold values for the AAA accounting low-memory threshold:

```
Router> enable
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa memory threshold accounting disable 2
```

Related Commands

Command	Description
show aaa memory	Displays the output of the AAA data structure memory tracing information.

aaa nas cisco-nas-port use-async-info

To display physical interface information and parent interface details as part of the of the cisco-nas-port vendor-specific attribute (VSA) for login calls, use the **aaa nas cisco-nas-port use-async-info** command in global configuration mode. To disable the command, use the **no** form of the command.

aaa nas cisco-nas-port use-async-info

no aaa nas cisco-nas-port use-async-info

Syntax Description

This command has no arguments or keywords.

Defaults

The cisco-nas-port attribute has the format of tty*x*/*y* for login calls. Physical interface information is not included.

Command Modes

Global configuration

Command History

Release	Modification
12.3(17)	This command was introduced on the Cisco AS5800.

Usage Guidelines

This command enables the display of interface and parent interface details for login calls.

When this command is not configured, the cisco-nas-port attribute provides only tty*x*/*y* information for login calls. No physical interface information is included. For example:

```
Oct 14 18:42:53.113: RADIUS:  Vendor, Cisco       [26]  17
Oct 14 18:42:53.113: RADIUS:   cisco-nas-port     [2]   11  "tty1/2/07"
```

Other calls, such as PPP, include the physical interface and parent interface details. For example:

```
Oct 14 18:36:00.692: RADIUS:  Vendor, Cisco       [26]  33
Oct 14 18:36:00.692: RADIUS:   cisco-nas-port     [2]   27  "Async1/2/07*Serial1/1/2:0"
```

When you issue the **aaa nas cisco-nas-port use-async-info** command, the interface and parent interface details are included in the login calls.

Examples

The following example shows how to enable the display of interface and parent interface details in the login calls:

```
aaa nas cisco-nas-port use-async-info
```

To replace the NAS-Port attribute with RADIUS IETF attribute 26 and to display extended field information, use the **aaa nas port extended** command in global configuration mode. To display no extended field information, use the **no** form of this command.

aaa nas port extended

no aaa nas port extended

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

On platforms with multiple interfaces (ports) per slot, the Cisco RADIUS implementation will not provide a unique NAS-Port attribute that permits distinguishing between the interfaces. For example, if a dual PRI interface is in slot 1, calls on both Serial1/0:1 and Serial1/1:1 will appear as NAS-Port = 20101 due to the 16-bit field size limitation associated with RADIUS IETF NAS-Port attribute.

In this case, the solution is to replace the NAS-Port attribute with a vendor-specific attribute (RADIUS IETF Attribute 26). Cisco's vendor ID is 9, and the Cisco-NAS-Port attribute is subtype 2. Vendor-specific attributes (VSAs) can be turned on by entering the **radius-server vsa send** command. The port information in this attribute is provided and configured using the **aaa nas port extended** command.

The standard NAS-Port attribute (RADIUS IETF attribute 5) will continue to be sent. If you do not want this information to be sent, you can suppress it by using the **no radius-server attribute nas-port** command. When this command is configured, the standard NAS-Port attribute will no longer be sent.

Examples

The following example specifies that RADIUS will display extended interface information:

```
radius-server vsa send
aaa nas port extended
```

Related Commands

Command	Description
radius-server extended-portnames	Displays expanded interface information in the NAS-Port attribute.
radius-server vsa send	Configures the network access server to recognize and use vendor-specific attributes.

aaa nas port option82

To send the remote-id and circuit-id as the NAS-Port-Id attribute in the Access-Request and Accounting-Request, use the **aaa nas port option82** command in global configuration mode. To disable this option, use the **no** form of this command.

aaa nas port option82

no aaa nas port option82

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2SB	This command was introduced in Cisco IOS Release 12.2SB.

Usage Guidelines

On platforms with multiple interfaces (ports) per slot, the Cisco RADIUS implementation will not provide a unique NAS-Port attribute that permits distinguishing between the interfaces. For example, if a dual PRI interface is in slot 1, calls on both Serial1/0:1 and Serial1/1:1 will appear as NAS-Port = 20101 due to the 16-bit field size limitation of the RADIUS IETF NAS-Port attribute.

In this case, the solution is to replace the NAS-Port attribute with the vendor-specific attribute (VSA) RADIUS IETF Attribute 26. The Cisco vendor ID is 9, and the Cisco-NAS-Port attribute is subtype 2. VSAs can be turned on by entering the **radius-server vsa send** command. The NAS-Port string information in this attribute is provided and configured using the **aaa nas port option82** command.

The standard NAS-Port attribute (RADIUS IETF attribute 5) will continue to be sent. If you do not want this information to be sent, you can suppress it by using the **no radius-server attribute nas-port** command. When this command is configured, the standard NAS-Port attribute will no longer be sent.

The NAS-Port information is populated in the Intelligent Service Gateway (ISG) interface that has received the DHCP **option82** packet. When the **aaa nas port option82** command is configured, the NAS-Port is populated with the information regarding the remote-id and circuit-id. If this command is not configured, the NAS-Port is populated with the local ISG NAS-Port-Id.

Examples

The following example specifies that RADIUS will display extended interface information:

```
radius-server vsa send
aaa nas port option82
```

Related Commands

Command	Description
radius-server vsa send	Configures the network access server to recognize and use VSAs.

aaa nas redirected-station

To include the original number in the information sent to the authentication server when the number dialed by a device is redirected to another number for authentication, use the **aaa nas redirected-station** command in global configuration mode. To leave the original number out of the information sent to the authentication server, use the **no** form of this command.

aaa nas redirected-station

no aaa nas redirected-station

Syntax Description

This command has no arguments or keywords.

Defaults

The original number is not included in the information sent to the authentication server.

Command Modes

Global configuration

Command History

Release	Modification
12.1 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If a customer is being authenticated by a RADIUS or TACACS+ server and the number dialed by the cable modem (or other device) is redirected to another number for authentication, the **aaa nas redirected-station** command will enable the original number to be included in the information sent to the authentication server.

This functionality allows the service provider to determine whether the customer dialed a number that requires special billing arrangements, such as a toll-free number.

The original number can be sent as a Cisco Vendor Specific Attribute (VSA) for TACACS+ servers and as RADIUS Attribute 93 (Ascend-Redirect-Number) for RADIUS servers. The RADIUS Attribute 93 is sent by default; to also send a VSA attribute for TACACS+ servers, use the **radius-server vsa send accounting** and **radius-server vsa send authentication** commands. To configure the RADIUS server to use RADIUS Attribute 93, add the non-standard option to the **radius-server host** command.

Note This feature is valid only when using port adapters that are configured for a T1 or E1 ISDN PRI or BRI interface. In addition, the telco switch performing the number redirection must be able to provide the redirected number in the Q.931 Digital Subscriber Signaling System Network Layer.

Examples

The following example enables the original number to be forwarded to the authentication server:

```
!
aaa authorization config-commands
aaa accounting exec default start-stop group radius
aaa accounting system default start-stop broadcast group apn23
aaa nas redirected-station
aaa session-id common
ip subnet-zero
!
```

Related Commands

Command	Description
radius-server host	Specifies a RADIUS server host.
radius-server vsa	Configures the network access server to recognize and use vendor-specific attributes.

aaa new-model

To enable the authentication, authorization, and accounting (AAA) access control model, issue the **aaa new-model** command in global configuration mode. To disable the AAA access control model, use the **no** form of this command.

aaa new-model

no aaa new-model

Syntax Description

This command has no arguments or keywords.

Command Default

AAA is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.4(4)T	Support for IPv6 was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2(33)SXI	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command enables the AAA access control system.

Examples

The following example initializes AAA:

```
aaa new-model
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.
aaa authentication arap	Enables an AAA authentication method for ARAP using TACACS+.
aaa authentication enable default	Enables AAA authentication to determine if a user can access the privileged command level.
aaa authentication login	Sets AAA authentication at login.

Command	Description
aaa authentication ppp	Specifies one or more AAA authentication method for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict user access to a network.

aaa password

To configure restrictions for an authentication, authorization, and accounting (AAA) password, use the **aaa password** command in in global configuration mode. To disable the password restriction, use the **no** form of this command.

aaa password restriction

no aaa password restriction

Syntax Description

restriction	Configures restrictions to the password.

Command Default

AAA passwords have no restrictions.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

The **aaa password** command can be used only if the **aaa new-model** command is configured. The restrictions are not applied to passwords in the startup configurations. The restrictions are not applied to passwords that already present in the configurations before the **aaa password** command is enabled.

Passwords are subject to the following restrictions:

- The new password must contain characters from at least three of the following classes: lowercase letters, uppercase letters, digits, and special characters.
- The new password should not have a character repeated more than three times consecutively.
- The new password should not be the same as the associated username. The password obtained by capitalization of the username or username reversed is not accepted.
- The new password should not be “cisco”, “ocsic”, or any variant obtained by changing the capitalization of letters therein, or by substituting “1” “|” or “!” for i, or by substituting “0” for “o”, or substituting “$” for “s”.

The restrictions can be applied to the passwords configured using the following commands: **aaa pod server**, **enable password**, **enable secret**, **radius-server key**, **radius-server host key**, **server-key**, and the **tacacs-server key**command.

Examples

The following example shows how to configure restrictions for an aaa password:

```
Router(config)# aaa password restriction
```

Related Commands

Command	Description
aaa pod server	Enables inbound user sessions to be disconnected when specific session attributes are presented.
enable password	Sets a local password to control access to various privilege levels.
enable secret	Specifies an additional layer of security over the enable password command.
radius-server key	Sets the authentication and encryption key for all RADIUS communications between the router and the RADIUS daemon.
radius-server host	Specifies a RADIUS server host.
server-key	Configure the RADIUS key to be shared between a device and RADIUS clients.
tacacs-server host	Sets the authentication encryption key used for all TACACS+ communications between the access server and the TACACS+ daemon.

aaa pod server

To enable inbound user sessions to be disconnected when specific session attributes are presented, use the **aaa pod server** command in global configuration mode. To disable the configuration, use the **no** form of this command.

aaa pod server [**clients** *ip-address1 ip-address2 ... ip-addressn*] [**port** *port-number*] {**auth-type** [**all ignore | any ignore**] **session-key server-key** *string* **| ignore** [**session-key**] **server-key | server-key** *string*}

no aaa pod server

Syntax Description

clients *ip-address*	(Optional) Registers the IP address of all the clients who can send POD requests. If this configuration is present and a POD request originates from a device that is not on the list, it is rejected. You can specify only four client IP addresses.
port *port number*	(Optional) Network access server User Datagram Protocol (UDP) port to use for packet of disconnect (POD) requests. Default value is 1700.
auth-type	Type of authorization required for disconnecting sessions. If no authentication type is specified, **auth-type** is the default.
all	(Optional) Only a session that matches all four key attributes is disconnected. The default is **all**.
any	(Optional) Session that matches all of the attributes sent in the POD packet is disconnected. The POD packet may contain one or more of four key attributes (user-name, framed-IP-address, session-ID, and session-key).
ignore	Ignores the session key or the server key received in the POD packet for session matching.
session-key	Session with a matching session-key attribute is disconnected. All other attributes are ignored.
server-key	Configures the shared-secret text string.
string	Shared-secret text string that is shared between the network access server and the client workstation. This shared-secret string must be the same on both systems.

Defaults

The POD server function is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Release	Modification
12.2(2)XB	The *encryption-type* argument was added, as well as support for the voice applications and the Cisco 3600 series, and Cisco AS5350, and Cisco AS5400 routers.
12.2(2)XB1	Support for the Cisco AS5800 was added.
12.2(11)T	The *encryption-type* argument and support for the voice applications were added. **Note** Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800 is not included in this release.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was modified. The **clients** and **ignore** keywords were added.

Usage Guidelines

To disconnect a session, the values in one or more of the key fields in the POD request must match the values for a session on one of the network access server ports. Which values must match depends on the **auth-type** attribute defined in the command. If no **auth-type** attribute is specified, all three values must match. If no match is found, all connections remain intact and an error response is returned. The key fields are as follows:

- An h323-conf-id vendor-specific attribute (VSA) with the same content as received from the gateway for this call.
- An h323-call-origin VSA with the same content as received from the gateway for the leg of interest.
- A 16-byte Message Digest 5 (MD5) hash value that is carried in the *authentication* field of the POD request.

Examples

The following example shows how to enable POD and set the secret key to “xyz123”:

```
aaa pod server server-key xyz123
```

Related Commands

Command	Description
aaa accounting delay-start	Delays generation of the start accounting record until the user IP address is established.
aaa accounting	Enables accounting records.
debug aaa pod	Displays debug messages for POD packets.
radius-server host	Identifies a RADIUS host.

aaa preauth

To enter authentication, authorization, and accounting (AAA) preauthentication configuration mode, use the **aaa preauth** command in global configuration mode. To disable preauthentication, use the **no** form of this command.

aaa preauth

no aaa preauth

Syntax Description

This command has no arguments or keywords.

Defaults

Preauthentication is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

To enter AAA preauthentication configuration mode, use the **aaa preauth** command. To configure preauthentication, use a combination of the **aaa preauth** commands: **group**, **clid**, **ctype**, **dnis**, and **dnis bypass**. You must configure the **group** command. You must also configure one or more of the **clid**, **ctype**, **dnis**, or **dnis bypass** commands.

In addition to using the preauthentication commands to configure preauthentication on the Cisco router, you must set up the preauthentication profiles on the RADIUS server.

You can use the **clid**, **ctype**, or **dnis** commands to define the list of the preauthentication elements. For each preauthentication element, you can also define options such as password (for all the elements, the default password is cisco). If you specify multiple elements, the preauthentication process will be performed on each element according to the order of the elements that you configure with the preauthentication commands. In this case, more than one RADIUS preauthentication profile is returned, but only the last preauthentication profile will be applied to the authentication and authorization later on, if applicable.

Examples

The following example enables dialed number identification service (DNIS) preauthentication using a RADIUS server and the password Ascend-DNIS:

```
aaa preauth
 dnis password Ascend-DNIS
```

Related Commands

Command	Description
dnis (authentication)	Enables AAA preauthentication using DNIS.
group (authentication)	Selects the security server to use for AAA preauthentication.
isdn guard-timer	Sets a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.

aaa processes

To allocate a specific number of background processes to be used to process authentication, authorization, and accounting (AAA) authentication and authorization requests for PPP, use the **aaa processes** command in global configuration mode. To restore the default value for this command, use the **no** form of this command.

aaa processes *number*

no aaa processes *number*

Syntax Description

number	Specifies the number of background processes allocated for AAA requests for PPP. Valid entries are 1 to 2147483647.

Defaults

The default for this command is one allocated background process.

Command Modes

Global configuration

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aaa processes** command to allocate a specific number of background processes to simultaneously handle multiple AAA authentication and authorization requests for PPP. Previously, only one background process handled all AAA requests for PPP, so only one new user could be authenticated or authorized at a time. This command configures the number of processes used to handle AAA requests for PPP, increasing the number of users that can be simultaneously authenticated or authorized.

The argument *number* defines the number of background processes earmarked to process AAA authentication and authorization requests for PPP. This argument also defines the number of new users that can be simultaneously authenticated and can be increased or decreased at any time.

Examples

The following examples shows the **aaa processes** command within a standard AAA configuration. The authentication method list “dialins” specifies RADIUS as the method of authentication, then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP. Ten background processes have been allocated to handle AAA requests for PPP.

```
aaa new-model
aaa authentication ppp dialins group radius local
aaa processes 10
interface 5
```

```
encap ppp
ppp authentication pap dialins
```

Related Commands

Command	Description
show ppp queues	Monitors the number of requests processed by each AAA background process.

aaa route download

To enable the static route download feature and set the amount of time between downloads, use the **aaa route download** command in global configuration mode. To disable this function, use the **no** form of this command.

aaa route download [*time*] [**authorization** *method-list*]

no aaa route download

Syntax Description

time	(Optional) Time between downloads, in minutes. The range is from 1 to 1440 minutes.
authorization *method-list*	(Optional) Specify a named method list to which RADIUS authorization requests for static route downloads are sent. If these attributes are not set, all RADIUS authorization requests will be sent to the servers that are specified by the default method list.

Defaults

The default period between downloads (updates) is 720 minutes.

Command Modes

Global configuration

Command History

Release	Modification
12.0(3)T	This command was introduced.
12.1	This command was integrated into Cisco IOS Release 12.1.
12.2(8)T	The **authorization** keyword was added; the *method-list* argument was added.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

This command is used to download static route details from the authorization, authentication, and accounting (AAA) server if the name of the router is *hostname*. The name passed to the AAA server for static routes is *hostname-1*, *hostname-2*... *hostname-n*—the router downloads static routes until it fails an index and no more routes can be downloaded.

Examples

The following example sets the AAA route update period to 100 minutes:

```
aaa route download 100
```

The following example sets the AAA route update period to 10 minutes and sends static route download requests to the servers specified by the method list name “list1”:

```
aaa route download 10 authorization list1
```

Related Commands

Command	Description
aaa authorization configuration default	Downloads static route configuration information from the AAA server using TACACS+ or RADIUS.
clear ip route download	Clears static routes downloaded from a AAA server.
show ip route	Displays all static IP routes, or those installed using the AAA route download function.

aaa server radius dynamic-author

To configure a device as an authentication, authorization, and accounting (AAA) server to facilitate interaction with an external policy server, use the **aaa server radius dynamic-author** command in global configuration mode. To remove this configuration, use the **no** form of this command.

aaa server radius dynamic-author

no aaa server radius dynamic-author

Syntax Description

This command has no arguments or keywords.

Command Default

The device will not function as a server when interacting with external policy servers.

Command Modes

Global configuration

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.4	This command was integrated into Cisco IOS Release 12.4.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.
12.2(5)SXI	This command was integrated into Cisco IOS Release 12.2(5)SXI.

Usage Guidelines

Dynamic authorization allows an external policy server to dynamically send updates to a device. Once the **aaa server radius dynamic-author** command is configured, dynamic authorization local server configuration mode is entered. Once in this mode, the RADIUS application commands can be configured.

Dynamic Authorization for the Intelligent Services Gateway (ISG)

ISG works with external devices, referred to as policy servers, that store per-subscriber and per-service information. ISG supports two models of interaction between the ISG device and external policy servers: initial authorization and dynamic authorization.

The dynamic authorization model allows an external policy server to dynamically send policies to the ISG. These operations can be initiated in-band by subscribers (through service selection) or through the actions of an administrator, or applications can change policies on the basis of an algorithm (for example, change session quality of service (QoS) at a certain time of day). This model is facilitated by the Change of Authorization (CoA) RADIUS extension. CoA introduced peer-to-peer capability to RADIUS, enabling ISG and the external policy server each to act as a RADIUS client and server.

Examples

The following example configures the ISG to act as a AAA server when interacting with the client at IP address 10.12.12.12:

```
aaa server radius dynamic-author
 client 10.12.12.12 key cisco
 message-authenticator ignore
```

Related Commands

Command	Description
auth-type (ISG)	Specifies the server authorization type.
client	Specifies a RADIUS client from which a device will accept CoA and disconnect requests.
default	Sets a RADIUS application command to its default.
domain	Specifies username domain options.
ignore	Overrides a behavior to ignore certain paremeters.
port	Specifies a port on which local RADIUS server listens.
server-key	Specifies the encryption key shared with RADIUS clients.

aaa service-profile

To configure the service profile parameters for an authentication, authorization, and accounting (AAA) session, use the **aaa service-profile** command in global configuration mode. To disable the service profile parameters for AAA sessions, use the **no** form of this command.

aaa service-profile key username-with-nasport

no aaa service-profile key username-with-nasport

Syntax Description

key	Assigns a key to save and search service profiles.
username-with-nasport	Configures the AAA server to use the username and network access server (NAS) port as the service profile key.

Command Default

Service profiles are stored based on the username.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Examples

The following example shows how to configure the service profile parameters for a AAA session:

```
Router# enable
Router# configure terminal
Router(config)# aaa service-profile key username-with-nasport
```

Related Commands

Command	Description
show aaa service-profiles	Displays the service profiles downloaded and stored by a AAA session.

aaa session-id

To specify whether the same session ID will be used for each authentication, authorization, and accounting (AAA) accounting service type within a call or whether a different session ID will be assigned to each accounting service type, use the **aaa session-id** command in global configuration mode. To restore the default behavior after the **unique** keyword is enabled, use the **no** form of this command.

aaa session-id [**common** | **unique**]

no aaa session-id [**unique**]

Syntax Description

common	(Optional) Ensures that all session identification (ID) information that is sent out for a given call will be made identical. The default behavior is **common**.
unique	(Optional) Ensures that only the corresponding service access-requests and accounting-requests will maintain a common session ID. Accounting-requests for each service will have a different session ID.

Defaults

The **common** keyword is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(4)B	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **common** keyword behavior allows the first session ID request of the call to be stored in a common database; all proceeding session ID requests will retrieve the value of the first session ID. Because a common session ID is the default behavior, this functionality is written to the system configuration after the **aaa new-model** command is configured.

Note The router configuration will always have either the **aaa session-id common** or the **aaa session-id unique** command enabled; it is not possible to have neither of the two enabled. Thus, the **no aaa session-id unique** command will revert to the default functionality, but the **no aaa session-id common** command will not have any effect because it is the default functionality.

The **unique** keyword behavior assigns a different session ID for each accounting type (Auth-Proxy, Exec, Network, Command, System, Connection, and Resource) during a call. To specify this behavior, the unique keyword *must* be specified. The session ID may be included in RADIUS access requests by configuring the **radius-server attribute 44 include-in-access-req** command. The session ID in the access-request will be the same as the session ID in the accounting request for the same service; all other services will provide unique session IDs for the same call.

Examples

The following example shows how to configure unique session IDs:

```
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server attribute 44 include-in-access-req
aaa session-id unique
```

Related Commands

Command	Description
aaa new model	Enables AAA.
radius-server attribute 44 include-in-access-req	Sends RADIUS attribute 44 (Accounting Session ID) in access request packets before user authentication (including requests for preauthentication).

aaa session-mib

To configure MIB options for Simple Network Management Protocol (SNMP) authentication, authorization, and accounting (AAA) sessions, use the **aaa session-mib** command in global configuration mode. To disable these options, use the **no** form of this command.

aaa session-mib {**disconnect** | **populate** {**setup** | **start**}}

no aaa session-mib {**disconnect** | **populate** {**setup** | **start**}}

Syntax Description

disconnect	Enables an AAA session MIB to disconnect authenticated clients using SNMP.
populate setup	Specifies that the AAA session MIB starts to track a session at the setup of the session.
populate start	Specifies that the AAA session MIB starts to track a session when accounting starts (when the START record is sent).

Command Default

No MIB options for SNMP AAA sessions are configured. OR IS THE DEFAULT “populate setup” AS DISCUSSED IN THE ‘Evaluation’ ATTACHMENT OF THE ENGINEERING DDTS (http://cdetsweb-prd.cisco.com/cdets/cli/ViewNote.html?identifier=CSCec12532&title=Evaluation)???

Command Modes

Global configuration (config)

Release	Modification
12.1(3)T	This command was introduced.
12.3(5)	The populate, setup and start keywords were added.
12.3(5a)B	The populate, setup and start keywords were added.
12.3(7)T	The populate, setup and start keywords were added.
12.2(16)BX3	The populate, setup and start keywords were added.
12.3(7)XI	The populate, setup and start keywords were added.
12.3(12)	The populate, setup and start keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **disconnect** keyword enables termination of authenticated client connections via SNMP. Without this keyword, a network management station cannot perform set operations and disconnect users (it can only poll the table).

The **populate** keyword determines when reporting of a locally terminated sessions begins. Two options are provided: **setup** (default) and **start**. The **setup** keyword begins tracking the session parameters during the setup of a session while the **start** keyword begins when the accounting START notification is generated and sent. By default, Cisco AAA session MIB begins reporting sessions generated during setup.

Examples

The following example shows how to enable the disconnection of authenticated clients using SNMP:

```
Router> enable
Router# configure terminal
Router(config)# aaa session-mib disconnect
```

The following example shows how to start tracking of a session at setup:

```
Router> enable
Router# configure terminal
Router(config)# aaa session-mib populate setup
```

aaa traceback recording

To enable traceback recording on an authentication, authorization, and accounting (AAA) server, use the **aaa traceback recording** command in global configuration mode. To disable the configuration, use the **no** form of this command.

aaa traceback recording

no aaa traceback recording

Syntax Description

This command has no arguments or keywords.

Command Default

Traceback recording is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows how to enable traceback recording on a AAA server:

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa traceback recording
```

Related Commands

Command	Description
aaa new-model	Enables the AAA access control model.

aaa user profile

To create an authentication, authorization, and accounting (AAA) named user profile, use the **aaa user profile** command in global configuration mode. To remove a user profile from the configuration, use the **no** form of this command.

aaa user profile *profile-name*

no aaa user profile *profile-name*

Syntax Description

profile-name	Character string used to name the user profile. The maximum length of the character string is 63 characters. Longer strings will be truncated.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.3(3.8)	The maximum length of the *profile-name* argument is set at 63 characters.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

Use the **aaa user profile** command to create a AAA user profile. Used in conjunction with the **aaa attribute** command, which adds calling line identification (CLID) and dialed number identification service (DNIS) attribute values, the user profile can be associated with the record that is sent to the RADIUS server (via the **test aaa group** command), which provides the RADIUS server with access to CLID or DNIS attribute information when the server receives a RADIUS record.

Examples

The following example shows how to configure a dnis = dnisvalue user profile named “prfl1”:

```
aaa user profile prfl1
 aaa attribute dnis
 aaa attribute dnis dnisvalue
 no aaa attribute clid
! Attribute not found.
 aaa attribute clid clidvalue
 no aaa attribute clid
```

Related Commands

Command	Description
aaa attribute	Adds DNIS or CLID attribute values to a user profile.
test aaa group	Associates a DNIS or CLID user profile with the record that is sent to the RADIUS server.

access (firewall farm)

To route specific flows to a firewall farm, use the **access** command in firewall farm configuration mode. To restore the default settings, use the **no** form of this command.

access [**source** *source-ip netmask* | **destination** *destination-ip netmask* | **inbound** *inbound-interface* | **outbound** *outbound-interface*]

no access [**source** *source-ip netmask* | **destination** *destination-ip netmask* | **inbound** *inbound-interface* | **outbound** *outbound-interface*]

Syntax Description

source	(Optional) Routes flows based on source IP address.
source-ip	(Optional) Source IP address. The default is 0.0.0.0 (all sources).
netmask	(Optional) Source IP network mask. The default is 0.0.0.0 (all source subnets).
destination	(Optional) Routes flows based on destination IP address.
destination-ip	(Optional) Destination IP address. The default is 0.0.0.0 (all destinations).
netmask	(Optional) Destination IP network mask. The default is 0.0.0.0 (all destination subnets).
inbound *inbound-interface*	(Optional) Indicates that the firewall farm is to accept inbound packets only on the specified inbound interface.
outbound *outbound-interface*	(Optional) Indicates that the firewall farm is to accept outbound packets only on the specified outbound interface.

Defaults

The default source IP address is 0.0.0.0 (routes flows from all sources to this firewall farm).
The default source IP network mask is 0.0.0.0 (routes flows from all source subnets to this firewall farm).
The default destination IP address is 0.0.0.0 (routes flows from all destinations to this firewall farm).
The default destination IP network mask is 0.0.0.0 (routes flows from all destination subnets to this firewall farm).
If you do not specify an inbound interface, the firewall farm accepts inbound packets on all inbound interfaces.
If you do not specify an outbound interface, the firewall farm accepts outbound packets on all outbound interfaces.

Command Modes

Firewall farm configuration (config-slb-fw)

Command History

Release	Modification
12.1(7)E	This command was introduced.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(18)SXE	The **inbound** and **outbound** keywords and *inbound-interface* and *outbound-interface* arguments were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can specify more than one source or destination for each firewall farm. To do so, configure multiple **access** statements, making sure the network masks do not overlap each other.

You can specify up to two inbound interfaces and two outbound interfaces for each firewall farm. To do so, configure multiple **access** statements, keeping the following considerations in mind:

- All inbound and outbound interfaces must be in the same Virtual Private Network (VPN) routing and forwarding (VRF).
- All inbound and outbound interfaces must be different from each other.
- You cannot change inbound or outbound interfaces for a firewall farm while it is in service.

Examples

The following example routes flows with a destination IP address of 10.1.6.0 to firewall farm FIRE1:

```
Router(config)# ip slb firewallfarm FIRE1
Router(config-slb-fw)# access destination 10.1.6.0 255.255.255.0
```

Related Commands

Command	Description
show ip slb firewallfarm	Displays information about the firewall farm configuration.

access (server farm)

To configure an access interface for a server farm, use the **access** command in server farm configuration mode. To disable the access interface, use the **no** form of this command.

access *interface*

no access *interface*

Syntax Description

interface	Interface to be inspected. The server farm will handle outbound flows from real servers only on the specified interface.

Defaults

The server farm handles outbound flows from real servers on all interfaces.

Command Modes

Server farm configuration (config-slb-sfarm)

Command History

Release	Modification
12.2(18)SXE	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The virtual server and its associated server farm interfaces must be in the same Virtual Private Network (VPN) routing and forwarding (VRF).

You can specify up to two access interfaces for each server farm. To do so, configure two **access** statements, keeping the following considerations in mind:

- The two interfaces must be in the same VRF.
- The two interfaces must be different from each other.
- The access interfaces of primary and backup server farms must be the same.
- You cannot change the interfaces for a server farm while it is in service.

Examples

The following example limits the server farm to handling outbound flows from real servers only on access interface Vlan106:

```
Router(config)# ip slb serverfarm SF1
Router(config-slb-sfarm)# access Vlan106
```

Related Commands

Command	Description
show ip slb serverfarms	Displays information about the server farms.

access (virtual server)

To enable framed-IP routing to inspect the ingress interface, use the **access** command in virtual server configuration mode. To disable framed-IP routing, use the **no** form of this command.

access *interface* [**route framed-ip**]

no access *interface* [**route framed-ip**]

Syntax Description

interface	Interface to be inspected.
route framed-ip	(Optional) Routes flows using framed-IP routing.

Defaults

Framed-IP routing cannot inspect the ingress interface.

Command Modes

Virtual server configuration (config-slb-vserver)

Command History

Release	Modification
12.1(12c)E	This command was introduced.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(18)SXE	The command was modified to accept up to two framed-IP access interfaces (specified on separate commands).
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command enables framed-IP routing to inspect the ingress interface when routing subscriber traffic. All framed-IP sticky database entries created as a result of RADIUS requests to this virtual server will include the interface in the entry. In addition to matching the source IP address of the traffic with the framed-IP address, the ingress interface must also match this interface when this command is configured.

You can use this command to allow subscriber data packets to be routed to multiple service gateway service farms.

The virtual server and its associated server farm interfaces must be in the same Virtual Private Network (VPN) routing and forwarding (VRF).

You can specify up to two framed-IP access interfaces for each virtual server. To do so, configure two **access** statements, keeping the following considerations in mind:

- The two interfaces must be in the same VRF.
- The two interfaces must be different from each other.
- You cannot change the interfaces for a virtual server while it is in service.

Examples

The following example enables framed-IP routing to inspect ingress interface Vlan20:

```
Router(config)# ip slb vserver SSG_AUTH
Router(config-slb-vserver)# access Vlan20 route framed-ip
```

Related Commands

Command	Description
show ip slb vservers	Displays information about the virtual servers defined to IOS SLB.

access-class

To restrict incoming and outgoing connections between a particular vty (into a Cisco device) and the addresses in an access list, use the **access-class** command in line configuration mode. To remove access restrictions, use the **no** form of this command.

access-class *access-list-number* {**in** [**vrf-also**] | **out**}

no access-class *access-list-number* {**in** | **out**}

Syntax Description

access-list-number	Number of an IP access list. This is a decimal number from 1 to 199 or from 1300 to 2699.
in	Restricts incoming connections between a particular Cisco device and the addresses in the access list.
vrf-also	(Optional) Accepts incoming connections from interfaces that belong to a VRF.
out	Restricts outgoing connections between a particular Cisco device and the addresses in the access list.

Defaults

No access lists are defined.

Command Modes

Line configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2	The **vrf-also** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Remember to set identical restrictions on all the virtual terminal lines because a user can connect to any of them.

To display the access lists for a particular terminal line, use the **show line** EXEC command and specify the line number.

If you do not specify the **vrf-also** keyword, incoming Telnet connections from interfaces that are part of a VRF are rejected.

Examples

The following example defines an access list that permits only hosts on network 192.89.55.0 to connect to the virtual terminal ports on the router:

```
access-list 12 permit 192.89.55.0 0.0.0.255
```

```
 line 1 5
 access-class 12 in
```

The following example defines an access list that denies connections to networks other than network 10.0.0.0 on terminal lines 1 through 5:

```
access-list 10 permit 10.0.0.0 0.255.255.255
 line 1 5
 access-class 10 out
```

Related Commands

Command	Description
show line	Displays the parameters of a terminal line.

access-enable

To enable the router to create a temporary access list entry in a dynamic access list, use the **access-enable** command in EXEC mode.

access-enable [**host**] [**timeout** *minutes*]

Syntax Description

host	(Optional) Tells the software to enable access only for the host from which the Telnet session originated. If not specified, the software allows all hosts on the defined network to gain access. The dynamic access list contains the network mask to use for enabling the new network.
timeout *minutes*	(Optional) Specifies an idle timeout for the temporary access list entry. If the access list entry is not accessed within this period, it is automatically deleted and requires the user to authenticate again. The default is for the entries to remain permanently. We recommend that this value equal the idle timeout set for the WAN connection.

Defaults

No default behavior or values.

Command Modes

EXEC

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command enables the lock-and-key access feature.

You should always define either an idle timeout (with the **timeout** keyword in this command) or an absolute timeout (with the **timeout** keyword in the **access-list** command). Otherwise, the temporary access list entry will remain, even after the user terminates the session.

Use the **autocommand** command with the **access-enable** command to cause the **access-enable** command to execute when a user opens a Telnet session into the router.

Examples

The following example causes the software to create a temporary access list entry and tells the software to enable access only for the host from which the Telnet session originated. If the access list entry is not accessed within 2 minutes, it is deleted.

```
autocommand access-enable host timeout 2
```

Related Commands

Command	Description
access-list (IP extended)	Defines an extended IP access list.
autocommand	Configures the Cisco IOS software to automatically execute a command when a user connects to a particular line.
show ip accounting	Displays the active accounting or checkpointed database or displays access list violations.

access-group (identity policy)

To specify an access group to be applied to an identity policy, use the **access-group** command in identity policy configuration mode. To remove the access group, use the **no** form of this command.

access-group *group-name*

no access-group *group-name*

Syntax Description

group-name	Access list name.

Defaults

An access group is not specified.

Command Modes

Identity policy configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Using this command, you can access only named access lists.

Examples

The following example shows that access group "exempt-acl" is to be applied to the identity policy "policyname1":

```
Router (config)# identity policy policyname1
Router (config-identity-policy)# access-group exempt-acl
```

Related Commands

Command	Description
identity profile	Creates an identity profile.

access-group mode

To specify the override modes (for example, VLAN ACL [VACL] overrides Port ACL [PACL]) and the nonoverride modes (for example, merge or strict mode) for an access group, use the **access-group mode** command in interface configuration mode. To return to preferred port mode, use the **no** form of this command.

access-group mode {**prefer** {**port** | **vlan**} | **merge**}

no access-group mode {**prefer** {**port** | **vlan**} | **merge**}

Syntax Description

prefer port	Specifies that the PACL mode take precedence if PACLs are configured. If no PACL features are configured on the port, other features applicable to the interface are merged and applied on the interface.
prefer vlan	Specifies that the VLAN-based ACL mode take precedence. If no VLAN-based ACL features are configured on the port's VLAN, the PACL features on the port are applied.
merge	Merges applicable ACL features before they are programmed into the hardware.

Command Default

The default is **port** ACL override mode.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.

Usage Guidelines

On the Layer 2 interface, prefer port, prefer VLAN, and merge modes are supported. A Layer 2 interface can have one IP ACL applied in either direction (one inbound and one outbound).

Examples

This example shows how to configure an interface to use prefer port mode:

```
Router(config-if)# access-group mode prefer port
```

This example shows how to configure an interface to use merge mode:

```
Router(config-if)# access-group mode merge
```

Related Commands

Command	Description
show access-group mode interface	Displays the ACL configuration on a Layer 2 interface.

access-list (IP extended)

To define an extended IP access list, use the extended version of the **access-list** command in global configuration mode. To remove the access lists, use the **no** form of this command.

access-list *access-list-number* [**dynamic** *dynamic-name* [**timeout** *minutes*]] {**deny** | **permit**} *protocol source source-wildcard destination destination-wildcard* [**precedence** *precedence*] [**tos** *tos*] [**time-range** *time-range-name*] [**fragments**] [**log** [*word*] | **log-input** [*word*]]

no access-list *access-list-number*

Internet Control Message Protocol (ICMP)

access-list *access-list-number* [**dynamic** *dynamic-name* [**timeout** *minutes*]] {**deny** | **permit**} **icmp** *source source-wildcard destination destination-wildcard* [*icmp-type* [*icmp-code*] | *icmp-message*] [**precedence** *precedence*] [**tos** *tos*] [**time-range** *time-range-name*] [**fragments**] [**log** [*word*] | **log-input** [*word*]]

Internet Group Management Protocol (IGMP)

access-list *access-list-number* [**dynamic** *dynamic-name* [**timeout** *minutes*]] {**deny** | **permit**} **igmp** *source source-wildcard destination destination-wildcard* [*igmp-type*] [**precedence** *precedence*] [**tos** *tos*] [**time-range** *time-range-name*] [**fragments**] [**log** [*word*] | **log-input** [*word*]]

Transmission Control Protocol (TCP)

access-list *access-list-number* [**dynamic** *dynamic-name* [**timeout** *minutes*]] {**deny** | **permit**} **tcp** *source source-wildcard* [*operator* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**established**] [**precedence** *precedence*] [**tos** *tos*] [**time-range** *time-range-name*] [**fragments**] [**log** [*word*] | **log-input** [*word*]]

User Datagram Protocol (UDP)

access-list *access-list-number* [**dynamic** *dynamic-name* [**timeout** *minutes*]] {**deny** | **permit**} **udp** *source source-wildcard* [*operator* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**precedence** *precedence*] [**tos** *tos*] [**time-range** *time-range-name*] [**fragments**] [**log** [*word*] | **log-input** [*word*]]

Syntax Description

access-list-number	Number of an access list. This is a decimal number from 100 to 199 or from 2000 to 2699.
dynamic *dynamic-name*	(Optional) Identifies this access list as a dynamic access list. Refer to lock-and-key access documented in the "Configuring Lock-and-Key Security (Dynamic Access Lists)" chapter in the *Cisco IOS Security Configuration Guide*.
timeout *minutes*	(Optional) Specifies the absolute length of time, in minutes, that a temporary access list entry can remain in a dynamic access list. The default is an infinite length of time and allows an entry to remain permanently. Refer to lock-and-key access documented in the "Configuring Lock-and-Key Security (Dynamic Access Lists)" chapter in the *Cisco IOS Security Configuration Guide*.

deny	Denies access if the conditions are matched.
permit	Permits access if the conditions are matched.
protocol	Name or number of an Internet protocol. It can be one of the keywords **eigrp**, **gre**, **icmp**, **igmp**, **ip**, **ipinip**, **nos**, **ospf**, **pim**, **tcp**, or **udp**, or an integer in the range from 0 to 255 representing an Internet protocol number. To match any Internet protocol (including ICMP, TCP, and UDP) use the **ip** keyword. Some protocols allow further qualifiers described below.
source	Number of the network or host from which the packet is being sent. There are three alternative ways to specify the source: • Use a 32-bit quantity in four-part dotted decimal format. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** source as an abbreviation for a *source* and *source-wildcard* of source 0.0.0.0.
source-wildcard	Wildcard bits to be applied to source. Each wildcard bit 0 indicates the corresponding bit position in the source. Each wildcard bit set to 1 indicates that both a 0 bit and a 1 bit in the corresponding position of the IP address of the packet will be considered a match to this access list entry. There are three alternative ways to specify the source wildcard: • Use a 32-bit quantity in four-part dotted decimal format. Place 1s in the bit positions you want to ignore. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *source* as an abbreviation for a *source* and *source-wildcard* of *source* 0.0.0.0. Wildcard bits set to 1 need not be contiguous in the source wildcard. For example, a source wildcard of 0.255.0. would be valid.
destination	Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination: • Use a 32-bit quantity in four-part dotted decimal format. • Use the **any** keyword as an abbreviation for the *destination* and *destination-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *destination* as an abbreviation for a *destination* and *destination-wildcard* of destination 0.0.0.0.
destination-wildcard	Wildcard bits to be applied to the destination. There are three alternative ways to specify the destination wildcard: • Use a 32-bit quantity in four-part dotted decimal format. Place 1s in the bit positions you want to ignore. • Use the **any** keyword as an abbreviation for a *destination* and *destination-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** destination as an abbreviation for a *destination* and *destination-wildcard* of destination 0.0.0.0.

precedence *precedence*	(Optional) Packets can be filtered by precedence level, as specified by a number from 0 to 7, or by name as listed in the section "Usage Guidelines."
tos *tos*	(Optional) Packets can be filtered by type of service level, as specified by a number from 0 to 15, or by name as listed in the section "Usage Guidelines."
time-range *time-range-name*	(Optional) Name of the time range that applies to this statement. The name of the time range and its restrictions are specified by the **time-range** command.
icmp-type	(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.
icmp-code	(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.
icmp-message	(Optional) ICMP packets can be filtered by an ICMP message type name or ICMP message type and code name. The possible names are listed in the section "Usage Guidelines."
igmp-type	(Optional) IGMP packets can be filtered by IGMP message type or message name. A message type is a number from 0 to 15. IGMP message names are listed in the section "Usage Guidelines."
operator	(Optional) Compares source or destination ports. Possible operands include **lt** (less than), **gt** (greater than), **eq** (equal), **neq** (not equal), and **range** (inclusive range). If the operator is positioned after the *source* and *source-wildcard*, it must match the source port. If the operator is positioned after the *destination* and *destination-wildcard*, it must match the destination port. The **range** operator requires two port numbers. All other operators require one port number.
port	(Optional) The decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the section "Usage Guidelines." TCP port names can only be used when filtering TCP. UDP port names can only be used when filtering UDP. TCP port names can only be used when filtering TCP. UDP port names can only be used when filtering UDP.
established	(Optional) For the TCP protocol only: Indicates an established connection. A match occurs if the TCP datagram has the ACK or RST control bits set. The nonmatching case is that of the initial TCP datagram to form a connection.
fragments	(Optional) The access list entry applies to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.

log	(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the **logging console** command.) The log message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP, or a number; and if appropriate, the source and destination addresses and port numbers and the user-defined cookie or router-generated hash value. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval. The logging facility may drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list. After you specify the **log** keyword (and the associated *word* argument), you cannot specify any other keywords or settings for this command.
word	(Optional) User-defined cookie appended to the log message. The cookie: • cannot be more than characters • cannot start with hexadecimal notation (such as 0x) • cannot be the same as, or a subset of, the following keywords: **reflect**, **fragment**, **time-range** • must contain alphanumeric characters only The user-defined cookie is appended to the access control entry (ACE) syslog entry and uniquely identifies the ACE, within the access control list, that generated the syslog entry.
log-input	(Optional) Includes the input interface and source MAC address or virtual circuit in the logging output. After you specify the **log-input** keyword (and the associated *word* argument), you cannot specify any other keywords or settings for this command.

Defaults

An extended access list defaults to a list that denies everything. An extended access list is terminated by an implicit deny statement.

Command Modes

Global configuration (config)

Command History

Release	Modification
10.0	This command was introduced.
10.3	The following keywords and arguments were added: • *source* • *source-wildcard* • *destination* • *destination-wildcard* • **precedence** *precedence* • *icmp-type* • *icmp-code* • *icmp-message* • *igmp-type* • *operator* • *port* • **established**
11.1	The **dynamic** *dynamic-name* keyword and argument were added.
11.1	The **timeout** *minutes* keyword and argument were added.
11.2	The **log-input** keyword was added.
12.0(1)T	The **time-range** *time-range-name* keyword and argument were added.
12.0(11)	The **fragments** keyword was added.
12.2(13)T	The **non500-isakmp** keyword was added to the list of UDP port names. The **igrp** keyword was removed because the IGRP protocol is no longer available in Cisco IOS software.
12.4	The **drip** keyword was added to specify the TCP port number used for OER communication.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(22)T	The *word* argument was added to the **log** and **log-input** keywords.

Usage Guidelines

You can use access lists to control the transmission of packets on an interface, control vty access, and restrict the contents of routing updates. The Cisco IOS software stops checking the extended access list after a match occurs.

Fragmented IP packets, other than the initial fragment, are immediately accepted by any extended IP access list. Extended access lists used to control vty access or restrict the contents of routing updates must not match against the TCP source port, the type of service (ToS) value, or the precedence of the packet.

Note After a numbered access list is created, any subsequent additions (possibly entered from the terminal) are placed at the end of the list. In other words, you cannot selectively add or remove access list command lines from a specific numbered access list.

Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the **fragments** keyword can be summarized as follows:

If the Access-List Entry has...	Then..
...no **fragments** keyword (the default behavior), and assuming all of the access-list entry information matches,	For an access-list entry containing only Layer 3 information: • The entry is applied to nonfragmented packets, initial fragments and noninitial fragments. For an access list entry containing Layer 3 and Layer 4 information: • The entry is applied to nonfragmented packets and initial fragments. – If the entry is a **permit** statement, the packet or fragment is permitted. – If the entry is a **deny** statement, the packet or fragment is denied. • The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and – If the entry is a **permit** statement, the noninitial fragment is permitted. – If the entry is a **deny** statement, the next access-list entry is processed. **Note** The **deny** statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.
...the **fragments** keyword, and assuming all of the access-list entry information matches,	The access-list entry is applied only to noninitial fragments. **Note** The **fragments** keyword cannot be configured for an access-list entry that contains any Layer 4 information.

Be aware that you should not simply add the **fragments** keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the **fragments** keyword. Therefore, you may need two access list entries for every **deny** entry. The first **deny** entry of the pair will not include the **fragments** keyword, and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases where there are multiple **deny** access list entries for the same host but with different Layer 4 ports, a single **deny** access-list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

Note The **fragments** keyword cannot solve all cases involving access lists and IP fragments.

Fragments and Policy Routing

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address** command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the **fragments** keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

Permitting Optimized Edge Routing (OER) Communication

The **drip** keyword was introduced under the **tcp** keyword to support packet filtering in a network where OER is configured. The **drip** keyword specifies port 3949 that OER uses for internal communication. This option allows you to build a packet filter that permits communication between an OER master controller and border router(s). The **drip** keyword is entered following the TCP source, destination, and the **eq** operator. See the example at the end of this command reference page.

Examples

In the following example, serial interface 0 is part of a Class B network with the address 10.88.0.0, and the address of the mail host is 10.88.1.2. The **established** keyword is used only for the TCP protocol to indicate an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which indicates that the packet belongs to an existing connection.

```
access-list 102 permit tcp 0.0.0.0 255.255.255.255 10.88.0.0 0.0.255.255 established
access-list 102 permit tcp 0.0.0.0 255.255.255.255 10.88.1.2 0.0.0.0 eq 25
interface serial 0
 ip access-group 102 in
```

The following example permits Domain Naming System (DNS) packets and ICMP echo and echo reply packets:

```
access-list 102 permit tcp any 10.88.0.0 0.0.255.255 established
access-list 102 permit tcp any host 10.88.1.2 eq smtp
access-list 102 permit tcp any any eq domain
access-list 102 permit udp any any eq domain
access-list 102 permit icmp any any echo
access-list 102 permit icmp any any echo-reply
```

The following examples show how wildcard bits are used to indicate the bits of the prefix or mask that are relevant. Wildcard bits are similar to the bitmasks that are used with normal access lists. Prefix or mask bits corresponding to wildcard bits set to 1 are ignored during comparisons and prefix or mask bits corresponding to wildcard bits set to 0 are used in comparison.

The following example permits 192.168.0.0 255.255.0.0 but denies any more specific routes of 192.168.0.0 (including 192.168.0.0 255.255.255.0):

```
access-list 101 permit ip 192.168.0.0 0.0.0.0   255.255.0.0 0.0.0.0
access-list 101 deny ip 192.168.0.0 0.0.255.255 255.255.0.0 0.0.255.255
```

The following example permits 10.108.0/24 but denies 10.108/16 and all other subnets of 10.108.0.0:

```
access-list 101 permit ip 10.108.0.0 0.0.0.0     255.255.255.0 0.0.0.0
access-list 101 deny ip 10.108.0.0 0.0.255.255 255.255.0.0   0.0.255.255
```

The following example uses a time range to deny HTTP traffic on Monday through Friday from 8:00 a.m. to 6:00 p.m.:

```
time-range no-http
 periodic weekdays 8:00 to 18:00
!
access-list 101 deny tcp any any eq http time-range no-http
!
interface ethernet 0
 ip access-group 101 in
```

The following example permits communication, from any TCP source and destination, between an OER master controller and border router:

```
access-list 100 permit tcp any eq drip any eq drip
```

The following example shows how to configure the access list with the **log** keyword. It sets the *word* argument to UserDefinedValue. The word UserDefinedValue is appended to the related syslog entry:

```
Router(config)# access-list 101 permit tcp host 10.1.1.1 host 10.1.1.2 log
UserDefinedValue
```

Related Commands

Command	Description
access-class	Restricts incoming and outgoing connections between a particular vty (into a Cisco device) and the addresses in an access list.
access-list (IP standard)	Defines a standard IP access list.
access-list remark	Writes a helpful comment (remark) for an entry in a numbered IP access list.
clear access-template	Clears a temporary access list entry from a dynamic access list.
delay (tracking)	Sets conditions under which a packet does not pass a named access list.
distribute-list in (IP)	Filters networks received in updates.
distribute-list out (IP)	Suppresses networks from being advertised in updates.
ip access-group	Controls access to an interface.
ip access-list	Defines an IP access list by name.
ip access-list logging hash-generation	Enables hash value generation for ACE syslog entries.
ip accounting	Enables IP accounting on an interface.
logging console	Controls which messages are logged to the console, based on severity.
match ip address	Distributes any routes that have a destination network number address that is permitted by a standard or extended access list.
permit (IP)	Sets conditions under which a packet passes a named access list.
remark	Writes a helpful comment (remark) for an entry in a named IP access list.
show access-lists	Displays the contents of current IP and rate-limit access lists.
show ip access-list	Displays the contents of all current IP access lists.
time-range	Specifies when an access list or other feature is in effect.

access-list (IP standard)

To define a standard IP access list, use the standard version of the **access-list** command in global configuration mode. To remove a standard access list, use the **no** form of this command.

access-list *access-list-number* {**deny** | **permit**} *source* [*source-wildcard*] [**log** [*word*]]

no access-list *access-list-number*

Syntax Description

access-list-number	Number of an access list. This is a decimal number from 1 to 99 or from 1300 to 1999.
deny	Denies access if the conditions are matched.
permit	Permits access if the conditions are matched.
source	Number of the network or host from which the packet is being sent. There are two alternative ways to specify the source: • Use a 32-bit quantity in four-part, dotted-decimal format. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255.
source-wildcard	(Optional) Wildcard bits to be applied to the source. There are two alternative ways to specify the source wildcard: • Use a 32-bit quantity in four-part, dotted-decimal format. Place 1s in the bit positions you want to ignore. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255.
log	(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the **logging console** command.) The log message includes the access list number, whether the packet was permitted or denied, the source address, the number of packets, and if appropriate, the user-defined cookie or router-generated hash value. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval. The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

word	(Optional) User-defined cookie appended to the log message. The cookie: • cannot be more than characters • cannot start with hexadecimal notation (such as 0x) • cannot be the same as, or a subset of, the following keywords: **reflect**, **fragment**, **time-range** • must contain alphanumeric characters only The user-defined cookie is appended to the access control entry (ACE) syslog entry and uniquely identifies the ACE, within the access control list, that generated the syslog entry.

Defaults

The access list defaults to an implicit deny statement for everything. The access list is always terminated by an implicit deny statement for everything.

Command Modes

Global configuration (config)

Command History

Release	Modification
10.3	This command was introduced.
11.3(3)T	The **log** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(22)T	The *word* argument was added to the **log** keyword.

Usage Guidelines

Plan your access conditions carefully and be aware of the implicit deny statement at the end of the access list.

You can use access lists to control the transmission of packets on an interface, control vty access, and restrict the contents of routing updates.

Use the **show access-lists** EXEC command to display the contents of all access lists.

Use the **show ip access-list** EXEC command to display the contents of one access list.

Caution Enhancements to this command are backward compatible; migrating from releases prior to Cisco IOS Release 10.3 will convert your access lists automatically. However, releases prior to Release 10.3 are not upwardly compatible with these enhancements. Therefore, if you save an access list with these images and then use software prior to Release 10.3, the resulting access list will not be interpreted correctly. **This condition could cause you severe security problems.** Save your old configuration file before booting these images.

Examples

The following example of a standard access list allows access for only those hosts on the three specified networks. The wildcard bits apply to the host portions of the network addresses. Any host with a source address that does not match the access list statements will be rejected.

```
access-list 1 permit 192.168.34.0 0.0.0.255
access-list 1 permit 10.88.0.0 0.0.255.255
access-list 1 permit 10.0.0.0 0.255.255.255
! (Note: all other access implicitly denied)
```

The following example of a standard access list allows access for devices with IP addresses in the range from 10.29.2.64 to 10.29.2.127. All packets with a source address not in this range will be rejected.

```
access-list 1 permit 10.29.2.64 0.0.0.63
! (Note: all other access implicitly denied)
```

To specify a large number of individual addresses more easily, you can omit the wildcard if it is all zeros. Thus, the following two configuration commands are identical in effect:

```
access-list 2 permit 10.48.0.3
access-list 2 permit 10.48.0.3 0.0.0.0
```

The following example of a standard access list allows access for devices with IP addresses in the range from 10.29.2.64 to 10.29.2.127. All packets with a source address not in this range will be rejected.

```
access-list 1 permit 10.29.2.64 0.0.0.63
! (Note: all other access implicitly denied)
```

The following example of a standard access list allows access for devices with IP addresses in the range from 10.29.2.64 to 10.29.2.127. All packets with a source address not in this range will be rejected. In addition, the logging mechanism is enabled and the word SampleUserValue is appended to each syslog entry.

```
Router(config)# access-list 1 permit 10.29.2.64 0.0.0.63 log SampleUserValue
```

Related Commands

Command	Description
access-class	Restricts incoming and outgoing connections between a particular vty (into a Cisco device) and the addresses in an access list.
access-list (IP extended)	Defines an extended IP access list.
access-list remark	Writes a helpful comment (remark) for an entry in a numbered IP access list.
deny (IP)	Sets conditions under which a packet does not pass a named access list.
distribute-list in (IP)	Filters networks received in updates.
distribute-list out (IP)	Suppresses networks from being advertised in updates.
ip access-group	Controls access to an interface.
ip access-list logging hash-generation	Enables hash value generation for ACE syslog entries.
permit (IP)	Sets conditions under which a packet passes a named access list.
remark (IP)	Writes a helpful comment (remark) for an entry in a named IP access list.
show access-lists	Displays the contents of current IP and rate-limit access lists.
show ip access-list	Displays the contents of all current IP access lists.

access-list (NLSP)

To define an access list that denies or permits area addresses that summarize routes, use the NetWare Link-Services Protocol (NLSP) route aggregation version of the **access-list** command in global configuration mode. To remove an NLSP route aggregation access list, use the **no** form of this command.

access-list *access-list-number* {**deny** | **permit**} *network network-mask* [*interface*] [**ticks** *ticks*] [**area-count** *area-count*]

no access-list *access-list-number* {**deny** | **permit**} *network network-mask* [*interface*] [**ticks** *ticks*] [**area-count** *area-count*]

Syntax Description

access-list-number	Number of the access list. This is a number from 1200 to 1299.
deny	Denies redistribution of explicit routes if the conditions are matched. If you have enabled route summarization with route-aggregation command, the router redistributes an aggregated route instead.
permit	Permits redistribution of explicit routes if the conditions are matched.
network	Network number to summarize. An IPX network number is an eight-digit hexadecimal number that uniquely identifies a network cable segment. It can be a number in the range 1 to FFFFFFFE. A network number of 0 matches the local network. A network number of -1 matches all networks. You do not need to specify leading zeros in the network number. For example, for the network number 000000AA, you can enter AA.
network-mask	Specifies the portion of the network address that is common to all addresses in the route summary. The high-order bits of *network-mask* must be contiguous Fs, while the low-order bits must be contiguous zeros (0). An arbitrary mix of Fs and 0s is not permitted.
interface	(Optional) Interface on which the access list should be applied to incoming updates.
ticks *ticks*	(Optional) Metric assigned to the route summary. The default is 1 tick.
area-count *area-count*	(Optional) Maximum number of NLSP areas to which the route summary can be redistributed. The default is 6 areas.

Defaults

No access lists are predefined.

Command Modes

Global configuration

Command History

Release	Modification
11.1	This command was introduced.
12.0	The *interface* argument was added.

Release	Modification
12.2(13)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in12.2S-Family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the NLSP route aggregation access list in the following situations:

- When redistributing from an Enhanced IGRP or RIP area into a new NLSP area.

  Use the access list to instruct the router to redistribute an aggregated route instead of the explicit route. The access list also contains a "permit all" statement that instructs the router to redistribute explicit routes that are not subsumed by a route summary.

- When redistributing from an NLSP version 1.0 area into an NLSP version 1.1 area, and vice versa.

  From an NLSP version 1.0 area into an NLSP version 1.1 area, use the access list to instruct the router to redistribute an aggregated route instead of an explicit route and to redistribute explicit routes that are not subsumed by a route summary.

  From an NLSP version 1.1 area into an NLSP version 1.0 area, use the access list to instruct the router to filter aggregated routes from passing into the NLSP version 1.0 areas and to redistribute explicit routes instead.

Note NLSP version 1.1 routers refer to routers that support the route aggregation feature, while NLSP version 1.0 routers refer to routers that do not.

Examples

The following example uses NLSP route aggregation access lists to redistribute routes learned from RIP to NLSP area1. Routes learned via RIP are redistributed into NLSP area1. Any routes learned via RIP that are subsumed by aaaa0000 ffff0000 are not redistributed. An address summary is generated instead.

```
ipx routing
ipx internal-network 2000

interface ethernet 1
 ipx network 1001
 ipx nlsp area1 enable

interface ethernet 2
 ipx network 2001

access-list 1200 deny aaaa0000 ffff0000
access-list 1200 permit -1

ipx router nlsp area
 area-address 1000 fffff000
 route-aggregation
 redistribute rip access-list 1200
```

Related Commands

Command	Description
area-address (NLSP)	Defines a set of network numbers to be part of the current NLSP area.
deny (NLSP)	Filters explicit routes and generates an aggregated route for a named NLSP route aggregation access list.
ipx access-list	Defines an IPX access list by name.
ipx nlsp enable	Configures the interval between the transmission of hello packets.
ipx router	Specifies the routing protocol to use.
permit (NLSP)	Allows explicit route redistribution in a named NLSP route aggregation access list.
prc-interval	Controls the hold-down period between partial route calculations.
redistribute (IPX)	Redistributes from one routing domain into another.

access-list compiled

To enable the Turbo Access Control Lists (Turbo ACL) feature, use the **access-list compiled** command in global configuration mode. To disable the Turbo ACL feature, use the **no** form of this command.

access-list compiled

no access-list compiled

Syntax Description

This command has no arguments or keywords.

Defaults

Turbo ACL is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.1(1)E	This command was introduced for Cisco 7200 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.1(4)E	This command was implemented on the Cisco 7100 series.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

By default, the Turbo ACL feature is disabled. When Turbo ACL is disabled, normal ACL processing is enabled, and no ACL acceleration occurs.

When the Turbo ACL feature is enabled using the **access-list compiled** command, the ACLs in the configuration are scanned and, if suitable, compiled for Turbo ACL acceleration. This scanning and compilation may take a few seconds when the system is processing large and complex ACLs, or when the system is processing a configuration that contains a large number of ACLs.

Any configuration change to an ACL that is being accelerated, such as the addition of new ACL entries or the deletion of the ACL, triggers a recompilation of that ACL.

When Turbo ACL tables are being built (or rebuilt) for a particular ACL, the normal sequential ACL search is used until the new tables are ready for installation.

Examples

The following example enables the Turbo ACL feature:

```
access-list compiled
```

access-list compiled data-link limit memory

To change the amount of memory reserved for Turbo ACL processing for Layer 2 traffic in the Route Processor path for a Cisco 7304 router using a network services engine (NSE), use the **access-list compiled data-link limit memory** command in global configuration mode. To place no restrictions on the amount of memory reserved for Turbo ACL processing of Layer 2 traffic in the Route Processor path for a Cisco 7304 router using an NSE, use the **no** form of this command. To restore the default amount of memory reserved for Turbo ACL processing for Layer 2 traffic in the Route Processor path for a Cisco 7304 router using an NSE, use the **default** form of this command.

access-list compiled data-link limit memory *number*

no access-list compiled data-link limit memory

default access-list compiled data-link limit memory

Syntax Description

number	A number between 8 and 4095 that specifies the amount of memory, in megabytes, reserved for Turbo ACL processing of Layer 2 traffic in the Route Processor path for the Cisco 7304 router using an NSE.

Command Default

The default for *number* is 128.

Command Modes

Global configuration

Command History

Release	Modification
12.2(31)SB2	This command was introduced.

Usage Guidelines

The **show access-list compiled** command output provides information useful in helping to consider the exact memory limit to configure. The following sections of the **show access-list compiled** output, which are found in the "Compiled ACL statistics for Data-Link" section of the output, are especially useful:

- The "mem limits" output shows the number of times a compile has occurred and the ACL has reached its configured limit.
- The "Mb limit" output shows the current memory limit setting.
- The "Mb max memory" output shows the maximum amount of memory the current ACL configuration could actually consume under maximum usage conditions.

Note that there is a direct trade-off between memory used for ACL processing in the RP path and the memory used for other RP processes. Memory reserved for ACL processing cannot be used for other RP processes, and vice versa. If you need more memory for ACL processing, you should set a higher value for *number*. If you need more memory for other RP processes, you should set a lower value for *number*.

When configuring this memory limit, also note that a certain amount of RP memory is reserved for Layer 3 and Layer 4 ACL data. The amount of memory reserved for ACL data can be viewed using the **show access-list compiled** command, and can be changed using the **access-list compiled ipv4 limit memory** command.

Note that the **no** form of this command removes all memory limits for ACL processing, thereby allowing as much memory as is needed for Layer 2 ACL processing in the RP path.

To restore a default configuration of this command, which is 128 MB, enter the **default** form of this command.

Examples

The following example reserves 100 MB of memory for Layer 2 ACL processing in the RP path:

```
access-list compiled data-link limit memory 100
```

The following example allows Layer 2 ACL processing to use as much memory as is needed for Layer 2 ACL processing:

```
no access-list compiled data-link limit memory
```

The following example restores the default amount of memory reserved for Layer 2 ACL processing in the RP path:

```
default access-list compiled data-link limit memory
```

Related Commands

Command	Description
access-list compiled ipv4 limit memory	Configures limits on the amount of memory used for Turbo ACL processing of Layer 3 and Layer 4 traffic.
show access-list compiled	Displays the status and condition of the Turbo ACL tables associated with each access list.

access-list compiled ipv4 limit memory

To change the amount of memory reserved for Turbo ACL processing for Layer 3 and Layer 4 traffic in the Route Processor path for a Cisco 7304 router using a network services engine (NSE), use the **access-list compiled ipv4 limit memory** command in global configuration mode. To place no restrictions on the amount of memory reserved for Turbo ACL processing for Layer 3 and Layer 4 traffic in the Route Processor path for a Cisco 7304 router using an NSE, use the **no** form of this command. To restore the default amount of memory reserved for Turbo ACL processing for Layer 3 and Layer 4 traffic in the Route Processor path for a Cisco 7304 router using an NSE, use the **default** form of this command.

access-list compiled ipv4 limit memory *number*

no access-list compiled ipv4 limit memory

default access-list compiled ipv4 limit memory

Syntax Description

number	A number between 8 and 4095 that specifies the memory limit in megabytes.

Command Default

On an NSE-150, the default for *number* is always 256.

On an NSE-100, the default for *number* is determined by the amount of SDRAM on the NSE-100. If the NSE-100 has 512 MB of DRAM, the default for *number* is 256. If the NSE-100 has less than 512 MB DRAM, the default for *number* is 128.

Command Modes

Global configuration

Command History

Release	Modification
12.2(31)SB2	This command was introduced.

Usage Guidelines

The **show access-list compiled** command output provides information useful in helping to consider the exact memory limit to configure. The following sections of the **show access-list compiled** output, which are found in the "Compiled ACL statistics for IPv4:" section of the output, are especially useful:

- The "mem limits" output shows the number of times a compile has occurred and the ACL has reached its configured limit.
- The "Mb limit" output shows the current memory limit setting.
- The "Mb max memory" output shows the maximum amount of memory the current ACL configuration could actually consume under maximum usage conditions.

Note that there is a direct trade-off between memory used for ACL processing in the RP path and the memory used for other RP processes. Memory reserved for ACL processing cannot be used for other RP processes, and vice versa. If you need more memory for ACL processing, you should set a higher value for *number*. If you need more memory for other RP processes, you should set a lower value for *number*.

When configuring this memory limit, also note that a certain amount of RP memory is reserved for Layer 2 ACL data. The amount of memory reserved for ACL data can be viewed using the **show access-list compiled** command, and can be changed using the **access-list compiled data-link limit memory** command.

Note that the **no** form of this command removes all memory limits for ACL processing, thereby allowing as much memory as is needed for Layer 3 and Layer 4 ACL processing in the RP path.

To restore a default configuration of this command, enter the **default** form of this command.

Examples

The following example reserves 100 MB of memory for Layer 3 and Layer 4 ACL processing in the RP path:

```
access-list compiled ipv4 limit memory 100
```

The following example allows Layer 3 and Layer 4 ACL processing to use as much memory as is needed for Layer 3 and Layer 4 ACL processing:

```
no access-list compiled ipv4 limit memory
```

The following example restores the default amount of memory reserved for Layer 3 and Layer 4 ACL processing in the RP path:

```
default access-list compiled ipv4 limit memory
```

Related Commands

Command	Description
access-list compiled data-link limit memory	Configures memory limits on the amount of memory reserved for Turbo ACL processing of Layer 2 traffic.
show access-list compiled	Displays the status and condition of the Turbo ACL tables associated with each access list

access-list dynamic-extend

To allow the absolute timer of the dynamic access control list (ACL) to be extended an additional six minutes, use the **access-list dynamic-extend** command in global configuration mode. To disable this functionality, use the **no** form of this command.

access-list dynamic-extend

no access-list dynamic-extend

Syntax Description

This command has no arguments or keywords.

Defaults

6 minutes

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When you try to create a Telnet session to the router to re-authenticate yourself by using the lock-and-key function, use the **access-list dynamic-extend** command to extend the absolute timer of the dynamic ACL by six minutes.

The router must already be configured with the lock-and-key feature, and you must configure the extension *before* the ACL expires.

Examples

The following example shows how to extend the absolute timer of the dynamic ACL:

```
! The router is configured with the lock-and-key feature as follows
access-list 132 dynamic tactik timeout 6 permit ip any any
! The absolute timer will extended another six minutes.
access-list dynamic-extend
```

access-list remark

To write a helpful comment (remark) for an entry in a numbered IP access list, use the **access-list remark** command in global configuration mode.To remove the remark, use the **no** form of this command.

access-list *access-list-number* **remark** [*line*]

no access-list *access-list-number* **remark** [*line*]

Syntax Description

access-list-number	Number of an IP access list.
line	(Optional) Comment that describes the access list entry, up to 100 characters long.

Command Default

The access list entries have no remarks.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The remark can be up to 100 characters long; anything longer is truncated.

Examples

The following example shows how to write comments for workstation abc, which is allowed access, and workstation xyz, which is not allowed access:

```
access-list 1 remark Permit only abc workstation comment
access-list 1 permit 192.0.2.0
access-list 1 remark Do not allow xyz workstation comment
access-list 1 deny 192.0.2.13
```

Related Commands

Command	Description
access-list (IP extended)	Defines an extended IP access list.
access-list (IP standard)	Defines a standard IP access list.
ip access-list	Defines an IP access list by name.
remark	Writes a helpful comment (remark) for an entry in a named IP access list.

access-profile

To apply your per-user authorization attributes to an interface during a PPP session, use the **access-profile** command in privileged EXEC mode.

access-profile [**merge** | **replace**] [**ignore-sanity-checks**]

Syntax Description

merge	(Optional) Removes existing access control lists (ACLs) while retaining other existing authorization attributes for the interface. • However, using this option installs per-user authorization attributes in addition to the existing attributes. (The default form of the command installs only new ACLs.) The per-user authorization attributes come from all attribute-value (AV) pairs defined in the authentication, authorization, and accounting (AAA) per-user configuration (the user's authorization profile).
replace	(Optional) Removes existing ACLs and all other existing authorization attributes for the interface. • A complete new authorization configuration is then installed, using all AV pairs defined in the AAA per-user configuration. • This option is not normally recommended because it initially deletes all existing configurations, including static routes. This could be detrimental if the new user profile does not reinstall appropriate static routes and other critical information.
ignore-sanity-checks	(Optional) Enables you to use any AV pairs, whether or not they are valid.

Command Default

By default this command removes existing ACLs while retaining other existing authorization attributes for the interface.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRB	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRB.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.3	This command was integrated into Cisco IOS XE Release 2.3.

Usage Guidelines

Remote users can use the **access-profile** command to activate double authentication for a PPP session. Double authentication must be correctly configured for this command to have the desired effect.

You should use this command when remote users establish a PPP link to gain local network access.

The resulting authorization attributes of the interface are a combination of the previous and new configurations.

After you have been authenticated with Challenge Handshake Authentication Protocol (CHAP) or Password Authentication Protocol (PAP), you will have limited authorization. To activate double authentication and gain your appropriate user network authorization, you must open a Telnet session to the network access server and execute the **access-profile** command. (This command could also be set up as an autocommand, which would eliminate the need to enter the command manually.)

This command causes all subsequent network authorizations to be made in your username instead of in the remote host's username.

Any changes to the interface caused by this command will stay in effect for as long as the interface stays up. These changes will be removed when the interface goes down. This command does not affect the normal operation of the router or the interface.

The default form of the command, **access-profile**, causes existing ACLs to be unconfigured (removed), and new ACLs to be installed. The new ACLs come from your per-user configuration on an AAA server (such as a TACACS+ server). The ACL replacement constitutes a reauthorization of your network privileges.

The default form of the command can fail if your per-user configuration contains statements other than ACL AV pairs. Any protocols with non-ACL statements will be deconfigured, and no traffic for that protocol can pass over the PPP link.

The **access-profile merge** form of the command causes existing ACLs to be unconfigured and new authorization information (including new ACLs) to be added to the interface. This new authorization information consists of your complete per-user configuration on an AAA server. If any of the new authorization statements conflict with existing statements, the new statements could override the old statements or be ignored, depending on the statement and applicable parser rules. The resulting interface configuration is a combination of the original configuration and the newly installed per-user configuration.

Caution The new user authorization profile (per-user configuration) must *not* contain any invalid mandatory AV pairs, because the command will fail and PPP (containing the invalid pair) will be dropped. If invalid AV pairs are included as *optional* in the user profile, the command will succeed, but the invalid AV pair will be ignored. Invalid AV pair types are listed later in this section.

The **access-profile replace** form of the command causes the entire existing authorization configuration to be removed from the interface, and the complete per-user authorization configuration to be added. This per-user authorization consists of your complete per-user configuration on an AAA server.

Caution Use extreme caution when using the **access-profile replac**e form of the command. It might have detrimental and unexpected results, because this option deletes all authorization configuration information (including static routes) before reinstalling the new authorization configuration.

The following are invalid AV pair types:

- addr
- addr-pool
- frame-relay
- ip-addresses

- source-ip
- tunnel-id
- x25-addresses
- zonelist

Note These AV pair types are invalid only when used with double authentication in the user-specific authorization profile; they cause the **access-profile** command to fail. However, these AV pair types can be appropriate when used in other contexts.

Examples

The following example shows how to apply the per-user authorization attributes to an interface during a PPP session:

```
Router# access-profile merge ignore-sanity-checks
```

Related Commands

Command	Description
connect	Logs in to a host that supports Telnet, rlogin, or LAT.
telnet	Logs in to a host that supports Telnet.

access-restrict

To tie a particular Virtual Private Network (VPN) to a specific interface for access to the Cisco IOS gateway and the services it protects, use the **access-restrict** command in Internet Security Association Key Management Protocol (ISAKMP) group configuration mode. To remove the VPN, use the **no** form of this command.

access-restrict {*interface-name*}

no access-restrict {*interface-name*}

Syntax Description

interface-name	Interface to which the VPN should be tied.

Defaults

The VPN is not tied to a specific interface.

Command Modes

ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

The Access-Restrict attribute ties a particular VPN group to a specific interface for access to the Cisco IOS gateway and the services it provides.

It may be a requirement that particular customers or groups connect to the VPN gateway via a specific interface that uses a particular policy (as applied by the crypto map on that interface). If this specific interface is required, using the **access-restrict** command will result in validation that a VPN connection is connecting only via that interface (and hence, crypto map) to which it is allowed. If a violation is detected, the connection is terminated.

Multiple restricted interfaces may be defined per group. The Access-Restrict attribute is configured on a Cisco IOS router or in the RADIUS profile. This attribute has local (gateway) significance only and is not passed to the client.

You must enable the **crypto isakmp client configuration group** command, which specifies group policy information that has to be defined or changed, before enabling the **access-restrict** command.

Note

- The Access-Restrict attribute can be applied only by a RADIUS user.
- The attribute can be applied on a per-user basis after the user has been authenticated.
- The attribute can override any similar group attributes.

- User-based attributes are available only if RADIUS is used as the database.The attribute can override any similar group attributes.
- The Access-Restrict attribute is not required if ISAKMP profiles are implemented. ISAKMP profiles with specific policies per VPN group (as defined via the **match identity group** command, which is a subcommand of the **crypto isakmp profile** command), will achieve the same result.

An example of an attribute-value (AV) pair for the Access-Restrict attribute is as follows:

```
ipsec:access-restrict=<interface-name>
```

Examples

The following example shows that the VPN is tied to “ethernet 0”:

```
crypto isakmp client configuration group cisco
 access-restrict ethernet 0
```

Related Commands

Command	Description
acl	Configures split tunneling.
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

access-template

To manually place a temporary access list entry on a router to which you are connected, use the **access-template** command in privileged EXEC mode.

access-template {*access-list-number* | *name*} *template-name* {*source-address source-wildcard-bit* | **any** | **host** {*hostname* | *source-address*}} {*destination-address dest-wildcard-bit* | **any** | **host** {*hostname* | *destination-address*}} [**timeout** *minutes*]

Syntax Description

access-list-number	Number of the dynamic access list. The ranges are from 100 to 199 and from 2000 to 2699.
name	Name of an IP access list. • The name cannot contain a space or quotation mark, and must begin with an alphabetic character to avoid ambiguity with numbered access lists.
template-name	Name of a dynamic access list.
source-address	Source address in a dynamic access list. • All other attributes are inherited from the original access-list entry.
source-wildcard-bit	Source wildcard bits.
any	Specifies any source hostname.
host	Specifies a specific source host.
hostname	Name of the host.
destination-address	Destination address in a dynamic access list. • All other attributes are inherited from the original access-list entry.
dest-wildcard-bit	Destination wildcard bits.
timeout *minutes*	(Optional) Specifies a maximum time limit, in minutes for each entry within this dynamic list. The range is from 1 to 9999. • This is an absolute time, from creation, that an entry can reside in the list. The default is an infinite time limit and allows an entry to remain permanently.

Command Default

Temporary access lists are not placed on the router.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can use the **access-template** to enable the lock-and-key access feature.

You must always define either an idle timeout (with the **timeout** keyword in this command) or an absolute timeout (with the **timeout** keyword in the **access-list** command). Otherwise, the dynamic access list will remain, even after the user has terminated the session.

Examples

The following example shows how to enable IP access on incoming packets in which the source address is 172.29.1.129 and the destination address is 192.168.52.12. All other source and destination pairs are discarded.

```
Router> enable
Router# access-template 101 payroll host 172.29.1.129 host 192.168.52.12 timeout 2
```

Related Commands

Command	Description
access-list (IP extended)	Defines an extended IP access list.
autocommand	Configures the Cisco IOS software to automatically execute a command when a user connects to a particular line.
clear access-template	Clears a temporary access list entry from a dynamic access list manually.
show ip accounting	Displays the active accounting or checkpointed database or displays access list violations.

accounting

To enable authentication, authorization, and accounting (AAA) accounting services to a specific line or group of lines, use the **accounting** command in line configuration mode. To disable AAA accounting services, use the **no** form of this command.

accounting {**arap** | **commands** *level* | **connection** | **exec**} [**default** | *list-name*]

no accounting {**arap** | **commands** *level* | **connection** | **exec**} [**default** | *list-name*]

Syntax Description

arap	Enables accounting on lines configured for AppleTalk Remote Access Protocol (ARAP).
commands *level*	Enables accounting on the selected lines for all commands at the specified privilege level. Valid privilege level entries are 0 through 15.
connection	Enables both CHAP and PAP, and performs PAP authentication before CHAP.
exec	Enables accounting for all system-level events not associated with users, such as reloads on the selected lines.
default	(Optional) The name of the default method list, created with the **aaa accounting** command.
list-name	(Optional) Specifies the name of a list of accounting methods to use. If no list name is specified, the system uses the default. The list is created with the **aaa accounting** command.

Defaults

Accounting is disabled.

Command Modes

Line configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

After you enable the **aaa accounting** command and define a named accounting method list (or use the default method list) for a particular type of accounting, you must apply the defined lists to the appropriate lines for accounting services to take place. Use the **accounting** command to apply the specified method lists (or if none is specified, the default method list) to the selected line or group of lines.

Examples

The following example enables command accounting services (for level 15) using the accounting method list named charlie on line 10:

```
line 10
 accounting commands 15 charlie
```

accounting (gatekeeper)

To enable and define the gatekeeper-specific accounting method, use the **accounting** command in gatekeeper configuration mode. To disable gatekeeper-specific accounting, use the **no** form of this command.

accounting {**username h323id** | **vsa**}

no accounting

Syntax Description

username h323id	Enables H323ID in the user name field of accounting record.
vsa	Enables the vendor specific attribute accounting format.

Defaults

Accounting is disabled.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.1(5)XM	The **vsa** keyword was added.
12.2(2)T	The **vsa** keyword was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850 universal gateway.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.3(9)T	This **username h323id** keyword was added.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

To collect basic start-stop connection accounting data, the gatekeeper must be configured to support gatekeeper-specific H.323 accounting functionality. The **accounting** command enables you to send accounting data to the RADIUS server via IETF RADIUS or VSA attributes.

Specify a RADIUS server before using the **accounting** command.

There are three different methods of accounting. The H.323 method sends the call detail record (CDR) to the RADIUS server, the syslog method uses the system logging facility to record the CDRs, and the VSA method collects VSAs.

Examples

The following example enables the gateway to report user activity to the RADIUS server in the form of connection accounting records:

```
aaa accounting connection start-stop group radius
gatekeeper
 accounting
```

The following example shows how to enable VSA accounting:

```
aaa accounting connection start-stop group radius
gatekeeper
 accounting exec vsa
```

The following example configures H.323 accounting using IETF RADIUS attributes:

```
Router(config-gk)# accounting username h323id
```

The following example configures H.323 accounting using VSA RADIUS attributes:

```
Router(config-gk)# accounting vsa
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.
gatekeeper	Enters gatekeeper configuration mode.

accounting (line)

To enable authentication, authorization, and accounting (AAA) accounting services to a specific line or group of lines, use the **accounting** command in line configuration mode. To disable AAA accounting services, use the **no** form of this command.

accounting {**arap** | **commands** *level* | **connection** | **exec**} [**default** | *list-name*]

no accounting {**arap** | **commands** *level* | **connection** | **exec**} [**default** | *list-name*]

Syntax Description

arap	Enables accounting on lines configured for AppleTalk Remote Access Protocol (ARAP).
commands *level*	Enables accounting on the selected lines for all commands at the specified privilege level. Valid privilege level entries are 0 through 15.
connection	Enables both CHAP and PAP, and performs PAP authentication before CHAP.
exec	Enables accounting for all system-level events not associated with users, such as reloads on the selected lines.
default	(Optional) The name of the default method list, created with the **aaa accounting** command.
list-name	(Optional) Specifies the name of a list of accounting methods to use. If no list name is specified, the system uses the default. The list is created with the **aaa accounting** command.

Defaults

Accounting is disabled.

Command Modes

Line configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

After you enable the **aaa accounting** command and define a named accounting method list (or use the default method list) for a particular type of accounting, you must apply the defined lists to the appropriate lines for accounting services to take place. Use the **accounting** command to apply the specified method lists (or if none is specified, the default method list) to the selected line or group of lines.

Examples

The following example enables command accounting services (for level 15) using the accounting method list named charlie on line 10:

```
line 10
 accounting commands 15 charlie
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.

accounting (server-group)

To specify RADIUS accounting filters for attributes that are to be sent to the RADIUS server in accounting requests, use the **accounting** command in server-group configuration mode. To disable specific RADIUS accounting filters for attributes that are to be sent to the RADIUS server, use the **no** form of this command.

accounting {**accept** *list-name* | **reject** *list-name* | **acknowledge broadcast** | **reply** {**accept** *list-name* | **reject** *list-name*} | **request** {**accept** *list-name* | **reject** *list-name*} | **system host-config**}

no accounting {**accept** *list-name* | **reject** *list-name* | **acknowledge broadcast** | **reply** {**accept** *list-name* | **reject** *list-name*} | **request** {**accept** *list-name* | **reject** *list-name*} | **system host-config**}

Syntax Description

accept	All attributes are rejected except for required attributes and the attributes specified by the *list-name* argument.
reject	All attributes are accepted except for the attributes listed in the specified *list-name* argument.
list-name	The name of a specific configured RADIUS attribute list.
acknowledge	Sends the specified accounting response.
broadcast	Specifies broadcast accounting.
reply	Reply attributes are accepted or rejected as specified by the *list-name* argument.
request	Request attributes are accepted or rejected as specified by the *list-name* argument.
system	Enables system accounting generation.
host-config	Generates system accounting records when private servers are added or deleted.

Command Default

If specific attributes are not accepted or rejected, all attributes will be accepted.

Command Modes

Server-group configuration (config-sg-radius)#

Command History

Release	Modification
12.2(1)DX	This command was introduced.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(13)T	Platform support was added for the Cisco 7401ASR.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Release	Modification
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(20)T	The following new keywords were added: **system** and **host-config**

Usage Guidelines

An accept or reject list (also known as a filter) for RADIUS accounting allows users to send only the accounting attributes their business requires, thereby reducing unnecessary traffic and allowing users to customize their own accounting data.

Only one filter may be used for RADIUS accounting per server group.

Note The listname must be the same as the listname defined in the **radius-server attribute list** command, which is used with the **attribute** (server-group configuration) command to add to an accept or reject list.

Examples

The following example shows how to specify accept list "usage-only" for RADIUS accounting:

```
Router> enable
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa authentication ppp default group radius-sg
Router(config)# aaa authorization network default group radius-sg
Router(config)# aaa group server radius radius-sg
Router(config-sg-radius)# server 10.1.1.1
Router(config-sg-radius)# accounting accept usage-only
!
radius-server host 10.1.1.1 key mykey1
radius-server attribute list usage-only
 attribute 1,40,42-43,46
```

The following examples show how Accounting-On records or Accounting-Off records are generated when the **system host-config** keywords are configured using the **accounting** command in server-group configuration mode:

Accounting-On

In this example, Accounting-On records are generated when private server (server-private 10.10.1.1) is added to a server-group.

```
Router> enable
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa group server radius g2
Router#(config-sg-radius)# accounting system host-config
Router#(config-sg-radius)# server-private 10.10.1.1 --> Debugs when adding a private
server.

Related Commands

Command	Description
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict network access to the user.
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
attribute (server-group configuration)	Adds attributes to an accept or reject list.
authorization (server-group configuration)	Specifies an accept or reject list for attributes that are returned in an Access-Accept packet from the RADIUS server.
radius-server attribute list	Defines an accept or reject list name.

accounting acknowledge broadcast

To define a designated broadcast accounting server group, use the **accounting acknowledge broadcast** command in server group RADIUS configuration mode. To disable the broadcast functionality, use the **no** form of this command.

accounting acknowledge broadcast

no accounting acknowledge broadcast

Syntax Description

This command has no arguments or keywords.

Defaults

Accounting broadcast functionality is disabled for the RADIUS server group.

Command Modes

Server group RADIUS configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples

The following example enables accounting broadcast functionality on RADIUS server group abcgroup:

```
Router(config)# aaa group server radius abcgroup
Router(config-sg-radius)# accounting acknowledge broadcast
```

Related Commands

Command	Description
aaa accounting update	Enables periodic interim accounting records to be sent to the accounting server.
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
gw-accounting aaa	Enables VoIP gateway accounting through the AAA system.

accounting dhcp source-ip aaa list

To enable Per IP Subscriber DHCP Triggered RADIUS Accounting for billing or security purposes, use the **accounting dhcp source-ip aaa list** command in access interface configuration mode. To disable Per IP Subscriber DHCP Triggered RADIUS Accounting, use the **no** form of this command.

accounting dhcp source-ip aaa list *method-list-name*

no accounting

Syntax Description

method-list-name	Character string used to name at least one of the accounting methods, tried in a given sequence. Valid values are **default** or a named method list as defined by the **aaa accounting** command.

Command Default

This command is disabled by default. If the **accounting dhcp source-ip aaa list** command for RADIUS accounting is issued without a named method list specified, the default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list. If no default method list is defined, then no accounting takes place.

Command Modes

Access interface

Command History

Release	Modification
12.2(33)SRB	This command was introduced.

Usage Guidelines

Enter the **accounting dhcp source-ip aaa list** command to enable accounting. Use the **aaa accounting** command to create a named method list.

Examples

The following example shows how to define a command accounting method list named “default”.

```
accounting dhcp source-ip aaa list default
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
ip dhcp limit lease per interface	Limits the number of leases offered to DHCP clients behind an ATM RBE unnumbered or serial unnumbered interface.

acl (ISAKMP)

To configure split tunneling, use the **acl** command in Internet Security Association Key Management Protocol (ISAKMP) group configuration mode. To remove this command from your configuration and restore the default value, use the **no** form of this command.

acl *number*

no acl *number*

Syntax Description

number	Specifies a group of access control lists (ACLs) that represent protected subnets for split tunneling purposes.

Defaults

Split tunneling is not enabled; all data is sent via the Virtual Private Network (VPN) tunnel.

Command Modes

ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **acl** command to specify which groups of ACLs represent protected subnets for split tunneling. Split tunneling is the ability to have a secure tunnel to the central site and simultaneous clear text tunnels to the Internet.

You must enable the **crypto isakmp client configuration group** command, which specifies group policy information that has to be defined or changed, before enabling the **acl** command.

Examples

The following example shows how to correctly apply split tunneling for the group name “cisco.” In this example, all traffic sourced from the client and destined to the subnet 192.168.1.0 will be sent via the VPN tunnel.

```
crypto isakmp client configuration group cisco
  key cisco
  dns 10.2.2.2 10.3.2.3
  pool dog
  acl 199
!
access-list 199 permit ip 192.168.1.0 0.0.0.255 any
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies the policy profile of the group that will be defined.

acl (WebVPN)

To define an access control list (ACL) using a Secure Socket Layer Virtual Private Network (SSL VPN) gateway at the Application Layer level and to associate an ACL with a policy group, use the **acl** command in webvpn context configuration and webvpn group policy configuration modes. To remove the ACL definition, use the **no** form of this command.

acl *acl-name*

no acl *acl-name*

Syntax Description

acl-name	Name of the ACL.

Command Default

If a user session has no ACL attributes configured, all application requests are permitted.

Command Modes

Web context configuration
Webvpn group policy configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

The ACL can be defined for an individual user or for a policy group.

A defined ACL can be overridden by an individual user when the user logs on to the gateway (using AAA policy attributes).

Examples

The following example shows that "acl1" has been defined as the ACL and that it has been associated with policy group "default."

```
webvpn context context1
 acl acl1
  permit url "http://www.example.com"
 policy group default
  acl acl1
```

Related Commands

Command	Description
policy group	Configures a policy group and enters group policy configuration mode.
webvpn context	Configures the SSL VPN context and enters webvpn context configuration mode.

action-type

To enable the type of action to be performed on accounting records, use the **action-type** command in accounting method list configuration mode. To disable the action for the accounting records, use the **no** form this command.

action-type {**none** | **start-stop** | **stop-only**}

no action-type {**none** | **start-stop** | **stop-only**}

Cisco 1000 Series Router

action-type {**none** | **start-stop** [**periodic** {**disable** | **interval** *minutes*}] | **stop-only**}

no action-type {**none** | **start-stop** [**periodic** {**disable** | **interval** *minutes*}] | **stop-only**}

Syntax Description

none	Sets the action-type of the accounting records to none.
start-stop	Sets the start and stop action for the accounting records.
stop-only	Sets the stop action for the accounting records when service terminates.
periodic	(Optional) Specifies the periodic accounting action.
disable	Disables periodic accounting action.
interval	Sets the periodic accounting interval.
minutes	Periodic interval, in minutes, for accounting update records.

Command Default

If the periodic interval is not specified, information of all periodic accounting records is displayed.

Command Modes

accounting method list configuration (cfg-acct-mlist)

Command History

Release	Modification
15.0 (1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use the **action-type** command to enable the type of action to be performed on accounting records.

Examples

The following is sample output from the **action-type** command:

```
Router(config)# aaa accounting network default
Router(cfg-acct-mlist)# action-type start-stop periodic interval 1
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.

activate

To activate fail-close mode so that unencrypted traffic cannot pass through a group member before that member is registered with a key server, use the **activate** command in crypto map fail-close configuration mode. To disable fail-close mode, use the **no** form of this command.

activate

no activate

Syntax Description

This command has no arguments or keywords.

Command Default

Fail-close mode is not activated.

Command Modes

Crypto map fail-close configuration (crypto-map-fail-close)

Command History

Release	Modification
12.4(22)T	This command was introduced.
Cisco IOS XE Release 2.3	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

The **crypto map** command and **gdoi fail-clos**e keywords must precede this command. However, fail-close mode is not activated until the **activate** command is also configured.

Examples

The following example shows that fail-close mode has been activated, and unencrypted traffic from access list 102 is allowed before the group member is registered:

```
crypto map map1 gdoi fail-close
 match address 102
 activate crypto map map1 10 gdoi
 set group ks1_group
 match address 101
!
access-list 101 deny ip 10.0.1.0 0.0.0.255 10.0.1.0 0.0.0.255
access-list 102 deny tcp any eq telnet any
```

Related Commands

Command	Description
show crypto map gdoi fail-close	Displays information about the status of the fail-close mode.

add (WebVPN)

To add an ACL entry at a specified position, use the **add** command in webvpn acl configuration mode. To remove an entry from the position specified, use the **no** form of this command.

add *position acl-entry*

no add *position acl-entry*

Syntax Description

position	Position in the entry list to which the ACL rule is to be added.
acl-entry	Permit or deny command string.

Command Default

The ACL entry is appended to the end of the entry list.

Command Modes

Webvpn acl configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Examples

The following example shows that the ACL rule should be added to the third position of the ACL list:

```
webvpn context context1
 acl acl1
  add 3 permit url any
```

Related Commands

Command	Description
acl	Defines an ACL using a SSL VPN gateway at the Application Layer level.
wevpn context	Configures the SSL VPN context and enters webvpn context configuration mode.

address

To specify the IP address of the Rivest, Shamir, and Adelman (RSA) public key of the remote peer that you will manually configure in the keyring, use the **address** command in rsa-pubkey configuration mode. To remove the IP address, use the **no** form of this command.

address *ip-address*

no address *ip-address*

Syntax Description

ip-address	IP address of the remote peer.

Defaults

No default behavior or values

Command Modes

Rsa-pubkey configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

Before you can use this command, you must enter the **rsa-pubkey** command in the crypto keyring mode.

Examples

The following example specifies the RSA public key of an IP Security (IPSec) peer:

```
Router(config)# crypto keyring vpnkeyring
Router(conf-keyring)# rsa-pubkey name host.vpn.com
Router(config-pubkey-key)# address 10.5.5.1
Router(config-pubkey)# key-string
Router(config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973
Router(config-pubkey)# 2DD50A37 C4F4B0FD 9DADE748 429618D5
Router(config-pubkey)# 18242BA3 2EDFBDD3 4296142A DDF7D3D8
Router(config-pubkey)# 08407685 2F2190A0 0B43F1BD 9A8A26DB
Router(config-pubkey)# 07953829 791FCDE9 A98420F0 6A82045B
Router(config-pubkey)# 90288A26 DBC64468 7789F76E EE21
Router(config-pubkey)# quit
Router(config-pubkey-key)# exit
Router(conf-keyring)# exit
```

Related Commands

Command	Description
crypto keyring	Defines a crypto keyring to be used during IKE authentication.
key-string	Specifies the RSA public key of a remote peer.
rsa-pubkey	Defines the RSA manual key to be used for encryption or signatures during IKE authentication.

address (IKEv2 keyring)

To specify an IPv4 or IPv6 address or the range of the peer in an Internet Key Exchange Version 2 (IKEv2) keyring, use the **address** command in IKEv2 keyring peer configuration mode. To remove the IP address, use the **no** form of this command.

address {*ipv4-address* [*mask*] | *ipv6-address prefix*}

no address

Syntax Description

ipv4-address	IPv4 address of the remote peer.
mask	(Optional) Subnet mask.
ipv6-address	IPv6 address of the remote peer.
prefix	Prefix length

Command Default

The IP address is not specified.

Command Modes

IKEv2 keyring peer configuration (config-ikev2-keyring-peer)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(4)M	This command was modified. Support was added for IPv6 addresses.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify the peer's IP address, which is the IKE endpoint address and independent of the identity address.

Examples

The following examples show how to specify the preshared key of an IP Security (IPsec) peer:

```
Router(config)# crypto ikev2 keyring keyring1
Router(config-ikev2-keyring)# peer peer1
Router(config-ikev2-keyring-peer)# address 10.0.0.1 255.255.255.0

Router(config)# crypto ikev2 keyring keyring2
Router(config-ikev2-keyring)# peer peer2
Router(config-ikev2-keyring-peer)# address 2001:DB8:0:ABCD::1/2
```

Related Commands

Command	Description
crypto ikev2 keyring	Defines an IKEv2 keyring.
description (ikev2 keyring)	Describes an IKEv2 peer or a peer group for the IKEv2 keyring.
hostname (ikev2 keyring)	Specifies or modifies the hostname for the network server or peer.
peer	Defines a peer or a peer group for the keyring.
identity (ikev2 keyring)	Identifies the peer with IKEv2 types of identity.
pre-shared-key (ikev2 keyring)	Defines a preshared key for the IKEv2 peer.

address ipv4

To configure the IP address of a Diameter peer, use the **address ipv4** command in Diameter peer configuration submode. To disable the configured address, use the **no** form of this command.

address ipv4 *ip-address*

no address ipv4 *ip-address*

Syntax Description

ip address	The IP address of the host.

Command Default

No IP address is configured.

Command Modes

Diameter peer configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Examples

The following example shows how to configure the IP address of a Diameter peer:

```
Router (config-dia-peer)# address ipv4 192.0.2.0
```

Related Commands

Command	Description
diameter peer	Defines a Diameter peer and enters Diameter peer configuration mode.

address ipv4 (GDOI)

To set the source address, which is used as the source for packets originated by the local key server, use the **address ipv4** command in GDOI local server configuration mode. To remove the source address, use the **no** form of this command.

address ipv4 *ip-address*

no address ipv4 *ip-address*

Syntax Description

ip-address	Source address of the local key server.

Command Default

A source address is not configured.

Command Modes

GDOI local server configuration (config-local-server)

Command History

Release	Modification
12.4(11)T	This command was introduced.
Cisco IOS XE Release 2.3	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

When this command is used with unicast rekeys, the address is used as the source of the outgoing rekey message. When this command is used with redundancy, the address is used as the source of the outgoing announcement message. If both unicast rekeying and redundancy are configured, the same address is the source of both types of packets.

If multicast rekeying is configured and the **address ipv4** command is configured, the address (*ip-address)* is the source of the outgoing multicast packet. If multicast is configured but the **address ipv4** command is not configured, the access control list (ACL) specified in the **rekey address ipv4** command identifies the source of the outgoing multicast packet.

Examples

The following example shows the local server IP address is 10.1.1.0:

```
server local
 rekey algorithm aes 192
 rekey address ipv4 121
 rekey lifetime seconds 300
 rekey retransmit 10 number 2
 rekey authentication mypubkey rsa mykeys
 address ipv4 10.1.1.0
 sa ipsec 1
```

Related Commands

Command	Description
rekey address ipv4	Sends a rekey to a destination multicast address.
server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.

addressed-key

To specify which peer's RSA public key you will manually configure, use the **addressed-key** command in public key chain configuration mode.

addressed-key *key-address* [**encryption** | **signature**]

Syntax Description

key-address	Specifies the IP address of the remote peer's RSA keys.
encryption	(Optional) Indicates that the RSA public key to be specified will be an encryption special usage key.
signature	(Optional) Indicates that the RSA public key to be specified will be a signature special usage key.

Defaults

If neither the **encryption** nor **signature** keywords are used, general purpose keys will be specified.

Command Modes

Public key chain configuration. This command invokes public key configuration mode.

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command or the **named-key** command to specify which IP Security peer's RSA public key you will manually configure next.

Follow this command with the **key string** command to specify the key.

If the IPSec remote peer generated general-purpose RSA keys, do not use the **encryption** or **signature** keywords.

If the IPSec remote peer generated special-usage keys, you must manually specify both keys: use this command and the **key-string** command twice and use the **encryption** and **signature** keywords respectively.

Examples

The following example manually specifies the RSA public keys of two IPSec peers. The peer at 10.5.5.1 uses general-purpose keys, and the other peer uses special-usage keys.

```
Router(config)# crypto key pubkey-chain rsa
Router(config-pubkey-chain)# named-key otherpeer.example.com
Router(config-pubkey-key)# address 10.5.5.1
Router(config-pubkey-key)# key-string
Router(config-pubkey)# 005C300D 06092A86 4886F70D 01010105
Router(config-pubkey)# 00034B00 30480241 00C5E23B 55D6AB22
```

```
Router(config-pubkey)# 04AEF1BA A54028A6 9ACC01C5 129D99E4
Router(config-pubkey)# 64CAB820 847EDAD9 DF0B4E4C 73A05DD2
Router(config-pubkey)# BD62A8A9 FA603DD2 E2A8A6F8 98F76E28
Router(config-pubkey)# D58AD221 B583D7A4 71020301 0001
Router(config-pubkey)# quit
Router(config-pubkey-key)# exit
Router(config-pubkey-chain)# addressed-key 10.1.1.2 encryption
Router(config-pubkey-key)# key-string
Router(config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973
Router(config-pubkey)# 2DD50A37 C4F4B0FD 9DADE748 429618D5
Router(config-pubkey)# 18242BA3 2EDFBDD3 4296142A DDF7D3D8
Router(config-pubkey)# 08407685 2F2190A0 0B43F1BD 9A8A26DB
Router(config-pubkey)# 07953829 791FCDE9 A98420F0 6A82045B
Router(config-pubkey)# 90288A26 DBC64468 7789F76E EE21
Router(config-pubkey)# quit
Router(config-pubkey-key)# exit
Router(config-pubkey-chain)# addressed-key 10.1.1.2 signature
Router(config-pubkey-key)# key-string
Router(config-pubkey)# 0738BC7A 2BC3E9F0 679B00FE 53987BCC
Router(config-pubkey)# 01030201 42DD06AF E228D24C 458AD228
Router(config-pubkey)# 58BB5DDD F4836401 2A2D7163 219F882E
Router(config-pubkey)# 64CE69D4 B583748A 241BED0F 6E7F2F16
Router(config-pubkey)# 0DE0986E DF02031F 4B0B0912 F68200C4
Router(config-pubkey)# C625C389 0BFF3321 A2598935 C1B1
Router(config-pubkey)# quit
Router(config-pubkey-key)# exit
Router(config-pubkey-chain)# exit
Router(config)#
```

Related Commands

Command	Description
crypto key pubkey-chain rsa	Enters public key configuration mode (to allow you to manually specify the RSA public keys of other devices).
key-string (IKE)	Specifies the RSA public key of a remote peer.
named-key	Specifies which peer RSA public key you will manually configure.
show crypto key pubkey-chain rsa	Displays peer RSA public keys stored on your router.

administrator authentication list

To authenticate an administrative introducer for a Secure Device Provisioning (SDP) transaction, use the **administrator authentication list** command in tti-registrar configuration mode. To disable administrative introducer authentication, use the **no** form of this command.

administrator authentication list *list-name*

no administrator authentication list *list-name*

Syntax Description

list-name	Name of list.

Defaults

All introducers are authenticated as users; their username is used directly to build the device name.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

When you use the **administrator authentication list** command in SDP transactions, the RADIUS or TACACS+ authentication, authorization, and accounting (AAA) server checks for a valid account by looking at the username and password.

The authentication list and the authorization list usually both point to the same AAA list. It is possible that the lists can be on different databases, but it is generally not recommended.

Examples

The following example shows that an administrative authentication list named authen-rad and an administrative authorization list named author-rad have been configured on a RADIUS AAA server; a user authentication list named authen-tac and a user authorization list named author-tac have been configured on a TACACS+ server:

```
Router(config)# crypto provisioning registrar
Router(tti-registrar)# pki-server mycs
Router(tti-registrar)# administrator authentication list authen-rad
Router(tti-registrar)# administrator authorization list author-rad
Router(tti-registrar)# authentication list authen-tac
Router(tti-registrar)# authorization list author-tac
Router(tti-registrar)# template username ftpuser password ftppwd
Router(tti-registrar)# template config ftp://ftp-server/iossnippet.txt
Router(tti-registrar)# end
```

Related Commands

Command	Description
administrator authorization list	Specifies the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS CLI snippet that is sent back to the petitioner for an administrative introducer in an SDP transaction.
authentication list (tti-registrar)	Authenticates an introducer in an SDP transaction.
authorization list (tti-registrar)	Specifies the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS CLI snippet that is sent back to the petitioner for a user introducer in an SDP transaction.

administrator authorization list

To specify the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS command-line interface (CLI) snippet that is sent back to the petitioner for an administrative introducer in a Secure Device Provisioning (SDP) transaction, use the **administrator authorization list** command in tti-registrar configuration mode. To disable the subject name and list of template variables, use the **no** form of this command.

administrator authorization list *list-name*

no administrator authorization list *list-name*

Syntax Description

list-name	Name of list.

Defaults

There is no authorization information requested from the authentication, authorization, and accounting (AAA) server for the administrator.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When you use the **administrator authorization list** command in SDP transactions, the RADIUS or TACACS+ AAA server stores the subject name and template variables. The name and variables are sent back to the petitioner in the Cisco IOS CLI snippets. This list and the authorization list are usually on the same database, but they can be on different AAA databases. (Storing lists on different databases is not recommended.)

When a petitioner makes an introducer request, multiple queries are sent to the AAA list database on the RADIUS or TACACS+ server. The queries search for entries of the following form:

```
user Password <userpassword>
   cisco-avpair="ttti:subjectname=<<DN subjectname>>"
   cisco-avpair="tti:iosconfig#<<value>>"
   cisco-avpair="tti:iosconfig#<<value>>"
   cisco-avpair="tti:iosconfig#=<<value>>"
```

Note The existence of a valid AAA username record is enough to pass the authentication check. The cisco-avpair=tti information is necessary only for the authorization check.

If a subject name were received in the authorization response, the registrar stores it in the enrollment database, and that subject name overrides the subject name that is supplied in the subsequent certificate request (PKCS10) from the petitioner device.

The numbered tti:iosconfig values are expanded into the Cisco IOS snippet that is sent to the petitioner. The configurations replace any numbered ($1 through $9) template variable. Because the default Cisco IOS snippet template does not include the variables $1 through $9, these variables are ignored unless you configure an external Cisco IOS snippet template. To specify an external configuration, use the **template config** command.

Note The template configuration location may include a variable $n, which is expanded to the name that the administrator enters in the additional SDP dialog.

Examples

The following example shows that an administrative authentication list named authen-rad and an administrative authorization list named author-rad have been configured on a RADIUS AAA server; a user authentication list named authen-tac and a user authorization list named author-tac have been configured on a TACACS+ server:

```
Router(config)# crypto provisioning registrar
Router(tti-registrar)# pki-server mycs
Router(tti-registrar)# administrator authentication list authen-rad
Router(tti-registrar)# administrator authorization list author-rad
Router(tti-registrar)# authentication list authen-tac
Router(tti-registrar)# authorization list author-tac
Router(tti-registrar)# template username ftpuser password ftppwd
Router(tti-registrar)# template config ftp://ftp-server/iossnippet.txt
Router(tti-registrar)# end
```

Related Commands

Command	Description
administrator authentication list	Authenticates an administrative introducer for an SDP transaction.
authentication list (tti-registrar)	Authenticates a user introducer for an SDP transaction.
authorization list (tti-registrar)	Specifies the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS CLI snippet that is sent back to the petitioner for a user introducer in an SDP operation.

alert

To enable message logging when events, such as a text-chat, begin, use the **alert** command in the appropriate configuration mode. To change the configured setting or revert to the default setting, use the **no** form of this command.

alert {**on** | **off**}

no alert

Syntax Description

on	Enables message logging for instant messenger application policy events.
off	Disables message logging for instant messenger application policy events.

Command Default

If this command is not configured, the global setting for the **ip inspect alert-off** command will take effect.

Command Modes

cfg-appfw-policy-aim configuration

cfg-appfw-policy-ymsgr configuration

cfg-appfw-policy-msnmsgr configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.

Examples

The following example shows to enable audit trail messages for all AOL instant messenger traffic:

```
appfw policy-name my-im-policy
 application http
  port-misuse im reset
!
 application im aol
  server deny name login.user1.aol.com
  audit trail on
  alert on
```

Related Commands

Command	Description
ip inspect alert-off	Disables Cisco IOS firewall alert messages.

alert (zone-based policy)

To turn on and off Cisco IOS stateful packet inspection alert messages that are displayed on the console, use the **alert** command in parameter-map type inspect configuration mode or URL parameter-map configuration mode. To change the configured setting or revert to the default setting, use the **no** form of this command.

alert {**on** | **off**}

no alert {**on** | **off**}

Syntax Description

on	Alert messages are generated.
off	Alert messages are not generated.

Command Default

Alert messages are not issued.

Command Modes

Parameter-map type inspect configuration
URL parameter-map configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

You can use the **alert** subcommand when you are creating a parameter map.

When you are configuring an inspect type parameter map, you can enter the **alert** subcommand after you enter the **parameter-map type inspect** command.

When you are creating or modifying a URL parameter map, you can enter the **alert** subcommand after you enter the **parameter-map type urlfilter** command.

For more detailed information about creating a parameter map, see the **parameter-map type inspect** or **parameter-map type urlfilter** command.

Examples

The following example shows a sample inspect parameter map with the Cisco IOS stateful packet inspection alert messages enabled:

```
parameter-map type inspect insp-params
 alert on
```

Related Commands

Command	Description
ip inspect alert-off	Disables Cisco IOS firewall alert messages.
parameter-map type inspect	Configures an inspect parameter map for connecting thresholds, timeouts, and other parameters pertaining to the **inspect** action.
parameter-map type urlfilter	Creates or modifies a parameter map for URL filtering parameters.

alert-severity

To change the alert severity rating for a given signature or signature category, use the **alert-severity** command in signature-definition-action (config-sigdef-action) or IPS-category-action (config-ips-category-action) configuration mode. To return to the default action, use the **no** form of this command.

alert-severity {**high** | **medium** | **low** | **informational**}

no alert-severity

Syntax Description

high | **medium** | **low** | **informational**	Alert severity action for a given signature or signature category.

Command Default

No default behavior or values

Command Modes

Signature-definition-action configuration (config-sigdef-action)
IPS-category-action configuration (config-ips-category-action)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Before issuing the **alert-severity** command, you must specify either a signature via the **signature** command or a signature category (such as attack-type) via the **category** command.

Examples

The following example shows how to set the alert severity value to low for signature 5760:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip ips signature-definition
Router(config-sigdef)# signature 5726 0
Router(config-sigdef-sig)# alert-severity low
Router(config-sigdef)#^ZDo you want to accept these changes? [confirm]
Router#
*Nov 9 21:50:55.847: %IPS-6-ENGINE_BUILDING: multi-string - 3 signatures - 12 of 11
engines
*Nov 9 21:50:55.859: %IPS-6-ENGINE_READY: multi-string - build time 12 ms - packets for
this engine will be scanned
*Nov 9 21:50:55.859: %SYS-5-CONFIG_I: Configured from console by cisco on console
```

Related Commands

Command	Description
category	Specifies a signature category that is to be used for multiple signature actions or conditions.
signature	Specifies a signature for which the CLI user tunings will be changed.

algorithm

To specify the algorithm to be used for decrypting the filters, use the **algorithm** command in FPM match encryption filter configuration mode.

algorithm *algorithm*

Syntax Description

algorithm	The algorithm to be used for decrypting. Currently, aes256cbc is the only algorithm supported.

Command Default

No algorithm is specified.

Command Modes

FPM match encryption filter configuration (c-map-match-enc-config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If you have access to an encrypted traffic classification definition file (eTCDF) or if you know valid values to configure encrypted Flexible Packet Matching (FPM) filters, you can configure the same eTCDF through the command-line interface instead of using the preferred method of loading the eTCDF on the router. You must create a class map of type access-control using the **class-map type** command, and use the **match encrypted** command to configure the match criteria for the class map on the basis of encrypted FPM filters and enter FPM match encryption filter configuration mode. You can then use the appropriate commands to specify the algorithm, cipher key, cipher value, filter hash, filter ID, and filter version. You can copy the values from the eTCDF by opening the eTCDF in any text editor.

Use the **algorithm** command to specify the algorithm used for decrypting the filters.

Examples

The following example shows how to specify the algorithm for decrypting the filter:

```
Router(config)# class-map type access-control match-all c1
Router(config-cmap)# match encrypted
Router(c-map-match-enc-config)# algorithm aes256cbc
Router(c-map-match-enc-config)#
```

Related Commands

Command	Description
class-map type	Creates a class map to be used for matching packets to a specified class.
match encrypted	Configures the match criteria for a class map on the basis of encrypted FPM filters and enters FPM match encryption filter configuration mode.

all (profile map configuration)

To specify that all authentication and authorization requests be cached, use the **all** command in profile map configuration mode. To disable the caching of all requests, use the **no** form of this command.

all [**no-auth**]

no all

Syntax Description

no-auth	(Optional) Specifies that authentication is bypassed for this user.

Command Default

No requests are cached.

Command Modes

Profile map configuration (config-profile-map)

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use the **all** command to cache all authentication and authorization requests.

Use the **all** command for specific service authorization requests, but it should be avoided when dealing with authentication requests.

Examples

The following example caches all authorization requests in the localusers cache profile group. No authentication is performed for these users because the **no-auth** keyword is used.

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa cache profile localusers
Router(config-profile-map)# all no-auth
```

Related Commands

Command	Description
profile	Defines or modifies an individual authentication and authorization cache profile based on an exact username match.
regexp	Creates an entry in a cache profile group that allows authentication and authorization matches based on a regular expression.

allow-mode

To turn the default mode of the filtering algorithm on or off, use the **allow-mode** command in URL parameter-map configuration mode. To disable this feature, use the **no** form of this command.

allow-mode {**on** | **off**}

no allow-mode {**on** | **off**}

Syntax Description

on	Turns on the default mode of the filtering algorithm. The default is on.
off	Turns off the default mode of the filtering algorithm.

Command Default

The filtering algorithm is turned on.

Command Modes

URL parameter-map configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

When you are creating or modifying a URL parameter map, you can enter the **allow-mode** subcommand after you enter the **parameter-map type urlfilter** command.

For more detailed information about creating a parameter map, see the **parameter-map type urlfilter** command.

Examples

The following example turns on the filtering algorithm:

```
parameter-map type urlfilter eng-filter-profile
 allow-mode on
```

Related Commands

Command	Description
parameter-map type urlfilter	Creates or modifies a parameter map for URL filtering parameters.

appfw policy-name

To define an application firewall policy and put the router in application firewall policy configuration mode, use the **appfw policy-name** command in global configuration mode. To remove a policy from the router configuration, use the **no** form of this command.

appfw policy-name *policy-name*

no appfw policy-name *policy-name*

Syntax Description

policy-name	Name of application policy.

Defaults

If this command is not issued, an application firewall policy cannot be created.

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command puts the router in application firewall policy (appfw-policy-*protocol)* configuration mode, which allows you to begin defining the application firewall policy that will later be applied to the Cisco IOS Firewall via the **ip inspect name** command.

What Is an Application Firewall Policy?

The application firewall uses static signatures to detect security violations. A static signature is a collection of parameters that specifies which protocol conditions must be met before an action is taken. (For example, a signature may specify that an HTTP data stream containing the POST method must reset the connection.) These protocol conditions and reactions are defined by the end user via a command-line interface (CLI) to form an application firewall policy (also known as a security policy).

Examples

The following example shows how to define the HTTP application firewall policy “mypolicy.” This policy includes all supported HTTP policy rules. After the policy is defined, it is applied to the inspection rule “firewall,” which will inspect all HTTP traffic entering the FastEthernet0/0 interface.

```
! Define the HTTP policy.
appfw policy-name mypolicy
 application http
  strict-http action allow alarm
  content-length maximum 1 action allow alarm
  content-type-verification match-req-rsp action allow alarm
  max-header-length request 1 response 1 action allow alarm
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc default action allow alarm
```

```
  request-method extension default action allow alarm
  transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
 ip inspect firewall in
!
!
```

Related Commands

Command	Description
application	Puts the router in appfw-policy-*protocol* configuration mode and begin configuring inspection parameters for a given protocol.
ip inspect name	Defines a set of inspection rules.

appl (webvpn)

To configure an application to access a smart tunnel, use the **appl** command in WebVPN smart tunnel configuration mode. To disable an application from accessing the smart tunnel, use the **no** form of this command.

appl *display-name appl-name* **windows**

no appl *display-name appl-name* **windows**

Syntax Description

display-name	Name of the application to be displayed in the smart tunnel application access list on the web browser.
appl-name	Application name or path.
windows	Specifies the Windows platform.

Command Default

No applications have access to a smart tunnel.

Command Modes

WebVPN smart tunnel configuration mode (config-webvpn-smart-tunnel)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

You must configure the correct path and application name to allow the smart tunnel to provide access to applications.

Examples

The following example shows how to configure applications to access the smart tunnel:

```
Router(config)# webvpn context sslgw
Router(config-webvpn-context)# smart-tunnel list st1
Router(config-webvpn-smart-tunnel)# appl ie ieexplore.exe windows
Router(config-webvpn-smart-tunnel)# appl telnet telnet.exe windows
```

Related Commands

Command	Description
smart-tunnel list	Configures the smart tunnel list and enables it within a policy group.
webvpn context	Configures the SSL VPN context.

application (application firewall policy)

To put the router in appfw-policy-*protocol* configuration mode and begin configuring inspection parameters for a given protocol, use the **application** command in application firewall policy configuration mode. To remove protocol-specific rules, use the **no** form of this command.

application *protocol*

no application *protocol*

Syntax Description

protocol	Protocol-specific traffic will be inspected. One of the following protocols (keywords) can be specified: • **http** (HTTP traffic will be inspected.) • **im** {**aol** | **yahoo** | **msn**} (Traffic for the specified instant messenger application will be inspected.)

Command Default

You cannot set up protocol-specific inspection parameters.

Command Modes

cfg-appfw-policy-aim configuration

cfg-appfw-policy-ymsgr configuration

cfg-appfw-policy-msnmsgr configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(4)T	The **im**, **aol**, **yahoo**, and **msn** keywords were introduced to support instant message traffic detection and prohibition.

Examples

This command puts the router in appfw-policy-*protocol* configuration mode, where "*protocol*" is dependent upon the specified protocol.

HTTP-Specific Inspection Commands

After you issue the **application http** command and enter the appfw-policy-http configuration mode, begin configuring inspection parameters for HTTP traffic by issuing any of the following commands:

- **audit-trail**
- **content-length**
- **content-type-verification**
- **max-header-length**
- **max-uri-length**
- **port-misuse**

- **request-method**
- **strict-http**
- **timeout**
- **transfer-encoding**

Instant Messenger-Specific Inspection Commands

After you issue the **application im** command and specify an instant messenger application (AOL, Yahoo, or MSN), you can begin configuring inspection parameters for IM traffic by issuing any of the following commands:

- **alert**
- **audit trail**
- **server**
- **service**
- **timeout**

Examples

The following example shows how to define the HTTP application firewall policy "mypolicy." This policy includes all supported HTTP policy rules. After the policy is defined, it is applied to the inspection rule "firewall," which will inspect all HTTP traffic entering the FastEthernet0/0 interface.

```
! Define the HTTP policy.
appfw policy-name mypolicy
 application http
  strict-http action allow alarm
  content-length maximum 1 action allow alarm
  content-type-verification match-req-rsp action allow alarm
  max-header-length request 1 response 1 action allow alarm
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc default action allow alarm
  request-method extension default action allow alarm
  transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
 ip inspect firewall in
!
!
```

The following example shows to configure application policy "my-im-policy," which allows text-chat for Yahoo! instant messenger users and blocks instant messenger traffic for all other users:

```
appfw policy-name my-im-policy
 application http
  port-misuse im reset
!
 application im yahoo
  server permit name scs.msg.yahoo.com
  server permit name scsa.msg.yahoo.com
```

```
  server permit name scsb.msg.yahoo.com
  server permit name scsc.msg.yahoo.com
  service text-chat action allow
  service default action reset
!
 application im aol
  server deny name login.user1.aol.com
!
 application im msn
  server deny name messenger.hotmail.com
!
ip inspect name test appfw my-im-policy

interface FastEthernet0/0
 description Inside interface
 ip inspect test in
```

Related Commands

Command	Description
appfw policy-name	Defines an application firewall policy and puts the router in application firewall policy configuration mode.

application redundancy

To enter redundancy application configuration mode, use the **application redundancy** command in redundancy configuration mode.

application redundancy

Syntax Description

This command has no arguments or keywords.

Command Default

None

Command Modes

Redundancy configuration (config-red)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced.

Examples

The following example shows how to enter redundancy application configuration mode:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# application redundancy
Router(config-red-app)#
```

Related Commands

Command	Description
group(firewall)	Enters redundancy application group configuration mode.

arap authentication

To enable authentication, authorization, and accounting (AAA) authentication for AppleTalk Remote Access Protocol (ARAP) on a line, use the **arap authentication** command in line configuration mode. To disable authentication for an ARAP line, use the **no** form of this command.

arap authentication {**default** | *list-name*} [**one-time**]

no arap authentication {**default** | *list-name*}

Caution If you use a *list-name* value that was not configured with the **aaa authentication arap** command, ARAP will be disabled on this line.

Syntax Description

default	Default list created with the **aaa authentication arap** command.
list-name	Indicated list created with the **aaa authentication arap** command.
one-time	(Optional) Accepts the username and password in the username field.

Defaults

ARAP authentication uses the default set with **aaa authentication arap** command. If no default is set, the local user database is checked.

Command Modes

Line configuration

Command History

Release	Modification
10.3	This command was introduced.
11.0	The **one-time** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is a per-line command that specifies the name of a list of AAA authentication methods to try at login. If no list is specified, the default list is used (whether or not it is specified in the command line). You create defaults and lists with the **aaa authentication arap** command. Entering the **no** version of **arap authentication** has the same effect as entering the command with the **default** keyword. Before issuing this command, create a list of authentication processes by using the **aaa authentication arap** global configuration command.

Examples

The following example specifies that the TACACS+ authentication list called *MIS-access* is used on ARAP line 7:

```
line 7
 arap authentication MIS-access
```

Related Commands

Command	Description
aaa authentication arap	Enables an AAA authentication method for ARAP using TACACS+.

ase collector

Note Effective with Cisco IOS Release 12.4(24), the **ase collector** command is not available in Cisco IOS software.

To enter the destination IP address of the Automatic Signature Extraction (ASE) collector server, use the **ase collector** command in global configuration mode. To remove this IP address, use the **no** form of this command.

ase collector *ip-address*

no ase collector *ip-address*

Syntax Description

ip-address	Provides IP connectivity between the ASE sensor and ASE collector.

Command Default

No ASE collector IP address is specified.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T	This command was introduced.
12.4(24)	This command was removed.

Usage Guidelines

This command is used on the Cisco 1800, 2800, and 7200 series routers, Cisco 7301 router, and Integrated Services Routers (ISRs) as ASE sensors.

Examples

The following example shows how to configure an ASE collector IP address:

```
Router(config)# ase collector 10.10.10.3
```

Related Commands

Command	Description
ase enable	Enables the ASE feature on a specified interface.
ase group	Identifies the TIDP group number for the ASE feature.
ase signature extraction	Enables the ASE feature globally on the router.
clear ase signature	Clears ASE signatures that were detected on the router.
debug ase	Provides error, log, messaging, reporting, status, and timer information.
show ase	Shows the ASE run-time status, which includes the TIDP group number.

ase enable

Note Effective with Cisco IOS Release 12.4(24), the **ase enable** command is not available in Cisco IOS software.

To enable the Automatic Signature Extraction (ASE) feature on a specified interface, use the **ase enable** command in interface configuration mode. To disable the ASE feature on a specified interface, use the **no** form of this command.

ase enable

no ase enable

Syntax Description

This command has no arguments or keywords.

Command Default

The ASE feature is disabled on an interface.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.4(15)T	This command was introduced.
12.4(24)	This command was removed.

Usage Guidelines

This command is used on the Cisco 1800, 2800, and 7200 series routers, Cisco 7301 router, and Integrated Services Routers (ISRs) as ASE sensors.

Examples

The following example shows how to enable the ASE feature on a specified interface:

```
Router(config-if)# ase enable
```

Related Commands

Command	Description
ase collector	Enters the ASE collector server IP address so that the ASE sensor has IP connectivity to the ASE collector.
ase group	Identifies the TIDP group number for the ASE feature.
ase signature extraction	Enables the ASE feature globally on the router.
clear ase signature	Clears ASE signatures that were detected on the router.
debug ase	Provides error, log, messaging, reporting, status, and timer information.
show ase	Shows the ASE run-time status, which includes the TIDP group number.

ase group

Note Effective with Cisco IOS Release 12.4(24), the **ase group** command is not available in Cisco IOS software.

To identify the Threat Information Distribution Protocol (TIDP) group number used for exchange between the Automatic Signature Extraction (ASE) sensor and ASE collector, use the **ase group** command in global configuration mode. To disable this group number, use the **no** form of this command.

ase group *TIDP-group-number*

no ase group *TIDP-group-number*

Syntax Description

TIDP-group-number	TIDP group number for the ASE feature. The range of group numbers is between 1 and 65535.

Command Default

No TIDP group number is specified.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T	This command was introduced.
12.4(24)	This command was removed.

Usage Guidelines

This command is used on the Cisco 1800, 2800, and 7200 series routers, Cisco 7301 router, and Integrated Services Routers (ISRs) as ASE sensors.

Examples

The following example shows how to configure a TIDP group number for the ASE feature:

```
Router(config)# ase group 10
```

Related Commands

Command	Description
ase collector	Enters the ASE collector server IP address so that the ASE sensor has IP connectivity to the ASE collector.
ase enable	Enables the ASE feature on a specified interface.
ase signature extraction	Enables the ASE feature globally on the router.
clear ase signature	Clears ASE signatures that were detected on the router.

Command	Description
debug ase	Provides error, log, messaging, reporting, status, and timer information.
show ase	Shows the ASE run-time status, which includes the TIDP group number.

ase signature extraction

Note Effective with Cisco IOS Release 12.4(24), the **ase signature extraction** command is not available in Cisco IOS software.

To enable the Automatic Signature Extraction (ASE) feature globally on the router, use the **ase signature extraction** command in global configuration mode. To disable the ASE feature globally on the router, use the **no** form of this command.

ase signature extraction

no ase signature extraction

Syntax Description

This command has no arguments or keywords.

Command Default

The ASE feature is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T	This command was introduced.
12.4(24)	This command was removed.

Usage Guidelines

This command is used on the Cisco 1800, 2800, and 7200 series routers, Cisco 7301 router, and Integrated Services Routers (ISRs) as ASE sensors.

Examples

The following example shows how to enable the ASE feature globally on the router:

```
Router(config)# ase signature extraction
```

Related Commands

Command	Description
ase collector	Enters the ASE collector server IP address so that the ASE sensor has IP connectivity to the ASE collector.
ase group	Identifies the TIDP group number for the ASE feature.
ase enable	Enables the ASE feature on a specified interface.
clear ase signature	Clears ASE signatures that were detected on the router.
debug ase	Provides error, log, messaging, reporting, status, and timer information.
show ase	Displays the ASE run-time status, which includes the TIDP group number.

attribute (server-group)

To add attributes to an accept or reject list, use the **attribute** command in server-group configuration mode. To remove attributes from the list, use the **no** form of this command.

attribute *number* [*number* [*number*]...]

no attribute *number* [*number* [*number*]...]

Syntax Description

number [*number* [*number*]...]	Attributes to include in an accept or reject list. The value can be a single integer, such as 7, or a range of numbers, such as 56–59. At least one attribute value must be specified.

Defaults

If this command is not enabled, all attributes are sent to the network access server (NAS).

Command Modes

Server-group configuration

Command History

Release	Modification
12.2(1)DX	This command was introduced.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(13)T	Platform support was added for the Cisco 7401 ASR.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Used in conjunction with the **radius-server attribute list** command (which defines the list name), the **attribute** command can be used to add attributes to an accept or reject list (also known as a filter). Filters are used to prevent the network access server (NAS) from receiving and processing unwanted attributes for authorization or accounting.

The **attribute** command can be used multiple times to add attributes to a filter. However, if a required attribute is specified in a reject list, the NAS will override the command and accept the attribute. Required attributes are as follows:

Note The user-password (RADIUS attribute 2) and nas-ip (RADIUS attribute 4) attributes can be filtered together successfully in the access request if they are configured to be filtered. An access request must contain either a user-password or a CHAP password or a state. Also, either a NAS IP address or NAS identifier must be present in a RADIUS accounting request.

- For authorization:
  - 2 (user-password)
  - 6 (Service-Type)
  - 7 (Framed-Protocol)
- For accounting:
  - 4 (NAS-IP-Address)
  - 40 (Acct-Status-Type)
  - 41 (Acct-Delay-Time)
  - 44 (Acct-Session-ID)

Note The user will not receive an error at the point of configuring a reject list for required attributes because the list does not specify a purpose—authorization or accounting. The server will determine whether an attribute is required when it is known what the attribute is to be used for.

Examples

The following example shows how to add attributes 2, 4, 12, 217, 6–10, 13, 64–69, and 218 to the list name "standard":

```
radius-server attribute list standard
    attribute 2,4,12,217,6-10,13
    attribute 64-69,218
```

Related Commands

Command	Description
accounting (server-group configuration)	Specifies an accept or reject list for attributes that are to be sent to the RADIUS server in an accounting request.
authorization (server-group configuration)	Specifies an accept or reject list for attributes that are returned in an Access-Accept packet from the RADIUS server.
radius-server attribute list	Defines an accept or reject list name.

attribute map

To attach an attribute map to a particular Lightweight Directory Access Protocol (LDAP) server, use the **attribute map** command in LDAP server configuration mode. To remove the attribute maps, use the **no** form of this command.

attribute map *map-name*

no attribute map *map-name*

Syntax Description

map-name	Attribute map name.

Command Default

No attribute maps exist for any LDAP servers.

Command Modes

LDAP server configuration (config-ldap-server)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

To use the attribute mapping features correctly, you need to understand the Cisco LDAP attribute names and values as well as the user-defined attribute names and values.

Examples

The following example shows how to attach an attrribute map named attribute att_map_1 in an LDAP server:

```
Router(config)# ldap server server1
Router(config-ldap-server)# attribute map att_map_1
```

Related Commands

Command	Description
ldap attribute-map	Configures a dynamic LDAP attribute map.
map-type	Defines the mapping of a attribute in the LDAP server.
show ldap attribute	Displays information about default LDAP attribute mapping.

attribute nas-port format

To configure services to use specific named methods for different service types, which can be set to use their own respective RADIUS server groups, use the **attribute nas-port format** command in server-group configuration mode. To remove the override, which is to use specific named methods for different service types, use the **no** form of this command.

attribute nas-port format *format-type* [*string*]

no attribute nas-port format *format-type* [*string*]

Syntax Description

format-type	Type of format (see Table 13).
string	(Optional) Pattern of the data format (see Table 14).

Defaults

Default format type is used for all services.

Command Modes

Server-group configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.

Usage Guidelines

The following format types may be configured.

Table 13 Format Types

a	Format is type, channel, or port.
b	Either interface(16), isdn(16), or async(16).
c	Data format (bits): shelf(2), slot(4), port(5), or channel(5).
d	Data format (bits): slot(4), module(1), port(3), vpi(8), or vci(16).
e	Configurable data format (see Table 14).

The following characters may be used in the string pattern of the data format.

Table 14 Characters Supported by Format-Type e

0	Zero
1	One
f	DS0 shelf
s	DS0 slot

Table 14 Characters Supported by Format-Type e (continued)

a	DS0 adapter
P	DS0 port
i	DS0 subinterface
c	DS0 channel
F	Async shelf
S	Async slot
P	Async port
L	Async line
S	PPPoX slot (includes PPP over ATM [PPPoA], PPP over Ethernet over ATM [PPPoEoA], PPP over Ethernet over Ethernet [PPPoEoE], PPP over Ethernet over VLAN [PPPoEoVLAN], and PPP over Ethernet over Queue in Queue [PPPoEoQinQ]).
A	PPPoX adapter
P	PPPoX port
V	PPPoX VLAN ID
I	PPPoX virtual path identifier (VPI)
C	PPPoX virtual channel indicator (VCI)
U	Session ID

Examples

The following example shows that a leased-line PPP client has chosen to send no RADIUS Attribute 5 while the default is set for format d:

```
interface Serial2/0
 no ip address
 encapsulation ppp
 ppp accounting SerialAccounting
 ppp authentication pap

aaa accounting network default start-stop group radius
aaa accounting network SerialAccounting start-stop group group1

aaa group server radius group1
 server 10.101.159.172 auth-port 1645 acct-port 1646
 attribute nas-port none

radius-server host 10.101.159.172 auth-port 1645 acct-port 1646
radius-server attribute nas-port format d
```

Related Commands

Command	Description
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
ip radius source-interface	Forces RADIUS to use the IP addressing of a specified interface for all outgoing RADIUS packets.
radius-server host	Specifies a RADIUS server host.

attribute type

To define an attribute type that is to be added to an attribute list locally on a router, use the **attribute type** command in global configuration mode. To remove the attribute type from the list, use the **no** form of this command.

attribute type *name value* [**service** *service*] [**protocol** *protocol*] [*tag*]

no attribute type *name value* [**service** *service*] [**protocol** *protocol*] [*tag*]

Syntax Description

name	The Cisco IOS authentication, authorization, and accounting (AAA) internal name of the IETF RADIUS attribute to be added to the attribute list. For a list of supported attributes, use the CLI help option (**?**) on your platform.
value	A string, binary, or IPv4 address value. This is the RADIUS attribute that is being defined in Cisco IOS AAA format. A string added to the attribute value must be inside quotation marks. For example, if the value is "interface-config" and the string is "ip unnumbered FastEthernet0," you would write interface-config "ip unnumbered FastEthernet0".
service *service*	(Optional) Specifies the Access method, which is typically PPP.
protocol *protocol*	(Optional) Specifies the type of protocol, which can be ATM, IP, or virtual private dialup network (VPDN).
tag	(Optional) A means of grouping attributes that refer to the same VPDN tunnel.

Command Default

An attribute type is not added to the attribute list.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(55)SE	This command was modified in Cisco IOS Release 12.2(55)SE. The following options were added for the *service* argument: **ap-lsc-join** , **ap-mic-join**, **ap-ssc-join**, **lbs-mic-join**, and **lbs-ssc-join**.

Usage Guidelines

Attributes are added to the attribute list each time a new attribute type is defined. Attributes are not validated at configuration. The AAA subsystem "knows" only the format that is expected by the services when the service defines a given attribute inside a definition file. However, it cannot validate the attribute

information itself. This validation is done by a service when it first uses the attribute. This validation is applicable to both RADIUS and TACACS+ AAA servers. Thus, if you are not familiar in configuring a AAA server, Cisco recommends that you test your attribute list on a test device with the service that will be using the list before configuring and using it in a production environment.

Examples

The following example shows that the attribute list named "TEST" is to be added to the subscriber profile "example.com." The attribute TEST includes the attribute types interface-config "ip unnumbered FastEthernet0" and interface-config "ip vrf forwarding vrf1."

```
aaa authentication ppp template1 local
aaa authorization network template1 local
!
aaa attribute list TEST
   attribute type interface-config "ip unnumbered FastEthernet0" service ppp protocol lcp
   attribute type interface-config "ip vrf forwarding vrf1" service ppp protocol lcp
!
ip vrf blue
 description vrf vrf1 template1
 rd 1:1
 route-target export 1:1
 route-target import 1:1
!
subscriber authorization enable
!
subscriber profile example.com
 service local
 aaa attribute list TEST
!
bba-group pppoe grp1
 virtual-template 1
 service profile example.com
!
interface Virtual-Template1
 no ip address
 no snmp trap link-status
 no peer default ip address
 no keepalive
 ppp authentication pap template1
 ppp authorization template1
!
```

Related Commands

Command	Description
aaa attribute list	Defines a AAA attribute list locally on a router.

audit filesize

To change the size of the audit file, use the **audit filesize** command in global configuration mode. To return the audit file to its default size, use the **no** form of this command.

audit filesize *size*

no audit filesize *size*

Syntax Description

size	Size of the audit file in KB. Valid values range from 32 KB to 128 KB. 32 KB is the default size.

Defaults

The audit file is 32 KB.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)S	This command was introduced.
12.0(27)S	This feature was integrated into Cisco IOS Release 12.0(27)S.
12.2(27)SBC	This command was integrated into Cisco IOS Release 12.2(27)SBC.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The audit file is a fixed file size in the disk file system. The audit file contains syslog messages (also referred to as hashes), which monitor changes that have been made to your router. Because the audit file that is stored on the disk is circular, the number of messages that can be stored is dependent on the size of the selected file. Also, the size determines the number of messages that can be stored on the disk before a wrap around occurs.

You should always ensure that the audit file is secure. The audit file should be access protected so that only the audit subsystem can access it.

Note Audit logs are enabled by default and cannot be disabled.

Examples

The following example shows how to change the audit file size to 128 KB:

```
Router(config)# audit filesize 128
```

Related Commands

Command	Description
audit interval	Changes the time interval that is used for calculating hashes.
show audit	Displays contents of the audit file.

audit interval

To change the time interval that is used for calculating hashes, use the **audit interval** command in global configuration mode. To return to the default value, which is 5 minutes, use the **no** form of this command.

audit interval *seconds*

no audit interval *seconds*

Syntax Description

seconds	Time interval, in seconds, between hash calculations. Valid values range from 120 seconds to 3600 seconds. The default value is 300 seconds (5 minutes).

Defaults

300 seconds (5 minutes)

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)S	This command was introduced.
12.0(27)S	This feature was integrated into Cisco IOS Release 12.0(27)S.
12.2(27)SBC	This command was integrated into Cisco IOS Release 12.2(27) SBC.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Hashes are used to monitor changes in your router. A separate hash is maintained for each of the following areas:

- Running version—A hash of the information that is provided in the output of the **show version** command—running version, ROM information, BOOTLDR information, system image file, system and processor information, and configuration register contents.
- Hardware configuration—A hash of platform-specific information that is generally provided in the output of the **show diag** command.
- File system—A hash of the dir information on all of the flash file systems, which includes bootflash and any other flash file systems on the router.
- Running configuration—A hash of the running configuration.
- Startup configuration—A hash of the contents of the files on NVRAM, which includes the startup-config, private-config, underlying-config, and persistent-data files.

By default, the hashes are calculated every 5 minutes to see if any changes (events) have been made to the network. The time interval prevents a large number of hashes from being generated.

Note Audit logs are enabled by default and cannot be disabled.

Examples

The following example shows how to specify hashes to be calculated every 120 seconds (2 minutes):

```
Router(config)# audit interval 120
```

Related Commands

Command	Description
audit filesize	Changes the size of the audit file.
show audit	Displays contents of the audit file.

audit-trail

To enable message logging for established or torn-down connections, use the **audit-trail** command in the appropriate configuration mode. To return to the default value, use the **no** form of this command.

audit-trail {**on** | **off**}

no audit-trail {**on** | **off**}

Syntax Description

on	Audit trail messages are generated.
off	Audit trail messages are not generated.

Defaults

If this command is not issued, the default value specified via the **ip inspect audit-trail** command will be used.

Command Modes

cfg-appfw-policy-http configuration

cfg-appfw-policy-aim configuration

cfg-appfw-policy-ymsgr configuration

cfg-appfw-policy-msnmsgr configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(4)T	Support for the inspection of instant messenger applications was introduced.

Usage Guidelines

The **audit-trail** command will override the **ip inspect audit-trail** global command.

Before you can issue the **audit-trail** command, you must enable protocol inspection via the **application** command, which allows you to specify whether you want to inspect HTTP traffic or instant messenger application traffic. The **application** command puts the router in appfw-policy-*protocol* configuration mode, where "*protocol*" is dependent upon the specified protocol.

Examples

The following example, which shows how to define the HTTP application firewall policy "mypolicy," enables audit trail messages for the given policy. This policy includes all supported HTTP policy rules. After the policy is defined, it is applied to the inspection rule "firewall," which will inspect all HTTP traffic entering the FastEthernet0/0 interface.

```
! Define the HTTP policy.
appfw policy-name mypolicy
 application http
  audit trail on
  strict-http action allow alarm
  content-length maximum 1 action allow alarm
  content-type-verification match-req-rsp action allow alarm
  max-header-length request 1 response 1 action allow alarm
```

```
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc default action allow alarm
  request-method extension default action allow alarm
  transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
 ip inspect firewall in
!
!
```

Related Commands

Command	Description
ip inspect audit-trail	Turns on audit trail messages.

audit-trail (zone)

To turn audit trail messages on or off, use the **audit-trail** command in parameter-map type inspect configuration mode or URL parameter-map configuration mode. To disable this feature, use the **no** form of this command.

audit trail {**on** | **off**}

no audit trail {**on** | **off**}

Syntax Description

on	Audit trail messages will be issued.
off	Audit trail messages will not be issued.

Command Default

There are no audit trail messages.

Command Modes

Parameter-map type inspect configuration
URL parameter-map configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

You can use the **audit-trail** subcommand when you are creating a parameter map. For each inspected protocol, you can set the audit trail to **on** or **off**.

When you are configuring an inspect type parameter map, you can enter the **audit-trail** subcommand after you enter the **parameter-map type inspect** command.

When you are creating or modifying a URL parameter map, you can enter the **audit-trail** subcommand after you enter the **parameter-map type urlfilter** command.

For more detailed information about creating a parameter map, see the **parameter-map type inspect** or **parameter-map type urlfilter** command.

Examples

The following example generates audit trail messages:

```
parameter-map type inspect insp-params
 audit-trail on
```

Related Commands

Command	Description
parameter-map type inspect	Configures an inspect parameter map for connecting thresholds, timeouts, and other parameters pertaining to the **inspect** action.
parameter-map type urlfilter	Creates or modifies a parameter map for URL filtering parameters.

authentication

To configure clear text authentication and MD5 authentication under a redundancy group protocol, use the **authentication** command in redundancy application protocol configuration mode**.** To disable the authentication settings in the redundancy group, use the **no** form of this command.

authentication {**text** *string* | **md5 key-string** [**0** | **7**] *key* | **md5 key-chain** *key-chain-name*}

no authentication {**text** *string* | **md5 key-string** [**0** | **7**] *key* | **md5 key-chain** *key-chain-name*}

Syntax Description

text *string*	Uses clear text authentication.
md5 key-string	Uses MD5 key authentication. The *key* argument can be up to 64 characters in length (at least 16 characters is recommended). Specifying 7 means the key will be encrypted.
0	(Optional) Specifies that the text following immediately is not encrypted.
7	(Optional) Specifies that the text is encrypted using a Cisco-defined encryption algorithm.
md5 key-chain *key-chain-name*	Uses MD5 key-chain authentication.

Command Default

The key is not encrypted.

Command Modes

Redundancy application protocol configuration (config-red-app-prtcl)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced.

Examples

The following example shows how to configure clear text authentication for a redundancy group:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# application redundancy
Router(config-red-app)# protocol 1
Router(config-red-app-prtcl)# authentication text name1
```

Related Commands

Command	Description
application redundancy	Enters redundancy application configuration mode.
group(firewall)	Enters redundancy application group configuration mode.
name	Configures the redundancy group with a name.
preempt	Enables preemption on the redundancy group.

Command	Description
protocol	Defines a protocol instance in a redundancy group.
timers hellotime	Configures timers for hellotime and holdtime messages for a redundancy group.

authentication (IKE policy)

To specify the authentication method within an Internet Key Exchange (IKE) policy, use the **authentication** command in ISAKMP policy configuration mode. IKE policies define a set of parameters to be used during IKE negotiation. To reset the authentication method to the default value, use the **no** form of this command.

authentication {**rsa-sig** | **rsa-encr** | **pre-share** | **ecdsa-sig**}

no authentication

Syntax Description

rsa-sig	Specifies RSA signatures as the authentication method. This method is not supported in IPv6.
rsa-encr	Specifies RSA encrypted nonces as the authentication method. This method is not supported in IPv6.
pre-share	Specifies preshared keys as the authentication method.
ecdsa-sig	Specifies the Elliptic Curve Digital Signature Algorithm (ECDSA) signature (ECDSA-sig) as the authentication method.

Command Default

The RSA signatures authentication method is used.

Command Modes

ISAKMP policy configuration (config-isakmp)

Command History

Release	Modification
11.3 T	This command was introduced.
12.4(4)T	Support for IPv6 was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.1	This command was introduced on Cisco ASR 1000 Series Routers.
15.1(2)T	This command was modified. The **ecdsa-sig** keyword was added.

Usage Guidelines

Use this command to specify the authentication method to be used in an IKE policy.

If you specify RSA signatures, you must configure your peer routers to obtain certificates from a certification authority (CA).

If you specify RSA encrypted nonces, you must ensure that each peer has the other peer's RSA public keys. (See the **crypto key pubkey-chain rsa**, **addressed-key**, **named-key**, **address**, and commands.)

If you specify preshared keys, you must also separately configure these preshared keys. (See the **crypto isakmp identity** and **crypto isakmp key** commands.)

Examples

The following example configures an IKE policy with preshared keys as the authentication method (all other parameters are set to the defaults):

```
Router(config)# crypto isakmp policy 15
Router(config-isakmp)# authentication pre-share
Router(config-isakmp)# exit
```

Related Commands

Command	Description
crypto isakmp key	Configures a preshared authentication key.
crypto isakmp policy	Defines an IKE policy.
crypto key generate rsa (IKE)	Generates RSA key pairs.
encryption (IKE policy)	Specifies the encryption algorithm within an IKE policy.
group (IKE policy)	Specifies the Diffie-Hellman group identifier within an IKE policy.
hash (IKE policy)	Specifies the hash algorithm within an IKE policy.
lifetime (IKE policy)	Specifies the lifetime of an IKE SA.
show crypto isakmp policy	Displays the parameters for each IKE policy.

authentication (IKEv2 profile)

To specify the local and remote authentication methods in an Internet Key Exchange Version 2 (IKEv2) profile, use the **authentication** command in IKEv2 profile configuration mode. To delete the authentication method, use the **no** form of this command.

authentication {**local** {**rsa-sig** | **pre-share** | **ecdsa-sig**} | **remote** {**eap** [**query-identity**]| **rsa-sig** | **pre-share** | **ecdsa-sig**}

no authentication {**local** {**rsa-sig** | **pre-share** | **ecdsa-sig**} | **remote** {**eap** | **rsa-sig** | **pre-share** | **ecdsa-sig**}

Syntax Description

local	Specifies the local authentication method.
rsa-sig	Specifies the RSA signature as the authentication method.
pre-share	Specifies the preshared key as the authentication method.
ecdsa-sig	Specifies the Elliptic Curve Digital Signature Algorithm (ECDSA) signature (ECDSA-sig) as the authentication method.
remote	Specifies the remote authentication method.
eap	Specifies Extensible Authentication Protocol (EAP) as the authentication method.
query-identity	(Optional) Queries EAP identity from the peer.

Command Default

The default local and remote authentication method is pre-share.

Command Modes

IKEv2 profile configuration (crypto-ikev2-profile)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(2)T	This command was modified. The **ecdsa-sig** keyword was added.
15.1(3)T	This command was modified. The **eap** and **query-identity** keywords were added.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify the local and remote authentication methods in an IKEv2 profile. You can configure only one local authentication method and multiple remote authentication methods. Multiple remote authentication methods are allowed as the profile caters to multiple peers and the authentication method that a peer uses is not known. However, each remote authentication method must be specified in a separate command.

If the RSA signature is configured as the local or remote authentication method, you must specify the PKI trustpoints to obtain the signing and verification certificates using the **pki trustpoint** command.

If a preshared key is configured as the local or remote authentication method, you must separately configure the preshared keys and the keyring using the command **keyring** to specify the local and remote keys.

If the **query-identity** keyword is specified, the EAP identity request is sent when the remote peer indicates the intent to use EAP authentication by skipping Auth payload in the IKE-AUTH request and the local policy allows EAP authentication for remote peer. The remote EAP identity is used in the following scenarios:

- When the EAP identity is used to switch to another IKEv2 profile.
- The remote EAP identity is passed to the RADIUS EAP server as the username for the peer to be authenticated for external EAP.
- The remote EAP identity is used to derive a name for requests using a name mangler.

Examples

The following example shows how to specify an authentication method to an IKEv2 profile:

```
Router(config)# crypto ikev2 profile profile1
Router(config-ikev2-profile)# match identity remote address 192.168.1.1
Router(config-ikev2-profile)# authentication local pre-share
Router(config-ikev2-profile)# authentication remote pre-share
Router(config-ikev2-profile)# authentication remote rsa-sig
Router(config-ikev2-profile)# identity local email user1@abc.com
Router(config-ikev2-profile)# keyring keyring-1
Router(config-ikev2-profile)# pki trustpoint tp-remote verify
```

In the above example, the profile profile1 specifies pre-share as the local authentication method and pre-share and rsa-sig as the remote authentication methods that use keyring keyring-1 and the trustpoint tp-remote.

The following example shows how to configure an IKEv2 profile for two peers using different authentication methods:

```
Router(config)# crypto ikev2 profile profile2
Router(config-ikev2-profile)# match identity local email user1@abc.com
Router(config-ikev2-profile)# match identity remote email user2@abc.com
Router(config-ikev2-profile)# authentication local pre-share
Router(config-ikev2-profile)# authentication remote pre-share
```

The above profile caters to two peers: user1@abc.com authenticated with pre-share and user2@abc.com authenticated with rsa-signature.

Related Commands

Command	Description
crypto ikev2 keyring	Defines an IKEv2 keyring.
keyring	Specifies the keyring that used with a preshared key authentication method.
pki trustpoint	Specifies the PKI trustpoints used with RSA signature authentication method.
show crypto ikev2 profile	Displays the IKEv2 profile.

authentication bind-first

To configure the sequence of search and bind of an authentication request in the Lightweight Directory Access Protocol (LDAP) server, use the **authentication bind-first** command in LDAP server configuration mode. To remove the search and bind configuration, use the **no** form of this command.

authentication bind-first

no authentication bind-first

Syntax Description

This command has no arguments or keywords.

Command Default

The search operation is performed first and bind operation is performed later.

Command Modes

LDAP server configuration (config-ldap-server)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

In an LDAP deployment, search operation is performed first and bind operation is performed later. This operation is performed because, if the password attribute is returned as part of the search operation, then password verification can be done locally on the LDAP client and there is no need for an extra bind operation. If the password attribute is not returned, a bind operation can be performed later. Another advantage of performing the search operation first and bind operation later is that the distinguished name (DN) received in the search result can be used as the user DN instead of forming a DN by prefixing the username (cn attribute) with base DN.

Examples

The following example shows how to configure the search and bind operations for an authentication request:

```
Router(config)# ldap server server1
Router(config-ldap-server)# authentication bind-first
```

Related Commands

Command	Description
ldap server	Defines an LDAP server and enters LDAP server configuration mode.

authentication command

To specify the HTTP command that is sent to the certification authority (CA) for authentication, use the **authentication command** in ca-profile-enroll configuration mode.

authentication command {*http-command*}

Syntax Description

http-command	Defines the HTTP command. **Note** The *http-command* argument is not the HTTP URL.

Defaults

No default behavior or values

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

Use the **authentication command** to send the HTTP request to the CA server for certificate authentication. Before enabling this command, you must use the **authentication url** command.

After enabling this command, you can use the **parameter** command to specify enrollment parameters for your enrollment profile.

Examples

The following example shows how to configure certificate authentication via HTTP for the enrollment profile named “E”:

```
crypto ca trustpoint Entrust
  enrollment profile E
  serial

crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
authentication url	Specifies the URL of the CA server to which to send authentication requests.
crypto ca profile enrollment	Defines an enrollment profile.
parameter	Specifies parameters for an enrollment profile.

authentication command bounce-port ignore

To configure the router to ignore a RADIUS Change of Authorization (CoA) bounce port command, use the **authentication command bounce-port ignore** command in global configuration mode. Use the **no** form of this command to return to the default status.

authentication command bounce-port ignore

no authentication command bounce-port ignore

Syntax Description

This command has no arguments or keywords.

Defaults

The router accepts a RADIUS CoA bounce port command.

Command Modes

Global configuration

Command History

Release	Modification
12.2(52)SE	This command was introduced.
12.2(33)SXI4	This command was integrated into Cisco IOS Release 12.2(33)SXI4.

Usage Guidelines

A RADIUS CoA bounce port command sent from a RADIUS server can cause a link flap on an authentication port, which triggers DHCP renegotiation from one or more hosts connected to this port. This incident can occur when there is a VLAN change and the endpoint is a device (such as a printer), that does not have a mechanism to detect a change on this authentication port. The **authentication command bounce-port ignore** command configures the router to ignore the RADIUS CoA bounce port command to prevent a link flap from occuring on any host(s) that are connected to an authentication port.

Examples

This example shows how to configure the router to ignore a CoA bounce port command:

```
Router(config)# aaa new-model
Router(config)# authentication command bounce-port ignore
```

Related Commands

Command	Description
authentication command disable-port ignore	Configures the router to ignore a RADIUS server CoA disable port command.

authentication command disable-port ignore

To allow the router to ignore a RADIUS server Change of Authorization (CoA) disable port command, use the **authentication command disable-port ignore** command in global configuration mode. Use the **no** form of this command to return to the default status.

authentication command disable-port ignore

no authentication command disable-port ignore

Syntax Description

This command has no arguments or keywords.

Defaults

The router accepts a RADIUS CoA disable port command.

Command Modes

Global configuration

Command History

Release	Modification
12.2(52)SE	This command was introduced.
12.2(33)SXI4	This command was integrated into Cisco IOS Release 12.2(33)SXI4.

Usage Guidelines

The RADIUS server CoA disable port command administratively shuts down the authentication port that is hosting a session, resulting in session termination. Use the **authentication command disable-port ignore** command to configure the router to ignore the RADIUS server CoA disable port command so that the authentication port and other hosts on this authentication port are not disconnected.

Examples

This example shows how to configure the router to ignore a CoA **disable port** command:

```
Router(config)# aaa new-model
Router(config)# authentication command disable-port ignore
```

Related Commands

Command	Description
authentication command bounce-port ignore	Configures the router to ignore a RADIUS server CoA bounce port command.

authentication compare

To replace a bind request with a compare request for an authentication, use the **authentication compare** command in LDAP server configuration mode. To disable the comparison of bind operations for the authentication requests, use the **no** form of this command.

authentication compare

no authentication compare

Syntax Description

This command has no arguments or keywords.

Command Default

Authentication request is performed with bind request.

Command Modes

LDAP server configuration (config-ldap-server)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Examples

The following example shows how to replace a bind request with a compare request for an authentication:

```
Router(config)# ldap server server1
Router(config-ldap-server)# authentication compare
```

Related Commands

Command	Description
ldap server	Defines an LDAP server and enters LDAP server configuration mode.

authentication control-direction

To set the direction of authentication control on a port, use the **authentication control-direction** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

authentication control-direction {**both** | **in**}

no authentication control-direction

Syntax Description

both	Enables bidirectional control on the port.
in	Enables unidirectional control on the port.

Command Default

The port is set to bidirectional mode.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

The IEEE 802.1x standard is implemented to block traffic between the nonauthenticated clients and network resources. This means that nonauthenticated clients cannot communicate with any device on the network except the authenticator. The reverse is true, except for one circumstance—when the port has been configured as a unidirectional controlled port.

Unidirectional State

The IEEE 802.1x standard defines a unidirectional controlled port, which enables a device on the network to "wake up" a client so that it continues to be reauthenticated. When you use the **authentication control-direction in** command to configure the port as unidirectional, the port changes to the spanning-tree forwarding state, thus allowing a device on the network to wake the client, and force it to reauthenticate.

Bidirectional State

When you use the **authentication control-direction both** command to configure a port as bidirectional, access to the port is controlled in both directions. In this state, the port does not receive or send packets.

Examples

The following example shows how to enable unidirectional control:

```
Switch(config-if)# authentication control-direction in
```

The following examples show how to enable bidirectional control:

```
Switch(config-if)# authentication control-direction both
```

authentication critical recovery delay

To configure the Auth Manager critical recovery delay, use the **authentication critical recovery delay** command in global configuration mode. To remove a previously configured recovery delay, us the **no** form of this command.

authentication critical recovery delay *milliseconds*

no authentication critical recovery delay

Syntax Description

milliseconds	The period of time, in milliseconds, that the Auth Manager waits to reinitialize a critical port when an unavailable RADIUS server becomes available; valid values are from 1 to 10000.

Command Default

The default delay is 1000 milliseconds.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Examples

The following example shows how to configure the critical recovery delay period to 1500 milliseconds:

```
Switch(config)# authentication critical recovery delay 1500
```

authentication event fail

To specify how the Auth Manager handles authentication failures as a result of unrecognized user credentials, use the **authentication event fail** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

authentication event fail [**retry** *retry-count*] **action** {**authorize vlan** *vlan-id* | **next-method**}

no authentication event fail

Syntax Description

retry *retry-count*	(Optional) Specifies how many times the authentication method is tried after an initial failure.
action	Specifies the action to be taken after an authentication failure as a result of incorrect user credentials.
authorize vlan *vlan-id*	Authorizes a restricted VLAN on a port after a failed authentication attempt.
next-method	Specifies that the next authentication method be invoked after a failed authentication attempt. The order of authentication methods is specified by the **authentication order** command.

Command Default

Authentication is attempted two times after the initial failed attempt.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Only the dot1x authentication method can signal this type of authentication failure.

Examples

The following example specifies that after three failed authentication attempts the port is assigned to a restricted VLAN:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet0/3
Switch(config-if)# authentication event fail retry 3 action authorize vlan 40
Switch(config-if)# end
```

Related Commands

Command	Description
authentication event no-response action	Specifies the action to be taken when authentication fails due to a nonresponsive host.
authentication order	Specifies the order in which authentication methods are attempted.

authentication event no-response action

To specify how the Auth Manager handles authentication failures as a result of a nonresponsive host, use the **authentication event no-response action** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

authentication event no-response action authorize vlan *vlan-id*

no authentication event no-response

Syntax Description

authorize vlan *vlan-id*	Authorizes a restricted VLAN on a port after a failed authentication attempt.

Command Default

Authentication fails.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication event no-response action** command to specify how to handle authentication failures as a result of a nonresponsive host.

Examples

The following example specifies that when authentication fails as a result of a non-responsive host, the port is assigned to a VLAN:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet0/3
Switch(config-if)# authentication event no-response action authorize vlan 40
Switch(config-if)# end
```

Related Commands

Command	Description
authentication event fail	Specifies how the Auth Manager handles authentication failures as a result of unrecognized user credentials

authentication event server alive action reinitialize

To reinitialize an authorized Auth Manager session when a previously unreachable authentication, authorization, and accounting (AAA) server becomes available, use the **authentication event server alive action reinitialize** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

authentication event server alive action reinitialize

no authentication event server alive action reinitialize

Syntax Description

This command has no arguments or keywords.

Command Default

The session is not reinitialized.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication event server alive action reinitialize** command to reinitialize authorized sessions when a previously unreachable AAA server becomes available.

Examples

The following example specifies that authorized sessions are reinitialized when a previously unreachable AAA server becomes available:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet0/3
Switch(config-if)# authentication event server alive action reinitialize
Switch(config-if)# end
```

Related Commands:

Command	Description
authentication event server dead action authorize	Specifies how to handle authorized sessions when the AAA server is unreachable.

authentication event server dead action authorize

To authorize Auth Manager sessions when the authentication, authorization, and accounting (AAA) server becomes unreachable, use the **authentication event server dead action authorize** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

authentication event server dead action authorize vlan *vlan-id*

no authentication event server dead action authorize

Syntax Description

vlan *vlan-id*	Authorizes a restricted VLAN on a port after a failed authentication attempt.

Command Default

No session is authorized.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication event server dead action authorize** command to authorize sessions even when the AAA server is unavailable.

Examples

The following example specifies that when the AAA server becomes unreachable, the port is assigned to a VLAN:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet0/3
Switch(config-if)# authentication event server dead action authorize vlan 40
Switch(config-if)# end
```

Related Commands

Command	Description
authentication event server alive action reinitialize	Reinitializes an authorized session when a previously unreachable AAA server becomes available.

authentication fallback

To enable a web authentication fallback method, use the **authentication fallback** command in interface configuration mode. To disable web authentication fallback, use the **no** form of this command.

authentication fallback *fallback-profile*

no authentication fallback

Syntax Description

fallback-profile	The name of the fallback profile for web authentication.

Command Default

Web authentication fallback is not enabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication fallback** command to specify the fallback profile for web authentication. Use the **fallback profile** command to specify the details of the profile.

Examples

The following example shows how to specify a fallback profile on a port:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet1/0/3
Switch(config-if)# authentication fallback profile1
Switch(config-if)# end
```

Related Commands

Command	Description
fallback profile	Specifies the profile for web authentication.

authentication host-mode

To allow hosts to gain access to a controlled port, use the **authentication host-mode** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

authentication host-mode {**single-host** | **multi-auth** | **multi-domain** | **multi-host**} [**open**]

no authentication host-mode

Syntax Description

single-host	Specifies that only one client can be authenticated on a port at any given time. A security violation occurs if more than one client is detected.
multi-auth	Specifies that multiple clients can be authenticated on the port at any given time.
multi-domain	Specifies that only one client per domain (DATA or VOICE) can be authenticated at a time.
multi-host	Specifies that after the first client is authenticated, all subsequent clients are allowed access.
open	(Optional) Specifies that the port is open; that is, there are no access restrictions.

Command Default

Access to a port is not allowed.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Before you use this command, you must use the **authentication port-control** command with the keyword **auto**.

In **multi-host** mode, only one of the attached hosts has to be successfully authorized for all hosts to be granted network access. If the port becomes unauthorized (reauthentication fails or an Extensible Authentication Protocol over LAN [EAPOL] logoff message is received), all attached clients are denied access to the network.

Examples

:The following example shows how to enable authentication in multi-host mode:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet2/0/1
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-host
```

authentication list (tti-registrar)

To authenticate the introducer in an Secure Device Provisioning (SDP) transaction, use the **authentication list** command in tti-registrar configuration mode. To disable the authentication, use the **no** form of this command.

authentication list *list-name*

no authentication list *list-name*

Syntax Description

list-name	Name of the list.

Defaults

An introducer is not authenticated.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

This command is used in SDP transactions. When the command is configured, the RADIUS or TACACS+ AAA server checks for a valid account by looking at the username and password.

The authentication list and the authorization list will usually both point to the same AAA list, but it is possible that the lists can be on different databases. This latter scenario is not recommended.

Examples

The following example shows that an authentication list named “authen-tac” has been configured. In this example, the authentication list is on a TACACS+ AAA server and the authorization list is on a RADIUS AAA server.

```
Router(config)# crypto wui tti registrar
Router(tti-registrar)# pki-server mycs
Router(tti-registrar)# authentication list authen-tac
Router(tti-registrar)# authorization list author-rad
Router(tti-registrar)# template username ftpuser password ftppwd
Router(tti-registrar)# template config ftp://ftp-server/iossnippet.txt
Router(tti-registrar)# end
```

Related Commands

Command	Description
authorization list (tti-registrar)	Specifies the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS CLI snippet that is sent back to the petitioner in an SDP operation.
debug crypto wui	Displays information about an SDP operation.

Command	Description
template config	Specifies a remote URL for a Cisco IOS CLI configuration template.
template username	Establishes a template username and password to access the configuration template on the file system.

authentication open

To enable open access on this port, use the **authentication open** command in interface configuration mode. To disable open access on this port, use the **no** form of this command.

authentication open

no authentication open

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	Support for this command was introduced.

Usage Guidelines

Open Access allows clients or devices to gain network access before authentication is performed.

You can verify your settings by entering the **show authentication** privileged EXEC command.

This command overrides the **authentication host-mode** *session-type* **open** global configuration mode command for the port only.

Examples

The following example shows how to enable open access to a port:

```
Router(config-if)# authentication open
Router(config-if)#
```

The following example shows how to enable open access to a port:

```
Router(config-if)# no authentication open
Router(config-if)#
```

Related Commands

Command	Description
show authentication	Displays Authentication Manager information.

authentication order

To specify the order in which the Auth Manager attempts to authenticate a client on a port, use the **authentication order** command in interface configuration mode. To return to the default authentication order, use the **no** form of this command.

authentication order {**dot1x** [**mab** | **webauth**] [**webauth**] | **mab** [**dot1x** | **webauth**] [**webauth**] | **webauth**}

no authentication order

Syntax Description

dot1x	Specifies IEEE 802.1X authentication.
mab	Specifies MAC-based authentication.
webauth	Specifies web-based authentication.

Command Default

The default authentication order is **dot1x**, **mab**, and **webauth**.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication order** command to specify explicitly which authentication methods are run and the order in which they are run. Each method may be entered only once in the list and no method can be listed after **webauth**.

Examples

The following example sets the authentication order for a port:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet0/1
Switch(config-if)# authentication order mab dot1x
Switch(config-if)# end
Switch#
```

Related Commands

Command	Description
authentication priority	Specifies the priority of authentication methods.

authentication periodic

To enable automatic reauthentication on a port, use the **authentication periodic** command in interface configuration mode. To disable, use the **no** form of this command.

Note Effective with Cisco IOS Release 12.2(33)SXI, the **authentication periodic** command replaces the **dot1x reauthentication** command.

authentication periodic

no authentication periodic

Syntax Description

This command has no arguments or keywords.

Command Default

Reauthentication is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication periodic** command to enable automatic reauthentication on a port. To configure the interval between reauthentication attempts, use the **authentication timer reauthenticate** command.

Examples

The following example enables reauthentication and sets the interval to 1800 seconds:

```
Switch(config)# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet0/2
Switch(config-if)# authentication periodic
Switch(config-if)# authentication timer reauthenticate 1800
```

Related Commands

Command	Description
authentication timer reauthenticate	Specifies the period of time between attempts to reauthenticate an authorized port.

authentication port-control

To configure the authorization state of a controlled port, use the **authentication port-control** command in interface configuration mode. To disable the port-control value, use the **no** form of this command.

Note Effective with Cisco IOS Release 12.2(33)SXI, the **authentication port-control** command replaces the **dot1x port-control** command.

authentication port-control {**auto** | **force-authorized** | **force-unauthorized**}

no authentication port-control

Syntax Description

auto	Enables port-based authentication and causes the port to begin in the unauthorized state, allowing only Extensible Authentication Protocol over LAN (EAPOL) frames to be sent and received through the port.
force-authorized	Disables IEEE 802.1X on the interface and causes the port to change to the authorized state without requiring any authentication exchange. The port transmits and receives normal traffic without 802.1X-based authentication of the client. The **force-authorized** keyword is the default.
force-unauthorized	Denies all access through this interface by forcing the port to change to the unauthorized state, ignoring all attempts by the client to authenticate.

Command Default

Ports authorized without authentication exchanges.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

To verify port-control settings, use the **show interfaces** command and check the Status column in the 802.1X Port Summary section of the display. An enabled status means that the port-control value is set to auto or to force-unauthorized.

The authentication process begins when the link state of the port transitions from down to up or when an EAPOL-start frame is received. The system requests the identity of the client and begins relaying authentication messages between the client and the authentication server.

Examples

The following specifies that the authorization status of the client will be determined by the authentication process:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch(config)# interface ethernet0/2
Switch(config-if)# authentication port-control auto
```

Related Commands

Command	Description
show interfaces	Displays information about interfaces.

authentication priority

To specify the priority of authentication methods on a port, use the **authentication priority** command in interface configuration mode. To return to the default, use the **no** form of this command.

authentication order {**dot1x** [**mab** | **webauth**] [**webauth**] | **mab** [**dot1x** | **webauth**] [**webauth**] | **webauth**}

no authentication order

Syntax Description

dot1x	Specifies IEEE 802.1X authentication.
mab	Specifies MAC-based authentication.
webauth	Specifies web-based authentication.

Command Default

The default priority order is **dot1x**, **mab**, and **webauth**.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

The **authentication order** command specifies the order in which authentication methods are attempted. This order is the default priority. To override the default priority and allow higher priority methods to interrupt a running authentication method, use the **authentication priority** command.

Examples

The following example configures the authentication order and the authentication priority on a port:

```
Switch# configure terminal
Switch(config)# interface fastethernet0/1
Switch(config-if)# authentication order mab dot1x webauth
Switch(config-if)# authentication priority dot1x mab
Switch(config-if)# end
Switch#
```

Related Commands

Command	Description
authentication order	Specifies the order in which the Auth Manager attempts to authenticate a client on a port.

authentication terminal

To manually cut-and-paste certificate authentication requests, use the **authentication terminal** command in ca-profile-enroll configuration mode. To delete a current authentication request, use the **no** form of this command.

authentication terminal

no authentication terminal

Syntax Description

This command has no arguments or keywords.

Defaults

An authentication request is not specified.

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

A user may manually cut-and-paste certificate authentication requests when a network connection between the router and certification authority (CA) is not available. After this command is enabled, the authentication request is printed on the console terminal so that it can be manually copied (cut) by the user.

Examples

The following example shows how to specify manual certificate authentication and certificate enrollment via HTTP:

```
crypto ca profile enrollment E
 authentication terminal
 enrollment terminal
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
crypto ca profile enrollment	Defines an enrollment profile.

authentication timer inactivity

To configure the time after which an inactive Auth Manager session is terminated, use the **authentication timer inactivity** command in interface configuration mode. To disable the inactivity timer, use the **no** form of this command.

authentication timer inactivity {*seconds* | **server**}

no authentication timer inactivity

Syntax Description

seconds	The period of inactivity, in seconds, allowed before an Auth Manager session is terminated and the port is unauthorized. The range is from 1 to 65535.
server	Specifies that the period of inactivity is defined by the Idle-Timeout value (RADIUS Attribute 28) on the authentication, authorization, and accounting (AAA) server.

Command Default

The inactivity timer is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

In order to prevent reauthentication of inactive sessions, use the **authentication timer inactivity** command to set the inactivity timer to an interval shorter than the reauthentication interval set with the **authentication timer reauthenticate** command.

Examples

The following example sets the inactivity interval on a port to 900 seconds:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet6/0
Switch(config-if)# authentication timer inactivity 900
Switch(config-if)# end
```

Related Commands

Command	Description
configuration timer reauthenticate	Specifies the time after which the Auth Manager attempts to reauthenticate an authorized port.
authentication timer restart	Specifies the interval after which the Auth Manager attempts to authenticate an unauthorized port.

authentication timer reauthenticate

To specify the period of time between which the Auth Manager attempts to reauthenticate authorized ports, use the **authentication timer reauthenticate** command in interface configuration mode. To reset the reauthentication interval to the default, use the **no** form of this command.

authentication timer reauthenticate {*seconds* | **server**}

no authentication timer reauthenticate

Syntax Description

seconds	The number of seconds between reauthentication attempts. The default is 3600.
server	Specifies that the interval between reauthentication attempts is defined by the Session-Timeout value (RADIUS Attribute 27) on the authentication, authorization, and accounting (AAA) server.

Command Default

The automatic reauthentication interval is set to 3600 seconds.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication timer reauthenticate** command to set the automatic reauthentication interval of an authorized port. If you use the **authentication timer inactivity** command to configure an inactivity interval, configure the reauthentication interval to be longer than the inactivity interval.

Examples

The following example sets the reauthentication interval on a port to 1800 seconds:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet6/0
Switch(config-if)# authentication timer reauthenticate 1800
Switch(config-if)# end
```

Related Commands

Command	Description
authentication periodic	Enables automatic reauthentication.
authentication timer inactivity	Specifies the interval after which the Auth Manager ends an inactive session.
authentication timer restart	Specifies the interval after which the Auth Manager attempts to authenticate an unauthorized port.

authentication timer restart

To specify the period of time after which the Auth Manager attempts to authenticate an unauthorized port, use the **authentication timer restart** command in interface configuration mode. To reset the interval to the default value, use the **no** form of this command.

authentication timer restart *seconds*

no authentication timer restart

Syntax Description

seconds	The number of seconds between attempts to authenticate an unauthorized port. The range is 1 to 65535. The default is 60.

Command Default

No attempt is made to authenticate unauthorized ports.

Command Modes

Configuration interface (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication timer restart** command to specify the interval between attempts to authenticate an unauthorized port. The default interval is 60 seconds.

Examples

The following example sets the authentication timer interval to 120 seconds:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet6/0
Switch(config-if)# authentication timer restart 120
Switch(config-if)# end
```

Related Commands

Command	Description
authentication timer inactivity	Specifies the period of time after which the Auth Manager attempts to authenticate an unauthorized port.
configuration timer reauthenticate	Specifies the time after which the Auth Manager attempts to reauthenticate an authorized port.

authentication trustpoint

To specify the trustpoint used to authenticate the Secure Device Provisioning (SDP) petitioner device's existing certificate, use the **authentication trustpoint** command in tti-registrar configuration mode. To change the specified trustpoint or use the default trustpoint, use the **no** form of this command.

authentication trustpoint {*trustpoint-label* | **use-any**}

no authentication trustpoint {*trustpoint-label* | **use-any**}

Syntax Description

trustpoint-label	Name of trustpoint.
use-any	Use any configured trustpoint.

Defaults

If this command is not specified, the petitioner-signing certificate is not verified.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Issue the **authentication trustpoint** command in tti-registrar configuration mode to validate the signing certificate that the petitioner used.

Examples

The following example shows how to specify the trustpoint mytrust for the petitioner-signing certificate:

```
crypto provisioning registrar
 authentication trustpoint mytrust
```

After the SDP exchange is complete, the petitioner automatically enrolls with the registrar and obtains a certificate. The following sample output from the **show running-config** command shows an automatically generated configuration with the default trustpoint tti:

```
crypto pki trustpoint tti
 enrollment url http://pki1-36a.cisco.com:80
 revocation-check crl
 rsakeypair tti 1024
 auto-enroll 70
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.
crypto provisioning petitioner	Configures a device to become an SDP petitioner and enters tti-petitioner configuration mode.
trustpoint signing	Specifies the trustpoint associated with the SDP exchange between the petitioner and the registrar for signing the SDP data including the certificate.

authentication violation

To specify the action to be taken when a security violation occurs on a port, use the **authentication violation** command in interface configuration mode. To return to the default action, use the **no** form of this command.

authentication violation {**restrict** | **shutdown**}

no authentication violation

Syntax Description

restrict	Specifies that the port restrict traffic with the domain from which the security violation occurs.
shutdown	Specifies that the port shuts down upon a security violation.

Command Default

Ports are shut down when a security violation occurs.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use the **authentication violation** command to specify the action to be taken when a security violation occurs on a port.

Examples

The following example configures the GigabitEthernet interface to restrict traffic when a security violation occurs:

```
Switch(config)# interface GigabitEthernet6/2
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config-if)# authentication violation restrict
Switch(config-if)# end
```

authentication url

To specify the URL of the certification authority (CA) server to which to send authentication requests, use the **authentication url** command in ca-profile-enroll configuration mode. To delete the authentication URL from your enrollment profile, use the **no** form of this command.

authentication url *url*

no authentication url *url*

Syntax Description

url	URL of the CA server to which your router should send authentication requests. If you are using Simple Certificate Enrollment Protocol (SCEP) for enrollment, the *url* argument must be in the form http://CA_name, where CA_name is the host Domain Name System (DNS) name or IP address of the CA. If you are using TFTP for enrollment, the *url* argument must be in the form tftp://certserver/file_specification. (If the URL does not include a file specification, the fully qualified domain name [FQDN] of the router will be used.)

Defaults

Your router does not recognize the CA URL until you declare one using this command.

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

If you do not specify the **authentication command** after you enable the **authentication url** command, the **authentication url** command functions the same as the **enrollment url** *url* command in trustpoint configuration mode. That is, the **authentication url** command will then be used only for certificate enrollment—not authentication.

This command allows the user to specify a different URL or a different method for authenticating a certificate and enrolling a certificate; for example, manual authentication and TFTP enrollment.

Examples

The following example shows how to configure an enrollment profile for direct HTTP enrollment with a CA server. In this example, the **authentication command** is also present.

```
crypto ca trustpoint Entrust
  enrollment profile E
  serial
```

```
crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

The following example shows how to configure the enrollment profile named "E" to perform certificate authentication via HTTP and manual certificate enrollment:

```
crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment terminal
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
authentication command	Specifies the HTTP command that is sent to the CA for authentication.
crypto ca profile enrollment	Defines an enrollment profile.
enrollment	Specifies the enrollment parameters of your CA.

authorization

To enable authentication, authorization, and accounting (AAA) authorization for a specific line or group of lines, use the **authorization** command in line configuration mode. To disable authorization, use the **no** form of this command.

authorization {**arap** | **commands** *level* | **exec** | **reverse-access**} [**default** | *list-name*]

no authorization {**arap** | **commands** *level* | **exec** | **reverse-access**} [**default** | *list-name*]

Syntax Description

arap	Enables authorization for lines configured for AppleTalk Remote Access (ARA) protocol.
commands	Enables authorization on the selected lines for all commands at the specified privilege level.
level	Specific command level to be authorized. Valid entries are 0 through 15.
exec	Enables authorization to determine if the user is allowed to run an EXEC shell on the selected lines.
reverse-access	Enables authorization to determine if the user is allowed reverse access privileges.
default	(Optional) The name of the default method list, created with the **aaa authorization** command.
list-name	(Optional) Specifies the name of a list of authorization methods to use. If no list name is specified, the system uses the default. The list is created with the **aaa authorization** command.

Defaults

Authorization is not enabled.

Command Modes

Line configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

After you enable the **aaa authorization** command and define a named authorization method list (or use the default method list) for a particular type of authorization, you must apply the defined lists to the appropriate lines for authorization to take place. Use the **authorization** command to apply the specified method lists (or if none is specified, the default method list) to the selected line or group of lines.

Examples

The following example enables command authorization (for level 15) using the method list named charlie on line 10:

```
line 10
 authorization commands 15 charlie
```

Related Commands

Command	Description
aaa authorization	Sets parameters that restrict user access to a network.

authorization (server-group)

To filter attributes in outbound Access Requests to the RADIUS server for purposes of authentication or authorization, use the **authorization** command in server-group configuration mode. To remove the filter on the authorization request or reply, use the **no** form of the command.

authorization [**request | reply**] [**accept | reject**] *list-name*

no authorization [**request | reply**] [**accept | reject**] *list-name*

Syntax Description

request	(Optional) Defines filters for outgoing authorization Access Requests.
reply	(Optional) Defines filters for incoming authorization Accept or Reject packets and for outgoing accounting requests.
accept	(Optional) Indicates that the required attributes and the attributes specified in the *list-name* argument will be accepted. All other attributes will be rejected.
reject	(Optional) Indicates that the attributes specified in the *list-name* will be rejected. All other attributes will be accepted.
list-name	Defines the given name for the accept or reject list.

Command Default

If specific attributes are not accepted or rejected, all attributes will be accepted.

Command Modes

Server-group configuration

Command History

Release	Modification
12.2(1)DX	This command was introduced.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(13)T	Platform support was added for the Cisco 7401ASR.
12.3(3)B	The **request** and **reply** keywords were added.
12.3(7)T	The **request** and **reply** keywords were integrated into Cisco IOS Release 12.3(7)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

An accept or reject list (also known as a filter) for RADIUS authorization allows users to configure the network access server (NAS) to restrict the use of specific attributes, thereby preventing the NAS from processing unwanted attributes.

Only one filter may be used for RADIUS authorization per server group.

Note The listname must be the same as the listname defined in the **radius-server attribute list** command, which is used with the **attribute (server-group configuration)** command to add to an accept or reject list.

Examples

The following example shows how to configure accept list "min-author" in an Access-Accept packet from the RADIUS server:

```
aaa new-model
aaa authentication ppp default group radius-sg
aaa authorization network default group radius-sg
aaa group server radius radius-sg
 server 10.1.1.1
 authorization accept min-author
!
radius-server host 10.1.1.1 key mykey1
radius-server attribute list min-author
 attribute 6-7
```

The following example shows that the attribute "all-attr" will be rejected in all outbound authorization Access Request messages:

```
aaa group server radius ras
 server 192.168.192.238 auth-port 1745 acct-port 1746
 authorization request reject all-attr
```

Related Commands

Command	Description
aaa authentication ppp	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
aaa authorization	Sets parameters that restrict network access to the user.
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
aaa new-model	Enables the AAA access control model.
accounting (server-group configuration)	Specifies an accept or reject list for attributes that are to be sent to the RADIUS server in an accounting request.
attribute (server-group configuration)	Adds attributes to an accept or reject list.
radius-server attribute list	Defines an accept or reject list name.

authorization (tti-registrar)

To enable authentication, authorization, and accounting (AAA) authorization for an introducer or a certificate, use the **authorization** command in tti-registrar configuration mode. To disable authorization, use the **no** form of this command.

authorization {**login**} | {**certificate**} | {**login certificate**}

no authorization {**login**} | {**certificate**} | {**login certificate**}

Syntax Description

login	Use the username of the introducer for AAA authorization.
certificate	Use the certificate of the petitioner for AAA authorization.
login certificate	Use the username of the introducer and the certificate of the petitioner for AAA authorization.

Defaults

If an authorization list is configured, then authorization is enabled by default.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command controls the authorization of the introduction. Authorization can be based on the following:

- The login of the petitioner (username and password) to the registrar
- The current certificate of the petitioner
- Both the login of the introducer and the current certificate of the petitioner

If you issue the **authorization login** command, the introducer logs in with a username and password such as ttiuser and mypassword, which are used against the configured authorization list to contact the AAA server and determine the appropriate authorization.

If you issue the **authorization certificate** command, the certificate of the petitioner is used to build an AAA username, which is used to obtain authorization information.

If you issue the **authorization login certificate** command, authorization for the introducer combines with authorization for the petitioner's current certificate. This means that two AAA authorization lookups occur. In the first lookup, the introducer username is used to retrieve any AAA attributes associated with the introducer. The second lookup is done using the configured certificate name field. If an AAA attribute appears in both lookups, the second one prevails.

Examples

The following example shows how to specify authorization for both the introducer and the current certificate of the petitioner:

```
crypto provisioning registrar
 authorization login certificate
```

Related Commands

Command	Description
authorization list (tti-registrar)	Specifies the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS CLI snippet that is sent back to the petitioner for a user introducer in an SDP transaction.

authorization address ipv4

To specify a list of addresses for a Group Domain of Interpretation (GDOI) group, use the **authorization address ipv4** command in GDOI local server configuration mode. To remove an address from the group, use the **no** form of this command.

authorization address ipv4 {*access- list-name* | *access-list number*}

no authorization address ipv4 {*access- list-name* | *access-list number*}

Syntax Description

access-list-name	Name of an access control list (ACL).
access-list number	Standard IP access list number. Value: 1 through 99

Command Default

A list of addresses is not specified.

Command Modes

GDOI local server configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

If the identity of the Internet Key Exchange (IKE) authentication matches an entry in the access control list, the address is authorized.

Examples

The following example shows that access list number 99 has been specified to be part of a GDOI group:

```
authorization address ipv4 99
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group and enters GDOI group configuration mode.
server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.

authorization identity

To specify an authorization identity for a Group Domain of Interpretation (GDOI) group based on a distinguished name (DN) or Fully Qualified Domain Name (FQDN), use the **authorization identity** command in GDOI local server configuration mode. To delete a GDOI group authorization identity, use the **no** form of this command.

authorization identity *name*

no authorization identity *name*

Syntax Description

name	The name of the authorization identity, which can be a DN or FQDN.

Command Default

An authorization identity for a GDOI group is not defined.

Command Modes

GDOI local server configuration (gdoi-local-server)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Cisco Group Encrypted Transport Virtual Private Network (GET VPN) supports GDOI group member (GM) authorization using the **authorization identity** command when using Public Key Infrastructure (PKI) authentication between the GM and a key server (KS).

An authorization identity for a GDOI group is used to restrict registration of group members within a GDOI group. In order to successfully register with the KS, the DN or FQDN of the group members should match the configured identity string in this command. Use the **authorization identity** command to configure an authorization identity for a GDOI group.

Examples

The following example specifies an authorization identity using a DN called GETVPN_FILTER for the GETVPN GDOI group:

```
Router(config)# crypto gdoi group GETVPN
Router(config-gdoi-group)# server local
Router(gdoi-local-server)# authorization identity GETVPN_FILTER
Router(gdoi-local-server)# exit
Router(config-gdoi-group)# exit
Router(config)# crypto indentity GETVPN_FILTER
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group and enters GDOI group configuration mode.
crypto identity	Configures the identity of a router with a given list of DNs in the certificate of the router.
server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.

authoization list (global)

To specify the authentication, authorization, and accounting (AAA) authorization list, use the **authorization list** command in global configuration mode. To disable the authorization list, use the **no** form of this command.

authorization list *list-name*

no authorization list *list-name*

Syntax Description

list-name	Name of the AAA authorization list.

Defaults

An authorization list is not configured.

Command Modes

Global configuration

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines

Use the **authorization list** command to specify a AAA authorization list. For components that do not support specifying the application label, a default label of “any” from the AAA server will provide authorization. Likewise, a label of “none” from the AAA database indicates that the specified certificate is not valid. (The absence of any application label is equivalent to a label of “none,” but “none” is included for completeness and clarity.)

Examples

The following example shows that the AAA authorization list “maxaa” is specified:

```
aaa authorization network maxaaa group tacac+
aaa new-model
crypto ca trustpoint msca
enrollment url http://caserver.mycompany.com
 authorization list maxaa
 authorization username subjectname serialnumber
```

Related Commands

Command	Description
authorization username	Specifies the parameters for the different certificate fields that are used to build the AAA username.

authorization list (tti-registrar)

To specify the appropriate authorized fields for both the certificate subject name and the list of template variables to be expanded into the Cisco IOS command-line interface (CLI) snippet that is sent back to the petitioner in an Secure Device Provisioning (SDP) operation, use the **authorization list** command in tti-registrar configuration mode. To disable the subject name and list of template variables, use the **no** form of this command.

authorization list *list-name*

no authorization list *list-name*

Syntax Description

list-name	Name of the list.

Defaults

There is no authorization list on the AAA server.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

This command is used in SDP operations. When the command is used, the RADIUS or TACACS+ AAA server stores the subject name and template variables. The name and variables are sent back to the petitioner in the Cisco IOS CLI snippets. This list and the authorization list are usually on the same database, but they can be on different AAA databases. (Storing lists on different databases is not recommended.)

When a petitioner makes an introducer request, multiple queries are sent to the AAA list database on the RADIUS or TACACS+ server. The queries search for entries of the following form:

```
user Password <userpassword>
   cisco-avpair="ttti:subjectname=<<DN subjectname>>"
   cisco-avpair="tti:iosconfig#<<value>>"
   cisco-avpair="tti:iosconfig#<<value>>"
   cisco-avpair="tti:iosconfig#=<<value>>"
```

Note The existence of a valid AAA username record is enough to pass the authentication check. The "cisco-avpair=tti" information is necessary only for the authorization check.

If a subject name was received in the authorization response, the TTI registrar stores it in the enrollment database, and that "subjectname" overrides the subject name that is supplied in the subsequent certificate request (PKCS10) from the petitioner device.

The numbered “tti:iosconfig” values are expanded into the TTI Cisco IOS snippet that is sent to the petitioner. The configurations replace any numbered ($1 through $9) template variable. Because the default Cisco IOS snippet template does not include the variables $1 through $9, these variables are ignored unless you configure an external Cisco IOS snippet template. To specify an external configuration, use the **template config** command.

Note The template configuration location may include a variable “$n,” which is expanded to the name with which the user is logged in.

Examples

The following example shows that the authorization list name is “author-rad.” In this example, the authentication list is on a TACACS+ AAA server and the authorization list is on a RADIUS AAA server.

```
Router(config)# crypto wui tti registrar
Router(tti-registrar)# pki-server mycs
Router(tti-registrar)# authentication list authen-tac
Router(tti-registrar)# authorization list author-rad
Router(tti-registrar)# template username ftpuser password ftppwd
Router(tti-registrar)# template config ftp://ftp-server/iossnippet.txt
Router(tti-registrar)# end
```

Related Commands

Command	Description
authentication list (tti-registrar)	Authenticates the introducer in an SDP operation.
debug crypto wui	Displays information about an SDP operation.
template config	Specifies a remote URL for a Cisco IOS CLI configuration template.
template username	Establishes a template username and password to access the configuration template on the file system.

authorization username

To specify the parameters for the different certificate fields that are used to build the authentication, authorization and accounting (AAA) username, use the **authorization username** command in global configuration mode. To disable the parameters, use the **no** form of this command.

authorization username {**subjectname** *subjectname*}

no authorization username {**subjectname** *subjectname*}

Syntax Description

subjectname	AAA username that is generated from the certificate subject name.
subjectname	Builds the username. The following are options that may be used as the AAA username: • **all**—Entire distinguished name (subject name) of the certificate. • **commonname**—Certificate common name. • **country**—Certificate country. • **email**—Certificate email. • **ipaddress**—Certificate ipaddress. • **locality**—Certificate locality. • **organization**—Certificate organization. • **organizationalunit**—Certificate organizational unit. • **postalcode**—Certificate postal code. • **serialnumber**—Certificate serial number. • **state**—Certificate state field. • **streetaddress**—Certificate street address. • **title**—Certificate title. • **unstructuredname**—Certificate unstructured name.

Defaults

Parameters for the certificate fields are not specified.

Command Modes

Global configuration

Command History

Release	Modification
12.3(1)	This command was introduced.
12.3(11)T	The **all** option for the *subjectname* argument was added.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.

Examples

The following example shows that the serialnumber option is to be used as the authorization username:

```
aaa authorization network maxaaa group tacac+
aaa new-model
crypto ca trustpoint msca
enrollment url http://caserver.mycompany.com
 authorization list maxaaa
 authorization username subjectname serialnumber
```

Related Commands

Command	Description
authorization list	Specifies the AAA authorization list.

authorization username (tti-registrar)

To specify the parameters for the different certificate fields that are used to build the authentication, authorization, and accounting (AAA) username, use the **authorization username** command in tti-registrar configuration mode. To disable the parameters, use the **no** form of this command.

authorization username {**subjectname** *subjectname*}

no authorization username {**subjectname** *subjectname*}

Syntax Description

subjectname	AAA username that is generated from the certificate subject name.
subjectname	Builds the username. The following options can be used as the AAA username: • **all**—Entire distinguished name (subject name) of the certificate • **commonname**—Certificate common name • **country**—Certificate country • **email**—Certificate e-mail • **ipaddress**—Certificate IP address • **locality**—Certificate locality • **organization**—Certificate organization • **organizationalunit**—Certificate organizational unit • **postalcode**—Certificate postal code • **serialnumber**—Certificate serial number • **state**—Certificate state field • **streetaddress**—Certificate street address • **title**—Certificate title • **unstructuredname**—Certificate unstructured name

Defaults

Parameters for the certificate fields are not specified.

Command Modes

tti-registrar configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Examples

The following example shows that the **serialnumber** option is used as the authorization username:

```
aaa authorization network maxaaa group tacac+
aaa new-model
```

```
crypto ca trustpoint msca
enrollment url http://caserver.mycompany.com
 authorization list maxaaa
 authorization username subjectname serialnumber
```

Related Commands

Command	Description
authorization list	Specifies the AAA authorization list.

authorize accept identity

To configure an identity policy profile, use the **authorize accept identity** command in parameter-map-type consent configuration mode. To remove an identity policy profile, use the **no** form of this command with the configured policy name.

authorize accept identity *identity-policy-name*

no authorize accept identity *identity-policy-name*

Syntax Description

identity-policy-name	Name of an identify profile.

Command Default

An identity policy does not exist.

Command Modes

Parameter-map-type consent (config-profile)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

If an identity policy is not configured, the interface policy will be used.

Examples

The following example shows how to configure accept policies within the consent-specific parameter maps:

```
parameter-map type consent consent_parameter_map
 copy tftp://192.168.104.136/consent_page.html flash:consent_page.html
 authorize accept identity consent_identity_policy
 timeout file download 35791
 file flash:consent_page.html
 logging enabled
 exit
!
parameter-map type consent default
 copy tftp://192.168.104.136/consent_page.html flash:consent_page.html
 authorize accept identity test_identity_policy
 timeout file download 35791
 file flash:consent_page.html
 logging enabled
 exit
!
```

auth-type

To set policy for devices that are dynamically authenticated or unauthenticated, use the **auth-type** command in identity profile configuration mode. To remove the policy that was specified, use the **no** form of this command.

auth-type {**authorize** | **not-authorize**} **policy** *policy-name*

no auth-type {**authorize** | **not-authorize**} **policy** *policy-name*

Syntax Description

authorize	Policy is specified for all authorized devices.
not-authorize	Policy is specified for all unauthorized devices.
policy *policy-name*	Specifies the name of the identity policy to apply for the associated authentication result.

Defaults

A policy is not set for authorized or unauthorized devices.

Command Modes

Identity profile configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

This command is used when a device is dynamically authenticated or unauthenticated by the network access device, and the device requires the name of the policy that should be applied for that authentication result.

Examples

The following example shows that 802.1x authentication applies to the identity policy “grant” for all dynamically authenticated hosts:

```
Router (config)# ip access-list extended allow-acl
Router (config-ext-nacl)# permit ip any any
Router (config-ext-nacl)# exit

Router (config)# identity policy grant
Router (config-identity-policy)# access-group allow-acl
Router (config-identity-policy)# exit

Router (config)# identity profile dot1x
Router (config-identity-prof)# auth-type authorize policy grant
```

Related Commands

Command	Description
identity policy	Creates an identity policy.
identity profile dot1x	Creates an 802.1x identity profile.

auth-type (ISG)

To specify the type of authorization Intelligent Services Gateway (ISG) will use for RADIUS clients, use the **auth-type** command in dynamic authorization local server configuration mode. To return to the default authorization type, use the **no** form of this command.

auth-type {**all** | **any** | **session-key**}

no auth-type {**all** | **any** | **session-key**}

Syntax Description

all	All attributes must match for authorization to be successful. This is the default.
any	Any attribute must match for authorization to be successful.
session-key	The session-key attribute must match for authorization to be successful. **Note** The only exception is if the session-id attribute is provided in the RADIUS Packet of Disconnect (POD) request, then the session ID is valid.

Command Default

All attributes must match for authorization to be successful.

Command Modes

Dynamic authorization local server configuration

Command History

Release	Modification
12.2(28)SB	This command was introduced.

Usage Guidelines

An ISG can be configured to allow external policy servers to dynamically send policies to the ISG. This functionality is facilitated by the Change of Authorization (CoA) RADIUS extension. CoA introduced peer to peer capability to RADIUS, enabling ISG and the external policy server each to act as a RADIUS client and server. Use the **auth-type** command to specify the type of authorization ISG will use for RADIUS clients.

Examples

The following example configures the ISG authorization type:

```
aaa server radius dynamic-author
 client 10.0.0.1
 auth-type any
```

Related Commands

Command	Description
aaa server radius dynamic-author	Configures an ISG as a AAA server to facilitate interaction with an external policy server.

auto-enroll

To enable certificate autoenrollment, use the **auto-enroll** command in ca-trustpoint configuration mode. To disable certificate autoenrollment, use the **no** form of this command.

auto-enroll [*percent*] [**regenerate**]

no auto-enroll [*percent*] [**regenerate**]

Syntax Description

percent	(Optional) The renewal percentage parameter, causing the router to request a new certificate after the specified percent lifetime of the current certificate is reached. If the percent lifetime is not specified, the request for a new certificate is made when the old certificate expires. The specified percent value must not be less than 10. If a client certificate is issued for less than the configured validity period due to the impending expiration of the certification authority (CA) certificate, the rollover certificate will be issued for the balance of that period. A minimum of 10 percent of the configured validity period, with an absolute minimum of 3 minutes is required, to allow rollover enough time to function.
regenerate	(Optional) Generates a new key for the certificate even if the named key already exists.

Command Default

Certificate autoenrollment is not enabled.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.3(7)T	The *percent* argument was added to support key rollover.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

Use the **auto-enroll** command to automatically request a router certificate from the CA that is using the parameters in the configuration. This command will generate a new Rivest, Shamir, and Adelman (RSA) key only if a new key does not exist with the requested label.

A trustpoint that is configured for certificate autoenrollment will attempt to reenroll when the router certificate expires.

Use the **regenerate** keyword to provide seamless key rollover for manual certificate enrollment. A new key pair is created with a temporary name, and the old certificate and key pair are retained until a new certificate is received from the CA. When the new certificate is received, the old certificate and key pair are discarded and the new key pair is renamed with the name of the original key pair. Some CAs require a new key for reenrollment to work.

If the key pair being rolled over is exportable, the new key pair will also be exportable. The following comment will appear in the trustpoint configuration to indicate whether the key pair is exportable:

```
! RSA keypair associated with trustpoint is exportable
```

Note If you are using a Secure Shell (SSH) service, you should set up specific RSA key pairs (different private keys) for the trustpoint and the SSH service. (If the Public Key Infrastructure [PKI] and the SSH infrastructure share the same default RSA key pair, a temporary disruption of SSH service could occur. The RSA key pair could become invalid or change because of the CA system, in which case you would not be able to log in using SSH. You could receive the following error message: "key changed, possible security problem.")

Examples

The following example shows how to configure the router to autoenroll with the CA named "trustme1" on startup. In this example, the **regenerate** keyword is issued, so a new key will be generated for the certificate. The renewal percentage is configured as 90; so if the certificate has a lifetime of one year, a new certificate is requested 36.5 days before the old certificate expires.

```
crypto ca trustpoint trustme1
 enrollment url http://trustme1.example.com/
 subject-name OU=Spiral Dept., O=example1.com
 ip-address ethernet0
 serial-number none
 auto-enroll 90 regenerate
 password revokeme
 rsakeypair trustme1 2048
 exit
crypto ca authenticate trustme1
```

Related Commands

Command	Description
crypto ca authenticate	Retrieves the CA certificate and authenticates it.
crypto ca trustpoint	Declares the CA that your router should use.

auto-rollover

To enable the automated certificate authority (CA) certificate rollover functionality, use the **auto-rollover** command in certificate server mode. To disable the automated rollover functionality, use the **no** form of this command.

auto-rollover [*time-period*]

no auto-rollover

Syntax Description

time-period	(Optional) Indicates when the shadow CA certificate should be generated in absolute time (not a percentage). Default is 30 calendar days before the expiration of the active private key infrastructure (PKI) root certificate.

Defaults

Automated CA rollover is not enabled.

Command Modes

Certificate server configuration

Command History

Release	Modification
12.4(2)T	This command was introduced.

Usage Guidelines

CAs, like their clients, have certificates with expiration dates that have to be reissued when the current certificate is about to expire. CAs also have key pairs used to sign client certificates. When the CA certificate is expiring it must generate a new certificate and possibly a new key pair. This process, called rollover, allows for continuous operation of the network while clients and the certificate server are switching from an expiring CA certificate to a new CA certificate.

The command **auto-rollover** initiates the automatic CA certificate rollover process.

Examples

The following example shows how to configure automated CA certificate rollover.

```
Router(config)# crypto pki server mycs
Router(cs-server)# auto-rollover 25
Router(cs-server)# no shut

%Some server settings cannot be changed after CA certificate generation.
% Generating 1024 bit RSA keys, keys will be non-exportable...[OK]
% Exporting Certificate Server signing certificate and keys...

% Certificate Server enabled.

Router(cs-server)#
```

With auto rollover enabled, the show crypto pki server command displays the current configuration of the certificate server.

```
Router# show crypto pki server
Certificate Server mycs:
    Status:enabled
    Server's configuration is locked  (enter "shut" to unlock it)
    Issuer name:CN=mycs
    CA cert fingerprint:70AFECA9 211CDDCC 6AA9D7FF 3ADB03AE
    Granting mode is:manual
    Last certificate issued serial number:0x1
    CA certificate expiration timer:00:49:26 PDT Jun 20 2008
    CRL NextUpdate timer:00:49:29 PDT Jun 28 2005
    Current storage dir:nvram:
    Database Level:Minimum - no cert data written to storage
    Auto-Rollover configured, overlap period 25 days
    Autorollover timer:00:49:26 PDT May 26 2008....
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate configuration mode.
show crypto pki server	Displays current state and configuration of the certificate server.

auto secure

To secure the management and forwarding planes of the router, use the **auto secure** command in privileged EXEC mode.

auto secure [**management** | **forwarding**] [**no-interact** | **full**] [**ntp** | **login** | **ssh** | **firewall** | **tcp-intercept**]

Syntax Description

management	(Optional) Only the management plane will be secured.
forwarding	(Optional) Only the forwarding plane will be secured.
no-interact	(Optional) The user will not be prompted for any interactive configurations. If this keyword is not enabled, the command will show the user the noninteractive configuration and the interactive configurations thereafter.
full	(Optional) The user will be prompted for all interactive questions. This is the default.
ntp	(Optional) Specifies the configuration of the Network Time Protocol (NTP) feature in the AutoSecure command line-interface (CLI).
login	(Optional) Specifies the configuration of the Login feature in the AutoSecure CLI.
ssh	(Optional) Specifies the configuration of the Secure Shell (SSH) feature in the AutoSecure CLI.
firewall	(Optional) Specifies the configuration of the firewall feature in the AutoSecure CLI.
tcp-intercept	(Optional) Specifies the configuration of the TCP-Intercept feature in the AutoSecure CLI.

Defaults

Autosecure is not enabled.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(1)	This command was introduced.
12.2(18)S	This command was integrated into Cisco IOS Release 12.2(18)T.
12.3(4)T	The following keywords were added in Cisco IOS Release 12.3(4)T: **full**, **ntp**, **login**, **ssh**, **firewall**, and **tcp-intercept**.
12.3(8)T	Support for the roll-back functionality and system logging messages were added to Cisco IOS Release 12.3(8)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **auto secure** command allows a user to disable common IP services that can be exploited for network attacks by using a single CLI. This command eliminates the complexity of securing a router both by automating the configuration of security features and by disabling certain features that are enabled by default and that could be exploited for security holes.

Caution If you are using Security Device Manager (SDM), you must manually enable the HTTP server via the **ip http server** command.

This command takes you through a semi-interactive session (also known as the AutoSecure dialogue) in which to secure the management and forwarding planes. This command gives you the option to secure just the management or forwarding plane; if neither option is selected, the dialogue will ask you to configure both planes.

Caution If your device is managed by a network management (NM) application, securing the management plane could turn off vital services and disrupt the NM application support.

This command also allows you to go through all noninteractive configuration portions of the dialogue before the interactive portions. The noninteractive portions of the dialogue can be enabled by selecting the optional **no-interact** keyword.

Roll-back and System Logging Message Support

In Cisco IOS Release 12.3(8)T, support for roll-back of the AutoSecure configuration is introduced. Roll-back enables a router to revert back to its preautosecure configuration state if the AutoSecure configuration fails.

System Logging Messages capture any changes or tampering of the AutoSecure configuration that were applied on the running configuration.

Note Prior to Cisco IOS Release 12.3(8)T, roll-back of the AutoSecure configuration is unavailable; thus, you should always save the running configuration before configuring AutoSecure.

Examples

The following example shows how to enable AutoSecure to secure only the management plane:

```
Router# auto secure management
```

Related Commands

Command	Description
ip http server	Enables the HTTP server on your system, including the Cisco web browser user interface.
show auto secure config	Displays AutoSecure configurations.

auto-update client

To configure automatic update parameters for an Easy VPN remote device, use the **auto-update client** command in global configuration mode. To disable the parameters, use the **no** form of this command.

auto-update client {*type-of-system*} {**url** *url*} {**rev** *review-version*}

no auto-update client {*type-of-system*} {**url** *url*} {**rev** *review-version*}

Syntax Description

type-of-system	Free-format string (see Table 15).
url *url*	URL from which the Easy VPN device obtains the automatic update.
rev *review-version*	The version number is a comma-delimited string of acceptable versions.

Command Default

Automatic updates cannot occur.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

The URL is a generic way to specify the protocol, username, password, address of the server, directory, and filename. The format of a URL is as follows: protocol://username:password@server address:port/directory/filename.

The automatic update on the remote device is triggered only if the current version of the software is earlier than the one specified in the revision string. Otherwise, the automatic update is ignored.

Table 15 lists possible free-format strings to be used for the type-of-system argument.

Table 15 Possible Free-format Strings

Free-Format String	Operating System
Win	Microsoft Windows
Win95	Microsoft Windows 95
Win98	Microsoft Windows 98
WinNt	Microsoft Windows NT
Win2000	Microsoft Windows 2000
Linux	Linux

Table 15 Possible Free-format Strings

Free-Format String	Operating System
Mac	Macintosh
VPN3002	Cisco VPN 3002 Hardware Client

Examples

The following example shows update parameters have been set for a Windows 2000 operating system, a URL of http:www.ourcompanysite.com/newclient, and versions 3.0.1(Rel) and 3.1(Rel):

```
crypto isakmp client configuration group {group-name}
 auto-update client Win2000 url http:www.ourcompanysite.com/newclient rev 3.0.1(Rel),
  3.1(Rel)
```

backoff exponential

To configure the router for exponential backoff retransmit of accounting requests per RADIUS server group, enter the **backoff exponential** command in server-group RADIUS configuration mode. To disable this functionality, use the **no** form of this command.

backoff exponential [**max-delay** *minutes*] [**backoff-retry** *retransmits*]

no backoff exponential [**max-delay** *minutes*] [**backoff-retry** *retransmits*]

Syntax Description

max-delay *minutes*	(Optional) Number of retransmissions done in exponential max-delay mode. Valid range for the *minutes* argument is 1 through 120; if minutes is not specified, the default value (60 minutes) will be used.
backoff-retry *retransmits*	(Optional) Number of retransmissions done in exponential backoff mode in addition to normal and max-delay retransmissions. Valid range for the *retransmits* argument is 1 through 50; if retransmits is not specified, the default value (5 retransmits) will be used.

Command Default

This command is not enabled.

Command Modes

Server-group RADIUS configuration (config-sg-radius)

Command History

Release	Modification
12.2(15)B	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

Before enabling this command, you must configure the **aaa group server radius** command, which allows you to specify a server group and enter server-group RADIUS configuration mode.

The **backoff exponential** command allows you to configure an exponential backoff retransmission per RADIUS server group. That is, after the normally configured retransmission retries have been used, the router will keep on trying with an interval that doubles on each retransmit failure until a configured maximum interval is reached. This functionality allows you to retransmit accounting requests for many hours without overloading the RADIUS server when it does come back up.

Examples

The following example shows how to configure an exponential backoff retransmission:

```
aaa group server radius cat
 backoff exponential max-delay 90 backoff-retry 10
```

Related Commands

Command	Description
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
radius-server-backoff exponential	Configures the router for exponential backoff retransmit of accounting requests.

backup-gateway

To configure a server to "push down" a list of backup gateways to the client, use the **backup-gateway** command in global configuration mode. To remove a backup gateway, use the **no** form of this command.

backup-gateway {*ip-address* | *hostname*}

no backup-gateway {*ip-address* | *hostname*}

Syntax Description

ip-address	IP address of the gateway.
hostname	Host name of the gateway.

Defaults

A list of backup gateways is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

Before using the **backup-gateway** command, you must first configure the **crypto isakmp client configuration group** command.

An example of an attribute-value (AV) pair for the backup gateway attribute is as follows:

```
ipsec:ipsec-backup-gateway=10.1.1.1
```

Note

- If you have to configure more than one backup gateway, you have to add a **backup-gateway** command line for each.
- You can configure a maximum of 10 backup gateways.

Examples

The following example shows that gateway 10.1.1.1 has been configured as a backup gateway:

```
crypto isakmp client configuration group group1
 backup-gateway 10.1.1.1
```

The following output example shows that five backup gateways have been configured:

```
crypto isakmp client configuration group sdm
 key 6 RMZPPMRQMSdiZNJg`EBbCWTKSTi\d[
```

```
pool POOL1
acl 150
backup-gateway 172.16.12.12
backup-gateway 172.16.12.13
backup-gateway 172.16.12.14
backup-gateway 172.16.12.130
backup-gateway 172.16.12.131
max-users 250
max-logins 2
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

banner

To configure an extended authentication (Xauth) banner string under a group policy definition, use the **banne**r command in global configuration mode. To disable the banner, use the **no** form of this command.

banner c {*banner-text*} **c**

no c {*banner-text*} **c**

Syntax Description

c	Delimiting character that must precede and follow the banner text. The delimiting character may be a character of your choice, such as "c" or "@."
banner-text	Text string of the banner. Maximum number of characters = 1024.

Command Default

If a banner is not configured, a banner will not be displayed.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

Follow this command with one or more blank spaces and a delimiting character of your choice. Then enter one or more lines of text, terminating the message with the second occurrence of the delimiting character.

Examples

The following example shows that the banner "The quick brown fox jumped over the lazy dog" has been specified:

```
crypto isakmp client configuration group EZVPN
 banner @ The quick brown fox jumped over the lazy dog @
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

banner (WebVPN)

To configure a banner to be displayed after a successful login, use the **banner** command in webvpn group policy configuration mode. To remove the banner from the policy group configuration, use the **no** form of this command.

banner *string*

no banner

Syntax Description

string	Text string that contains 7-bit ASCII values and HTML tags and escape sequences. The text banner must be in quotation marks if it contains spaces.

Command Default

A banner is not displayed after a successful login.

Command Modes

Webvpn group policy configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Examples

The following example configures “Login Successful” to be displayed after login:

```
Router(config)# webvpn context context1
Router(config-webvpn-context)# policy group ONE
Router(config-webvpn-group)# banner “Login Successful”
Router(config-webvpn-group)#
```

Related Commands

Command	Description
policy group	Enters webvpn group policy configuration mode to configure a policy group.
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.

base-dn

To configure a base distinguished name (DN) that you want to use to perform search operations in the Lightweight Directory Access Protocol (LDAP) server directory tree, use the **base-dn** command in LDAP server configuration mode. To delete a configured base DN for the LDAP server, use the **no** form of this command.

base-dn *string*

no base-dn *string*

Syntax Description

string	Distinguished name of the search base.

Command Default

No distinguished names are created.

Command Modes

LDAP server configuration (config-ldap-server)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

This command is valid only for LDAP servers. A base DN can take a form such as dc=example,dc=domain, where the base DN uses the Domain Name Server (DNS) domain name as its basis and is split into the domain components.

Examples

The following example shows how to configure the base DN for an LDAP server:

```
Router(config)# ldap server server1
Router(config-ldap-server)# base-dn "dc=sns,dc=example,dc=com"
```

Related Commands

Command	Description
ipv4 (**ldap**)	Creates an IPv4 address within an LDAP server address pool.
ldap server	Defines an LDAP server and enters LDAP server configuration mode.
transport port (**ldap**)	Configures the transport protocol for establishing a connection with the LDAP server.

bidirectional

To enable incoming and outgoing IP traffic to be exported across a monitored interface, use the **bidirectional** command in router IP traffic export (RITE) configuration mode. To return to the default functionality, use the **no** form of this command.

bidirectional

no bidirectional

Syntax Description

This command has no arguments or keywords.

Defaults

If this command is not enabled, only incoming traffic is exported.

Command Modes

RITE configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.2(25)S	This command was integrated into Cisco IOS Release 12.2(25)S.

Usage Guidelines

By default, only incoming IP traffic is exported. If you choose to export outgoing IP traffic, you must issue both the **bidirectional** command, which enables outgoing traffic to be exported, and the **outgoing** command, which specifies how the outgoing traffic will be filtered.

The **ip traffic-export profile** command allows you to begin a profile that can be configured to export IP packets as they arrive or leave a selected router ingress interface. A designated egress interface exports the captured IP packets out of the router. Thus, the router can export unaltered IP packets to a directly connected device.

Examples

The following example shows how to export both incoming and outgoing IP traffic on the FastEthernet interface:

```
Router(config)# ip traffic-export profile johndoe
Router(config-rite)# interface FastEthernet1/0.1
Router(config-rite)# bidirectional
Router(config-rite)# incoming access-list 101
Router(config-rite)# outgoing access-list 101
Router(config-rite)# mac-address 6666.6666.3333
```

Related Commands

Command	Description
interface (RITE)	Specifies the outgoing interface for exporting traffic.
ip traffic-export profile	Creates or edits an IP traffic export profile and enables the profile on an ingress interface.
outgoing	Configures filtering for outgoing export traffic.

binary file

To specify the binary file location on the registrar and the destination binary file location on the petitioner, use the **binary file** command in tti-registrar configuration mode.

binary file *sourceURL destinationURL*

Syntax Description

sourceURL	Specifies the source URL on the registrar for the binary file using one of the keywords in Table 15.
destinationURL	Specifies the destination URL on the petitioner for binary file using one of the keywords in Table 15.

Command Default

None

Command Modes

tti-registrar configuration (tti-registrar)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Use the **binary file** command to specify the location where a binary file will be retrieved from and copied to during the Trusted Transitive Introduction (TTI) exchange. There may be up to nine binary files transferred, each with a different source and destination location. A destination URL could also be a token on the petitioner, such as usbtoken0:

The binary files are retrieved from the registrar and copied to the petitioner. Source URLs for the binary file location are expanded on the registrar. Destination URLs are expanded on the petitioner. Binary files are not processed through the binary expansion functions.

Table 16 Source and Destination URL Keywords

Keyword	Description
archive:	Retrieves from the archive location.
cns:	Retrieves from the Cisco Networking Services (CNS) configuration engine.
disk0:	Retrieves from disk0.
disk1:	Retrieves from disk1.
flash:	Retrieves from flash memory.
ftp:	Retrieves from the FTP network server.
http:	Retrieves from a HTTP server.
https:	Retrieves from a Secure HTTP (HTTPS) server.
null:	Retrieves from the file system.
nvram:	Retrieves from the NVRAM of the router.

Table 16 Source and Destination URL Keywords

Keyword	Description
rcp:	Retrieves from a remote copy (rcp) protocol network server.
scp:	Retrieves from a network server that supports Secure Shell (SSH).
system:	Retrieves from system memory, which includes the running configuration.
tar:	Retrieves from a compressed file in tar format.
tftp:	Retrieves from a TFTP network server.
tmpsys:	Retrieves from a temporary system location.
unix:	Retrieves from the UNIX system location.
usbtoken:	Retrieves from the USB token.

Examples

The following example shows how to specify on the registrar where the source binary files are located and where the binary files will be copied to on the petitioner:

```
crypto provisioning registrar
  pki-server cs1
  binary file http://myserver/file1 usbtoken0://file1
  binary file http://myserver/file2 flash://file2
```

Related Commands

Command	Description
crypto provisioning registrar	Configures a device to become a secure device provisioning (SDP) registrar and enter tti-registrar configuration mode.
template file	Specifies the source template file location on the registrar and the destination template file location on the petitioner.

bind authenticate

To authenticate the client to a Lightweight Directory Access Protocol (LDAP) server, use the **bind authenticate** command in LDAP server configuration mode. To disable authenticated bind and to allow anonymous bind, use the **no** form of this command.

bind authenticate root-dn *username* **password** [**0** *string* | **7** *string*] *string*

no bind authenticate root-dn *username* **password** [**0** *string* | **7** *string*] *string*

Syntax Description

root-dn	Specifies the bind distinguished name (DN) for an authenticated user.
username	Root user of the LDAP server.
password	Specifies the LDAP server password.
0	(Optional) Specifies the unencrypted (cleartext) shared key.
7	(Optional) Specifies the hidden shared key.
string	The unencrypted (cleartext) shared key.

Command Default

Anonymous bind is performed. Anonymous bind refers to a simple bind operation with no DN and password.

Command Modes

LDAP server configuration (config-ldap-server)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Examples

The following example shows how to authenticate the user named user1 to the LDAP server using the password 123:

```
Router(config)# ldap server server1
Router(config-ldap-server)# bind authenticate root-dn
cn=user1,cn=users,dc=nac-blr2,dc=example,dc=com password 123
```

Related Commands

Command	Description
ipv4 (**ldap**)	Creates an IPv4 address within an LDAP server address pool.
ldap server	Defines an LDAP server and enters LDAP server configuration mode.
transport port (**ldap**)	Configures the transport protocol for establishing a connection with the LDAP server.

block count

To lock out group members for a length of time after a set number of incorrect passwords are entered, use the **block count** command in local RADIUS server group configuration mode. To remove the user block after invalid login attempts, use the **no** form of this command.

block count *count* **time** {*seconds* | **infinite**}

no block count *count* **time** {*seconds* | **infinite**}

Syntax Description

count	Number of failed passwords that triggers a lockout. Range is from 1 to 4294967295.
time	Specifies the time to block the account.
seconds	Number of seconds that the lockout should last. Range is from 1 to 4294967295.
infinite	Specifies the lockout is indefinite.

Defaults

No default behavior or values

Command Modes

Local RADIUS server group configuration

Command History

Release	Modification
12.2(11)JA	This command was introduced on the Cisco Aironet Access Point 1100 and the Cisco Aironet Access Point 1200.
12.3(11)T	This command was integrated into Cisco IOS Release 12.3(11)T and implemented on the following platforms: Cisco 2600XM, Cisco 2691, Cisco 2811, Cisco 2821, Cisco 2851, Cisco 3700, and Cisco 3800 series routers.

Usage Guidelines

If the **infinite** keyword is entered, an administrator must manually unblock the locked username.

Examples

The following command locks out group members for 120 seconds after three incorrect passwords are entered:

```
Router(config-radsrv-group)# block count 3 time 120
```

Related Commands

Command	Description
clear radius local-server	Clears the statistics display or unblocks a user.
debug radius local-server	Displays the debug information for the local server.
group	Enters user group configuration mode and configures shared setting for a user group.
nas	Adds an access point or router to the list of devices that use the local authentication server.

Command	Description
radius-server host	Specifies the remote RADIUS server host.
radius-server local	Enables the access point or router to be a local authentication server and enters into configuration mode for the authenticator.
reauthentication time	Specifies the time (in seconds) after which access points or wireless-aware routers must reauthenticate the members of a group.
show radius local-server statistics	Displays statistics for a local network access server.
ssid	Specifies up to 20 SSIDs to be used by a user group.
user	Authorizes a user to authenticate using the local authentication server.
vlan	Specifies a VLAN to be used by members of a user group.

browser-attribute import

To import user-defined browser attributes into a webvpn context, use the **browser-attribute import** command in webvpn context configuration mode. To remove a browser attribute, use the **no** form of this command.

browser-attribute import *device*:*file*

no browser-attribute import *device*:*file*

Syntax Description

device:*file*	• *device*:—Storage device on the system. • *file*—Name of file to be imported. The file name should include the directory location.

Command Default

Default values of the attributes are used.

Command Modes

Webvpn context configuration (config-webvpn-context)

Command History

Release	Modification
12.4(22)T	This command was introduced. Attributes that are currently supported are primary color, secondary color, text color, secondary text color, login-message, browser title, and title color.

Usage Guidelines

This command will override any other browser attributes that have already been configured using command-line interface (CLI).

Examples

The following example shows that the file “test-attr.xml” is to be imported from flash:

```
Router (config)# webvpn context sslvpn
 Router (config-webvpn-context)# browser-attribute import flash:test-attr.xml
```

Related Commands

Command	Description
webvpn create template	Creates templates for multilanguage support for messages in an SSL VPN.

browser-proxy

To apply browser-proxy parameter settings to a group, use the **browser-proxy** command in ISAKMP group configuration mode. To disable the parameter settings, use the **no** form of this command.

browser-proxy {*browser-proxy-map-name*}

no browser-proxy {*browser-proxy-map-name*}

Syntax Description

browser-proxy-map-name	Name of the browser proxy.

Command Default

Browser-proxy settings are not applied to a group.

Command Modes

ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

Ensure that you define the browser proxy name before you define the crypto Internet Security Association and Key Management Protocol (ISAKMP) client configuration group name. The two names have to be the same.

Examples

The following example shows that browser proxy map “EZVPN” has been applied to the group “EZVPN”:

```
crypto isakmp client configuration group EZVPN
 browser-proxy EZVPN
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

ca trust-point

To identify the trustpoints that is used to validate a certificate during Internet Key Exchange (IKE) authentication, use the **ca trust-point** command in ISAKMP profile configuration mode. To remove the trustpoint, use the **no** form of this command.

ca trust-point *trustpoint-name*

no ca trust-point *trustpoint-name*

Syntax Description

trustpoint-name	The trustpoint name as defined in the global configuration.

Defaults

If there is no trustpoint defined in the Internet Security Association and Key Management Protocol (ISAKMP) profile configuration, the default is to validate the certificate using all the trustpoints that are defined in the global configuration.

Command Modes

ISAKMP profile configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

The **ca trust-point** command can be used multiple times to define more than one trustpoint.

This command is useful when you want to restrict validation of certificates to a list of trustpoints. For example, the router global configuration has two trustpoints, A and B, which are trusted by VPN1 and VPN2, respectively. Each Virtual Private Network (VPN) wants to restrict validation only to its trustpoint.

Before you can use this command, you must enter the **crypto isakmp profile** command.

Note A router initiating IKE and a router responding to the IKE request should have symmetrical trustpoint configurations. For example, a responding router (in IKE Main Mode) performing RSA signature encryption and authentication might use trustpoints that were defined in the global configuration when sending the CERT-REQ payloads. However, the router might use a restricted list of trustpoints that were defined in the ISAKMP profile for the certificate verification. If the peer (the IKE initiator) is configured to use a certificate whose trustpoint is in the global list of the responding router but not in ISAKMP profile of the responding router, the certificate is rejected. (However, if the initiating router does not know about the trustpoints in the global configuration of the responding router, the certificate can still be authenticated.)

Examples

The following example specifies two trustpoints, A and B. The ISAKMP profile configuration restricts each VPN to one trustpoint.

```
crypto ca trustpoint A
enrollment url http://kahului:80
crypto ca trustpoint B
enrollment url http://arjun:80
!
crypto isakmp profile vpn1
 trustpoint A
!
crypto isakmp profile vpn2
 ca trust-point B
```

Related Commands

Command	Description
crypto isakmp profile	Defines an ISAKMP profile.

cache authentication profile (server group configuration)

To specify a cache authentication profile to use in a named RADIUS or TACACS+ server group, use the **cache authentication profile** command in server group configuration mode. To disable an authentication cache profile, use the **no** form of this command.

cache authentication profile *name*

no cache authentication profile *name*

Syntax Description

name	Name of an authentication cache profile.

Command Default

No authentication cache profile is enabled.

Command Modes

Server group configuration (config-sg-radius)

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use this command to specify a cache authentication profile for a RADIUS or TACACS+ server group.

Configure the authentication profile prior to applying it to a RADIUS or TACACS+ server group to avoid an error message.

Examples

The following example caches authentication responses from a RADIUS server according to the rules configured in the authentication profile authen-profile:

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa group server radius networkauthentications
Router(config-sg-radius)# cache authentication profile authen-profile
```

Related Commands

Command	Description
cache authorization profile	Specifies an authorization cache profile to use in a named RADIUS or TACACS+ server group.

cache authorization profile (server group configuration)

To specify a cache authorization profile to use in a named RADIUS or TACACS+ server group, use the **cache authorization profile** command in server group configuration mode. To disable an authorization cache profile, use the **no** form of this command.

cache authorization profile *name*

no cache authorization profile *name*

Syntax Description

name	Name of a cache authorization profile to apply to either a RADIUS or TACACS+ server group.

Command Default

No authorization cache profile is enabled.

Command Modes

Server group configuration (config-sg-radius)

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use this command to specify an authorization profile for a RADIUS or TACACS+ server group.

Examples

The following example caches authorization responses from a RADIUS server according to the rules configured in the authorization profile author-profile:

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa group server radius authorizations
Router(config-sg-radius)# cache authorization profile author-profile
```

The authorization profile author-profile must be configured prior to applying it to a RADIUS or TACACS+ server group or an error message is generated.

Related Commands

Command	Description
cache authentication profile	Specifies an authentication cache profile to use in a named RADIUS or TACACS+ server group.

cache clear age

To specify when, in minutes, cache entries expire and the cache is cleared, use the **cache clear age** command in AAA filter configuration mode. To return to the default value, use the **no** form of this command.

cache clear age *minutes*

no cache clear age

Syntax Description

minutes	Any value from 0 to 4294967295; the default value is 1440 minutes.

Defaults

1440 minutes (1 day)

Command Modes

AAA filter configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

After enabling the **aaa cache filter** command, which allows you to configure cache filter parameters, you can use the **cache clear age** command to specify when cache entries should expire. If this command is not specified, the default value (1440 minutes) will be enabled.

Examples

The following example shows how to configure the cache entries to expire every 60 minutes:

```
aaa cache filter
 cache clear age 60
```

Related Commands

Command	Description
aaa cache filter	Enables filter cache configuration.

cache disable

To disable the cache, use the **cache disable** command in AAA filter configuration mode. To return to the default, use the **no** form of this command.

cache disable

no cache disable

Syntax Description

This command has no arguments or keywords.

Defaults

Caching is enabled.

Command Modes

AAA filter configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

After enabling the **aaa cache filter** command, which allows you to configure cache filter parameters, you can use the **cache disable** command to disable filter caching. This command can be used to verify that the access control lists (ACLs) are being downloaded.

Examples

The following example shows how to disable filter caching:

```
aaa cache filter
 cache disable
```

Related Commands

Command	Description
aaa cache filter	Enables filter cache configuration.

cache expiry (server group configuration)

To configure how long cached database profile entries in RADIUS or TACACS+ server groups are stored before they expire, use the **cache expiry** command in server group configuration mode. To reset the expiration time to the default value, use the **no** form of this command.

cache expiry *hours* [**enforce** | **failover**]

no cache expiry

Syntax Description

hours	Length of time, in hours, for a cache database profile entry to expire. Range is from 0 to 2147483647. Default is 24 hours.
enforce	(Optional) Specifies to not use expired entries.
failover	(Optional) Specifies to use an expired entry if all other methods fail.

Command Default

Cache entries expire in 24 hours.

Command Modes

Server group configuration (config-sg-radius)

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use this command to set the amount of time before a cache entry expires (becomes stale). A stale entry is still usable, but the entry will, by default, revise its record with more updated information.

Examples

The following example sets the expiry time for cache profile entries to 10 days such that the expired entries cannot be used:

```
Router# configure terminal
Router(config)# aaa new-model
Router(config)# aaa group server radius networkusers
Router(config-sg-radius)# cache expiry 240 enforce
```

Related Commands

Command	Description
cache authentication profile	Specifies an authentication cache profile to use in a named RADIUS or TACACS+ server group.
cache authorization profile	Specifies an authorization cache profile to use in a named RADIUS or TACACS+ server group.

cache max

To limit the absolute number of entries that a cache can maintain for a particular server, use the **cache max** command in AAA filter configuration mode. To return to the default value, use the **no** form of this command.

cache max *number*

no cache max

Syntax Description

number	Maximum number of entries the cache can maintain. Any value from 0 to 4294967295; the default value is 100 entries.

Defaults

100 entries

Command Modes

AAA filter configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

After enabling the **aaa cache filter** command, which allows you to configure cache filter parameters, you can use the **cache max** command to specify the maximum number of entries the cache can have at any given time. If this command is not specified, the default value (100 entries) will be enabled.

Examples

The following example shows how to configure the cache to maintain a maximum of 150 entries:

```
aaa cache filter
 password mycisco
 cache max 150
```

Related Commands

Command	Description
aaa cache filter	Enables filter cache configuration.

cache refresh

To refresh a cache entry after a new session begins, use the **cache refresh** command in AAA filter configuration mode. To disable this functionality, use the **no** form of this command.

cache refresh

no cache refresh

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

AAA filter configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

The **cache refresh** command is used in an attempt to keep cache entries from the filter server, that are being referred to by new sessions, within the cache. This command resets the idle timer for these entries when they are referenced by new calls.

Examples

The following example shows how to disable the **cache refresh** command:

```
aaa cache filter
 password mycisco
 no cache refresh
 cache max 100
```

Related Commands

Command	Description
aaa cache filter	Enables filter cache configuration.

call admission limit

To instruct Internet Key Exchange (IKE) to drop security association (SA) requests (that is, calls for Call Admission Control [CAC]) when a specified level of system resources is being consumed, use the **call admission limit** command in global configuration mode. To disable this feature, use the **no** form of this command.

call admission limit *charge*

no call admission limit *charge*

Syntax Description

charge	Level of the system resources that, when used, causes IKE to stop accepting new SA requests. Valid values are 1 to 100000.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(18)SXD1	This command was integrated into Cisco IOS Release 12.2(18)SXD1.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

To prevent IKE processes from using excessive CPU resources, you can set a limit value depending on the network topology, the capabilities of the router, and the traffic patterns.

Examples

The following example causes IKE to drop calls when a given level of system resources are being used:

```
Router(config)# call admission limit 90000
```

Related Commands

Command	Description
call admission load	Configures a CAC metric for scaling WAN protocol session load.
crypto call admission limit	Specifies the maximum number of IKE SAs that the router can establish before IKE begins rejecting new SA requests.
show call admission statistics	Monitors the global CAC configuration parameters and the behavior of CAC.

call guard-timer

To set a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request, use the **call guard-timer** command in controller configuration mode. To remove the **call guard-timer** command from your configuration file, use the **no** form of this command.

call guard-timer *milliseconds* [**on-expiry** {**accept** | **reject**}]

no call guard-timer *milliseconds* [**on-expiry** {**accept** | **reject**}]

Syntax Description

milliseconds	Specifies the number of milliseconds to wait for a response from the RADIUS server.
on-expiry accept	(Optional) Accepts the call if a response is not received from the RADIUS server within the specified time.
on-expiry reject	(Optional) Rejects the call if a response is not received from the RADIUS server within the specified time.

Defaults

No default behavior or values.

Command Modes

Controller configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows a guard timer that is set at 20000 milliseconds. A call will be accepted if the RADIUS server has not responded to a preauthentication request when the timer expires.

```
controller T1 0
 framing esf
 clock source line primary
 linecode b8zs
 ds0-group 0 timeslots 1-24 type e&m-fgb dtmf dnis
 cas-custom 0
  call guard-timer 20000 on-expiry accept

aaa preauth
group radius
  dnis required
```

Related Commands

Command	Description
aaa preauth	Enters AAA preauthentication configuration mode.

category (ips)

To specify a signature category that is to be used for multiple signature actions or conditions, use the **category** command in IPS-category configuration mode.

category *category* [*sub-category*]

Syntax Description

category	Category name. For a list of supported top-level categories, use the router CLI help (**?**).
sub-category	(Optional) Category submode. Submode categories are dependent on the category type; that is, submode categories vary from category to category. For a list of supported submode categories, use the router CLI help (**?**).

Command Default

None

Command Modes

IPS-category configuration (config-ips-category)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Cisco IOS Intrusion Prevention System (IPS) 5.x uses signatures and signature categories. All signatures are pregrouped into categories; the categories are hierarchical. An individual signature can belong to more than one category. Top-level categories help to define general types of signatures. Subcategories exist beneath each top-level signature category.

Examples

The following example shows how to tune event-action parameters for the signature category "adware/spyware." All tuning information will be applied to all signatures that belong to the adware/spyware category.

```
Router(config)# ip ips signature-category
Router(config-ips-category)# category attack adware/spyware
Router(config-ips-category-action)# event-action produce-alert
Router(config-ips-category-action)# event-action deny-packet-inline
Router(config-ips-category-action)# event-action reset-tcp-connection
Router(config-ips-category-action)# retired false
Router(config-ips-category-action)# ^Z
Do you want to accept these changes? [confirm]y
```

Related Commands

Command	Description
ip ips signature-category	Enters IPS category (config-ips-category) configuration mode, which allows you to tune Cisco IOS IPS signature parameters on the basis of a signature category.

cdp-url

To specify a certificate revocation list (CRL) distribution point (CDP) to be used in certificates that are issued by the certificate server, use the **cdp-url** command in certificate server configuration mode. To remove a CDP from your configuration, use the **no** form of this command.

cdp-url *url*

no cdp-url *url*

Syntax Description

url	HTTP URL where CRLs are published.

Command Default

When verifying a certificate that does not have a specified CDP, Cisco IOS public key infrastructure (PKI) clients will use Simple Certificate Enrollment Protocol (SCEP) to retrieve the CRL directly from their configured certificate server.

Command Modes

Certificate server configuration (cs-server)

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

CRLs can be distributed via SCEP, which is the default method, or a CDP, if configured and available. If you set up a CDP, use the **cdp-url** command to specify the CDP location. The CDP URL may be changed after the certificate server is running, but existing certificates will not be reissued with the new CDP that is specified via the **cdp-url** command.

You may specify the CDP location by a simple HTTP URL string for example,

cdp-url http://server.company.com/ca1.crl

The certificate server supports only one CDP; thus, all certificates that are issued include the same CDP.

If you have PKI clients that are not running Cisco IOS software and that do not support a SCEP GetCRL request, you can specify a non-SCEP request for the retrieval of the CRL from the certificate server by specifying **cdp-url** command with the URL in the following format where *cs-addr* is the location of the certificate server:

cdp-url http://*cs-addr*/cgi-bin/pkiclient.exe?operation=GetCRL

Note If your Cisco IOS certificate authority (CA) is also configured as your HTTP CDP server, specify your CDP with the **cdp-url** http://*cs-addr*/cgi-bin/pkiclient.exe?operation=GetCRL command syntax.

It is the responsibility of the network administrator to ensure that the CRL is available from the location that is specified via the **cdp-url** command.

In order to force the parser to retain the embedded question mark within the specified location, enter Ctrl-v prior to the question mark. If this action is not taken, CRL retrieval via HTTP will return an error message.

Examples

The following example shows how to configure a CDP location where the PKI clients do not support SCEP GetCRL requests:

```
Router(config)# crypto pki server aaa
Router(cs-server)# database level minimum
Router(cs-server)# database url tftp://10.1.1.1/username1/
Router(cs-server)# issuer-name CN=aaa
Router(cs-server)# cdp-url http://server.company.com/certEnroll/aaa.crl
```

The following example shows how to configure a CDP location where the PKI clients support SCEP GetCRL requests:

```
Router(config)# crypto pki server aaa
Router(cs-server)# database level minimum
Router(cs-server)# database url tftp://10.1.1.1/username1 /
Router(cs-server)# issuer-name CN=aaa
Router(cs-server)# cdp-url http://aaa/cgi-bin/pkiclient.exe?operation=GetCRL
```

Verifying a CDP Configuration

The following example is sample output from the **show crypto ca certificates** command, which allows you to verify the specified CDP. In this example, the CDP is "http://msca-root.cisco.com/certEnroll/aaa.crl."

```
Router# show crypto ca certificates

Certificate
  Status: Available
  Certificate Serial Number: 03
  Certificate Usage: General Purpose
  Issuer:
    CN = aaa
  Subject:
    Name: Router.cisco.com
    OID.1.2.840.113549.1.9.2 = Router.cisco.com
  CRL Distribution Point:
    http://msca-root.cisco.com/certEnroll/aaa.crl
  Validity Date:
    start date: 18:44:49 GMT Jun 6 2003
    end   date: 18:44:49 GMT Jun 5 2004
    renew date: 00:00:00 GMT Jan 1 1970
  Associated Trustpoints: bbb
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto pki server revoke	Revokes a certificate based on its serial number.
lifetime crl	Defines the lifetime of the CRL that is used by the certificate server.
show crypto ca certificates	Displays information about your certificate, the certification authority certificate, and any registration authority certificates.

certificate

To manually add certificates, use the **certificate** command in certificate chain configuration mode. To delete your router's certificate or any registration authority certificates stored on your router, use the **no** form of this command.

certificate *certificate-serial-number*

no certificate *certificate-serial-number*

Syntax Description

certificate-serial-number	Serial number of the certificate to add or delete.

Defaults

No default behavior or values.

Command Modes

Certificate chain configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You could use this command to manually specify a certificate. However, this command is rarely used in this manner. Instead, this command is usually used only to add or delete certificates.

Examples

The following example deletes the router's certificate. In this example, the router had a general purpose RSA key pair with one corresponding certificate. The **show** command is used in this example to determine the serial number of the certificate to be deleted.

```
myrouter# show crypto ca certificates

Certificate
  Subject Name
    Name: myrouter.example.com
    IP Address: 10.0.0.1
  Status: Available
  Certificate Serial Number: 0123456789ABCDEF0123456789ABCDEF
  Key Usage: General Purpose

CA Certificate
  Status: Available
  Certificate Serial Number: 3051DF7123BEE31B8341DFE4B3A338E5F
  Key Usage: Not Set

myrouter# configure terminal
```

```
myrouter(config)# crypto ca certificate chain myca
myrouter(config-cert-chain)# no certificate 0123456789ABCDEF0123456789ABCDEF
% Are you sure you want to remove the certificate [yes/no]? yes
% Be sure to ask the CA administrator to revoke this certificate.
myrouter(config-cert-chain)# exit
```

Related Commands

Command	Description
crypto ca certificate chain	Enters the certificate chain configuration mode.

chain-validation

To configure the level to which a certificate chain is processed on all certificates, including subordinate certificate authority (CA) certificates, use the **chain-validation** command in ca-trustpoint configuration mode. To revert to the command default, use the **no** form of this command.

chain-validation [{**stop** | **continue**} [*parent-trustpoint*]]

no chain-validation [{**stop** | **continue**} [*parent-trustpoint*]]

Syntax Description

stop	(Optional) Specifies that the certificate is already trusted. This is the default setting.
continue	(Optional) Specifies that the subordinate CA certificate associated with the trustpoint must be validated.
parent-trustpoint	(Optional) The name of the CA parent trustpoint.

Command Default

Certificate chain path processing continues until the first trusted certificate, or trustpoint, is reached.

Command Modes

Ca-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.4(6)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

Configuring the level to which a certificate chain is processed allows for the reauthentication of trusted certificates, the extension of a trusted certificate chain, or the completion of a certificate chain that contains a gap. Devices must be enrolled in your PKI hierarchy and the appropriate key pair associated with the certificate.

If there is more than one parent trustpoint configured, Cisco IOS will select a parent trustpoint based upon configured settings to validate the certificate chain. If you want a specific parent trustpoint to validate certificates, then that trustpoint must be configured with the *parent-trustpoint* argument specified. All certificates, peer and subordinate CA certificates, are validated in the same manner. All trustpoint settings—ACLs, AAA authorization lists, CDP or OCSP overrides—will apply, as will trustpoint policies for trusted and untrusted certificates.

A trustpoint associated with the root CA cannot be configured to be validated to the next level. If **chain-validation continue** is configured for the trustpoint associated with the root CA, an error message will be displayed and the chain validation will revert to the default **chain-validation stop**.

Examples

In the following configuration example, all of the certificates will be validated—the peer, SubCA11, SubCA1, and RootCA certificates.

```
crypto pki trustpoint RootCA
 enrollment terminal
 chain-validation stop
 revocation-check none
 rsakeypair RootCA

crypto pki trustpoint SubCA1
 enrollment terminal
 chain-validation continue RootCA
 revocation-check none
 rsakeypair SubCA1

crypto pki trustpoint SubCA11
 enrollment terminal
 chain-validation continue SubCA1
 revocation-check none
 rsakeypair SubCA11
```

In the following configuration example, the following certificates will be validated—the peer and SubCA1 certificates.

```
crypto pki trustpoint RootCA
 enrollment terminal
 chain-validation stop
 revocation-check none
 rsakeypair RootCA

crypto pki trustpoint SubCA1
 enrollment terminal
 chain-validation continue RootCA
 revocation-check none
 rsakeypair SubCA1

crypto pki trustpoint SubCA11
 enrollment terminal
 chain-validation continue SubCA1
 revocation-check none
 rsakeypair SubCA11
```

In the following configuration example, SubCA1 is not in the configured Cisco IOS hierarchy but is expected to have been supplied in the certificate chain presented by the peer.

If the peer sends SubCA1, SubCA11, and the peer certificates in the certificate chain, the following certificates will be validated—the peer, SubCA11, and SubCA1 certificates.

If the peer does not supply the SubCA1 certificate in the presented certificate chain, the chain validation will fail.

```
crypto pki trustpoint RootCA
 enrollment terminal
 chain-validation stop
 revocation-check none
 rsakeypair RootCA

crypto pki trustpoint SubCA11
 enrollment terminal
 chain-validation continue RootCA
 revocation-check none
 rsakeypair SubCA11
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.
revocation-check	Checks the revocation status of a certificate.

cifs-url-list

To enter webvpn URL list configuration mode to configure a list of Common Internet File System (CIFS) server URLs to which a user has access on the portal page of a Secure Sockets Layer Virtual Private Network (SSL VPN) and to attach the URL list to a policy group, use the **cifs-url-list** command in webvpn context configuration and webvpn group policy configuration mode, respectively. To remove the CIFS server URL list from the SSL VPN context configuration and from the policy group, use the **no** form of this command.

cifs-url-list *name*

no cifs-url-list *name*

Syntax Description

name	Name of the URL list. The list name can up to 64 characters in length.

Command Default

Webvpn URL list configuration mode is not entered, and a list of URLs to which a user has access on the portal page of an SSL VPN website is not configured. If the command is not used to attach a CIFS server URL list to a policy group, then a URL list is not attached to a group policy.

Command Modes

Webvpn context configuration (config-webvpn-context)
Webvpn group policy configuration (config-webvpn-group)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Entering this command places the router in webvpn URL list configuration mode. In this mode, the list of CIFS server URLs is configured. A URL list can be configured under the SSL VPN context configuration and then separately for each individual policy group configuration. Individual CIFS server URL list configurations must have unique names.

Examples

The following example shows that CIFS URL lists have been added under the webvpn context and for a policy group:

```
webvpn context context1
 ssl authenticate verify all
 !
 acl "acl1"
   error-msg "warning!!!..."
   permit url "http://www.exampleurl1.com"
   deny url "http://www.exampleurl2.com"
   permit http any any
 !
 nbns-list l1
   nbns-server 10.1.1.20
 !
 cifs-url-list "c1"
```

```
  heading "cifs-url"
  url-text "SSLVPN-SERVER2" url-value "\\SSLVPN-SERVER2"
  url-text "SSL-SERVER2" url-value "\\SSL-SERVER2"
!
policy group default
  acl "acl1"
  cifs-url-list "c1"
  nbns-list "l1"
  functions file-access
  functions file-browse
  functions file-entry
default-group-policy default
gateway public
inservice
```

Related Commands

Command	Description
heading	Configures the heading that is displayed above URLs listed on the portal page of a SSL VPN website.
policy group	Attaches a URL list to policy group configuration.
url-text	Adds an entry to a URL list.
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.

cipherkey

To specify the symmetric keyname that is used to decrypt the filter, use the **cipherkey** command in FPM match encryption filter configuration mode.

cipherkey *keyname*

Syntax Description

keyname	String that is used to decrypt the filter. The value that can be used is realm-etcdf-01.sym.

Command Default

No symmetric keyname is specified.

Command Modes

FPM match encryption filter configuration (c-map-match-enc-config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If you have access to an encrypted traffic classification definition file (eTCDF) or if you know valid values to configure encrypted Flexible Packet Matching (FPM) filters, you can configure the same eTCDF through the command-line interface instead of using the preferred method of loading the eTCDF on the router. You must create a class map of type access-control using the **class-map type** command, and use the **match encrypted** command to configure the match criteria for the class map on the basis of encrypted FPM filters and enter FPM match encryption filter configuration mode. You can then use the appropriate commands to specify the algorithm, cipher key, cipher value, filter hash, filter ID, and filter version. You can copy the values from the eTCDF by opening the eTCDF in any text editor.

Use the **cipherkey** command to specify the the symmetric keyname that is used to decrypt the filter.

Examples

The following example shows how to configure the cipherkey for filter decryption:

```
Router(config)# class-map type access-control match-all c1
Router(config-cmap)# match encrypted
Router(c-map-match-enc-config)# cipherkey realm-abc.sym
Router(c-map-match-enc-config)#
```

Related Commands

Command	Description
class-map type	Creates a class map to be used for matching packets to a specified class.
match encrypted	Configures the match criteria for a class map on the basis of encrypted FPM filters and enters FPM match encryption filter configuration mode.

ciphervalue

To specify the encrypted filter contents, use the **ciphervalue** command in FPM match encryption filter configuration mode.

ciphervalue *contents*

Syntax Description

contents	The encrypted filter contents in the format c encrypted-filter-contents c, where c is any delimiting character except + (plus sign), = (equals sign), and / (forward slash).

Command Default

No filter content is specified.

Command Modes

FPM match encryption filter configuration (c-map-match-enc-config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If you have access to an encrypted traffic classification definition file (eTCDF) or if you know valid values to configure encrypted Flexible Packet Matching (FPM) filters, you can configure the same eTCDF through the command-line interface instead of using the preferred method of loading the eTCDF on the router. You must create a class map of type access-control using the **class-map type** command, and use the **match encrypted** command to configure the match criteria for the class map on the basis of encrypted FPM filters and enter FPM match encryption filter configuration mode. You can then use the appropriate commands to specify the algorithm, cipher key, cipher value, filter hash, filter ID, and filter version. You can copy the values from the eTCDF by opening the eTCDF in any text editor.

Use the **ciphervalue** command to specify the encrypted filter contents. You can enter up to 200 characters at a time in a multiline input mode for the encrypted filter contents. The new line character (\n) and line feed character (\r) entered in the multiline input mode are ignored in the final cipher value contents.

Examples

The following example shows how to specify the encrypted filter contents:

```
Router(config)# class-map type access-control match-all c1
Router(config-cmap)# match encrypted
Router(c-map-match-enc-config)# ciphervalue #2bcXhFL8Ld1v+DqU+dnxgmONCxl4JrYfcLl95xg
ET0b2B1z0sjoCkozE8YxiH/SXL+eG2wf3ogaA7/Fh
awIH7OF3tUcS5Jwim/u95Xlzh2RLNw819tuIBCdorV
Cu0ZzWCF3vqwpGQzaxtSE4sFgPAvSE2LxZc/VT22
F7EQKBhRo=#
Router(c-map-match-enc-config)#
```

Related Commands

Command	Description
class-map type	Creates a class map to be used for matching packets to a specified class.
match encrypted	Configures the match criteria for a class map on the basis of encrypted FPM filters and enters FPM match encryption filter configuration mode.

cisco (ips-auto-update)

To enable automatic Cisco IOS Intrusion Prevention System (IPS) signature updates from Cisco.com, use the **cisco** command in IPS-auto-update configuration mode. To disable automatic IPS signature updates from Cisco.com, use the **no** form of this command.

cisco

no cisco

Syntax Description

This command has no arguments or keywords.

Command Default

Automatic IPS signature updates from Cisco.com are not enabled.

Command Modes

IPS-auto-update configuration (config-ips-auto-update)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

The **cisco** command cannot be used in conjunction with the **url** command.

Examples

The following example shows how to configure automatic signature updates from Cisco.com that occur at the third hour of the 5 day of the month, at the 56th minute of this hour.

Note Adjustments are made for months without 31 days and daylight savings time.

```
Router(config)# ip ips auto-update
Router(config-ips-auto-update)# cisco
Router(config-ips-auto-update)# occur-at monthly 5 56 3
```

Related Commands

Command	Description
ip ips auto-update	Enables automatic signature updates for Cisco IOS IPS.
occur-at	Defines a preset time for which the Cisco IOS Intrusion Prevention System (IPS) automatically obtains updated signature information.

citrix enabled

To enable Citrix application support for end users in a policy group, use the **citrix enabled** command in webvpn group policy configuration mode. To remove Citrix support from the policy group configuration, use the **no** form of this command.

citrix enabled

no citrix enabled

Syntax Description

This command has no arguments or keywords.

Command Default

Citrix application support is not enabled.

Command Modes

Webvpn group policy configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

Citrix support allows a citrix client to use applications running on a remote server as if they were running locally. Entering the **citrix-enabled** command configures Citrix support for the policy group.

Examples

The following example configures Citrix support under the policy group:

```
Router(config)# webvpn context context1
Router(config-webvpn-context)# policy group ONE
Router(config-webvpn-group)# citrix enabled
Router(config-webvpn-group)#
```

Related Commands

Command	Description
filter citrix	Configures a Citrix application access filter.
policy group	Enters webvpn group policy configuration mode to configure a policy group.
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.

class type inspect

To specify the traffic (class) on which an action is to be performed, use the **class type inspect** command in policy-map configuration mode. To delete a class, use the **no** form of this command.

class type inspect *class-map-name*

no class type inspect *class-map-name*

Layer 7 (Application-Specific) Traffic Class Syntax

class type inspect *protocol-name class-map-name*

no class type inspect *protocol-name class-map-name*

Syntax Description

class-map-name	Name of the class on which an action is to be performed. The *class-map-name* must match the appropriate class name specified via the **class-map type inspect** command.
protocol-name	Layer 7 application-specific traffic class. The supported protocols are as follows: • **aol**—America Online Instant Messenger (IM) • **edonkey**—eDonkey peer-to-peer (P2P) • **fasttrack**—FastTrack traffic P2P • **gnutella**—Gnutella Version 2 traffic P2P • **h323** —H.323 protocol, Version 4 • **http**—HTTP • **icq**—I Seek You (ICQ) IM protocol • **imap**—Internet Message Access Protocol (IMAP) • **kazaa2**—Kazaa Version 2 P2P protocol • **msnmsgr**—MSN Messenger IM protocol • **pop3**—Post Office Protocol, Version 3 (POP3) • **sip**—Session Initiation Protocol (SIP) • **smtp**—Simple Mail Transfer Protocol (SMTP) • **sunrpc**—SUN Remote Procedure Call (SUNRPC) • **winmsgr**—Windows Messenger IM protocol • **ymsgr**—Yahoo IM

Command Default

None

Command Modes

Policy-map configuration (config-pmap)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(9)T	Support for the IM protocol and following keywords was added: **aol**, **msnmsgr**, **ymsgr** Support for the P2P protocol and following keywords was added: **edonkey**, **fasttrack**, **gnutella**, **kazaa2**
12.4(20)T	Support for the ICQ and Windows Messenger IM protocols and following keywords was added: **icq**, **winmsgr** Support for the H.323 protocol and following keyword was added: **h323** Support for SIP and following keyword was added: **sip**

Usage Guidelines

Use the **class type inspect** command to specify the class and protocol (if applicable) on which an action is to be performed.

Thereafter, you can specify any of the following actions: drop, inspect, pass, reset, urlfilter, or attach a Layer 7 (application-specific) policy-map to a "top-level" (Layer 3 or Layer 4) policy-map (via the **service-policy (policy-map)** command).

Note A Layer 7 policy is considered to be a nested policy of the top-level policy, and it is called a child policy.

Examples

The following example shows how to configure the policy-map "my-im-pmap" with two IM classes—AOL and Yahoo Messenger—and only allow text-chat messages to pass through. When any packet with a service other than "text-chat" is seen, the connection will be reset.

```
class-map type inspect aol match-any my-aol-cmap
 match service text-chat
!
class-map type inspect ymsgr match-any my-ysmgr-cmap
 match service any
!
policy-map type inspect im my-im-pmap
 class type inspect aol my-aol-cmap
 allow
 log
!
 class type inspect ymsgr my-ysmgr-cmap
 rest
 log
```

Related Commands

Command	Description
class-map type inspect	Creates a Layer 3 and Layer 4 or a Layer 7 (application-specific) inspect type class map.
policy-map type inspect	Creates a Layer 3 and Layer 4 a or Layer 7 (application-specific) inspect type policy map.
service-policy (policy-map)	Attaches a Layer 7 policy map to a top-level Layer 3 or Layer 4 policy map.

class type urlfilter

To associate a URL filter class with a URL filtering policy map, use the **class type urlfilter** command in policy-map configuration mode. To disassociate the class, use the **no** form of this command.

class type urlfilter [trend | n2h2 | websense] *class-map-name*

no class type urlfilter [trend | n2h2 | websense] *class-map-name*

Syntax Description

trend	(Optional) Specifies that the class map applies to a Trend Micro filtering URL filtering policy. If a keyword is not specified, the class map applies to a local filtering policy.
n2h2	(Optional) Specifies that the class map applies to a SmartFilter URL filtering policy. If a keyword is not specified, the class map applies to a local filtering policy.
websense	(Optional) Specifies that the class map applies to a Websense URL filtering policy. If a keyword is not specified, the class map applies to a local filtering policy.
class-map-name	Name of the URL filter class map.

Command Default

No class is associated with a policy map.

Command Modes

Policy-map configuration (config-pmap)

Command History

Release	Modification
12.4(15)XZ	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use the **class type urlfilter** command to associate a class with a URL filtering policy map. You can associate one or more classes with the URL filtering policy map. You must create the class map for the class before you can associate the class with the policy map. In addition, you must use the **parameter type urlfpolicy** command to associate URL filtering parameters with the policy before you can associate a class with the URL filtering policy map.

Examples

The following example shows how the **class type urlfilter** command is used to create the URL filtering policy map trend-policy and associate three classes with the policy map—trusted-domain-class, untrusted-domain-class, and drop-category.

```
policy-map type inspect urlfilter trend-policy
 parameter type urlfpolicy trend trend-param-map
 class type urlfilter trusted-domain-class
  log
  allow
 class type urlfilter untrusted-domain-class
```

```
 log
 reset
class type urlfilter trend drop-category
 log
 reset
```

Related Commands

Command	Description
policy-map type inspect urlfilter	Creates or modifies a URL filter type inspect policy map.

class-map type inspect

To create a Layer 3 and Layer 4 or a Layer 7 (application-specific) inspect type class map, use the **class-map type inspect** command in global configuration mode. To remove a class map from the router configuration file, use the **no** form of this command.

Layer 3 and Layer 4 (Top Level) Class Map Syntax

class-map type inspect {**match-any** | **match-all**} *class-map-name*

no class-map type inspect {**match-any** | **match-all**} *class-map-name*

Layer 7 (Application-Specific) Class Map Syntax

class-map type inspect *protocol-name* {**match-any** | **match-all**} *class-map-name*

no class-map type inspect *protocol-name* {**match-any** | **match-all**} *class-map-name*

Syntax Description

match-any	Determines how packets are evaluated when multiple match criteria exist. Packets must meet one of the match criteria to be considered a member of the class.
match-all	Determines how packets are evaluated when multiple match criteria exist. Packets must meet all of the match criteria to be considered a member of the class. **Note** The **match-all** keyword is available only with Layer 3, Layer 4, and HTTP type class maps.

class-map-name	Name of the class map. The name can be a maximum of 40 alphanumeric characters. The class map name is used to configure policy for the class in the policy map.
protocol-name	Layer 7 application-specific class map. The supported protocols are as follows: • **aol**—America Online Instant Messenger (IM) • **edonkey**—eDonkey peer-to-peer (P2P) • **fasttrack**—FastTrack traffic P2P • **gnutella**—Gnutella Version 2 traffic P2P • **h323**—h323 Protocol, Version 4 • **http**—HTTP • **icq**—I Seek You (ICQ) IM • **imap**—Internet Message Access Protocol (IMAP) • **kazaa2**—Kazaa Version 2 P2P • **msnmsgr**—MSN Messenger IM protocol • **pop3**—Post Office Protocol, Version 3 (POP 3) • **sip**—Session Initiation Protocol (SIP) • **smtp**—Simple Mail Transfer Protocol (SMTP) • **sunrpc**—SUN Remote Procedure Call (SUNRPC) • **winmsgr**—Windows IM • **ymsgr**—Yahoo IM

Defaults

The behavior of the **match-any** keyword is the default.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(9)T	The following P2P protocol keywords were added: **edonkey**, **fasttrack**, **gnutella**, **kazaa2**. The following IM protocol keywords were added: **aol**, **msnmsgr**, **ymsgr**.
12.4(15)XZ	This command was integrated into Cisco IOS Release 12.4(15)XZ. Support for the SPA Interface Processor (SIP) protocol was added.
12.4(20)T	The following IM protocol keywords were added: **icq, winmsgr**. The following VoIP protocol keyword was added: **h323** (Version 4).

Usage Guidelines

Use the **class-map type inspect** command to specify the name and protocol (if applicable) of a Layer 3, Layer 4, or Layer 7 class map.

Layer 3 and Layer 4 (Top Level) Class Maps

You can configure a top-level (Layer 3 or Layer 4) class map, which allows you to identify the traffic stream at a high level, by issuing the **match access-group** and **match protocol** commands. These class maps cannot be used to classify traffic at the application level (the Layer 7 level).

Layer 7 (Application-Specific) Class Maps

Application-specific class maps allow you to identify traffic based on the attributes of a given protocol. Match conditions in these class maps are specific to an application (for example, HTTP or SMTP). In addition to the type inspect, you must specify a protocol name (via the *protocol-name* argument) to create an application-specific class map.

Note Configuring the **match access-group** 101 filter enables Layer-4 inspection. As a result, Layer-7 inspection is skipped unless the class-map is of type **match-all**.

Examples

The following example shows how to configure class map c1 with the match criterion of ACL 101 based on the HTTP protocol:

```
class-map type inspect match-all c1
 match access-group 101
 match protocol http
```

The following example configures class map winmsgr-textchat with the match criterion of text-chat based on the Windows IM protocol:

```
class-map type inspect match-any winmsgr winmsgr-textchat
 match service text-chat
```

Related Commands

Command	Description
match access-group	Configures the match criteria for a class map based on the specified ACL number or name.
match class-map	Uses a traffic class as a classification policy.
match protocol	Configures the match criteria for a class map based on the specified protocol.
match service	Configures the match criteria for a class map based on the specified IM protocol.

class-map type urlfilter

To create or modify a URL filter class map, use the **class-map type urlfilter** command in global configuration mode. To remove the class map, use the **no** form of this command.

class-map type urlfilter [**trend | n2h2 | websense**] [**match-any**] *class-map-name*

no class-map type urlfilter [**trend | n2h2 | websense**] [**match-any**] *class-map-name*

Syntax Description

trend	(Optional) Specifies that the class map applies to a Trend Micro URL filtering policy. If a keyword is not specified, the class map applies to a local URL filtering policy.
n2h2	(Optional) Specifies that the class map applies to a SmartFilter URL filtering policy. If a keyword is not specified, the class map applies to a local URL filtering policy.
websense	(Optional) Specifies that the class map applies to a Websense URL filtering policy. If a keyword is not specified, the class map applies to a local URL filtering policy.
match-any	(Optional) Specifies how URL requests are evaluated when multiple match criteria exist in a class map.
class-map-name	Name of the URL filter class map.

Command Default

No class maps are created.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)XZ	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use the **class-map type urlfilter** command to enter class-map configuration mode and create or modify a URL filter class map. The class map is used as a traffic filter to segregate HTTP traffic for which a URL filtering policy applies. If you specify multiple match criteria and want to segregate the traffic when there is at least one match, use the **match-any** keyword. If you do not specify a type of filtering policy with the **trend**, **n2h2**, or **websense** keyword, then the class map applies to a local URL filtering policy.

Local Class Maps

Use the **class-map type urlfilter match-any** *class-map-name* to create or modify a local class map. filtering mode. Typically, you create three local class maps: one to specify trusted domains, one to specify untrusted domains, and one to specify keywords to block.

To specify the match criteria for the trusted and untrusted domain classes, use the following command:

- **match server-domain urlf-glob** *parameter-map-name*

Before you use this command, you must configure the **urlf-glob** parameter with the **parameter-map type urlf-glob** command.

To specify the match criteria for the keyword class map use the following command:

- **match url-keyword urlf-glob** *parameter-map-name*

Before you use this command, you must configure the **urlf-glob** keyword with the **parameter-map type urlf-glob** command.

Trend Micro Class Maps

Use the **class-map type urlfilter trend match-any** *class-map-name* command to create or modify a URL class map for the Trend Router Provisioning Server (TRPS). Typically, you create two Trend Micro class maps: one to specify URL categories and one to specify URL reputations.

To specify the Trend Micro URL categories for which filtering takes place, use the following command:

- **match url category** *category-name*

To specify the Trend Micro URL reputations for which filtering takes place, use the following command:

- **match url reputation** *reputation-name*

SmartFilter Class Maps

Use the **class-map type urlfilter n2h2** *class-map-name* command to create or modify a URL filter class map for a SmartFilter filtering service. Use the following command to specify the match condition for the class map:

- **match server-response any**

Websense Class Maps

Use the **class-map type urlfilter websense** *class-map-name* command to create or modify a URL filter class map for a Websense filtering server. Use the following command to specify the match condition for the class map:

- **match server-response any**

Examples

The following example configures the parameters for local filtering, and then specifies three class maps for local URL filtering: trusted-domain-class, untrusted-domain-class, and keyword-class:

```
parameter-map type urlf-glob trusted-domains-param
 pattern www.example.com
 pattern *.example1.com

parameter-map type urlf-glob untrusted-domain-param
 pattern www.example2.com
 pattern www.example3.org

parameter-map type urlf-glob keyword-param
 pattern games
 pattern adult

class-map type urlfilter match-any trusted-domain-class
 match server-domain urlf-glob trusted-domain-param

class-map type urlfilter match-any untrusted-domain-class
 match server-domain urlf-glob untrusted-domain-param

class-map type urlfilter match-any keyword-class
 match url-keyword urlf-glob keyword-param
```

The following example configures two class maps for Trend Micro filtering: drop-category and drop-reputation:

```
class-map type urlfilter trend match-any drop-category
 match url category Gambling
 match url category Personals-Dating

class-map type urlfilter trend match-any drop-reputation
 match url reputation PHISHING
 match url reputation ADWARE
```

The following example specifies a class map for SmartFilter filtering called n2h2-class and configures the match criteria as any response from the SmartFilter server:

```
class-map type urlfilter n2h2 match-any n2h2-class
 match server-response any
```

Related Commands

Command	Description
match server-domain urlf-glob	Specifies the server domain match criteria for a URL filtering class map.
match server-response any	Specifies the match criterion for SmartFilter and Websense class maps.
match url category	Specifies the URL category match criteria for a URL filtering class map.
match url-keyword urlf-glob	Specifies the URL keyword match criteria for a URL filtering class map.
match url reputation	Specifies the URL reputation match criteria for a URL filtering class map.
parameter-map type urlf-glob	Specifies the filtering parameters for trusted domains, untrusted domains, and blocked keywords.

clear aaa cache filterserver acl

To clear the cache status for a particular filter or all filters, use the **clear aaa cache filterserver acl** command in EXEC mode.

clear aaa cache filterserver acl [*filter-name*]

Syntax Description

filter-name	(Optional) Cache status of a specified filter is cleared.

Command Modes

EXEC

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
122(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

After you clear the cache status for a particular filter or all filters, it is recommended that you enable the **show aaa cache filterserver** command to verify that the cache status.

Examples

The following example shows how to clear the cache for all filters:

```
clear aaa cache filterserver acl
```

Related Commands

Command	Description
show aaa cache filterserver	Displays the cache status.

clear aaa cache filterserver group

To clear contents of the server group cache, use the **clear aaa cache filterserver group** command in privileged EXEC mode.

clear aaa cache filterserver group *name*{**all** | **profile** *name*}

Syntax Description

name	Name of the server group being cleared.
all	Clears all profiles.
profile *name*	Clears an individual profile.

Command Default

All profiles are cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.

Examples

The following example shows how to clear all RADIUS server IDs:

```
Router# clear aaa cache filterserver group group1
```

Related Commands

Command	Description
aaa cache filterserver	Enables AAA filter server definitions.

clear aaa cache group

To clear an individual entry or all entries in the cache, use the **clear aaa cache group** command in privileged EXEC mode.

clear aaa cache group *name* {**profile** *name* | **all**}

Syntax Description

name	Text string representing the name of a cache server group.
profile *name*	Specifies the name of an individual profile entry to clear.
all	Specifies that all profiles in the named cache group are cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(28)SB	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use this command to clear cache entries.

Note To update an old record with profile cache settings and to remove an old record from the cache, clear the cache for the profile.

Examples

The following example clears all cache entries in the localusers group:

```
Router# clear aaa cache group localusers all
```

Related Commands

Command	Description
show aaa cache group	Displays all of the cache entries stored by the AAA cache.

clear aaa counters servers

To clear the authentication, authorization, and accounting (AAA) server information, use the **clear aaa counters servers** command in privileged EXEC mode.

clear aaa counters servers {**all** | **radius** {*server-id* | **all**} | **sg** *name*}

Syntax Description

all	Clears all server information.
radius	Clears RADIUS server information.
server-id	Clears all server IDs displayed by **show aaa servers** command. The range is from 0 to 2147483647.
all	Clears all server IDs.
sg	Clear all servers in a server group.
name	Server group name.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release2 .1	This command was integrated into Cisco IOS XE Release 2.1.

Examples

The following example shows how to clear AAA counter server information:

```
Router# clear aaa counters servers all
```

Related Commands

Command	Description
aaa cache filterserver	Enables AAA filter server definitions.

clear aaa local user fail-attempts

To clear the unsuccessful login attempts of a user, use the **clear aaa local user fail-attempts** command in privileged EXEC mode.

clear aaa local user fail-attempts {**username** *username* | **all**}

Syntax Description

username *username*	Specifies the name of the user.
all	Clears unsuccessful login attempts for all users.

Defaults

Unsuccessful login attempts are not cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRE	This command was modified. It was integrated into Cisco IOS Release 12.2(33)SRE.

Usage Guidelines

This command is available only to users having the root privilege.

Examples

The following example shows that the unsuccessful login attempts for all users will be cleared:

```
Router# clear aaa local user fail-attempts all
```

Related Commands

Command	Description
aaa local authentication attempts max-fail	Specifies the maximum number of unsuccessful authentication attempts before a user is locked out.
clear aaa local user lockout	Unlocks the locked-out users.
show aaa local user locked	Displays a list of all locked-out users.

clear aaa local user lockout

To unlock the locked-out users, use the **clear aaa local user lockout** command in privileged EXEC mode.

clear aaa local user lockout {**username** *username* | **all**}

Syntax Description

username *username*	Specifies the name of the user to be unlocked.
all	Specifies that all users are to be unlocked.

Defaults

Locked-out users remain locked out.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRE	This command was modified. It was integrated into Cisco IOS Release 12.2(33)SRE.

Usage Guidelines

Only a user having the root privilege can use this command.

Examples

The following example shows that all locked-out users will be unlocked:

```
Router# clear aaa local user lockout all
```

Related Commands

Command	Description
aaa local authentication attempts max-fail	Specifies the maximum number of unsuccessful authentication attempts before a user is locked out.
clear aaa local user fail-attempts	Clears the unsuccessful login attempts of a user.
show aaa local user loced	Displays a list of all locked-out users.

clear access-list counters

To clear the counters of an access list, use the **clear access-list counters** command in privileged EXEC mode.

clear access-list counters {*access-list-number* | *access-list-name*}

Syntax Description

access-list-number	Access list number of the access list for which to clear the counters.
access-list-name	Name of an IP access list. The name cannot contain a space or quotation mark, and must begin with an alphabetic character to avoid ambiguity with numbered access lists.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Some access lists keep counters that count the number of packets that pass each line of an access list. The **show access-lists** command displays the counters as a number of matches. Use the **clear access-list counters** command to restart the counters for a particular access list to 0.

Examples

The following example clears the counters for access list 101:

```
Router# clear access-list counters 101
```

Related Commands

Command	Description
show access-lists	Displays the contents of current IP and rate-limit access lists.

clear access-template

To manually clear a temporary access list entry from a dynamic access list, use the **clear access-template** command in privileged EXEC mode.

clear access-template {*access-list-number* | *name*} *template-name* {*source-address source-wildcard-bit* | **any** | **host** {*hostname* | *source-address*}} {*destination-address dest-wildcard-bit* | **any** | **host** {*hostname* | *destination-address*}} [**timeout** *minutes*]

Syntax Description

access-list-number	Number of the dynamic access list. The ranges are from 100 to 199 and from 2000 to 2699.
name	Name of an IP access list. • The name cannot contain a space or quotation mark, and must begin with an alphabetic character to avoid ambiguity with numbered access lists.
template-name	Name of a dynamic access list.
source-address	Source address in a dynamic access list. • All other attributes are inherited from the original access-list entry.
source-wildcard-bit	Source wildcard bits.
any	Specifies any source hostname.
host	Specifies a specific source host.
hostname	Name of the host.
destination-address	Destination address in a dynamic access list. • All other attributes are inherited from the original access-list entry.
dest-wildcard-bit	Destination wildcard bits.
timeout *minutes*	(Optional) Specifies a maximum time limit, in minutes, for each entry within this dynamic list. The range is from 1 to 9999. • This is an absolute time, from creation, that an entry can reside in the list. The default is an infinite time limit and allows an entry to remain permanently.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **any**, **host** *hostname*, and **timeout** *minutes* keywords and arguments were added.

Usage Guidelines

The **clear access-template** command is related to the lock-and-key access feature. It clears any temporary access list entries that match the parameters you define.

Examples

The following example shows how to clear any temporary access list entries with a source of 172.20.1.12 from the dynamic access list named vendor:

```
Router> enable
Router# clear access-template vendor 172.20.1.12 any host 172.20.1.13
```

Related Commands

Command	Description
access-list (IP extended)	Defines an extended IP access list.
access-template	Places a temporary access list entry on a router to which you are connected manually.
show ip accounting	Displays the active accounting or checkpointed database or displays access list violations.

clear appfw dns cache

To clear at least one IP address from the Domain Name System (DNS) cache, use the **clear appfw dns cache** command in privileged EXEC mode.

clear appfw dns cache name *dns-name* [**address** *address*]

Syntax Description

name *dns-name*	DNS name of the IM server as entered in the **server name** command in application firewall policy.
address *address*	(Optional) Deletes a specific IP address from the DNS server cache. If an IP address is not specified, all IP addresses for the *dns-name* are deleted from the DNS server cache.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

Resolved IP addresses are never "timed out" and not automatically removed from the DNS cache. Thus, if you find an obsolete IP address in the instant messenger database (DNS cache), you can issue the **clear appfw dns cache** command to remove the IP address and prevent the address from being interpreted by the router as an IM server.

Only one IP address can be deleted at a time. If the deleted IP address appears in the subsequent DNS resolution, the IP address is added to the DNS cache again.

Examples

The following example shows how to clear the IP address "172.16.0.0" from the cache of the DNS server "logon.cat.aol.com":

```
Router# clear appfw dns cache name logon.cat.aol.com address 172.16.0.0
```

Related Commands

Command	Description
server	Configures a set of DNS servers for which the specified instant messenger application will be interacting.

clear ase signatures

Note Effective with Cisco IOS Release 12.4(24), the **clear ase signatures** command is not available in Cisco IOS software.

To remove all Automatic Extraction Signatures (ASEs), use the **clear ase signatures** command in privileged EXEC configuration mode.

clear ase signatures

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(15)T	This command was introduced.
12.4(24)	This command was removed.

Usage Guidelines

This command is used to remove all the generated signatures that are displayed in the **show ase signatures** command output.

This command is used on the Cisco 1800, 2800, and 7200 series routers, Cisco 7301 router, and Integrated Services Routers (ISRs) as ASE sensors.

Examples

The following example output demonstrates the result of removing generated signatures:

```
Router# show ase signatures

Automatic Signature Extraction Detected Signatures
==================================================

Signature Hash: 0x1E4A2076AAEA19B1, Offset: 54, Dest Port: TCP 135,
Signature: 05 00 00 03 10 00 00 00 F0 00 10 00 01 00 00 00 B8 00 00 00 00 00 03 00 01 00
00 00 00 00 00 00 00 00 00 00 00 00 00 00
Signature Hash: 0x24EC60FB1CF9A800, Offset: 72, Dest Port: TCP 445,
Signature: 00 00 00 00 00 00 00 00 00 00 00 00 FF FE 00 00 00 00 00 62 00 02 50 43 20 4E
45 54 57 4F 52 4B 20 50 52 4F 47 52 41 4D
Signature Hash: 0x0B0275535FFF480C, Offset: 54, Dest Port: TCP 445,
Signature: 00 00 00 85 FF 53 4D 42 72 00 00 00 00 18 53 C8 00 00 00 00 00 00 00 00 00 00
00 00 00 00 FF FE 00 00 00 00 00 62 00 02

Router# clear ase signatures

Router# show ase signatures

Automatic Signature Extraction Detected Signatures
==================================================
```

Table 17 describes the significant fields shown in the display.

Table 17 clear ase signatures Field Descriptions

Field	Description
Signature Hash	Hash (total) value of the 40-byte pattern, used as a check number for error control
Offset	Offset within the packet where the pattern begins
Dest Port	Layer 4 destination port for packets that contain this pattern
Signature	40 bytes of packet data used to potentially identify a piece of malware

Related Commands

Command	Description
ase collector	Enters the ASE collector server IP address so that the ASE sensor has IP connectivity to the ASE collector.
ase group	Identifies the TIDP group number for the ASE feature.
ase enable	Enables the ASE feature on a specified interface.
ase signature extraction	Enables the ASE feature globally on the router.
debug ase	Provides error, log, messaging, reporting, status, and timer information.
show ase	Shows the ASE run-time status, which includes the TIDP group number.

clear authentication sessions

To clear information about current Auth Manager sessions and force 802.1X clients on all 802.1X-enabled interfaces to initialize or reauthenticate, use the **clear authentication sessions** command in privileged EXEC mode.

Note Effective with Cisco IOS Release 12.2(33)SXI, the **clear authentication session** command replaces the **dot1x intitialize** and **dot1x re-authenticate** commands.

clear authentication sessions [**handle** *handle-id*] [**interface** *type number*] [**mac** *mac-address*] [**method** *method-name*] [**session-id** *session-name*]

Syntax Description

handle *handle-id*	(Optional) Specifies the particular handle for which Auth Manager information is to be displayed.
interface *type number*	(Optional) Specifies a particular interface type and number for which Auth Manager information is to be displayed.
mac *mac-address*	(Optional) Specifies the particular MAC address for which you want to display information.
method *method-name*	(Optional) Specifies the particular authentication method for which Auth Manager information is to be displayed.
session-id *session-name*	(Optional) Clears a particular authentication session by reference to its session ID.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Examples

The following example shows how to use the **clear authentication sessions** command to clear information for all Auth Manager sessions:

```
Switch# clear authentication sessions
```

The following example shows how to use the **clear authentication sessions** command to clear information for the Auth Manager session on a particular interface:

```
Switch# clear authentication sessions interface GigabitEthernet/0/23
```

The following example shows how to use the **clear authentication sessions** command to clear information for the Auth Manager session on a particular MAC address:

```
Switch# clear authentication sessions mac 000e.84af.59bd
```

Related Commands

Command	Description
show authentication sessions	Displays information about current Auth Manager sessions.

clear crypto call admission statistics

To clear the counters that track the number of accepted and rejected Internet Key Exchange (IKE) requests, use the **call admission limit** command in global configuration mode.

clear crypto call admission statistics

Syntax Description

This command has no arguments or keywords.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(18)SXD1	This command was integrated into Cisco IOS Release 12.2(18)SXD1.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Examples

The following example sets to zero the number of accepted and rejected IKE requests:

```
Router(config)# clear crypto call admission statistics
```

Related Commands

Command	Description
show crypto call admission statistics	Monitors Crypto CAC statistics.

clear crypto ctcp

To clear all Cisco Tunnel Control Protocol (cTCP) sessions and all Internet Key Exchange (IKE) and IPsec security associations (SAs) that are created on those sessions, use the **clear crypto ctcp** command in privileged EXEC mode.

clear crypto ctcp [**peer** *ip-address*]

no clear crypto ctcp [**peer** *ip-address*]

Syntax Description

peer	(Optional) Clears a specific cTCP peer.
ip-address	(Optional) IP address of the peer to be cleared.

Defaults

cTCP sessions are not cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(9)T	This command was introduced.

Examples

The following example shows that all cTCP sessions and all IKE and IPsec SAs that are created on those sessions are to be cleared:

```
Router# clear crypto ctcp
```

The following example shows that only cTCP sessions for peer 10.76.235.21 and all IKE and IPsec SAs that are created on those sessions are to be cleared.

```
Router# clear crypto ctcp peer 10.76.235.21
```

Related Commands

Command	Description
crypto ctcp	Configures cTCP encapsulation for Easy VPN.

clear crypto datapath

To clear the counters or error history buffers in an encrypted network, use the **clear crypto datapath** command in privileged EXEC mode.

clear crypto datapath {**ipv4** | **ipv6**} [**error** | **internal** | **punt** | **success**]

Syntax Description

ipv4	Clears all counters in a network using IPv4.
ipv6	Clears all counters in a network using IPv6.
error	(Optional) Clears the error history buffer.
internal	(Optional) Clears the internal event counter.
punt	(Optional) Clears the punt event counter.
success	(Optional) Clears the success event counter.

Command Default

All counters are cleared, unless a keyword is entered to specify one counter.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Use the **clear crypto datapath** command to clear the history buffers or counters associated with an encrypted data path. You must specify the IP version for the network. If you only use the IP version keyword, all counters will be cleared. To clear only a specific counter, enter the keyword for that counter.

Examples

The following example shows how to clear all the counters in a network using IP version 4:

```
Router# clear crypto datapath ipv4
```

This example shows how to clear the success counter only:

```
Router# clear crypto datapath ipv4 success
```

Related Commands

Command	Description
show crypto datapath	Displays the counters associated with an encrypted data path.

clear crypto engine accelerator counter

To reset the statistical and error counters of the hardware accelerator of the router or the IPsec Virtual Private Network (VPN) Shared Port Adapter (SPA) to zero, use the **clear crypto engine accelerator counter** command in privileged EXEC mode.

clear crypto engine accelerator counter

IPsec VPN SPA

clear crypto engine accelerator statistic [**slot** *slot*/*subslot* | **all**] [**detail**]

Syntax Description

slot *slot*/*subslot*	(IPsec VPN SPA only—Optional) Chassis slot number and secondary slot number on the SPA Interface Processor (SIP) where the SPA is installed. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. Resets platform statistics for the corresponding IPsec VPN SPA to zero. This output will not include network interface controller statistics.
all	(IPsec VPN SPA only—Optional) Resets platform statistics for all IPsec VPN SPAs on the router to zero. This reset will not include network interface controller statistics.
detail	(IPsec VPN SPA only—Optional) Resets platform statistics for the IPsec VPN SPA and network interface controller statistics to zero.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.1(3)XL	This command was introduced for the Cisco uBR905 cable access router.
12.2(2)XA	Support was added for the Cisco uBR925 cable access router.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T and implemented for the AIM-VPN/EPII and AIM-VPN/HPII on the following platforms: Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.2(15)ZJ	This command was implemented for the AIM-VPN/BPII on the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, and Cisco 2651XM.
12.3(4)T	The AIM-VPN/BPII was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, and Cisco 2651XM.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA to support the IPsec VPN SPA on Cisco 7600 series routers and Catalyst 6500 series switches.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

No specific usage guidelines apply to the hardware accelerators.

IPsec VPN SPA

Enter the **slot** keyword to reset platform statistics for the corresponding IPsec VPN SPA to zero. This reset will not include network interface controller statistics.

Enter the **all** keyword to reset platform statistics for all IPsec VPN SPAs on the router to zero. This reset will not include network interface controller statistics.

Enter the **detail** keyword to reset both the platform statistics for the IPsec VPN SPA and network interface controller statistics to zero.

Examples

Hardware VPN Module

The following example shows the statistical and error counters of the hardware accelerator being cleared to zero:

```
Router# clear crypto engine accelerator counter
```

IPsec VPN SPA

The following example shows the platform statistics for the IPsec VPN SPA in slot 2, subslot 1 being cleared to zero:

```
Router# clear crypto engine accelerator counter slot 2/1
```

The following example shows the platform statistics for all IPsec VPN SPAs on the router being cleared to zero:

```
Router# clear crypto engine accelerator counter all
```

Related Commands

Command	Description
crypto ca	Defines the parameters for the certification authority used for a session.
crypto cisco	Defines the encryption algorithms and other parameters for a session.
crypto dynamic-map	Creates a dynamic map crypto configuration for a session.
crypto engine accelerator	Enables the use of the onboard hardware accelerator for IPsec encryption.
crypto ipsec	Defines the IPSec security associations and transformation sets.
crypto isakmp	Enables and defines the IKE protocol and its parameters.

Command	Description
crypto key	Generates and exchanges keys for a cryptographic session.
crypto map	Creates and modifies a crypto map for a session.
debug crypto engine accelerator control	Displays each control command as it is given to the crypto engine.
debug crypto engine accelerator packet	Displays information about each packet sent for encryption and decryption.
show crypto engine accelerator ring	Displays the contents of command and transmits rings for the crypto engine.
show crypto engine accelerator sa-database	Displays the active (in-use) entries in the crypto engine SA database.
show crypto engine accelerator statistic	Displays the current run-time statistics and error counters for the crypto engine.
show crypto engine brief	Displays a summary of the configuration information for the crypto engine.
show crypto engine configuration	Displays the version and configuration information for the crypto engine.
show crypto engine connections	Displays a list of the current connections maintained by the crypto engine.

clear crypto gdoi

To clear the state of the current session of a Group Domain of Interpretation (GDOI) group member with the key server, use the **clear crypto gdoi** command in privileged EXEC mode.

clear crypto gdoi [**group** *group-name* | **ks coop counters** | **ks policy** | **replay counter** | **ks members counters**]

Syntax Description

group *group-name*	(Optional) Name of the group.
ks coop counters	(Optional) Clears the counters for the cooperative key server.
ks policy	(Optional) Clears all policies on the key server. **Note** (Configuring this keyword does not trigger the re-election of the key servers.)
replay counter	(Optional) Clears the anti-replay counters.
ks members counters	(Optional) Clear the counters for all GMs on the current key server.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(11)T	The **group** and **replay** keywords and the *group-name* argument were added.
Cisco IOS XE Release 2.3	This command was implemented on the Cisco ASR 1000 series routers.
15.1(3)T	This command was modified. The **ks members counters** keyword combination was added.

Usage Guidelines

If this command is issued on the group member, the policy of the group member is deleted, and the group member reregisters with the key server.

If this command is issued on the key server, the state on the key server is deleted. If redundancy is configured and this command is issued on the key server, the key server goes back into election mode to elect a new primary key server.

Examples

If the following command is issued on the key server, the state on the key server is cleared. If the command is issued on a group member, the state is cleared for the entire group and a reregistration to the key server is forced.

```
Router# clear crypto gdoi
```

If the following command is issued on the key server, the state of the group that is specified is cleared on the key server. If the command is issued on a group member, the state of the group that is specified is cleared on the group member, and reregistration to the key server is forced.

```
Router# clear crypto gdoi group group1
```

The following command clears the anti-replay counters for the GDOI groups:

```
Router# clear crypto gdoi replay counter
```

The following command clears the counters for the cooperative key server:

```
Router# clear crypto gdoi ks coop counters
```

The following command clears all policy on the key server but does not trigger the re-election of the key servers:

```
Router# clear crypto gdoi ks policy
```

The following command clears all counters for all GMs on the current key server:

```
Router# clear crypto gdoi ks members counters
```

clear crypto gdoi ks cooperative role

To reset the cooperative role of the key server and to initiate the election process on the key server, use the **clear crypto gdoi ks cooperative role** command in privileged EXEC mode.

clear crypto gdoi ks cooperative role

Syntax Description

This command has no arguments or keywords.

Command Default

Cooperative role is not reset.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

If the **clear crypto gdoi ks cooperative role** command is executed on a secondary key server, the election is triggered on that secondary key server although that server would most likely remain a secondary key server because there has been an elected primary key server. However, if the **clear crypto gdoi ks cooperative role** command is executed on the primary key server, the primary key server is reassigned to a secondary role, and as a result, a new election that involves all the key servers is triggered. If the previous primary server has the highest priority (of all the key servers), it again becomes the primary server. If the previous primary server does not have the highest priority, the server having the highest priority is elected as the new primary server.

Examples

The following example shows that the cooperative role of the key server has been reset and that the election process is to be initiated:

```
clear crypto gdoi ks cooperative role
```

Related Commands

Command	Description
clear crypto gdoi	Clears the state of the current session of a group member with the key server.

clear crypto ikev2 sa

To clear the Internet Key Exchange Version 2 (IKEv2) security associations (SA), use the **clear crypto ikev2 sa** command in privileged EXEC mode.

clear crypto ikev2 sa [**local** {*ipv4-address* | *ipv6-address*} | **remote** {*ipv4-address* | *ipv6-address*} | **fvrf** *vrf-name* | **psh** *number*]

Syntax Description

local {*ipv4-address* | *ipv6-address*}	(Optional) Clears the IKEv2 security associations matching the local address.
remote {*ipv4-address* | *ipv6-address*}	(Optional) Clears the IKEv2 security associations matching the remote address.
fvrf *vrf-name*	(Optional) Clears the IKEv2 security associations matching the specified front door virtual routing and forwarding (FVRF) instance.
psh *number*	(Optional) Clears the IKEv2 platform service handler matching the specified connection ID.

Command Default

The security associations are not cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(4)M	This command was modified. Support was added for IPv6 addresses.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to clear an IKEv2 security association and the child security associations.

Examples

The following example shows how to clear the IKEv2 security associations:

```
Router# clear crypto ikev2 sa
```

clear crypto ikev2 stat

To clear the Internet Key Exchange Version 2 (IKEv2) statistics, use the **clear crypto ikev2 stat** command in privileged EXEC mode.

clear crypto ikev2 stat

Syntax Description

This command has no arguments or keywords.

Command Default

The IKEv2 security associations statistics are not cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to clear IKEv2 SA statistics.

Examples

The following example shows the IKEv2 statistics being reset and the output of the command:

```
Router# clear crypto ikev2 stat
Cleared crypto ikev2 statistics
```

clear crypto ipsec client ezvpn

To reset the Cisco Easy VPN remote state machine and bring down the Cisco Easy VPN remote connection on all interfaces or on a given interface (tunnel), use the **clear crypto ipsec client ezvpn** command in privileged EXEC mode. If a tunnel name is specified, only the specified tunnel is cleared.

clear crypto ipsec client ezvpn [*name*]

Syntax Description

name	(Optional) Identifies the IPSec virtual private network (VPN) tunnel to be disconnected or cleared with a unique, arbitrary name. If no name is specified, all existing tunnels are disconnected or cleared.

Defaults

If no tunnel name is specified, all active tunnels on the machine are cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(4)YA	This command was introduced for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(8)YJ	This command was enhanced to specify an IPSec VPN tunnel to be cleared or disconnected for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

The **clear crypto ipsec client ezvpn** command resets the Cisco Easy VPN remote state machine, bringing down the current Cisco Easy VPN remote connection and bringing it back up on the interface. If you specify a tunnel name, only that tunnel is cleared. If no tunnel name is specified, all active tunnels on the machine are cleared.

If the Cisco Easy VPN remote connection for a particular interface is configured for autoconnect, this command also initiates a new Cisco Easy VPN remote connection.

Examples

The following example shows the Cisco Easy VPN remote state machine being reset:

```
Router# clear crypto ipsec client ezvpn
```

Related Commands

Command	Description
crypto ipsec client ezvpn (global)	Creates a Cisco Easy VPN remote configuration.
crypto ipsec client ezvpn (interface)	Assigns a Cisco Easy VPN remote configuration to an interface.

clear crypto isakmp

To clear active Internet Key Exchange (IKE) connections, use the **clear crypto isakmp** command in privileged EXEC mode.

clear crypto isakmp [*connection-id*] [**active** | **standby**]

Syntax Description

connection-id	(Optional) ID of the connection that is to be cleared. If this argument is not used, all existing connections will be cleared.
active	(Optional) Clears only IKE security associations (SAs) in the active state. For each active SA that is cleared, the standby router will be notified to clear the corresponding standby SA.
standby	(Optional) Clears only IKE SAs in the standby (secondary) state. **Note** If the router is in standby mode, the router will immediately resynchronize the standby SAs; thus, it may appear as though the standby SAs were not cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3 T	This command was introduced.
12.3(11)T	The **active** and **standby** keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Caution If the *connection-id* argument is not used, all existing IKE connections will be cleared when this command is issued.

Examples

The following example clears an IKE connection between two peers connected by interfaces 172.21.114.123 and 172.21.114.67:

```
Router# show crypto isakmp sa

    dst           src          state        conn-id   slot
172.21.114.123 172.21.114.67  QM_IDLE           1       0
209.165.201.1  209.165.201.2  QM_IDLE           8       0

Router# clear crypto isakmp 1
```

```
Router# show crypto isakmp sa

    dst             src          state        conn-id   slot
209.165.201.1  209.165.201.2  QM_IDLE           8       0

Router#
```

Related Commands

Command	Description
show crypto isakmp sa	Displays current IKE SAs.

clear crypto sa

To delete IP Security (IPSec) security associations (SAs), use the **clear crypto sa** command in privileged EXEC mode.

clear crypto sa [**active** | **standby**]

Virtual Routing and Forwarding (VRF) Syntax

clear crypto sa peer [**vrf** *fvrf-name*] *address*

clear crypto sa [**vrf** *ivrf-name*]

Crypto Map Syntax

clear crypto sa map *map-name*

IP Address, Security Protocol Standard, and SPI Syntax

clear crypto sa entry *destination-address protocol spi*

Traffic Counters Syntax

clear crypto sa counters

Syntax Description

active	(Optional) Clears only IPSec SAs that are in the active state.
standby	(Optional) Clears only IPSec SAs that are in the standby state. **Note** If the router is in standby mode, the router will immediately resynchronize the standby SAs; thus, it may appear as though the standby SAs were not cleared.
peer [**vrf** *fvrf-name*] *address*	Deletes any IPSec SAs for the specified peer. The *fvrf-name* argument specifies the front door VRF (FVRF) of the peer address.
vrf *ivrf-name*	(Optional) Clears all IPSec SAs whose inside virtual routing and forwarding (IVRF) is the same as the *ivrf-name*.
map	Deletes any IPSec SAs for the named crypto map set.
map-name	Specifies the name of a crypto map set.
entry	Deletes the IPSec SA with the specified address, protocol, and security parameter index (SPI).
destination-address	Specifies the IP address of the remote peer.
protocol	Specifies either the Encapsulation Security Protocol (ESP) or Authentication Header (AH).
spi	Specifies an SPI (found by displaying the SA database).
counters	Clears the traffic counters maintained for each SA; the **counters** keyword does not clear the SAs themselves.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(15)T	The **vrf** keyword and *fvrf-name* argument for **clear crypto sa peer** were added. The **vrf** keyword and *ivrf-name* argument for **clear crypto sa** were added.
12.3(11)T	The **active** and **standby** keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

This command clears (deletes) IPSec SAs.

If the SAs were established via Internet Key Exchange (IKE), they are deleted and future IPSec traffic will require new SAs to be negotiated. (When IKE is used, the IPSec SAs are established only when needed.)

If the SAs are manually established, the SAs are deleted and reinstalled. (When IKE is not used, the IPSec SAs are created as soon as the configuration is completed.)

Note If the **peer**, **map**, **entry**, **counters, active**, or **standby** keywords are not used, all IPSec SAs will be deleted.

- The **peer** keyword deletes any IPSec SAs for the specified peer.
- The **map** keyword deletes any IPSec SAs for the named crypto map set.
- The **entry** keyword deletes the IPSec SA with the specified address, protocol, and SPI.
- The **active** and **standby** keywords delete the IPSec SAs in the active or standby state, respectively.

If any of the above commands cause a particular SA to be deleted, all the "sibling" SAs—that were established during the same IKE negotiation—are deleted as well.

The **counters** keyword simply clears the traffic counters maintained for each SA; it does not clear the SAs themselves.

If you make configuration changes that affect SAs, these changes will not apply to existing SAs but to negotiations for subsequent SAs. You can use the **clear crypto sa** command to restart all SAs so that they will use the most current configuration settings. In the case of manually established SAs, if you make changes that affect SAs you must use the **clear crypto sa** command before the changes take effect.

If the router is processing active IPSec traffic, it is suggested that you clear only the portion of the SA database that is affected by the changes, to avoid causing active IPSec traffic to temporarily fail.

Note that this command clears only IPSec SAs; to clear IKE state, use the **clear crypto isakmp** command.

Examples

The following example clears (and reinitializes if appropriate) all IPSec SAs at the router:

```
clear crypto sa
```

The following example clears (and reinitializes if appropriate) the inbound and outbound IPSec SAs established, along with the SA established for address 10.0.0.1 using the AH protocol with the SPI of 256:

```
clear crypto sa entry 10.0.0.1 AH 256
```

The following example clears all the SAs for VRF VPN1:

```
clear crypto sa vrf vpn1
```

Related Commands

Command	Description
clear crypto isakmp	Clears active IKE connections.

clear crypto session

To delete crypto sessions (IP security [IPsec] and Internet Key Exchange [IKE] security associations [SAs]), use the **clear crypto session** command in privileged EXEC mode.

clear crypto session [**local** {*ipv4-address* | *ipv6-address*} [**port** *local-port*]] [**remote** {*ipv4-address* | *ipv6-address*} [**port** *remote-port*]] | [**fvrf** *vrf-name*] [**ivrf** *vrf-name*] | [**isakmp group** *group-name*] | [**username** *user-name*]]

IPsec and IKE Stateful Failover Syntax

clear crypto session [**active** | **standby**]

Syntax Description

local {*ipv4-address* | *ipv6-address*}	(Optional) Clears crypto sessions for a local crypto endpoint. • The IP address is the IP address of the local crypto endpoint.
port *local-port*	(Optional) IKE port of the local endpoint. The *local-port* value can be 1 through 65535. The default value is 500.
remote {*ipv4-address* | *ipv6-address*}	(Optional) Clears crypto sessions for a remote IKE peer. • The IP address is the IP address of the remote IKE peer.
port *remote-port*	(Optional) IKE port of the remote endpoint to be deleted. The *remote-port* value can be from 1 through 65535. The default value is 500.
fvrf *vrf-name*	(Optional) Specifies the front door virtual routing and forwarding (FVRF) session that is to be cleared.
ivrf *vrf-name*	(Optional) Specifies the inside VRF (IVRF) session that is to be cleared.
isakmp group *group-name*	(Optional) Clears the specified crypto session using the isakmp group.
username *user-name*	(Optional) Clears the crypto session for the specified xauth or pki-aaa username.
active	(Optional) Clears only IPsec and IKE SAs in the active state.
standby	(Optional) Clears only IPsec and IKE SAs in the standby state. **Note** If the router is in standby mode, the router will immediately resynchronize the standby SAs with the active router.

Defaults

All existing sessions will be deleted. The IPsec SAs will be deleted first. Then the IKE SAs are deleted.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.3(11)T	The **active** and **standby** keywords were added.

Release	Modification
12.4(11)T	The **isakmp group** *group-name* and **username** *user-name* keywords and associated arguments were added.
15.1(4)M	This command was modified. Support was added for IPv6 addresses.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

To clear a specific crypto session or a subset of all the sessions, you need to provide session-specific parameters, such as a local or remote IP address, a local or remote port, an FVRF name, or an IVRF name.

If a local IP address is provided as a parameter when you use the **clear crypto session** command, all the sessions (and their IKE SAs and IPsec SAs) that share the IP address as a local crypto endpoint (IKE local address) will be deleted.

Examples

The following example shows that all crypto sessions will be deleted:

```
Router# clear crypto session
```

The following example shows that the crypto session of the FVRF named “blue” will be deleted:

```
Router# clear crypto session fvrf blue
```

The following example shows that the crypto sessions of the FVRF “blue” and the IVRF session “green” will be deleted:

```
Router# clear crypto session fvrf blue ivrf green
```

The following example shows that the crypto sessions of the local endpoint 10.1.1.1 and remote endpoint 10.2.2.2 will be deleted. The local endpoint port is 5, and the remote endpoint port is 10.

```
Router# clear crypto session local 10.1.1.1 port 5 remote 10.2.2.2 port 10
```

Related Commands

Command	Description
show crypto isakmp peer	Displays peer descriptions.
show crypto session	Displays status information for active crypto sessions in a router.

clear crypto pki benchmarks

To clear Public Key Infrastructure (PKI) benchmarking data and release all memory associated with this data, use the **clear crypto pki benchmarks** command in privileged EXEC mode.

clear crypto pki benchmarks

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use the **clear crypto pki benchmarks** command to clear all PKI benchmarking data and release all memory associated with this data. PKI benchmarking data is used for IOS PKI performance monitoring and optimization. PKI performance monitoring and optimization is turned on or off by using the **crypto pki benchmark** command.

Examples

The following example shows how to clear PKI benchmarking data:

```
Router# clear crypto pki benchmarks
```

Related Commands

Command	Description
crypto pki benchmark	Starts or stops benchmarking data for PKI performance monitoring and optimization.
show crypto pki benchmarks	Displays benchmarking data for PKI performance monitoring and optimization that was collected.

clear crypto pki crls

To remove the certificate revocation list (CRL) database that determines the validity status of digital certificates presented by encryption peers in a PKI, use the **clear crypto pki crls** command in privileged EXEC mode.

clear crypto pki crls

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

The the **clear crypto pki crls** command removes the CRL database that was configured with the **crypto pki certificate chain** command, which is used to configure a certificate authority (CA).

Related Commands

Command	Description
crypto pki certificate chain	Enters certificate chain configuration mode for a specified CA.

clear dmvpn session

To clear Dynamic Multipoint VPN (DMVPN) sessions, use the **clear dmvpn session** command in privileged EXEC mode.

clear dmvpn session [**interface tunnel** *number* | **peer** {*ipv4-address* | *FQDN-string*} | **vrf** *vrf-name*] [**static**]

Syntax Description

interface	(Optional) Displays DMVPN information based on a specific interface.
tunnel *number*	(Optional) Specifies the tunnel address for the DMVPN peer. The range is from 0 to 2147483647.
peer	(Optional) Specifies a DMVPN peer.
ipv4-address	(Optional) The IPv4 address for the DMVPN peer.
FQDN-string	(Optional) Next hop server (NHS) fully qualified domain name (FQDN) string.
vrf *vrf-name*	(Optional) Clears all Next Hop Resolution Protocol (NHRP) sessions related to the specified virtual routing and forwarding (VRF) configuration.
static	(Optional) Clears all static and dynamic NHRP entries. • You must use the **static** keyword for all NHS FQDN configurations. **Note** If the **static** keyword is not specified, only dynamic NHRP entries are cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(9)T	This command was introduced.
12.4(20)T	This command was modified. The *ipv6-address* argument was added.
Cisco IOS XE Release 2.5	This command was integrated into Cisco IOS XE Release 2.5 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.
15.1(2)T	This command was modified. The *FQDN-string* argument was added.

Usage Guidelines

This command clears existing DMVPN sessions based on input parameters.

Examples

The following example shows how to clear all DMVPN sessions, both static and dynamic, for the specified peer nonbroadcast multiple access (NBMA) address:

```
Router# clear dmvpn session peer nbma static
```

The following example shows how to clear all DMVPN sessions, both static and dynamic, for the specified peer FQDN string:

```
Router# clear dmvpn session peer examplehub.example1.com static
```

Related Commands

Command	Description
clear ip nhrp	Clears all dynamic entries from the IPv4 NHRP cache.
clear ipv6 nhrp	Clears all dynamic entries from the IPv6 NHRP cache.

clear dmvpn statistics

To clear Dynamic Multipoint VPN (DMVPN) related counters, use the **clear dmvpn statistics** command in privileged EXEC mode.

clear dmvpn statistics [**peer** {**nbma** | **tunnel**} *ip-address*] [**interface** {**tunnel** *number*}] [**vrf** *vrf-name*]

Syntax Description

peer	(Optional) Specifies a DMVPN peer.
nbma	(Optional) Specifies nonbroadcast mapping access (NBMA).
tunnel	(Optional) Specifies a tunnel.
ip-address	(Optional) Specifies the IP address for the DMVPN peer.
interface	(Optional) Displays DMVPN information based on a specific interface.
tunnel *number*	(Optional) Specifies tunnel address for DMVPN peer.
vrf *vrf-name*	(Optional) Clears all DMVPN counters related to the specified virtual routing forwarding (VRF) configuration.

Command Default

DMVPN counters will not be cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Based on input parameters, DMVPN related session counters will be cleared.

Examples

The following example shows how to clear DMVPN related session counters for the specified tunnel interface:

```
Router# clear dmvpn statistics peer tunnel 192.0.2.3
```

Related Commands

Command	Description
clear dmvpn session	Clears DMVPN sessions.

clear dot1x

To clear 802.1X interface information, use the **clear dot1x** command in privileged EXEC mode.

clear dot1x {**all** | **interface** *interface-name*}

Syntax Description

all	Clears 802.1X information for all interfaces.
interface *interface-name*	Clears 802.1X information for the specified interface.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(2)XA	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.2(25)SEE	This command was integrated into Cisco IOS Release 12.2(25)SEE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following configuration shows that 802.1X information will be cleared for all interfaces:

```
Router# clear dot1x all
```

The following configuration shows that 802.1X information will be cleared for the Ethernet 0 interface:

```
Router# clear dot1x interface ethernet 0
```

You can verify that the information was deleted by entering the **show dot1x** command.

Related Commands

Command	Description
debug dot1x	Displays 802.1X debugging information.
identity profile default	Creates an identity profile and enters identity profile configuration mode.
show dot1x	Displays details for an identity profile.

clear eap

To clear Extensible Authentication Protocol (EAP) information on a switch or for a specified port, use the **clear eap** command in privileged EXEC mode.

clear eap [**sessions** [**credentials** *credentials-name* | **interface** *interface-name* | **method** *method-name* | **transport** *transport-name*]]

Syntax Description

sessions	(Optional) Clears EAP sessions on a switch or a specified port.
credentials *credentials-name*	(Optional) Clears EAP credential information for only the specified profile.
interface *interface-name*	(Optional) Clears EAP credential information for only the specified interface.
method *method-name*	(Optional) Clears EAP credential information for only the specified method.
transport *transport-name*	(Optional) Clears EAP credential information for only the specified lower layer.

Command Default

All active EAP sessions are cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(25)SEE	This command was introduced.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.

Usage Guidelines

You can clear all counters by using the **clear eap** command with the **sessions** keyword, or you can clear only the specified information by using the **credentials**, **interface**, **method**, or **transport** keywords.

Examples

The following example shows how to clear all EAP information:

```
Router# clear eap sessions
```

The following example shows how to clear EAP session information for the specified profile:

```
Router# clear eap sessions credentials type1
```

Related Commands

Command	Description
show eap registrations	Displays EAP registration information.
show eap sessions	Displays active EAP session information.

clear eou

To clear all client device entries that are associated with a particular interface or that are on the network access device (NAD), use the **clear eou** command in privileged EXEC mode.

clear eou {**all** | **authentication** {**clientless** | **eap** | **static**} | **interface** {*interface-type*} | **ip** {*ip-address*} | **mac** {*mac-address*} | **posturetoken** {*name*}}

Syntax Description

all	Clears all client device entries.
authentication	Authentication type.
clientless	Authentication type is clientless.
eap	Authentication type is Extensible Authentication Procotol (EAP).
static	Authentication type is static.
interface	Provides information about the interface.
interface-type	Type of interface (see Table 18 for a list of interface types).
ip	Specifies an IP address.
ip-address	IP address of the client device.
mac	Specifies a MAC address.
mac-address	The 48-bit address of the client device.
posturetoken	Posture token name.
name	Name of the posture token.

Command Modes

Privileged EXEC#

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Table 18 lists the interface types that may be used for the *interface-type* argument.

Table 18 Description of Interface Types

Interface Type	Description
Async	Asynchronous interface
BVI	Bridge-Group Virtual Interface
CDMA-Ix	Code division multiple access Internet exchange (CDMA Ix) interface
CTunnel	Connectionless Network Protocol (CLNS) tunnel (Ctunnel) interface
Dialer	Dialer interface
Ethernet	IEEE 802.3 standard interface
Lex	Lex interface

Table 18 Description of Interface Types (continued)

Interface Type	Description
Loopback	Loopback interface
MFR	Multilink Frame Relay bundle interface
Multilink	Multilink-group interface
Null	Null interface
Serial	Serial interface
Tunnel	Tunnel interface
Vif	Pragmatic General Multicast (PGM) Multicase Host interface
Virtual-PPP	Virtual PPP interface
Virtual-Template	Virtual template interface
Virtual-TokenRing	Virtual TokenRing interface

Examples

The following example shows that all client device entries are to be cleared:

```
Router# clear eou all
```

Related Commands

Command	Description
eou	Displays information about EAPoUDP.

clear ip access-list counters

To clear IP access list counters, use the **clear ip access-list counters** command in privileged EXEC mode.

clear ip access-list counters [*access-list-number* | *access-list-name*]

Syntax Description

access-list-number | *access-list-name*	(Optional) Number or name of the IP access list for which to clear the counters. If no name or number is specified, all IP access list counters are cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.0	This command was introduced.

Usage Guidelines

The counter counts the number of packets that match each **permit** or **deny** statement in an access list. You might clear the counters if you want to start at zero to get a more recent count of the packets that are matching an access list. The **show ip access-lists** command displays the counters as a number of matches.

Examples

The following example clears the counter for access list 150:

```
Router# clear ip access-list counters 150
```

Related Commands

Command	Description
show ip access list	Displays the contents of IP access lists.

clear ip access-template

To clear statistical information on the access template, use the **clear ip access-template** command in privileged EXEC mode.

clear ip access-template {*access-list-number* | *name*} *dynamic-name* {*source-address source-wildcard-bit* | **any** | **host** {*hostname* | *source-address*}} {*destination-address dest-wildcard-bit* | **any** | **host** {*hostname* | *destination-address*}}

Syntax Description

access-list-number	Access list number. Range is from 100 to 199 for an IP extended access list and from 2000 to 2699 for an expanded-range IP extended access list.
name	Name of an IP access list. • The name cannot contain a space or quotation mark, and must begin with an alphabetic character to avoid ambiguity with numbered access lists.
dynamic-name	Name of a dynamic access list.
source-address	Source address in a dynamic access list. • All other attributes are inherited from the original access-list entry.
source-wildcard-bit	Source wildcard bits.
any	Specifies any source host name.
host	Specifies a specific source host.
hostname	Name of the host.
destination-address	Destination address in a dynamic access list. • All other attributes are inherited from the original access-list entry.
dest-wildcard-bit	Destination wildcard bits.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **any**, **host** *hostname*, and **timeout** *minutes* keywords and arguments were added.

Examples

This example shows how to clear statistical information on the access list:

```
Router# clear ip access-template 201 list1 any 172.0.2.1 172.0.2.2
```

Related Commands

Command	Description
show mls netflow	Displays configuration information about the NetFlow hardware.

clear ip admission cache

To clear IP admission cache entries from the router, use the **clear ip admission cache** command in privileged EXEC mode.

clear ip admission cache {***** | **host ip address**}

Syntax Description

*****	Clears all IP admission cache entries and associated dynamic access lists.
host ip address	Clears all IP admission cache entries and associated dynamic access lists for the specified host.

Command Modes

Privileged EXEC #

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Use this command to clear entries from the admission control cache before they time out.

Examples

The following example shows that all admission entries are to be deleted:

```
Router# clear ip admission cache *
```

The following example shows that the authentication proxy entry for the host with the IP address 192.168.4.5 is to be deleted:

```
Router# clear ip admission cache 192.168.4.5
```

Related Commands

Command	Description
show ip admission cache	Displays the admission control entries or the running admission control configuration.

clear ip audit configuration

To disable Cisco IOS Firewall IDS, remove all intrusion detection configuration entries, and release dynamic resources, use the **clear ip audit configuration** command in EXEC mode.

clear ip audit configuration

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(13)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **clear ip audit configuration** EXEC command to disable Cisco IOS Firewall IDS, remove all intrusion detection configuration entries, and release dynamic resources.

Examples

The following example clears the existing IP audit configuration:

```
clear ip audit configuration
```

clear ip audit statistics

To reset statistics on packets analyzed and alarms sent, use the **clear ip audit statistics** command in EXEC mode.

clear ip audit statistics

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(13)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco IOS 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **clear ip audit statistics** EXEC command to reset statistics on packets analyzed and alarms sent.

Examples

The following example clears all IP audit statistics:

```
clear ip audit statistics
```

clear ip auth-proxy cache

To clear authentication proxy entries from the router, use the **clear ip auth-proxy cache** command in EXEC mode.

clear ip auth-proxy cache {***** | *host-ip-address*}

Syntax Description

*	Clears all authentication proxy entries, including user profiles and dynamic access lists.
host-ip-address	Clears the authentication proxy entry, including user profiles and dynamic access lists, for the specified host.

Command Modes

EXEC

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to clear entries from the translation table before they time out.

Examples

The following example deletes all authentication proxy entries:

```
clear ip auth-proxy cache *
```

The following example deletes the authentication proxy entry for the host with IP address 192.168.4.5:

```
clear ip auth-proxy cache 192.168.4.5
```

Related Commands

Command	Description
show ip auth-proxy	Displays the authentication proxy entries or the running authentication proxy configuration.

clear ip auth-proxy watch-list

To delete a single watch-list entry or all watch-list entries in Privileged EXEC configuration command mode, use the **clear ip auth-proxy watch-list** command.

clear ip auth-proxy watch-list {*ip-addr* | *****}

Syntax Description

ip-addr	IP address to be deleted from the watch list.
*****	All watch-list entries from the watch list.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is supported on the systems that are configured with a Supervisor Engine 2 only.

If you see entries in the watch list that you suspect are not valid, you can enter the **clear ip auth-proxy watch-list** command to clear them manually instead of waiting for the watch list to expire.

Examples

This example shows how to delete a single watch-list entry:

```
Router# clear ip auth-proxy watch-list 10.0.0.2

Router#
```

This example shows how to delete all watch-list entries:

```
Router# clear ip auth-proxy watch-list *
Router#
```

Related Commands

Command	Description
ip auth-proxy max-login-attempts	Limits the number of login attempts at a firewall interface and QoS filtering and enter the ARP ACL configuration submode.

Command	Description
ip auth-proxy watch-list	Enables and configures an authentication proxy watch list.
show ip auth-proxy watch-list	Displays the information about the authentication proxy watch list.

clear ip inspect ha

To delete the Firewall stateful failover sessions information from a router's memory, use the **clear ip inspect ha** command in privileged EXEC mode.

clear ip inspect ha [sessions all | statistics]

Syntax Description

sessions all	(Optional) Clears all the firewall HA sessions.
statistics	(Optional) Clears the HA statistics on the device.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

If the **clear ip inspect ha sessions all** command is used on the standby device, the standby HA sessions are cleared. This initiates re-synchronization of all HA sessions from the active device to the standby device.

Examples

The following example shows all sessions being deleted:

```
Router# clear ip inspect ha sessions all
```

The following example shows statistics being deleted.

```
Router# clear ip inspect ha statistics
```

clear ip inspect session

To delete Context-Based Access Control (CBAC) configuration and session information from a router's memory, use the **clear ip inspect session** command in privileged EXEC mode.

clear ip inspect session *session-address*

Syntax Description

session-address	Deletes a specific session; the format is 0-FFFFFFFF.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

Sessions consist of control channels and data channels.

Use the **clear ip inspect session** command to delete a control channel or a data channel. If you specify a control channel session, then data channel sessions may also be deleted, depending on the application protocols being used. If you specify a data channel session, then only that specific session is deleted.

If you attempt to delete a session and the **clear ip inspect session** command is not supported for the specified protocol, then an error message is generated.

If you want to delete a specific session, use the **show ip inspect session** command to display all session addresses.

Note The **clear ip inspect session** command is recommended for advanced users only because it may disrupt network operations if traffic is still flowing through the session.

Examples

The following example displays the current session addresses:

```
Router# show ip inspect session

Established Sessions

 Session 25A3318 (10.0.0.1:20)=>(10.1.0.1:46068) ftp-data SIS_OPEN

 Session 25A6E1C (10.1.0.1:46065)=>(10.0.0.1:21) ftp SIS_OPEN
```

The following example shows a specific session being deleted:

```
Router# clear ip inspect session 25A6E1C
```

Related Commands

Command	Description
show ip inspect	Displays CBAC configuration and session information.

clear ip ips configuration

To disable Cisco IOS Firewall Intrusion Prevention System (IPS), remove all intrusion detection configuration entries, and release dynamic resources, use the **clear ip ips configuration** command in EXEC mode.

clear ip ips configuration

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(8)T	The command name was changed from the **clear ip audit configuration** command to the **clear ip ips configuration** command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example clears the existing IPS configuration:

```
clear ip ips configuration
```

clear ip ips statistics

To reset statistics on packets analyzed and alarms sent, use the **clear ip ips statistics** command in privileged EXEC mode.

clear ip ips statistics [**vrf** *vrf-name*]

Syntax Description

vrf	(Optional) Resets statistics on packets analyzed and alarms sent per VRF.
vrf-name	User specific VRF.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(8)T	The command name was changed from the **clear ip audit statistics** command to the **clear ip ips statistics** command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(20)T	The **vrf** keyword and argument were added.

Examples

The following example clears all Intrusion Protection System (IPS) statistics:

```
clear ip ips statistics
```

Sample Output for the clear ip ips statistics vrf Command

The following example displays the output of the **clear ip ips statistics vrf** *vrf-name* command:

```
Router# clear ip ips statistics vrf VRF_600
Router# show ip ips statistics vrf VRF_600
Signature statistics [process switch:fast switch]
  signature 5170:1 packets checked: [0:2]
Interfaces configured for ips 3
Session creations since subsystem startup or last reset 0
Current session counts (estab/half-open/terminating) [0:0:0]
Maxever session counts (estab/half-open/terminating) [0:0:0]
Last session created 00:02:34
Last statistic reset never
TCP reassembly statistics
  received 8 packets out-of-order; dropped 0
  peak memory usage 12 KB; current usage: 0 KB
  peak queue length 6
```

clear ip sdee

To clear Security Device Event Exchange (SDEE) events or subscriptions, use the **clear ip sdee** command in privileged EXEC mode.

clear ip sdee {**events** | **subscriptions**}

Syntax Description

events	Clears SDEE events from the event buffer.
subscriptions	Clears SDEE subscriptions.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Because subscriptions are properly closed by the Cisco IOS Intrusion Prevention System (IPS) client, this command is typically used only to help with error recovery.

Examples

The following example shows how to clear all open SDEE subscriptions on the router:

```
Router# clear ip sdee subscriptions
```

Related Commands

Command	Description
ip ips notify	Specifies the method of event notification.
ip sdee events	Sets the maximum number of SDEE events that can be stored in the event buffer.
ip sdee subscriptions	Sets the maximum number of SDEE subscriptions that can be open simultaneously.

clear ip trigger-authentication

To clear the list of remote hosts for which automated double authentication has been attempted, use the **clear ip trigger-authentication** command in privileged EXEC mode.

clear ip trigger-authentication

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command when troubleshooting automated double authentication. This command clears the entries in the list of remote hosts displayed by the **show ip trigger-authentication** command.

Examples

The following example clears the remote host table:

```
Router# show ip trigger-authentication

Trigger-authentication Host Table:
Remote Host          Time Stamp
172.21.127.114       2940514234
Router# clear ip trigger-authentication
Router# show ip trigger-authentication
```

Related Commands

Command	Description
show ip trigger-authentication	Displays the list of remote hosts for which automated double authentication has been attempted.

clear ip urlfilter cache

To clear the cache table, use the **clear ip urlfilter cache** command in user EXEC mode.

clear ip urlfilter cache {*ip-address* | **all**} [**vrf** *vrf-name*]

Syntax Description

ip-address	Clears the cache table of a specified server IP address.
all	Clears the cache table completely.
vrf *vrf-name*	(Optional) Clears the cache table only for the specified Virtual Routing and Forwarding (VRF) interface.

Command Modes

User EXEC

Command History

Release	Modification
12.2(11)YU	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The cache table consists of the most recently requested IP addresses and the respective authorization status for each IP address.

Examples

The following example shows how to clear the cache table of IP address 172.18.139.21:

```
clear ip urlfilter cache 172.18.139.21
```

The following example shows how to clear the cache table of all IP addresses:

```
clear ip urlfilter cache all
```

The following example shows how to clear the cache table of all IP addresses in the vrf named bank.

```
clear ip urlfilter cache all vrf bank
```

Related Commands

Command	Description
ip urlfilter cache	Configures cache parameters.
show ip urlfilter cache	Displays the destination IP addresses that are cached into the cache table.

clear kerberos creds

To delete the contents of the credentials cache, use the **clear kerberos creds** command in privileged EXEC mode.

clear kerberos creds

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Credentials are deleted when this command is issued.

Cisco supports Kerberos 5.

Examples

The following example illustrates the **clear kerberos creds** command:

```
Router# show kerberos creds
Default Principal: chet@cisco.com
Valid Starting          Expires                 Service Principal
18-Dec-1995 16:21:07    19-Dec-1995 00:22:24    krbtgt/CISCO.COM@CISCO.COM

Router# clear kerberos creds
Router# show kerberos creds
No Kerberos credentials.
```

Related Commands

Command	Description
show kerberos creds	Displays the contents of your credentials cache.

clear ldap server

To clear the TCP connection with the Lightweight Directory Access Protocol (LDAP) server, use the **clear ldap server** command in privileged EXEC mode.

clear ldap server *server-name* [**statistics**]

Syntax Description

server-name	LDAP server name.
statistics	(Optional) Clears the statistical information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

Statistics details are not cleared when the server is cleared. To clear the statistics information, use the **statistics** keyword.

Examples

The following example shows how to clear the statistical information:

```
Router# clear ldap server server1 statistics
```

Related Commands

Command	Description
ldap server	Defines an LDAP server and enters LDAP server configuration mode.

clear logging ip access-list cache

To clear all the entries from the Optimized ACL Logging (OAL) cache and send them to the syslog, use the **clear logging ip access-list cache** command in privileged EXEC mode.

clear logging ip access-list cache

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17d)SXB	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Cisco 7600 series routers that are configured with a Supervisor Engine 720 only.

Examples

This example shows how to clear all the entries from the OAL cache and send them to the syslog:

```
Router# clear logging ip access-list cache
```

Related Commands

Command	Description
logging ip access-list cache (global configuration)	Configures the OAL parameters globally.
logging ip access-list cache (interface configuration)	Enables an OAL-logging cache on an interface that is based on direction.
show logging ip access-list	Displays information about the logging IP access list.

clear parameter-map type protocol-info

To clear the Domain Name System (DNS) cache for name resolution of servers within a parameter map, use the **clear parameter-map type protocol-info** command in privileged EXEC mode.

clear parameter-map type protocol-info dns-cache *dns-name* [**ip-address** *ip-address]*

Syntax Description

dns-cache *dns-name*	Cache of the specified DNS server will be cleared.
ip-address *ip-address*	(Optional) Specified IP address is removed from the cache of the DNS server. If an IP address is not specified, all IP addresses from the specified DNS server are cleared from the cache.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced.

Examples

The following example shows how to clear the cache of the DNS server “sdsc.msg.yahoo.com:

```
Router# clear parameter-map type protocol-info dns-cache sdsc.msg.yahoo.com
```

Related Commands

Command	Description
parameter-map type	Creates or modifies a parameter map.

clear policy-firewall

To reset the information collected by the firewall, use the **clear policy-firewall** command in user EXEC or privileged EXEC mode.

clear policy-firewall {**session** [*session address* | **class-map** *class-map-name* | **policy-map** *policy-map-name*] | **stats** [*drop-counters*] | **summary-log** | **zone-pair**}

Syntax Description

session *session address*	Clears the session.
class-map *class-map-name*	Clears the class map.
policy-map *policy-map-name*	Clears the policy map.
stats [*drop-counters*]	Clears the statistics and the drop-counters.
summary-log	Clears the summary log.
zone-pair	Clears the zone-pair.

Command Default

The firewall information is not cleared.

Command Modes

EXEC (>)
Privileged EXEC (#)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

Use this command to clear the information that is collected by the firewall. The cleared counters include drop-counters, summary-log buffers, sessions and zone pairs.

Examples

The following example shows how to clear the zone pair:

```
Router(mode-prompt)# clear policy-firewall zone-pair
```

Related Commands

Command	Description
show policy-firewall config	Displays the entire configuration of the firewall in the router.
show policy-firewall sessions	Displays the details of the firewall sessions.

Command	Description
show policy-firewall stats	Displays the statistics of all firewall activities in the router.
show policy-firewall summary-log	Displays the summary log of the firewall.

clear policy-firewall stats vrf

To clear the policy firewall statistics at a VPN Routing and Forwarding (VRF) level, use the **clear policy-firewall stats vrf** command in privileged EXEC mode.

clear policy-firewall stats vrf *vrf-name*

Syntax Description

vrf-name	Name of the VRF.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.3S	This command was introduced.

Examples

The following example shows how to clear the configured policy firewall VRF statistics:

```
Router# clear policy-firewall stats vrf vrf1
```

Related Commands

Command	Description
show policy-firewall stats vrf	Displays VRF-level policy firewall statistics.

clear policy-firewall stats vrf global

To clear the global VPN Routing and Forwarding (VRF) policy firewall statistics, use the **clear policy-firewall stats vrf global** command in privileged EXEC mode.

clear policy-firewall stats vrf global

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.3S	This command was introduced.

Examples

The following example shows how to clear the global policy firewall statistics:

```
Router# clear policy-firewall stats vrf global
```

Related Commands

Command	Description
show policy-firewall stats vrf global	Displays information about the global VRF firewall policies.

clear policy-firewall stats zone

To clear the policy firewall statistics at a zone level, use the **clear policy-firewall stats zone** command in privileged EXEC mode.

clear policy-firewall stats zone *zone-name*

Syntax Description

zone-name	Name of the zone.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.3S	This command was introduced.

Examples

The following example shows how to clear the configured policy firewall zone statistics:

```
Router# clear policy-firewall stats zone zone1
```

Related Commands

Command	Description
show policy-firewall stats zone	Displays policy firewall statistics at a zone level.

clear port-security

To delete configured secure MAC addresses and sticky MAC addresses from the MAC address table in the Privileged EXEC configuration command mode, use the **clear port-security** command.

clear port-security dynamic [**address** *mac-addr* | **interface** *interface-id*] [**vlan** *vlan-id*]

Syntax Description

address *mac-addr*	(Optional) Deletes the specified secure MAC address or sticky MAC address.
interface *interface-id*	(Optional) Deletes all secure MAC addresses and sticky MAC addresses on the specified physical port or port channel.
vlan *vlan-id*	(Optional) Deletes the specified secure MAC address or sticky MAC address from the specified VLAN.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	The output of this command was changed to support sticky MAC addresses on the Supervisor Engine 720 only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on negotiated trunks only.

If you enter the **clear port-security** command without adding any keywords or arguments, the switch removes all the secure MAC addresses and sticky MAC addresses from the MAC address table.

If you enter the **clear port-security dynamic interface** *interface-id* command, all the secure MAC addresses and sticky MAC addresses on an interface are removed from the MAC address table.

You can verify that the information was deleted by entering the **show port-security** command.

Examples

This example shows how to remove a specific secure address from the MAC address table:

```
Router# clear port-security dynamic address 0008.0070.0007
Router#
```

This example shows how to remove all the secure MAC addresses and sticky MAC addresses learned on a specific interface:

```
Router# clear port-security dynamic interface gigabitethernet0/1
Router#
```

Related Commands

Command	Description
show port-security	Displays information about the port-security setting.
switchport port-security mac-address	Adds a MAC address to the list of secure MAC addresses.

clear radius

To clear the RADIUS server information, use the **clear radius** command in privileged EXEC mode.

clear radius {**sg-stats** | **statistics**}

Syntax Description

sg-stats	Clears the RADIUS server group statistics.
statistics	Clears the RADIUS statistics.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows how to clear the RADIUS statistics information:

```
Router# clear radius statistics
```

Related Commands

Command	Description
radius-server host	Configures a RADIUS server host.

clear radius local-server

To clear the display on the local server or to unblock a locked username, use the **clear radius local-server** command in privileged EXEC mode.

clear radius local-server {**statistics** | **user** *username*}

Syntax Description

statistics	Clears the display of statistical information.
user	Unblocks the locked username specified.
username	Locked username.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)JA	This command was introduced on the Cisco Aironet Access Point 1100 and the Cisco Aironet Access Point 1200.
12.3(11)T	This command was integrated into Cisco IOS Release 12.3(11)T and implemented on the following platforms: Cisco 2600XM, Cisco 2691, Cisco 2811, Cisco 2821, Cisco 2851, Cisco 3700, and Cisco 3800 series routers.

Examples

The following example shows how to unblock the locked username “smith”:

```
Router# clear radius local-server user smith
```

Related Commands

Command	Description
block count	Configures the parameters for locking out members of a group to help protect against unauthorized attacks.
debug radius local-server	Displays the debug information for the local server.
group	Enters user group configuration mode and configures shared setting for a user group.
nas	Adds an access point or router to the list of devices that use the local authentication server.
radius-server host	Specifies the remote RADIUS server host.
radius-server local	Enables the access point or router to be a local authentication server and enters into configuration mode for the authenticator.
reauthentication time	Specifies the time after which access points or wireless-aware routers must reauthenticate the members of a group.
show radius local-server statistics	Displays statistics for a local network access server.
ssid	Specifies up to 20 SSIDs to be used by a user group.

clear webvpn nbns

To clear the NetBIOS name service (NBNS) cache on a SSL VPN gateway, use the **clear webvpn nbns** command in privileged EXEC mode.

clear webvpn nbns [**context** {*name* | **all**}]

Syntax Description

context	(Optional) Clears NBNS statistics for a specific context or all contexts.
name	Clears NBNS statistics for a specific context.
all	Clears NBNS statistics for all contexts.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

Entering this command without any keywords or arguments clears all NBNS counters on the network device.

Examples

The following example clears all NBNS counters:

```
Router# clear webvpn nbns
```

Related Commands

Command	Description
clear webvpn session	Clears remote users sessions on a SSL VPN gateway.
clear webvpn stats	Clears application and access counters on a SSL VPN gateway.

clear webvpn session

To clear SSL VPN remote user sessions, use the **clear webvpn session** command in privileged EXEC mode.

clear webvpn session [**user** *name*] **context** {*name* | **all**}

Syntax Description

user *name*	(Optional) Clears session information for a specific user.
context {*name* | **all**}	Clears session information for a specific context or all contexts.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

This command is used to clear the session for either the specified remote user or all remote users in the specified context.

Examples

The following example clears all session information:

```
Router# clear webvpn session context all
```

Related Commands

Command	Description
clear webvpn nbns	Clears the NBNS cache on a SSL VPN gateway.
clear webvpn stats	Clears application and access counters on a SSL VPN gateway.

clear webvpn stats

To clear (or reset) SSL VPN application and access counters, use the **clear webvpn stats** command in privileged EXEC mode.

clear webvpn stats [[**cifs** | **citrix** | **mangle** | **port-forward** | **sso** | **tunnel**] [**context** {*name* | **all**}]]

Syntax Description

cifs	(Optional) Clears Windows file share (CIFS) statistics.
citrix	(Optional) Clears Citrix application statistics.
mangle	(Optional) Clears URL mangling statistics.
port-forward	(Optional) Clears port forwarding statistics.
sso	(Optional) Clears statistics for Single SignOn (SSO) activities.
tunnel	(Optional) Clears Cisco AnyConnect VPN Client tunnel statistics.
context {*name* | **all**}	(Optional) Clears information for either a specific context or all contexts.

Command Default

If no keywords are entered, all SSL VPN application and access counters are cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(11)T	The **sso** keyword was added.

Usage Guidelines

This command is used to clear counters for Windows file shares, Citrix applications, URL mangling, application port forwarding, SSO, and Cisco AnyConnect VPN Client tunnels. The counters are cleared for either the specified context or all contexts on the SSL VPN gateway.

Examples

The following example clears all statistics counters for all SSL VPN processes:

```
Router# clear webvpn stats
```

The following example clears statistics for SSO activities:

```
Router# clear webvpn stats sso
```

Related Commands

Command	Description
clear webvpn nbns	Clears the NBNS cache on a SSL VPN gateway.
clear webvpn session	Clears remote users sessions on a SSL VPN gateway.

clear zone-pair

To clear the policy map counters, inspect sessions, or the URL filter cache on a zone-pair, use the **clear zone-pair** command in privileged EXEC mode.

clear zone-pair [*zone-pair-name*] {**counter** | **inspect session** | **urlfilter cache**}

Syntax Description

zone-pair-name	(Optional) Name of the zone-pair on which counters, inspect sessions, or the uRL filter cache are cleared.
counter	Clears the policy-map counters. Resets the statistics of the inspect type policy map on the specified zone-pair.
inspect session	Deletes the inspect sessions on the specified zone-pair.
urlfilter cache	Clears the URL filter cache on the specified zone-pair.

Command Default

Disabled (it is not necessary to enter this command).

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(15)XZ	This command was implemented on the following platforms: Cisco 881 and Cisco 888.

Usage Guidelines

If you do not specify a zone-pair name, the policy map counters, sessions, or the URL filter cache are cleared for all the configured zone-pairs.

Examples

The following example deletes the inspect sessions on the zp zone-pair:

```
Router# clear zone-pair zp inspect session
```

The following example clears the URL filter cache on the zp zone-pair.

```
Router# clear zone-pair zp urlfilter cache
```

clid

To preauthenticate calls on the basis of the Calling Line IDentification (CLID) number, use the **clid** command in AAA preauthentication configuration mode. To remove the **clid** command from your configuration, use the **no** form of this command.

clid [**if-avail | required**] [**accept-stop**] [**password** *password*]

no clid [**if-avail | required**] [**accept-stop**] [**password** *password*]

Syntax Description

if-avail	(Optional) Implies that if the switch provides the data, RADIUS must be reachable and must accept the string in order for preauthentication to pass. If the switch does not provide the data, preauthentication passes.
required	(Optional) Implies that the switch must provide the associated data, that RADIUS must be reachable, and that RADIUS must accept the string in order for preauthentication to pass. If these three conditions are not met, preauthentication fails.
accept-stop	(Optional) Prevents subsequent preauthentication elements such as ctype or dnis from being tried once preauthentication has succeeded for a call element.
password *password*	(Optional) Defines the password for the preauthentication element. The default password string is cisco.

Command Default

The **if-avail** and **required** keywords are mutually exclusive. If the **if-avail** keyword is not configured, the preauthentication setting defaults to **required**.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines

You may configure more than one of the authentication, authorization and accounting (AAA) preauthentication commands (**clid**, **ctype**, **dnis**) to set conditions for preauthentication. The sequence of the command configuration decides the sequence of the preauthentication conditions. For example, if you configure **dnis**, then **clid**, then **ctype**, in this order, then this is the order of the conditions considered in the preauthentication process.

In addition to using the preauthentication commands to configure preauthentication on the Cisco router, you must set up the preauthentication profiles on the RADIUS server.

Examples

The following example specifies that incoming calls be preauthenticated on the basis of the CLID number:

```
aaa preauth
 group radius
 clid required
```

Related Commands

Command	Description
ctype	Preauthenticates calls on the basis of the call type.
dnis (RADIUS)	Preauthenticates calls on the basis of the DNIS number.
dnis bypass (AAA preauthentication configuration)	Specifies a group of DNIS numbers that will be bypassed for preauthentication.
group (RADIUS)	Specifies the AAA RADIUS server group to use for preauthentication.

client

To specify a RADIUS client from which a device will accept Change of Authorization (CoA) and disconnect requests, use the **client** command in dynamic authorization local server configuration mode. To remove this specification, use the **no** form of this command.

client {*name* | *ip-address*} [**key** [**0** | **7**] *word*] [**vrf** *vrf-id*]

no client {*name* | *ip-address*} [**key** [**0** | **7**] *word*] [**vrf** *vrf-id*]

Syntax Description

name	Hostname of the RADIUS client.
ip-address	IP address of the RADIUS client.
key	(Optional) Configures the RADIUS key to be shared between a device and a RADIUS client.
0	(Optional) Specifies that an unencrypted key will follow.
7	(Optional) Specifies that a hidden key will follow.
word	(Optional) Unencrypted server key.
vrf *vrf-id*	(Optional) Virtual Routing and Forwarding (VRF) ID of the client.

Command Default

CoA and disconnect requests are dropped.

Command Modes

Dynamic authorization local server configuration

Command History

Release	Modification
12.2(28)SB	This command was introduced.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

A device (such as a router) can be configured to allow an external policy server to dynamically send updates to the router. This functionality is facilitated by the CoA RADIUS extension. CoA introduced peer-to-peer capability to RADIUS, enabling a router and external policy server each to act as a RADIUS client and server. Use the **client** command to specify the RADIUS clients for which the router will act as server.

Examples

The following example configures the router to accept requests from the RADIUS client at IP address 10.0.0.1:

```
aaa server radius dynamic-author
 client 10.0.0.1 key cisco
```

Related Commands

Command	Description
aaa server radius dynamic-author	Configures an ISG as a AAA server to facilitate interaction with an external policy server.

client authentication list

To configure Internet Key Exchange (IKE) extended authentication (Xauth) in an Internet Security Association and Key Management Protocol (ISAKMP) profile, use the **client authentication list** command in ISAKMP profile configuration mode. To restore the default behavior, which is that Xauth is not enabled, use the **no** form of this command.

client authentication list *list-name*

no client authentication list *list-name*

Syntax Description

list-name	Character string used to name the list of authentication methods activated when a user logs in. The list name must match the list name that was defined during the authentication, authorization, and accounting (AAA) configuration.

Defaults

No default behaviors or values

Command Modes

ISAKMP profile configuration (config-isakmp-profile)

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11.5)	Xauth no longer has to be disabled globally for it to be enabled on a profile basis.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

Before configuring Xauth, you must set up an authentication list using AAA commands.

Xauth can be enabled on a profile basis if it has been disabled globally.

Effective with Cisco IOS Release 12.4(11.5), Xauth on either a server or client does not need to be disabled globally to enable it on profile basis.

Examples

The following example shows that user authentication is configured. User authentication is a list of authentication methods called “xauthlist” in an ISAKMP profile called “vpnprofile.”

```
crypto isakmp profile vpnprofile
 client authentication list xauthlist
```

The following example shows that Xauth has been disabled globally and enabled for the profile “nocerts”:

```
no crypto xauth FastEthernet0/0
!
crypto isakmp policy 1
 encr 3des
 group 2
!
crypto isakmp policy 10
 encr 3des
 authentication pre-share
 group 2
crypto isakmp client configuration group HRZ

crypto isakmp client configuration group vpngroup
 key cisco123
 pool vpnpool
crypto isakmp profile cert_sig
   match identity group HRZ
   isakmp authorization list isakmpauth
   client configuration address respond
   client configuration group HRZ
crypto isakmp profile nocerts
   match identity group vpngroup
   client authentication list vpn-login
   isakmp authorization list isakmpauth
   client configuration address respond
```

Related Commands

Command	Description
aaa authentication login	Sets AAA authentication at login.

client configuration address

To configure Internet Key Exchange (IKE) configuration mode in the Internet Security Association and Key Management Protocol (ISAKMP) profile, use the **client configuration address** command in ISAKMP profile configuration mode. To disable IKE configuraton mode, use the **no** form of this command.

client configuration address {**initiate** | **respond**}

no client configuration address {**initiate** | **respond**}

Syntax Description

initiate	Router will attempt to set IP addresses for each peer.
respond	Router will accept requests for IP addresses from any requesting peer.

Defaults

IKE configuration is not enabled.

Command Modes

ISAKMP profile configuration (config-isa-prof)

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

Before you can use this command, you must enter the **crypto isakmp profile** command.

Examples

The following example shows that IKE mode is configured to either initiate or respond in an ISAKMP profile called “vpnprofile”:

```
crypto isakmp profile vpnprofile
 client configuration address initiate
 client configuration address respond
```

Related Commands

Command	Description
crypto isakmp profile	Defines an ISAKMP profile.

client configuration group

To associate a group with the peer that has been assigned an Internet Security Association Key Management Protocol (ISAKMP) profile, use the **client configuration group** command in crypto ISAKMP profile configuration mode. To disable this option, use the **no** form of this command.

client configuration group *group-name*

no client configuration group *group-name*

Syntax Description

group-name	Name of the group to be associated with the peer.

Defaults

No default behavior or values

Command Modes

Crypto ISAKMP profile configuration (conf-isa-prof)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

The **client configuration group** command is used after the crypto map has been configured and the ISAKMP profiles have been assigned to them.

Examples

The following example shows that the group “some_group” is to be associated with the peer:

```
crypto isakmp profile id_profile
   ca trust-point 2315
   match identity host domain cisco.com
   client configuration group some_group
```

Related Commands

Command	Description
match certificate (ISAKMP)	Assigns an ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate.

client pki authorization list

To specify the authorization list of AAA servers that will be used to obtain per-user AAA attributes on the basis of the username that is constructed from the certificate, use the **client pki authorization list** command in crypto ISAKMP profile configuration mode. To disable the list name, use the **no** form of this command.

client pki authorization list *listname*

no client pki authorization list *listname*

Syntax Description

listname	Definition of the argument needed, including syntax-level defaults, if any.

Command Default

User attributes are not pushed to the remote device.

Command Modes

Crypto ISAKMP profile configuration (config-isakmp-profile)

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

This command is used inside the crypto Internet Security Association and Key Management Protocol (ISAKMP) profile.

Examples

The following example shows that user attributes are to be obtained from the AAA server (list name “usrgrp”) and pushed to the remote device:

```
crypto isakmp profile ISA-PROF
   match certificate CERT-MAP
   isakmp authorization list usrgrp
   client pki authorization list usrgrp
   client configuration address respond
   client configuration group pkiuser
   virtual-template 2
```

Related Commands

Command	Description
crypto isakmp profile	Defines an ISAKMP profile and audits IPsec user sessions.

client rekey encryption

To set the client acceptable rekey ciphers for the key-encryption-key (KEK), use the **client rekey encryption** command in GDOI group configuration mode. To remove the client acceptable rekey ciphers, use the **no** form of this command.

client rekey encryption *cipher* [...[*cipher*]]

no client rekey encryption

Syntax Description

cipher	Any of the following ciphers: • **3des-cbc**—Specifies triple Data Encryption Standard (3DES) in Cipher-block chaining (CBC) mode. • **aes 128**—Specifies 128-bit Advanced Encryption Standard (AES). • **aes 192**—Specifies 192-bit AES. • **aes 256**—Specifies 256-bit AES. • **des-cbc**—Specifies DES in CBC mode.

Command Default

Any cipher assigned by the key server is accepted.

Command Modes

GDOI group configuration (config-gdoi-group)

Command History

Release	Modification
Cisco IOS XE Release 2.4.1	This command was introduced.
Cisco IOS Release 15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines

Use the **client rekey encryption** command to specify the acceptable ciphers for KEK. Multiple ciphers can be specified. If a cipher is not set using this command, the cipher assigned by the key server is accepted.

Examples

The following example shows how to set the acceptable ciphers for KEK:

```
Router# configure terminal
Router(config)# crypto gdoi group GETVPN
Router(config-gdoi-group)# identity number 1111
Router(config-gdoi-group)# server address ipv4 192.10.2.10
Router(config-gdoi-group)# client rekey encryption 3des-cbc aes 192 aes 256
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group and enters GDOI group configuration mode.

client rekey hash

To set acceptable hash algorithms for rekey message signing, use the **client rekey hash** command in GDOI group configuration mode. To remove the acceptable hash algorithms, use the **no** form of this command.

client rekey hash *hash*

no client rekey hash

Syntax Description

hash	Hash for rekey message signing. The supported hash in Cisco IOS XE Release 2.4.1 is Secure Hash Standard (**sha**).

Command Default

Any hash selected by the key server is accepted.

Command Modes

GDOI group configuration (config-gdoi-group)

Command History

Release	Modification
Cisco IOS XE Release 2.4.1	This command was introduced.
Cisco IOS Release 15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines

Use the **client rekey hash** command to select the acceptable hash for the rekey message signing. If a hash is not set using this command, the hash selected by the key server is accepted.

Examples

The following example shows how to set the acceptable hash for rekey message signing:

```
Router# configure terminal
Router(config)# crypto gdoi group GETVPN
Router(config-gdoi-group)# identity number 1111
Router(config-gdoi-group)# server address ipv4 192.10.2.10
Router(config-gdoi-group)# client rekey hash sha
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group and enters GDOI group configuration mode.

client transform-sets

To specify up to 6 acceptable transform-set tags used by the traffic-encryption-key (TEK) for data encryption or authentication, use the **client transform-sets** command in GDOI group configuration mode. To remove the acceptable transform-set tags, use the **no** form of this command.

client transform-sets *transform-set-name1* [... [*transform-set-name6*]]

no client transform-sets

Syntax Description

transform-set-name	Transform-tags used by the TEK for data encryption or authentication.

Command Default

The transform-set selected by the key server is accepted.

Command Modes

GDOI group configuration (config-gdoi-group)

Command History

Release	Modification
Cisco IOS XE Release 2.4.1	This command was introduced.
Cisco IOS Release 15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines

Use the **client transform-sets** command to specify up to 6 transform-set tags used by the TEK for data encryption or authentication. If this command is not issued, the transform-set selected by the key server is accepted. The security protocol configured in the transform set must be Encapsulating Security Payload (ESP), which is the only protocol supported by GETVPN in Cisco IOS XE Release 2.4.1.

Examples

The following example shows how to set the transform-set tags used by TEK for data encryption or authentication:

```
Router# configure terminal
Router(config)# crypto ipsec transform-set g1 esp-aes 192 esp-sha-hmac
Router(cfg-crypto-trans)# exit
Router(config)# crypto gdoi group GETVPN
Router(config-gdoi-group)# client transform-sets g1
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group and enters GDOI group configuration mode.
crypto ipsec transform-set	Defines a transform set—an acceptable combination of security protocols and algorithms.

commands (view)

To add commands or an interface to a command-line interface (CLI) view, use the **commands** command in view configuration mode. To delete a command or an interface from a CLI view, use the **no** form of this command.

Syntax for Adding and Deleting Commands to a View

commands *parser-mode* {**include** | **include-exclusive** | **exclude**} [**all**] [*command*]

no commands *parser-mode* {**include** | **include-exclusive** | **exclude**} [**all**] [*command*]

Syntax for Adding and Deleting Interfaces to a View

commands *parser-mode* {**include** | **include-exclusive**} [**all**] [**interface** *name*] [*command*]

no commands *parser-mode* {**include** | **include-exclusive**} [**all**] [**interface** *name*] [*command*]

Syntax Description

parser-mode	Mode in which the specified command exists. See Table 19 in the "Usage Guidelines" section for a list of available options for this argument.
include	Adds a specified command or a specified interface to the view and allows the same command or interface to be added to a view.
include-exclusive	Adds a specified command or a specified interface to the view and excludes the same command or interface from being added to all other views.
exclude	Denies access to commands in the specified parser mode. **Note** This keyword is available only for command-based views.
all	(Optional) A "wildcard" that allows every command in a specified configuration mode that begins with the same keyword or every subinterface within a specified interface to be part of the view.
command	(Optional) Command that is added to the view. **Note** If no commands are specified, all commands within the specified parser mode are included or excluded, as appropriate.
interface *name*	(Optional) Interface that is added to the view.

Defaults

If this command is not enabled, a view will not have adequate information to deny or allow access to users.

Command Modes

View configuration (config-view)

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.3(11)T	The **exclude** keyword and the **interface** *interface-name* option were added.
12.2(33)SRB	This command was integrated into Cisco IOS Release 12.2(33)SRB.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

If a network administrator does not enter a specific command (via the *command* argument) or interface (via the **interface** *interface-name* option), users are granted access (via the **include** or **include-exclusive** keyword) or denied access (via the **exclude** keyword) to all commands within the specified parser mode.

parser-mode Options

Table 19 shows some of the keyword options for the *parser-mode* argument in the **commands** command. The available mode keywords vary depending on your hardware and software version. To display a list of available mode options on your system, use the **commands ?** command.

Table 19 parser-mode Argument Options

Command	Description
accept-dialin	VPDN accept-dialin group configuration mode
accept-dialout	VPDN accept-dialout group configuration mode
address-family	Address family configuration mode
alps-ascu	ALPS ASCU configuration mode
alps-circuit	ALPS circuit configuration mode
atm-bm-config	ATM bundle member configuration mode
atm-bundle-config	ATM bundle configuration mode
atm-vc-config	ATM virtual circuit configuration mode
atmsig_e164_table_mode	ATMSIG E164 Table
cascustom	Channel-associated signaling (cas) custom configuration mode
config-rtr-http	RTR HTTP raw request configuration mode
configure	Global configuration mode
controller	Controller configuration mode
crypto-map	Crypto map configuration mode
crypto-transform	Crypto transform configuration mode
dhcp	DHCP pool configuration mode
dspfarm	DSP farm configuration mode
exec	EXEC mode
flow-cache	Flow aggregation cache configuration mode
gateway	Gateway configuration mode

Table 19 parser-mode Argument Options (continued)

Command	Description
interface	Interface configuration mode
interface-dlci	Frame Relay DLCI configuration mode
ipenacl	IP named extended access-list configuration mode
ipsnacl	IP named simple access-list configuration mode
ip-vrf	Configure IP VRF parameters
lane	ATM Lan Emulation Lecs Configuration Table
line	Line configuration mode
map-class	Map-class configuration mode
map-list	Map-list configuration mode
mpoa-client	MPOA client
mpoa-server	MPOA server
null-interface	Null interface configuration mode
preaut	AAA Preauth definitions
request-dialin	VPDN accept-dialin group configuration mode
request-dialout	VPDN accept-dialout group configuration mode
route-map	Route-map configuration mode
router	Router configuration mode
rsvp_policy_local	RSVP local policy configuration mode
rtr	RTR entry configuration mode
sg-radius	RADIUS server group definition
sg-tacacs+	TACACS+ server group
sip-ua	SIP UA configuration mode
subscriber-policy	Subscriber policy configuration mode
tcl	Tcl mode
tdm-conn	TDM connection configuration mode
template	Template configuration mode
translation-rule	Translation Rule configuration mode
vc-class	VC class configuration mode
voiceclass	Voice class configuration mode
voiceport	Voice configuration mode
voipdialpeer	Dial peer configuration mode
vpdn-group	VPDN group configuration mode

Examples

The following example shows how to add the privileged EXEC command **show version** to both CLI views “first” and “second.” Because the **include** keyword was issued, the **show version** command can be added to both views.

```
Router(config)# parser view first
Router(config-view)# secret 5 secret
Router(config-view)# commands exec include show version
!
Router(config)# parser view second
Router(config-view)# secret 5 myview
Router(config-view)# commands exec include show version
```

The following example shows how to allow users in the view “first” to execute all commands that start with the word “show” except the **show interfaces** command, which is excluded by the view “second”:

```
Router(config)# parser view first
Router(config-view)# secret 5 secret
Router(config-view)# commands exec include all show
!
Router(config)# parser view second
Router(config-view)# secret 5 myview
Router(config-view)# commands exec include-exclusive show interfaces
```

Related Commands

Command	Description
parser view	Creates or changes a CLI view and enters view configuration mode.
secret 5	Associates a CLI view or a superview with a password.

configuration url

To specify on a server the URL that an Easy VPN remote device must use to get a configuration in a Mode Configuration Exchange, use the **configuration url** command in global configuration mode. To delete the URL, use the **no** form of this command.

configuration url {*url*}

no configuration url {*url*}

Syntax Description

url	Specifies the URL the Easy VPN remote device must use to get the configuration from the server. • The URL must be a non-NULL terminated ASCII string that specifies the complete path of the configuration file.

Command Default

An Easy VPN remote device cannot request a configuration from a server in a Mode Configuration Exchange.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

After the server "pushes" the URL to a Cisco Easy VPN remote device, the remote device can download the content located at the URL site and apply the configuration content to its running configuration.

Before this command can be configured, the **crypto isakmp client configuration group** command must already have been configured.

Examples

The file served by the configuration URL should have a Cisco IOS command-line interface(CLI) listing. The listing can have an optional "transient" section. The keyword to begin the transient section is "!%transient," and the keyword should be on a single line. A persistent section can be optionally identified by the keyword "!%persistent," also shown on a single line. An example of a CLI listing follows:

```
ip cef
cdp advertise-v2
!%transient
ip domain-name example.com
ntp server 10.2.3.4
```

```
ntp update-calendar
```

In the above example, the first two lines stay in the configuration even after the tunnel is disconnected (but they are not written into the nonvolatile configuration). The last three lines are effective only as long as the tunnel is "up."

The following example shows that a server has specified the URL the Easy VPN remote device must use to download the URL:

```
crypto isakmp client configuration group group1
 configuration url http://10.10.8.8/easy.cfg
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

configuration version

To specify on a server the version that a Cisco Easy VPN remote device must use to get a particular configuration in a Mode Configuration Exchange, use the **configuration version** command in global configuration mode. To delete the version number, use the **no** form of this command.

configuration version {*version-number*}

no configuration version {*version-number*}

Syntax Description

version-number	Specifies the version of the configuration. • The version number will be an unsigned integer in the range 1 through 32767.

Command Default

A version number is not sent.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

Before this command can be configured, the **crypto isakmp client configuration group** command must already have been configured.

Examples

The following example shows that a server has specified the version number a Cisco Easy VPN remote device must use to obtain that particular configuration version:

```
crypto isakmp client configuration group group1
 configuration version 10
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

content-length

To permit or deny HTTP traffic through the firewall on the basis of message size, use the **content-length** command in appfw-policy-http configuration mode. To remove message-size limitations from your configuration, use the **no** form of this command.

content-length {**min** *bytes* **max** *bytes* | **min** *bytes* | **max** *bytes*} **action** {**reset** | **allow**} [**alarm**]

no content-length {**min** *bytes* **max** *bytes* | **min** *bytes* | **max** *bytes*} **action** {**reset** | **allow**} [**alarm**]

Syntax Description

min *bytes*	Minimum content length, in bytes, allowed per message. Number of bytes range: 0 to 65535.
max *bytes*	Maximum content length, in bytes, allowed per message. Number of bytes range: 0 to 65535.
action	Messages whose size do not meet the minimum or exceed the maximum number of bytes are subject to the specified action (**reset** or **allow**).
reset	Sends a TCP reset notification to the client or server if the HTTP message fails the mode inspection.
allow	Forwards the packet through the firewall.
alarm	(Optional) Generates system logging (syslog) messages for the given action.

Defaults

If this command is not enabled, message size is not considered when permitting or denying HTTP messages.

Command Modes

appfw-policy-http configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

All messages exceeding the specified content-length range, will be subjected to the configured action (**reset** or **allow**).

Examples

The following example, which shows how to define the HTTP application firewall policy “mypolicy,” will not permit HTTP messages longer than 1 byte. This policy includes all supported HTTP policy rules. After the policy is defined, it is applied to the inspection rule “firewall,” which will inspect all HTTP traffic entering the FastEthernet0/0 interface.

```
! Define the HTTP policy.
appfw policy-name mypolicy
 application http
  strict-http action allow alarm
  content-length max 1 action allow alarm
  content-type-verification match-req-resp action allow alarm
```

```
  max-header-length request 1 response 1 action allow alarm
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc default action allow alarm
  request-method extension default action allow alarm
  transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
 ip inspect firewall in
!
!
```

content-type-verification

To permit or deny HTTP traffic through the firewall on the basis of content message type, use the **content-type-verification** command in appfw-policy-http configuration mode. To disable this inspection parameter, use the **no** form of this command.

content-type-verification [**match-req-resp**] **action** {**reset** | **allow**} [**alarm**]

no content-type-verification [**match-req-resp**] **action** {**reset** | **allow**} [**alarm**]

Syntax Description

match-req-resp	(Optional) Verifies the content type of the HTTP response against the accept field of the HTTP request.
action	Messages that match the specified content type are subject to the specified action (**reset** or **allow**).
reset	Sends a TCP reset notification to the client or server if the HTTP message fails the mode inspection.
allow	Forwards the packet through the firewall.
alarm	(Optional) Generates system logging (syslog) messages for the given action.

Defaults

If this command is not issued, all traffic will be allowed.

Command Modes

appfw-policy-http configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

After the **content-type-verification** command is issued, all HTTP messages are subjected to the following inspections:

- Verify that the content type of the message header is listed as a supported content type. (See Table 20.)
- Verify that the content type of the header matches the content of the message data or entity body portion of the message.

Table 20 contains a list of supported content types.

Table 20 HTTP Header Supported Content Types

Supported Content Types
video/mpeg
video/quicktime
video/sgi
video/x-avi
video/x-fli
video/x-mng
video/x-msvideo

The following example shows how to define the HTTP application firewall policy "mypolicy." This policy includes all supported HTTP policy rules. After the policy is defined, it is applied to the inspection rule "firewall," which will inspect all HTTP traffic entering the FastEthernet0/0 interface.

```
! Define the HTTP policy.
appfw policy-name mypolicy
 application http
  strict-http action allow alarm
  content-length max 1 action allow alarm
  content-type-verification match-req-resp action allow alarm
  max-header-length request 1 response 1 action allow alarm
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc default action allow alarm
  request-method extension default action allow alarm
  transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
 ip inspect firewall in
!
!
```

control

To configure the control interface type and number for a redundancy group, use the **control** command in redundancy application group configuration mode**.** To remove the control interface for the redundancy group, use the **no** form of this command.

control *interface-type interface-number* **protocol** *id*

no control

Syntax Description

interface-type	Interface type.
interface-number	Interface number.
protocol	Specifies redundancy group protocol media.
id	Redundancy group protocol instance. The range is from 1 to 8.

Command Default

The control interface is not configured.

Command Modes

Redundancy application group configuration (config-red-app-grp)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced.

Examples

The following example shows how to configure the redundancy group protocol media and instance for the control Gigabit Ethernet interface:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# application redundancy
Router(config-red-app)# group 1
Router(config-red-app-grp)# control GigabitEthernet 0/0/0 protocol 1
```

Related Commands

Command	Description
application redundancy	Enters redundancy application configuration mode.
authentication	Configures clear text authentication and MD5 authentication for a redundancy group.
data	Configures the data interface type and number for a redundancy group.
group(firewall)	Enters redundancy application group configuration mode.
name	Configures the redundancy group with a name.

Command	Description
preempt	Enables preemption on the redundancy group.
protocol	Defines a protocol instance in a redundancy group.

copy (consent-parameter-map)

To configure a consent page to be downloaded from a file server, use the **copy** command in parameter-map type consent configuration mode.

copy *src-file-name dst-file-name*

Syntax Description

src-file-name	Source file location in which the specified file will be retrieved. The source file location must be TFTP; for example, tftp://10.1.1.1/username/myfile.
dst-file-name	Destination location in which a copy of the file will be stored. The destination file should be copied to Flash; for example, flash.username.html.

Command Default

The consent page that is specified via the default parameter-map will be used.

Command Modes

Parameter-map-type consent (config-profile)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Use the **copy** command to transfer a file (consent web page) from an external server to a local file system on a device. Thus, the file name specified via the **copy** command is retrieved from the destination file location and displayed to the end user as the consent page.

When a consent webpage is displayed to an end user, the filename specified via the **file** command is used. If the file command is not configured, the destination location specified via the **copy** command is used.

Examples

In the following example, both parameter maps are to use the consent file "tftp://192.168.104.136/consent_page.html" and store it in "flash:consent_page.html":

```
parameter-map type consent consent_parameter_map
 copy tftp://192.168.104.136/consent_page.html flash:consent_page.html
 authorize accept identity consent_identity_policy
 timeout file download 35791
 file flash:consent_page.html
 logging enabled
 exit
!
parameter-map type consent default
 copy tftp://192.168.104.136/consent_page.html flash:consent_page.html
 authorize accept identity test_identity_policy
 timeout file download 35791
 file flash:consent_page.html
 logging enabled
 exit
!
```

Related Commands

Command	Description
file (consent-parameter-map)	Specifies a local filename that is to be used as the consent webpage.

copy idconf

To load a signature package in Cisco IOS Intrusion Prevention System (IPS), use the **copy idconf** command in EXEC mode.

copy *url* **idconf**

Syntax Description

url	Specifies the location from which the router loads the signature file. Available URL locations are as follows: • Local flash, such as flash:sig.xml • FTP server, such as ftp://myuser:mypass@ftp_server.sig.xml • rcp, such as rcp://myuser@rcp_server/sig.xml • TFTP server, such as tftp://tftp_server/sig.xml

Command Default

None

Command Modes

EXEC

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Use the **copy** *url* **idconf** command to load a signature package into Cisco IOS IPS. You may wish to load a new signature package into Cisco IOS IPS if a signature (or signatures) with the current signature file is not providing your network with adequate protection from security threats. After the signature package has been loaded into the router, Cisco IOS IPS saves all signature information to the location specified via the **ip ips config location** command.

Signatures are loaded into the scanning table on the basis of importance. Parameters such as signature severity, signature fidelity rating, and time lapsed since signatures were released enable Cisco IOS IPS to compile the most important signatures first, followed by less important signatures, thereby, creating a load order and prioritizing which signatures are loaded first.

Note The **copy** *url* **idconf** command replaces the **copy ips-sdf** command.

Examples

The following example shows how to load a signature package into Cisco IOS IPS from the location "flash:IOS-S258-CLI-kd.pkg":

```
Router# copy flash:IOS-S258-CLI-kd.pkg idconf
*Nov 14 2006 17:19:47 MST: %IPS-6-ENGINE_BUILDS_STARTED: 17:19:47 MST Nov 14 2006

Related Commands

Command	Description
ip ips config-location	Specifies the location in which the router will save signature information.

copy ips-sdf

Note In Cisco IOS Release 12.4(11)T, the **copy ips-sdf** command was replaced with the **copy idconf** command. For more information, see the **copy idconf** command.

To load or save the signature definition file (SDF) in the router, use the **copy ips-sdf** command in EXEC mode.

Syntax for Loading the SDF

copy [**/erase**] *url* **ips-sdf**

Syntax for Saving the SDF

copy ips-sdf *url*

Syntax Description

/erase	(Optional) Erases the current SDF in the router before loading the new SDF. **Note** This option is typically available only on platforms with limited memory.
url	Description for the *url* argument is one of the following options: • If you want to load the SDF in the router, the *url* argument specifies the location in which to search for the SDF. • If you are saving the SDF, the *url* argument represents the location in which the SDF is saved after it has been generated. Regardless of what option the URL is used for, available URL locations are as follows: • local flash, such as flash:sig.xml • FTP server, such as ftp://myuser:mypass@ftp_server.sig.xml • rcp, such as rcp://myuser@rcp_server/sig.xml • TFTP server, such as tftp://tftp_server/sig.xml

Command Modes

EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(11)T	This command was replaced with the **copy idconf** command.

Usage Guidelines

Loading Signatures From the SDF

Issue the **copy** *url* **ips-sdf** command to load the SDF in the router from the location specified via the *url* argument. When the new SDF is loaded, it is merged with the SDF that is already loaded in the router, unless the **/erase** keyword is issued, which overwrites the current SDF with the new SDF.

Cisco IOS Intrusion Prevention System (IPS) will attempt to retrieve the SDF from each specified location in the order in which they were configured in the startup configuration. If Cisco IOS IPS cannot retrieve the signatures from any of the specified locations, the built-in signatures will be used.

If the **no ip ips sdf built-in** command is used, Cisco IOS IPS will fail to load. IPS will then rely on the configuration of the **ip ips fail** command to either fail open or fail closed.

Note For Cisco IOS Release 12.3(8)T, the SDF should be loaded directly from Flash.

After the signatures are loaded in the router, the signature engines are built. Only after the signature engines are built can Cisco IOS IPS beginning scanning traffic.

Note Whenever signatures are replaced or merged, the router is suspended while the signature engines for the newly added or merged signatures are being built. The router prompt will be available again after the engines are built.

Depending on your platform and how many signatures are being loaded, building the engine can take up to several minutes. It is recommended that you enable logging messages to monitor the engine building status.

The **ip sdf ips location** command can also be used to load the SDF. However, unlike the **copy ips-sdf** command, this command does not force and immediately load the signatures. Signatures are not loaded until the router reboots or IPS is initially applied to an interface (via the **ip ips** command).

Saving a Generated or Merges SDF

Issue the **copy ips-sdf** *url* command to save a newly created SDF file to a specified location. The next time the router is reloaded, IPS can refer to the SDF from the saved location by including the **ip ips sdf location** command in the configuration.

Tip It is recommended that you save the SDF back out to Flash. Also, you should save the file to a different name than the original attack-drop.sdf file; otherwise, you risk loosing the original file.

Examples

The following example shows how to configure the router to load and merge the attack-drop.sdf file with the default signatures. After you have merged the two files, it is recommended to copy the newly merged signatures to a separate file. The router can then be reloaded (via the **reload** command) or reinitalized to so as to recognize the newly merged file (as shown the following example)

```
!
ip ips name MYIPS
!
interface GigabitEthernet0/1
 ip address 10.1.1.16 255.255.255.0
 ip ips MYIPS in
 duplex full
 speed 100
```

```
 media-type rj45
 no negotiation auto
!
!
! Merge the flash-based SDF (attack-drop.sdf) with the built-in signatures.
copy disk2:attack-drop.sdf ips-sdf
! Save the newly merged signatures to a separate file.
copy ips-sdf disk2:my-signatures.sdf
!
! Configure the router to use the new file, my-signatures.sdf
configure terminal
ip ips sdf location disk2:my-signatures.sdf
! Reinitialize the IPS by removing the IPS rule set and reapplying the rule set.
interface gig 0/1
 no ip ips MYIPS in
!
*Apr 8 14:05:38.243:%IPS-2-DISABLED:IPS removed from all interfaces - IPS disabled
!
 ip ips MYIPS in
!
 exit
```

Related Commands

Command	Description
ip ips sdf location	Specifies the location in which the router should load the SDF.

crl

To query the certificate revocation list (CRL) to ensure that the certificate of the peer has not been revoked, use the **crl** command in ca-trustpoint configuration mode. To return to the default behavior in which the router will check the URL that is embedded in the certificate, use the **no** form of this command.

crl {**query** *url* | **optional** | **best-effort**}

no crl {**query** *url* | **optional** | **best-effort**}

Syntax Description

query *url*	The Lightweight Directory Access Protocol (LDAP) URL published by the certification authority (CA) server is specified to query the CRL; for example, ldap://another_server.
optional	CRL verification is optional.
best-effort	CRL verification will be attempted, but if the CRL is unavailable, the certificate will be accepted.

Defaults

If the **query** *url* option is not enabled, the router will check the CRL distribution point (CDP) that is embedded in the certificate. The **query** *url* option does not need to be configured if the CDP that is in the certificate is formatted as a URL (for example, http:// url or ldap:// url), including the fully qualified domain name (FQDN) of the host where the CRL is held.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SX.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The query Keyword

Use the **query** *url* option if the CDP is in LDAP form, which means that the CDP location in the certificate will indicate only where the CDP is located in the directory; that is, the CDP will not indicate the actual query location for the directory.

The optional Keyword

If your router does not have the applicable CRL and is unable to obtain one, your router will reject the peer's certificate—unless you include the **optional** keyword in your configuration. If you use the **optional** keyword, your router will check the CRL if it is cached in the router memory, but it will not download the CRL from the CDP. If the **optional** keyword is configured and a CRL is not available, the certificate will always be accepted. If the **crl optional** command is configured, you cannot manually download the CRL via the **crypto ca crl request** command because the manually downloaded CRL may not be deleted after it expires. The expired CRL may cause all certificate verifications to be denied.

The best-effort Keyword

If you prefer to have the CRL checked and accept certificates if the CRL is not available, use the **best-effort** keyword. This keyword allows the router to attempt to retrieve the CRL from the CDP that is contained in the certificate (or from a different location that is specified via the **crl query** *url* command). However, if the CRL is not available, the router will accept the certificate if it is presented within its validity period and if the certificate was issued by a trusted CA.

Note The **crypto ca trustpoint** command deprecates the **crypto ca identity** and **crypto ca trusted-root** commands and all related subcommands (all ca-identity and trusted-root configuration mode commands). If you enter a ca-identity or trusted-root subcommand, the configuration mode and command will be written back as ca-trustpoint.

Examples

The following example shows how to configure your router to query the CRL with the LDAP URL that is published by the CA named "bar":

```
crypto ca trustpoint bar
 enrollment url http://bar.cisco.com
 crl query ldap://bar.cisco.com
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.

crl best-effort

Note Effective with Cisco IOS Release 12.3(2)T, this command was replaced by the **revocation-check** command.

To download the certificate revocation list (CRL) but accept certificates if the CRL is not available, use the **crl best-effort** command in ca-identity configuration mode. To return to the default behavior in which CRL checking is mandatory before your router can accept a certificate, use the **no** form of this command.

Syntax Description

This command has no arguments or keywords.

Defaults

If this command is not configured, CRL checking is mandatory before your router can accept a certificate. That is, if CRL downloading is attempted and it fails, the certificate will be considered invalid and will be rejected.

Command Modes

Ca-identity configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.3(2)T	This command was replaced by the **revocation-check** command.

Usage Guidelines

When your router receives a certificate from a peer, it will search its memory for the appropriate CRL. If the appropriate CRL is in the router memory, the CRL will be used. Otherwise, the router will download the CRL from either the certificate authority (CA) or from a CRL distribution point (CDP) as designated in the certificate of the peer. Your router will then check the CRL to ensure that the certificate that the peer sent has not been revoked. (If the certificate appears on the CRL, your router will not accept the certificate and will not authenticate the peer.)

When a CA system uses multiple CRLs, the certificate of the peer will indicate which CRL applies in its CDP extension and should be downloaded by your router.

If your router does not have the applicable CRL in memory and is unable to obtain one, your router will reject the certificate of the peer—unless you include the **crl best-effort** command in your configuration. When the **crl best-effort** command is configured, your router will try to obtain a CRL, but if it cannot obtain a CRL, it will treat the certificate of the peer as not revoked.

When your router receives additional certificates from peers, the router will continue to attempt to download the appropriate CRL if it was previously unsuccessful. The **crl best-effort** command specifies only that when the router cannot obtain the CRL, the router will not be forced to reject the certificate of a peer.

Examples

The following configuration example declares a CA and permits your router to accept certificates when CRLs are not obtainable:

```
crypto ca identity myid
enrollment url http://mycaserver
crl best-effort
```

Related Commands

Command	Description
crypto ca identity	Declares the CA your router should use.

crl optional

Note Effective with Cisco IOS Release 12.3(2)T, this command was replaced by the **revocation-check** command.

To allow the certificates of other peers to be accepted without trying to obtain the appropriate CRL, use the **crl optional** command in ca-identity configuration mode. To return to the default behavior in which CRL checking is mandatory before your router can accept a certificate, use the **no** form of this command.

crl optional

no crl optional

Syntax Description

This command has no arguments or keywords.

Defaults

The router must have and check the appropriate CRL before accepting the certificate of another IP Security peer.

Command Modes

Ca-identity configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.3(2)T	This command was replaced by the **revocation-check** command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When your router receives a certificate from a peer, it will search its memory for the appropriate CRL. If the router finds the appropriate CRL, that CRL will be used. Otherwise, the router will download the CRL from either the certificate authority (CA) or from a CRL distribution point (CDP) as designated in the certificate of the peer. Your router will then check the CRL to ensure that the certificate that the peer sent has not been revoked. (If the certificate appears on the CRL, your router will not accept the certificate and will not authenticate the peer.) To instruct the router not to download the CRL and treat the certificate as not revoked, use the **crl optional** command.

Note If the CRL already exists in the memory (for example, by using the **crypto ca crl request** command to manually download the CRL), the CRL will still be checked even if the **crl optional** command is configured.

Examples

The following example declares a CA and permits your router to accept certificates without trying to obtain a CRL. This example also specifies a nonstandard retry period and retry count.

```
crypto ca identity myca
 enrollment url http://ca_server
 enrollment retry-period 20
 enrollment retry-count 100
 crl optional
```

Related Commands

Command	Description
crypto ca identity	Declares the CA your router should use.

crl query

If you have to query the certificate revocation list (CRL) to ensure that the certificate of the peer has not been revoked and you have to provide the Lightweight Directory Access Protocol (LDAP) server information, use the **crl query** command in ca-trustpoint configuration mode. To return to the default behavior, assuming that the CRL distribution point (CDP) has a complete LDAP URL, use **no** form of this command.

crl query ldap://*hostname***:**[*port*]

no crl query ldap://*hostname***:**[*port*]

Syntax Description

ldap://*hostname*	Query is made to the hostname of the LDAP server that serves the CRL for the certification authority (CA) server (for example, ldap://myldap.cisco.com).
:*port*	(Optional) Port number of the LDAP server (for example, ldap://myldap.cisco.com:3899).

Defaults

Not enabled. If **crl query ldap://***hostname***:**[*port*] is not enabled, the router assumes that the CDP that is embedded in the certificate is a complete URL (for example, ldap:myldap.cisco.com/CN=myCA,O=Cisco) and uses it to download the CRL.

If the port number is not configured, the default LDAP server port 389 will be used.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(8)T	This command replaced the **query url** command.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

When Cisco IOS software tries to verify a peer certificate (for example, during Internet Key Exchange [IKE] or Secure Sockets Layer [SSL] handshake), it queries the CRL to ensure that the certificate has not been revoked. To locate the CRL, it first looks for the CDP extension in the certificate. If the extension exists, it is used to download the CRL. Otherwise, the Simple Certificate Enrollment Protocol (SCEP) GetCRL mechanism is used to query the CRL from the CA server directly (some CA servers do not support this method).

Cisco IOS software supports three types of CDP:

- HTTP URL (Example1: http://10.10.10.10:81/myca.crl)
- LDAP URL (Example 2: ldap://10.10.10.10:3899/CN=myca, O=cisco or Example 3: ldap:///CN=myca, O=cisco)
- LDAP/X.500 DN (Example 4: CN=myca, O=cisco)

To locate the CRL, a complete URL needs to be formed. As a result, Example 3 and Example 4 still require the hostname and the port number. The **ldap://***hostname***:**[*port*} keywords and arguments are used to provide this information.

Note The **crypto ca trustpoint** command replaces the **crypto ca identity** and **crypto ca trusted-root** commands and all related subcommands (all ca-identity and trusted-root configuration mode commands). If you enter a ca-identity or trusted-root subcommand, the configuration mode and command will be written back as ca-trustpoint.

Examples

The following example shows how to configure your router to query the CRL with the LDAP URL that is published by the CA named "bar":

```
crypto ca trustpoint mytp
 enrollment url http://bar.cisco.com
 crl query ldap://bar.cisco.com:3899
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.
revocation-check	Checks the revocation status of a certificate.

crl-cache delete-after

To configure the maximum time a router will cache a certificate revocation list (CRL), use the **crl-cache delete-after** command in ca-trustpoint configuration mode. To enable default CRL caching, use the **no** form of this command.

crl-cache delete-after *time*

no crl-cache delete-after *time*

Syntax Description

time	The maximum lifetime of a CRL in minutes.

Command Default

A CRL is deleted from the cache when the CRL default lifetime expires.

Command Modes

Ca-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.4(9)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

Use this command to limit the amount of time a router will cache a CRL. You may use the **crl-cache delete-after** command to force a router to download a CRL before the existing CRL expires by configuring a value shorter than the default lifetime of the CRL.

By default, a new CRL will be downloaded after the currently cached CRL expires. The **crl-cache delete-after** command does not effect any currently cached CRLs. The configured lifetime will only effect CRLs downloaded after this command is configured.

When the maximum CRL time expires, the cached CRL will be deleted from the router cache. A new copy of the CRL will be downloaded from the issuing certificate authority (CA) the next time the router has to validate a certificate.

Note Only the **crl-cache none** command or the **crl-cache delete-after** command may be specified. If both commands are entered for a trustpoint, the last command executed will take effect and a message will be displayed to the user.

Examples

The following example shows how to configure a maximum lifetime of 2 minutes for all CRLs associated with the CA1 trustpoint:

```
crypto pki trustpoint CA1
 enrollment url http://CA1:80
 ip-address FastEthernet0/0
 crl query ldap://ldap_CA1
```

```
 revocation-check crl
 crl-cache delete-after 2
```

The current CRL is still cached immediately after executing the example configuration shown above:

```
Router# show crypto pki crls

CRL Issuer Name:
    cn=name Cert Manager,ou=pki,o=company.com,c=US
    LastUpdate: 18:57:42 GMT Nov 26 2005
    NextUpdate: 22:57:42 GMT Nov 26 2005
    Retrieved from CRL Distribution Point:
      ldap://ldap.company.com/CN=name Cert Manager,O=company.com
```

When the current CRL expires, a new CRL is then downloaded to the router at the NextUpdate time and the **crl-cache delete-after** command takes effect. This newly cached CRL and all subsequent CRLs will be deleted after a maximum lifetime of 2 minutes.

You can verify that the CRL will be cached for 2 minutes by executing the **show crypto pki crls** command. Note that the NextUpdate time is 2 minutes after the LastUpdate time.

```
Router# show crypto pki crls

CRL Issuer Name:
    cn=name Cert Manager,ou=pki,o=company.com,c=US
    LastUpdate: 22:57:42 GMT Nov 26 2005
    NextUpdate: 22:59:42 GMT Nov 26 2005
    Retrieved from CRL Distribution Point:
      ldap://ldap.company.com/CN=name Cert Manager,O=company.com
```

Related Commands

Command	Description
crl-cache none	Disables CRL caching.

crl-cache none

To disable certificate revocation list (CRL) caching, use the **crl-cache none** command in ca-trustpoint configuration mode. To enable default CRL caching, use the **no** form of this command.

crl-cache none

no crl-cache none

Syntax Description

This command has no arguments or keywords.

Command Default

CRL caching is enabled.

Command Modes

Ca-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.4(9)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

Use this command to disable CRL caching for all CRLs associated with a trustpoint. By default, a new CRL is issued when the currently cached CRL expires.

The **crl-cache none** command does not effect any currently cached CRLs. All CRLs downloaded after this command is configured will not be cached.

This functionality is useful is when a certification authority (CA) issues CRLs with no expiration date or with expiration dates far into the future–days or weeks.

Note Only the **crl-cache none** command or the **crl-cache delete-after** command may be specified. If both commands are entered for a trustpoint, the last command executed will take effect and a message will be displayed.

Examples

The following example shows how to disable CRL caching for all CRLs associated with the CA1 trustpoint:

```
crypto pki trustpoint CA1
 enrollment url http://CA1:80
 ip-address FastEthernet0/0
 crl query ldap://ldap_CA1
 revocation-check crl
 crl-cache none
```

The current CRL is still cached immediately after executing the example configuration shown above:

```
Router# show crypto pki crls

CRL Issuer Name:
    cn=name Cert Manager,ou=pki,o=company.com,c=US
    LastUpdate: 18:57:42 GMT Nov 26 2005
    NextUpdate: 22:57:42 GMT Nov 26 2005
    Retrieved from CRL Distribution Point:
      ldap://ldap.company.com/CN=name Cert Manager,O=company.com
```

When the current CRL expires, a new CRL is then downloaded to the router at the NextUpdate time. The **crl-cache none** command takes effect and all CRLs for the trustpoint are no longer cached; caching is disabled. You can verify that no CRL is cached by executing the **show crypto pki crls** command. No output will be shown because there are no CRLs cached.

Related Commands

Command	Description
crl-cache delete-after	Configures the maximum lifetime of a CRL.

crypto aaa attribute list

To define an authentication, authorization, and accounting (AAA) attribute list of per-user attributes on a local Easy VPN server, use the **crypto aaa attribute list** command in crypto isakmp group configuration mode. To remove the AAA attribute list, use the **no** form of this command.

crypto aaa attribute list *list-name*

no crypto aaa attribute list *list-name*

Syntax Description

list-name	Name of the local attribute list.

Command Default

A local attribute list is not defined.

Command Modes

Crypto isakmp group configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

There is no limit to the number of lists that can be defined (except for NVRAM storage limits).

Examples

The following example shows that per-user attributes have been defined on a local Easy VPN AAA server:

```
!

aaa new-model
!
!
aaa authentication login default local
aaa authentication login noAAA none
aaa authorization network default local
!
aaa attribute list per-group
 attribute type inacl "per-group-acl" service ike protocol ip mandatory
!
aaa session-id common
!
resource policy
!
ip subnet-zero
!
!
ip cef
!
!
username example password 0 example
!
```

```
!
crypto isakmp policy 3
 authentication pre-share
 group 2
crypto isakmp xauth timeout 90
!
crypto isakmp client configuration group PerUserAAA
 key cisco
 pool dpool

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

crypto ca authenticate

Note This command was replaced by the **crypto pki authenticate** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To authenticate the certification authority (by getting the certificate of the CA), use the **crypto ca authenticate** command in global configuration mode.

crypto ca authenticate *name*

Syntax Description

name	Specifies the name of the CA. This is the same name used when the CA was declared with the **crypto ca identity** command.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.

Usage Guidelines

This command is required when you initially configure CA support at your router.

This command authenticates the CA to your router by obtaining the self-signed certificate of the CA that contains the public key of the CA. Because the CA signs its own certificate, you should manually authenticate the public key of the CA by contacting the CA administrator when you perform this command.

If you are using RA mode (using the **enrollment mode ra** command) when you issue the **crypto ca authenticate** command, then registration authority signing and encryption certificates will be returned from the CA as well as the CA certificate.

This command is not saved to the router configuration. However. the public keys embedded in the received CA (and RA) certificates are saved to the configuration as part of the RSA public key record (called the "RSA public key chain").

Note If the CA does not respond by a timeout period after this command is issued, the terminal control will be returned so it will not be tied up. If this happens, you must re-enter the command. Cisco IOS software will not recognize CA certificate expiration dates set for beyond the year 2049. If the validity period of the CA certificate is set to expire after the year 2049, the following error message will be displayed when authentication with the CA server is attempted:

```
error retrieving certificate :incomplete chain
```

If you receive an error message similar to this one, check the expiration date of your CA certificate. If the expiration date of your CA certificate is set after the year 2049, you must reduce the expiration date by a year or more.

Examples

In the following example, the router requests the certificate of the CA. The CA sends its certificate and the router prompts the administrator to verify the certificate of the CA by checking the CA certificate's fingerprint. The CA administrator can also view the CA certificate's fingerprint, so you should compare what the CA administrator sees to what the router displays on the screen. If the fingerprint on the router's screen matches the fingerprint viewed by the CA administrator, you should accept the certificate as valid.

```
Router(config)# crypto ca authenticate myca
Certificate has the following attributes:
Fingerprint: 0123 4567 89AB CDEF 0123
Do you accept this certificate? [yes/no] y#
```

Related Commands

Command	Description
debug crypto pki transactions	Displays debug messages for the trace of interaction (message type) between the CA and the router.
show crypto pki certificates	Displays information about your certificate, the certificate of the CA, and any RA certificates.

crypto ca cert validate

Note This command was replaced by the **crypto pki cert validate** command effective with Cisco IOS Release 12.3(8)T and 12.2(18)SXE.

To determine if a trustpoint has been successfully authenticated, a certificate has been requested and granted, and if the certificate is currently valid, use the **crypto ca cert validate** command in global configuration mode.

crypto ca cert validate *trustpoint*

Syntax Description

trustpoint	The trustpoint to be validated.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

The **crypto ca cert validate** command validates the router's own certificate for a given trustpoint. Use this command as a sanity check after enrollment to verify that the trustpoint is properly authenticated, a certificate has been requested and granted for the trustpoint, and that the certificate is currently valid. A certificate is valid if it is signed by the trustpoint certification authority (CA), not expired, and so on.

Examples

The following examples show the possible output from the **crypto ca cert validate** command:

```
Router(config)# crypto ca cert validate ka

Validation Failed: trustpoint not found for ka

Router(config)# crypto ca cert validate ka

Validation Failed: can't get local certificate chain

Router(config)# crypto ca cert validate ka

Certificate chain has 2 certificates.
Certificate chain for ka is valid

Router(config)# crypto ca cert validate ka
```

```
Certificate chain has 2 certificates.
Validation Error: no certs on chain

Router(config)# crypto ca cert validate ka

Certificate chain has 2 certificates.
Validation Error: unspecified error
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the certification authority that the router should use.
show crypto pki trustpoints	Displays the trustpoints that are configured in the router.

crypto ca certificate chain

Note This command was replaced by the **crypto pki certificate chain** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To enter the certificate chain configuration mode, use the **crypto ca certificate chain** command in global configuration mode. (You need to be in certificate chain configuration mode to delete certificates.)

crypto ca certificate chain *name*

Syntax Description

name	Specifies the name of the CA. Use the same name as when you declared the CA using the **crypto pki trustpoint** command.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.

Usage Guidelines

This command puts you into certificate chain configuration mode. When you are in certificate chain configuration mode, you can delete certificates using the **certificate** command.

Examples

The following example deletes the router's certificate. In this example, the router had a general-purpose RSA key pair with one corresponding certificate. The show command is used to determine the serial number of the certificate to be deleted.

```
Router# show crypto ca certificates

Certificate
  Subject Name
    Name: myrouter.example.com
    IP Address: 10.0.0.1
  Status: Available
  Certificate Serial Number: 0123456789ABCDEF0123456789ABCDEF
  Key Usage: General Purpose

CA Certificate
  Status: Available
  Certificate Serial Number: 3051DF7123BEE31B8341DFE4B3A338E5F
  Key Usage: Not Set

Router# configure terminal
Rrouter(config)# crypto ca certificate chain myca
Router(config-cert-chain)# no certificate 0123456789ABCDEF0123456789ABCDEF
```

```
% Are you sure you want to remove the certificate [yes/no]? yes
% Be sure to ask the CA administrator to revoke this certificate.
Router(config-cert-chain)# exit
```

Related Commands

Command	Description
certificate	Adds certificates manually.

crypto ca certificate map

Note This command was replaced by the **crypto pki certificate map** command effective with Cisco IOS Release 12.3(7)T, 12.2(18)SXD, and 12.2(18)SXE.

To define certificate-based access control lists (ACLs), use the **crypto ca certificate map** command in ca-certificate-map configuration mode. To remove the certificate-based ACLs, use the **no** form of this command.

crypto ca certificate map *label sequence-number*

no crypto ca certificate map *label sequence-number*

Syntax Description

label	A user-specified label that is referenced within the **crypto ca trustpoint** command.
sequence-number	A number that orders the ACLs with the same label. ACLs with the same label are processed from lowest to highest sequence number. When an ACL is matched, processing stops with a successful result.

Defaults

No default behavior or value.

Command Modes

Ca-certificate-map configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

Issuing this command places the router in CA certificate map configuration mode where you can specify several certificate fields together with their matching criteria. The general form of these fields is as follows:

```
field-name match-criteria match-value
```

The *field-name* in the above example is one of the certificate fields. Field names are similar to the names used in the International Telecommunication Union Telecommunication Standardization Sector (ITU-T) X.509 standard. The **name** field is a special field that matches any subject name or related name field in the certificate, such as the **alt-subject-name**, **subject-name**, and **unstructured-subject-name** fields.

- **alt-subject-name**—Case-insensitive string.
- **expires-on**—Date field in the format dd mm yyyy hh:mm:ss or mmm dd yyyy hh:mm:ss.
- **issuer-name**—Case-insensitive string.
- **name**—Case-insensitive string.
- **subject-name**—Case-insensitive string.

- **unstructured-subject-name**—Case-insensitive string.
- **valid-start**—Date field in the format dd mm yyyy hh:mm:ss or mmm dd yyyy hh:mm:ss.

Note The time portion is optional in both the **expires-on** date and **valid-start** field and defaults to 00:00:00 if not specified. The time is interpreted according to the time zone offset configured for the router. The string **utc** can be appended to the date and time when they are configured as Universal Time, Coordinated (UTC) rather than local time.

The *match-criteria* in the example is one of the following logical operators:

- **eq**—equal (valid for name and date fields)
- **ne**—not equal (valid for name and date fields)
- **co**—contains (valid only for name fields)
- **nc**—does not contain (valid only for name fields)
- **lt**—less than (valid only for date fields)
- **ge**—greater than or equal to (valid only for date fields)

The *match-value* is a case-insensitive string or a date.

Examples

The following example shows how to configure a certificate-based ACL that will allow any certificate issued by Cisco Systems to an entity within the cisco.com domain. The label is Cisco, and the sequence is 10.

```
crypto ca certificate map Cisco 10
 issuer-name co Cisco Systems
 unstructured-subject-name co cisco.com
```

The following example accepts any certificate issued by Cisco Systems for an entity with DIAL or organizationUnit component ou=WAN. This certificate-based ACL consists of two separate ACLs tied together with the common label Group. Because the check for DIAL has a lower sequence number, it is performed first. Note that the string “DIAL” can occur anywhere in the subjectName field of the certificate, but the string WAN must be in the organizationUnit component.

```
crypto ca certificate map Group 10
 issuer-name co Cisco Systems
 subject-name co DIAL
crypto ca certificate map Group 20
 issuer-name co Cisco Systems
 subject-name co ou=WAN
```

Case is ignored in string comparisons; therefore, DIAL in the previous example will match dial, DIAL, Dial, and so on. Also note that the component identifiers (o=, ou=, cn=, and so on) are not required unless it is desirable that the string to be matched occurs in a specific component of the name. (Refer to the ITU-T security standards for more information about certificate fields and components such as ou=.)

If a component identifier is specified in the match string, the exact string, including the component identifier, must appear in the certificate. This requirement can present a problem if more than one component identifier is included in the match string. For example, “ou=WAN,o=Cisco Systems” will not match a certificate with the string “ou=WAN,ou=Engineering,o=Cisco Systems” because the “ou=Engineering” string separates the two desired component identifiers.

To match both “ou=WAN” and “o=Cisco Systems” in a certificate while ignoring other component identifiers, you could use this certificate map:

```
crypto ca certificate map Group 10
 subject-name co ou=WAN
 subject-name co o=Cisco
```

Any space character proceeding or following the equal sign (=) character in component identifiers is ignored. Therefore “o=Cisco” in the proceeding example will match “o = Cisco,” “o= Cisco,” “o =Cisco,” and so on.

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.

crypto ca certificate query (ca-trustpoint)

Note This command was replaced by the **crypto pki certificate query** (**ca-trustpoint**) command effective with Cisco IOS Release 12.3(7)T, 12.2(18)SXD, and 12.2(18)SXE.

To specify that certificates should not be stored locally but retrieved from a certification authority (CA) trustpoint, use the **crypto ca certificate query** command in ca-trustpoint configuration mode. To cause certificates to be stored locally per trustpoint, use the **no** form of this command.

crypto ca certificate query

no crypto ca certificate query

Syntax Description

This command has no arguments or keywords.

Defaults

CA trustpoints are stored locally in the router's NVRAM.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.

Usage Guidelines

Normally, certain certificates are stored locally in the router's NVRAM, and each certificate uses a moderate amount of memory. To save NVRAM space, you can use this command to put the router into query mode, preventing certificates from being stored locally; instead, they are retrieved from a specified CA trustpoint when needed. This will save NVRAM space but could result in a slight performance impact.

The **crypto ca certificate query** command is a subcommand for each trustpoint; thus, this command can be disabled on a per-trustpoint basis.

Before you can configure this command, you must enable the **crypto pki trustpoint** command, which puts you in ca-trustpoint configuration mode.

Note This command replaces the **crypto ca certificate query** command in global configuration mode. Although you can still enter the global configuration command, the configuration mode and command will be written back as ca-trustpoint.

Examples

The following example shows how to prevent certificates and certificate revocation lists (CRLs) from being stored locally on the router; instead, they are retrieved from the "ka" trustpoint when needed.

```
crypto ca trustpoint ka
```

```
.
.
.
crypto ca certificate query
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.

crypto ca certificate query (global)

The **crypto ca certificate query** command in global configuration mode is replaced by the **crypto ca certificate query** command in ca-trustpoint configuration mode. See the **crypto ca certificate query** command for more information.

crypto ca crl request

Note Effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE, this command was replaced by the **crypto pki crl request** command.

To request that a new certificate revocation list (CRL) be obtained immediately from the certification authority, use the **crypto ca crl request** command in global configuration mode.

crypto ca crl request *name*

Syntax Description

name	Specifies the name of the CA. This is the same name used when the CA was declared with the **crypto pki trustpoint** command.

Defaults

Normally, the router requests a new CRL when it is verifying a certificate and there is no CRL cached.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.3(7)T	This command was replaced by the **crypto pki crl request** command.

Usage Guidelines

A CRL lists all the certificates of the network device that have been revoked. Revoked certificates will not be honored by your router; therefore, any IPSec device with a revoked certificate cannot exchange IP Security traffic with your router.

The first time your router receives a certificate from a peer, it will download a CRL from the CA. Your router then checks the CRL to make sure the certificate of the peer has not been revoked. (If the certificate appears on the CRL, it will not accept the certificate and will not authenticate the peer.)

A CRL can be reused with subsequent certificates until the CRL expires. If your router receives the certificate of a peer after the applicable CRL has expired, it will download the new CRL.

If your router has a CRL which has not yet expired, but you suspect that the contents of the CRL are out of date, use the **crypto ca crl request** command to request that the latest CRL be immediately downloaded to replace the old CRL.

This command is not saved to the configuration.

Note This command should be used only after the trustpoint is enrolled.

Examples

The following example immediately downloads the latest CRL to your router:

```
crypto ca crl request
```

crypto ca enroll

Note This command was replaced by the **crypto pki enroll** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To obtain the certificate(s) of your router from the certification authority, use the **crypto ca enroll** command in global configuration mode. To delete a current enrollment request, use the **no** form of this command.

crypto ca enroll *name*

no crypto ca enroll *name*

Syntax Description

name	Specifies the name of the CA. Use the same name as when you declared the CA using the **crypto pki trustpoint** command.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.

Usage Guidelines

This command requests certificates from the CA for all of your router's RSA key pairs. This task is also known as enrolling with the CA. (Technically, enrolling and obtaining certificates are two separate events, but they both occur when this command is issued.)

Your router needs a signed certificate from the CA for each RSA key pairs of your router; if you previously generated general purpose keys, this command will obtain the one certificate corresponding to the one general purpose RSA key pair. If you previously generated special usage keys, this command will obtain two certificates corresponding to each of the special usage RSA key pairs.

If you already have a certificate for your keys you will be unable to complete this command; instead, you will be prompted to remove the existing certificate first. (You can remove existing certificates with the **no certificate** command.)

The **crypto ca enroll** command is not saved in the router configuration.

Note If your router reboots after you issue the **crypto ca enroll** command but before you receive the certificate(s), you must reissue the command.

Responding to Prompts

When you issue the **crypto ca enroll** command, you are prompted a number of times.

First, you are prompted to create a challenge password. This password can be up to 80 characters in length. This password is necessary in the event that you ever need to revoke your router's certificate(s). When you ask the CA administrator to revoke your certificate, you must supply this challenge password as a protection against fraudulent or mistaken revocation requests.

Note This password is not stored anywhere, so you need to remember this password.

If you lose the password, the CA administrator may still be able to revoke the router's certificate but will require further manual authentication of the router administrator identity.

You are also prompted to indicate whether or not your router's serial number should be included in the obtained certificate. The serial number is not used by IP Security or Internet Key Exchange but may be used by the CA to either authenticate certificates or to later associate a certificate with a particular router. (Note that the serial number stored is the serial number of the internal board, not the one on the enclosure.) Ask your CA administrator if serial numbers should be included. If you are in doubt, include the serial number.

Normally, you would not include the IP address because the IP address binds the certificate more tightly to a specific entity. Also, if the router is moved, you would need to issue a new certificate. Finally, a router has multiple IP addresses, any of which might be used with IPSec.

If you indicate that the IP address should be included, you will then be prompted to specify the interface of the IP address. This interface should correspond to the interface that you apply your crypto map set to. If you apply crypto map sets to more than one interface, specify the interface that you name in the **crypto map local-address** command.

Examples

In the following example, a router with a general-purpose RSA key pair requests a certificate from the CA. When the router displays the certificate fingerprint, the administrator verifies this number by calling the CA administrator, who checks the number. The fingerprint is correct, so the router administrator accepts the certificate.

There can be a delay between when the router administrator sends the request and when the certificate is actually received by the router. The amount of delay depends on the CA method of operation.

```
Router(config)# crypto ca enroll myca
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this
   password to the CA Administrator in order to revoke your certificate.
   For security reasons your password will not be saved in the configuration.
   Please make a note of it.

Password: <mypassword>
Re-enter password: <mypassword>

% The subject name in the certificate will be: myrouter.example.com
% Include the router serial number in the subject name? [yes/no]: yes
% The serial number in the certificate will be: 03433678
% Include an IP address in the subject name [yes/no]? yes
Interface: ethernet0/0
Request certificate from CA [yes/no]? yes
% Certificate request sent to Certificate Authority
% The certificate request fingerprint will be displayed.
% The 'show crypto pki certificates' command will also show the fingerprint.
```

Some time later, the router receives the certificate from the CA and displays the following confirmation message:

```
Router(config)#   Fingerprint: 01234567 89ABCDEF FEDCBA98 75543210

%CRYPTO-6-CERTRET: Certificate received from Certificate Authority

Router(config)#
```

If necessary, the router administrator can verify the displayed Fingerprint with the CA administrator.

If there is a problem with the certificate request and the certificate is not granted, the following message is displayed on the console instead:

```
%CRYPTO-6-CERTREJ: Certificate enrollment request was rejected by Certificate Authority
```

The subject name in the certificate is automatically assigned to be the same as the RSA key pair's name. In the above example, the RSA key pair was named "myrouter.example.com." (The router assigned this name.)

Requesting certificates for a router with special usage keys would be the same as the previous example, except that two certificates would have been returned by the CA. When the router received the two certificates, the router would have displayed the same confirmation message:

```
%CRYPTO-6-CERTRET: Certificate received from Certificate Authority
```

Related Commands

Command	Description
debug crypto pki messages	Displays debug messages for the details of the interaction (message dump) between the CA and the router.
debug crypto pki transactions	Displays debug messages for the trace of interaction (message type) between the CA and the router.
show crypto pki certificates	Displays information about your certificate, the certificate of the CA, and any RA certificates.

crypto ca export pem

Note This command was replaced by the **crypto pki export pem** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To export certificates and Rivest, Shamir, and Adelman (RSA) keys that are associated with a trustpoint in a privacy-enhanced mail (PEM)-formatted file, use the **crypto ca export pem** command in global configuration mode.

crypto ca export *trustpoint* **pem** {**terminal** | **url** *url*} {**3des** | **des**} *passphrase*

Syntax Description

trustpoint	Name of the trustpoint that the associated certificate and RSA key pair will export. The *trustpoint* argument must match the name that was specified via the **crypto pki trustpoint** command.
terminal	Certificate and RSA key pair that will be displayed in PEM format on the console terminal.
url *url*	URL of the file system where your router should export the certificate and RSA key pairs.
3des	Export the trustpoint using the Triple Data Encryption Standard (3DES) encryption algorithm.
des	Export the trustpoint using the DES encryption algorithm.
passphrase	Passphrase that is used to encrypt the PEM file for import. **Note** The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

The **crypto ca export pem** command allows you to export certificate and RSA key pairs in PEM-formatted files. The PEM files can then be imported back into the Cisco IOS router (via the **crypto pki import pem** command) or other public key infrastructure (PKI) applications.

Examples

The following example shows how to generate and export the RSA key pair "aaa" and certificates of the router in PEM files that are associated with the trustpoint "mycs":

```
Router(config)# crypto key generate rsa general-keys label aaa exportable
The name for the keys will be:aaa
Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose
Keys. Choosing a key modulus greater than 512 may take a few minutes.
!
How many bits in the modulus [512]:
% Generating 512 bit RSA keys ...[OK]
!
Router(config)# crypto pki trustpoint mycs
Router(ca-trustpoint)# enrollment url http://mycs
Router(ca-trustpoint)# rsakeypair aaa
Router(ca-trustpoint)# exit
Router(config)# crypto pki authenticate mycs
Certificate has the following attributes:
Fingerprint:C21514AC 12815946 09F635ED FBB6CF31
% Do you accept this certificate? [yes/no]:y
Trustpoint CA certificate accepted.
!
Router(config)# crypto pki enroll mycs
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this password to the CA
Administrator in order to revoke your certificate.
For security reasons your password will not be saved in the configuration.
Please make a note of it.

Password:
Re-enter password:

% The fully-qualified domain name in the certificate will be:Router
% The subject name in the certificate will be:bizarro.cisco.com
% Include the router serial number in the subject name? [yes/no]:n
% Include an IP address in the subject name? [no]:n
Request certificate from CA? [yes/no]:y
% Certificate request sent to Certificate Authority
% The certificate request fingerprint will be displayed.
% The 'show crypto ca certificate' command will also show the fingerprint.

```

Related Commands

Command	Description
crypto pki import pem	Imports certificates and RSA keys to a trustpoint from PEM-formatted files.
crypto pki trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of a CA.

crypto ca export pkcs12

Note This command was replaced by the **crypto pki export pkcs12** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To export Rivest, Shamir, and Adelman (RSA) keys within a PKCS12 file at a specified location, use the **crypto ca export pkcs12** command in global configuration mode.

crypto ca export *trustpointname* **pkcs12** *destination url passphrase*

Syntax Description

trustpointname	Name of the trustpoint who issues the certificate that a user is going to export. When you export the PKCS12 file, the trustpoint name is the RSA key name.
destination url	Location of the PKCS12 file to which a user wants to import the RSA key pair.
passphrase	Passphrase that is used to encrypt the PKCS12 file for export.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

The **crypto ca export pkcs12** command creates a PKCS 12 file that contains an RSA key pair. The PKCS12 file, along with a certificate authority (CA), is exported to the location that you specify with the destination URL. If you decide not to import the file to another router, you must delete the file.

Security Measures

Keep the PKCS12 file stored in a secure place with restricted access.

An RSA keypair is more secure than a passphrase because the private key in the key pair is not known by multiple parties. When you export an RSA key pair to a PKCS#12 file, the RSA key pair now is only as secure as the passphrase.

To create a good passphrase, be sure to include numbers, as well as both lowercase and uppercase letters. Avoid publicizing the passphrase by mentioning it in e-mail or cell phone communications because the information could be accessed by an unauthorized user.

Examples

The following example exports an RSA key pair with a trustpoint name “mytp” to a Flash file:

```
Router(config)# crypto ca export mytp pkcs12 flash:myexport mycompany
```

Related Commands

Command	Description
crypto pki import pkcs12	Imports RSA keys.

crypto ca identity

The **crypto ca identity** command is replaced by the **crypto ca trustpoint** command. See the **crypto ca trustpoint** command for more information.

crypto ca import

Note This command was replaced by the **crypto pki import** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXD.

To import a certificate manually via TFTP or as a cut-and-paste at the terminal, use the **crypto ca import** command in global configuration mode.

crypto ca import *name* **certificate**

Syntax Description

name **certificate**	Name of the certification authority (CA). This name is the same name used when the CA was declared with the **crypto pki trustpoint** command.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

You must enter the **crypto ca import** command twice if usage keys (signature and encryption keys) are used. The first time the command is entered, one of the certificates is pasted into the router; the second time the command is entered, the other certificate is pasted into the router. (It does not matter which certificate is pasted first.)

Examples

The following example shows how to import a certificate via cut-and-paste. In this example, the CA trustpoint is "MS."

```
crypto pki trustpoint MS
 enroll terminal
 crypto pki authenticate MS
!
crypto pki enroll MS
crypto ca import MS certificate
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of your CA.
enrollment terminal	Specifies manual cut-and-paste certificate enrollment.

crypto ca import pem

Note This command was replaced by the **crypto pki import pem** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To import certificates and Rivest, Shamir, and Adelman (RSA) keys to a trustpoint from privacy-enhanced mail (PEM)-formatted files, use the **crypto ca import pem** command in global configuration mode.

crypto ca import *trustpoint* **pem** [**usage-keys**] {**terminal** | **url** *url*} [**exportable**] *passphrase*

Syntax Description

trustpoint	Name of the trustpoint that is associated with the imported certificates and RSA key pairs. The *trustpoint* argument must match the name that was specified via the **crypto pki trustpoint** command.
usage-keys	(Optional) Specifies that two RSA special usage key pairs will be imported (that is, one encryption pair and one signature pair), instead of one general-purpose key pair.
terminal	Certificates and RSA key pairs will be manually imported from the console terminal.
url *url*	URL of the file system where your router should import the certificates and RSA key pairs.
exportable	(Optional) Specifies that the imported RSA key pair can be exported again to another Cisco device such as a router.
passphrase	Passphrase that is used to encrypt the PEM file for import. **Note** The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

The **crypto ca import pem** command allows you import certificates and RSA key pairs in PEM-formatted files. The files can be previously exported from another router or generated from other public key infrastructure (PKI) applications.

Examples

The following example shows how to import PEM files to trustpoint "ggg" via TFTP:

```
Router(config)# crypto ca import ggg pem url tftp://10.1.1.2/johndoe/msca cisco1234

% Importing CA certificate...
Address or name of remote host [10.1.1.2]?
Destination filename [johndoe/msca.ca]?
Reading file from tftp://10.1.1.2/johndoe/msca.ca
Loading johndoe/msca.ca from 10.1.1.2 (via Ethernet0):!
[OK - 1082 bytes]

% Importing private key PEM file...
Address or name of remote host [10.1.1.2]?
Destination filename [johndoe/msca.prv]?
Reading file from tftp://10.1.1.2/johndoe/msca.prv
Loading johndoe/msca.prv from 10.1.1.2 (via Ethernet0):!
[OK - 573 bytes]

% Importing  certificate PEM file...
Address or name of remote host [10.1.1.2]?
Destination filename [johndoe/msca.crt]?
Reading file from tftp://10.1.1.2/johndoe/msca.crt
Loading johndoe/msca.crt from 10.1.1.2 (via Ethernet0):!
[OK - 1289 bytes]
% PEM files import succeeded.
Router(config)#
```

Related Commands

Command	Description
crypto pki export pem	Exports certificates and RSA keys that are associated with a trustpoint in a PEM-formatted file.
crypto pki trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of a CA.

crypto ca import pkcs12

Note This command was replaced by the **crypto pki import pkcs12** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To import Rivest, Shamir, and Adelman (RSA) keys, use the **crypto ca import pkcs12** command in global configuration mode.

crypto ca import *trustpointname* **pkcs12** *source url passphrase*

Syntax Description

trustpointname	Name of the trustpoint who issues the certificate that a user is going to export or import. When importing, the trustpoint name will become the RSA key name.
source url	The location of the PKCS12 file to which a user wants to export the RSA key pair.
passphrase	Passphrase that must be entered to undo encryption when the RSA keys are imported.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

When you enter the **cyrpto ca import pkcs12** command, a ke pair and a trustpoint are generated. If you then decide you want to remove the key pair and trustpoint that were generated, enter the **crypto key zeroize rsa** command to zeroize the key pair and enter the **no crypto ca trustpoint** command to remove the trustpoint.

Note After you import RSA keys to a target router, you cannot export those keys from the target router to another router.

Examples

In the following example, an RSA key pair that has been associated with the trustpoint "forward" is to be imported:

```
Router(config)# crypto ca import forward pkcs12 flash:myexport mycompany
```

Related Commands

Command	Description
crypto pki export pkcs12	Exports RSA keys.
crypto pki trustpoint	Declares the CA that your router should use.
crypto key zeroize rsa	Deletes all RSA keys from your router.

crypto ca profile enrollment

Note This command was replaced with the **crypto pki profile enrollment** command effective with Cisco IOS Release 12.3(7)T and 12.2(18)SXE.

To define an enrollment profile, use the **crypto ca profile enrollment** command in global configuration mode. To delete all information associated with this enrollment profile, use the **no** form of this command.

crypto ca profile enrollment *label*

no crypto ca profile enrollment *label*

Syntax Description

label	Name for the enrollment profile; the enrollment profile name must match the name specified in the **enrollment profile** command.

Defaults

An enrollment profile does not exist.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

Before entering this command, you must specify a named enrollment profile using the **enrollment profile** in ca-trustpoint configuration mode.

After entering the **crypto ca profile enrollment** command, you can use any of the following commands to define the profile parameters:

- **authentication command**—Specifies the HTTP command that is sent to the certification authority (CA) for authentication.
- **authentication terminal**—Specifies manual cut-and-paste certificate authentication requests.
- **authentication url**—Specifies the URL of the CA server to which to send authentication requests.
- **enrollment command**—Specifies the HTTP command that is sent to the CA for enrollment.
- **enrollment terminal**—Specifies manual cut-and-paste certificate enrollment.
- **enrollment url**—Specifies the URL of the CA server to which to send enrollment requests.
- **parameter**—Specifies parameters for an enrollment profile. This command can be used only if the **authentication command** or the **enrollment command** is used.

Note The **authentication url**, **enrollment url**, **authentication terminal**, and **enrollment terminal** commands allow you to specify different methods for certificate authentication and enrollment, such as TFTP authentication and manual enrollment.

Examples

The following example shows how to define the enrollment profile named "E" and associated profile parameters:

```
crypto ca trustpoint Entrust
  enrollment profile E
  serial

crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.
enrollment profile	Specifies that an enrollment profile can be used for certificate authentication and enrollment.

crypto ca trusted-root

The **crypto ca trusted-root** command is replaced by the **crypto ca trustpoint** command. See the **crypto ca trustpoint** command for more information.

crypto ca trustpoint

Note Effective with Cisco IOS Release 12.3(8)T, 12.2(18)SXD, and 12.2(18)SXE, the **crypto ca trustpoint** command is replaced with the **crypto pki trustpoint** command. See the **crypto pki trustpoint** command for more information.

To declare the certification authority (CA) that your router should use, use the **crypto ca trustpoint** command in global configuration mode. To delete all identity information and certificates associated with the CA, use the **no** form of this command.

crypto ca trustpoint *name*

no crypto ca trustpoint *name*

Syntax Description

name	Creates a name for the CA. (If you previously declared the CA and just want to update its characteristics, specify the name you previously created.)

Defaults

Your router does not recognize any CAs until you declare a CA using this command.

Command Modes

Global configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(15)T	The **match certificate** subcommand was introduced.
12.3(7)T	This command was replaced by the **crypto pki trustpoint** command. You can still enter the **crypto ca trusted-root** or **crypto ca trustpoint** command, but the command will be written in the configuration as "crypto pki trustpoint."

Usage Guidelines

Use the **crypto ca trustpoint** command to declare a CA, which can be a self-signed root CA or a subordinate CA. Issuing the **crypto ca trustpoint** command puts you in ca-trustpoint configuration mode.

You can specify characteristics for the trustpoint CA using the following subcommands:

- **crl**—Queries the certificate revocation list (CRL) to ensure that the certificate of the peer has not been revoked.
- **default (ca-trustpoint)**—Resets the value of ca-trustpoint configuration mode subcommands to their defaults.
- **enrollment**—Specifies enrollment parameters (optional).
- **enrollment http-proxy**—Accesses the CA by HTTP through the proxy server.

- **match certificate**—Associates a certificate-based access control list (ACL) defined with the **crypto ca certificate map** command.
- **primary**—Assigns a specified trustpoint as the primary trustpoint of the router.
- **root**—Defines the Trivial File Transfer Protocol (TFTP) to get the CA certificate and specifies both a name for the server and a name for the file that will store the CA certificate.

Note Beginning with Cisco IOS Release 12.2(8)T, the **crypto ca trustpoint** command unified the functionality of the **crypto ca identity** and **crypto ca trusted-root** commands, thereby replacing these commands. Although you can still enter the **crypto ca identity** and **crypto ca trusted-root** commands, the configuration mode and command will be written in the configuration as "crypto ca trustpoint."

Examples

The following example shows how to declare the CA named "ka" and specify enrollment and CRL parameters:

```
crypto ca trustpoint ka
 enrollment url http://kahului:80
```

The following example shows a certificate-based access control list (ACL) with the label "Group" defined in a **crypto ca certificate map** command and included in the **match certificate** subcommand of the **crypto ca | pki trustpoint** command:

```
crypto ca certificate map Group 10
 subject-name co ou=WAN
 subject-name co o=Cisco
!
crypto ca trustpoint pki
 match certificate Group
```

Related Commands

Command	Description
crl	Queries the CRL to ensure that the certificate of the peer has not been revoked.
default (ca-trustpoint)	Resets the value of a ca-trustpoint configuration subcommand to its default.
enrollment	Specifies the enrollment parameters of your CA.
enrollment http-proxy	Accesses the CA by HTTP through the proxy server.
primary	Assigns a specified trustpoint as the primary trustpoint of the router.
root	Obtains the CA certificate via TFTP.

crypto call admission limit

To specify the maximum number of Internet Key Exchange (IKE) and IPsec security associations (SAs) that the router can establish before IKE begins rejecting new SA requests, use the **crypto call admission limit** command in global configuration mode. To disable this feature, use the **no** form of this command.

crypto call admission limit {**all in-negotiation-sa** *number* | **ipsec sa** *number* | **ike** {**in-negotiation-sa** *number* | **sa** *number*}}

no crypto call admission limit {**all in-negotiation-sa** *number* | **ipsec sa** *number* | **ike** {**in-negotiation-sa** *number* | **sa** *number*}}

Syntax Description

all	Indicates the total number of sessions in negotiation.
in-negotiation-sa	Specifies the maximum number of in-negotiation IKE SAs allowed.
number	Value for SAs. The range is from 0 to 99999.
ipsec	Configures the crypto Call Admission Control (CAC) active IPsec SA limit.
sa	Specifies the number of active IKE and IPsec SAs allowed.
ike	Configures the crypto CAC active IKE SA limit.

Command Default

No maximum number of IKE and IPsec SAs is specified.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(18)SXD1	This command was integrated into Cisco IOS Release 12.2(18)SXD1 on the Cisco 6500 and Cisco 7600 series routers.
12.4(6)T	This command was modified. The **in-negotiation-sa** keyword and *number* argument were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA on the Cisco 7600 series routers. The **in-negotiation-sa** keyword and *number* argument were not added to this release.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH. The **in-negotiation-sa** keyword and *number* argument were not added to this release.
15.1(3)T	This command was modified. The **all** and **ipsec** keywords were added.

Usage Guidelines

Use this command to limit the number of IKE SAs permitted to or from a router. By limiting the number of dynamic tunnels that can be created to the router, you can prevent the router from being overwhelmed if it is suddenly inundated with IKE SA requests. The ideal limit depends on the particular platform, the network topology, the application, and traffic patterns. When the specified limit is reached, IKE rejects

all new SA requests. If you specify an IKE SA limit that is less than the current number of active IKE SAs, a warning is displayed, but SAs are not terminated. New SA requests are rejected until the active SA count is below the configured limit.

The **ipsec sa** *number* and **ike sa** *number* keyword and argument pairs in the **crypto call admission limit** command set the limit for the number of established IPsec SAs and IKE SAs.

The **all in-negotiation-sa** *number* and **ike in-negotiation-sa** *number* keyword and argument pairs in the **crypto call admission limit** command limit all the SAs in negotiation and IKE SAs in negotiation.

Examples

The following example shows how to specify a maximum limit of 50 IKE SAs before IKE begins rejecting new SA requests:

```
Router(config)# crypto call admission limit ike sa 50
```

The following example shows how to specify a maximum limit of 100 in-negotiation IKE SAs before IKE begins rejecting new SA requests:

```
Router(config)# crypto call admission limit ike in-negotiation-sa 100
```

Related Commands

Command	Description
show crypto call admission statistics	Monitors Crypto CAC statistics.

crypto connect vlan

To create an interface VLAN for an IPSec VPN SPA and enter crypto-connect mode, use the **crypto connect vlan** command in interface configuration mode. To remove the interface VLAN status from the VLAN, use the **no** form of this command.

crypto connect vlan *vlan-id*

no crypto connect [**vlan** *vlan-id*]

Syntax Description

vlan-id	VLAN ID number.

Defaults

No default behavior or values.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SXE2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can enter the **crypto connect vlan** command only from the following:

- The associated port VLAN interface when the EtherChannel interface (port-channel interface) and participating interfaces are switch ports.
- The EtherChannel interface when the EtherChannel interface (port-channel interface) and participant interfaces are routed ports.

The **crypto engine subslot** command is only available for VLANs prior to the VLANs being made interface VLANs by the **crypto connect vlan** command.

When you enter the **crypto connect vlan** command, a target VLAN is made an interface VLAN if and only if the target VLAN is not currently an interface VLAN, and the target VLAN has been added to an inside trunk port using the **crypto engine subslot** command. If the VLAN has been added to more than one inside trunk port, the **crypto connect vlan** command is rejected.

The **no crypto engine subslot** command is allowed only after you enter the **no crypto connect vlan** command, or before you enter the **crypto connect vlan** command.

When you remove an interface VLAN from an inside trunk port and a corresponding crypto engine subslot configuration state exists, then that crypto engine subslot configuration state is not removed. If you remove a VLAN that has a crypto engine subslot configuration state, you need to manually add it back to recover. While in this inconsistent state, any attempt to enter the **no crypto connect vlan** command is rejected.

When you enter the **no crypto connect vlan** command, the interface VLAN status is removed from a VLAN. Any associated crypto engine subslot configuration state is not altered.

Examples

The following example adds port 2/1 to the outside access port VLAN and connects the outside access port VLAN to the inside interface VLAN:

```
Router(config)# interface Vlan101
Router(config-if)# ip address 192.168.101.1 255.255.255.0
Router(config-if)# crypto map cmap
Router(config-if)# crypto engine subslot 3/0

Router(config-if)# interface GigabitEthernet2/1
Router(config-if)# crypto connect vlan 101
```

Related Commands

Command	Description
crypto engine subslot	Assign an interface VLAN that requires encryption to the IPSec VPN SPA.
crypto map (interface IPSec)	Applies a previously defined crypto map set to an interface.
show crypto vlan	Displays the VPN running state for an IPSec VPN SPA.

crypto ctcp

To configure Cisco Tunneling Control Protocol (cTCP) encapsulation for Easy VPN, use the **crypto ctcp** command in global configuration mode. To remove the cTCP encapsulation, use the **no** form of this command.

crypto ctcp [**keepalive** *number-of-seconds* | **port** *port-number*]

no crypto ctcp [**keepalive** *number-of-seconds* | **port** *port-number*]

Syntax Description

keepalive	(Optional) Sets the interval of cTCP keepalives that are sent by the remote device. **Note** This command is configured on the remote device.
number-of-seconds	(Optional) Number of seconds between the keepalives. Value = 5 through 3600. If the **keepalive** keyword is not configured, the default is 5.
port	(Optional) Port number that cTCP will listen to. Up to 10 numbers can be configured. **Note** This keyword is configured only on the server.
port-number	(Optional) Actual port number. Value = 1 through 65535. If the **port** keyword is not configured, the default port number is 10000.

Command Default

cTCP encapsulation is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(9)T	The **crypto ctcp** command was introduced.
12.4(20)T	The **keepalive** keyword and *number-of-seconds* argument were added.

Usage Guidelines

If cTCP is enabled on a port, any application that uses that port will not function.

When cTCP encapsulation is enabled on the router, only packets less than or equal to 1407 in size can pass through the IPsec tunnel with the Don't Fragment (DF) bit set. If an attempt is made to send a larger size packet, the following syslog message is generated:

```
CRYPTO_ENGINE: locally-sourced pkt w/DF bit set is too big,ip->tl=1450, mtu=1407
```

Note If a Cisco IOS device is acting as a remote device, it has to send keepalives periodically to keep Network Address Translation (NAT) or firewall sessions from timing out.

Examples

The following example shows that cTCP encapsulation has been configured on port 120:

```
Router (config)# crypto ctcp port 120
```

The following example shows that the cTCP keepalive interval has been set at 30 seconds:

```
Router (config)# crypto ctcp keepalive 30
```

Related Commands

Command	Description
clear crypto ctcp	Clears cTCP encapsulation.
ctcp port	Sets the port number for cTCP encapsulation for Easy VPN.
debug crypto ctcp	Displays information about a cTCP session.
show crypto ctcp	Displays information about a cTCP session.

crypto dynamic-map

To create a dynamic crypto map entry and enter crypto map configuration command mode, use the **crypto dynamic-map** command in global configuration mode. To delete a dynamic crypto map set or entry, use the **no** form of this command.

crypto dynamic-map *dynamic-map-name dynamic-seq-num*

no crypto dynamic-map *dynamic-map-name* [*dynamic-seq-num*]

Syntax Description

dynamic-map-name	Specifies the name of the dynamic crypto map set.
dynamic-seq-num	Specifies the number of the dynamic crypto map entry.

Defaults

No dynamic crypto maps exist.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(15)T	This command was modified. All changes to PFS settings in the dynamic crypto map template are immediately passed on to the instantiated crypto map PFS settings.

Usage Guidelines

Use dynamic crypto maps to create policy templates that can be used when processing negotiation requests for new security associations from a remote IP security peer, even if you do not know all of the crypto map parameters required to communicate with the remote peer (such as the peer's IP address). For example, if you do not know about all the IPsec remote peers in your network, a dynamic crypto map allows you to accept requests for new security associations from previously unknown peers. (However, these requests are not processed until the Internet Key Exchange authentication has completed successfully.)

When a router receives a negotiation request via IKE from another IPsec peer, the request is examined to see if it matches a crypto map entry. If the negotiation does not match any explicit crypto map entry, it will be rejected unless the crypto map set includes a reference to a dynamic crypto map.

The dynamic crypto map is a policy template; it will accept "wildcard" parameters for any parameters not explicitly stated in the dynamic crypto map entry. This allows you to set up IPsec security associations with a previously unknown IPsec peer. (The peer still must specify matching values for the nonwildcard IPsec security association negotiation parameters.))

If the router accepts the peer's request, at the point that it installs the new IPsec security associations it also installs a temporary crypto map entry. This entry is filled in with the results of the negotiation. At this point, the router performs normal processing, using this temporary crypto map entry as a normal entry, even requesting new security associations if the current ones are expiring (based upon the policy specified in the temporary crypto map entry). Once the flow expires (that is, all of the corresponding security associations expire), the temporary crypto map entry is removed.

If changes are made to the Perfect Forward Secrecy (PFS) settings in the dynamic crypto map template,the changes are passed on to the PFS settings in the instantiated crypto map. During the next rekey process the new settings are used to negotiate with the remote peer.

Dynamic crypto map sets are not used for initiating IPsec security associations. However, they are used for determining whether or not traffic should be protected.

The only configuration required in a dynamic crypto map is the **set transform-set** command. All other configuration is optional.

Dynamic crypto map entries, like regular static crypto map entries, are grouped into sets. After you define a dynamic crypto map set (which commonly contains only one map entry) using this command, you include the dynamic crypto map set in an entry of the "parent" crypto map set using the **crypto map** (IPsec global configuration) command. The parent crypto map set is then applied to an interface.

You should make crypto map entries referencing dynamic maps the lowest priority map entries, so that negotiations for security associations will try to match the static crypto map entries first. Only after the negotiation request does not match any of the static map entries do you want it to be evaluated against the dynamic map.

To make a dynamic crypto map the lowest priority map entry, give the map entry referencing the dynamic crypto map the highest *seq-num* of all the map entries in a crypto map set.

For both static and dynamic crypto maps, if unprotected inbound traffic matches a **permit** statement in an access list, and the corresponding crypto map entry is tagged as "IPsec," then the traffic is dropped because it is not IPsec protected. (This is because the security policy as specified by the crypto map entry states that this traffic must be IPsec protected.)

For static crypto map entries, if outbound traffic matches a **permit** statement in an access list and the corresponding security association (SA) is not yet established, the router will initiate new SAs with the remote peer. In the case of dynamic crypto map entries, if no SA existed, the traffic would simply be dropped (because dynamic crypto maps are not used for initiating new SAs).

Note Use care when using the **any** keyword in **permit** entries in dynamic crypto maps. If it is possible for the traffic covered by such a **permit** entry to include multicast or broadcast traffic, the access list should include **deny** entries for the appropriate address range. Access lists should also include **deny** entries for network and subnet broadcast traffic, and for any other traffic that should not be IPsec protected.

Examples

The following example shows how to configure an IPsec crypto map set.

Crypto map entry "mymap 30" references the dynamic crypto map set "mydynamicmap," which can be used to process inbound security association negotiation requests that do not match "mymap" entries 10 or 20. In this case, if the peer specifies a transform set that matches one of the transform sets specified in "mydynamicmap," for a flow "permitted" by the access list 103, IPsec will accept the request and set up security associations with the remote peer without previously knowing about the remote peer. If accepted, the resulting security associations (and temporary crypto map entry) are established according to the settings specified by the remote peer.

The access list associated with "mydynamicmap 10" is also used as a filter. Inbound packets that match a **permit** statement in this list are dropped for not being IPsec protected. (The same is true for access lists associated with static crypto maps entries.) Outbound packets that match a **permit** statement without an existing corresponding IPsec SA are also dropped.

```
crypto map mymap 10 ipsec-isakmp
 match address 101
 set transform-set my_t_set1
 set peer 10.0.0.1
 set peer 10.0.0.2
crypto map mymap 20 ipsec-isakmp

Related Commands

Command	Description
crypto map (global IPsec)	Creates or modifies a crypto map entry and enters the crypto map configuration mode.
crypto map (interface IPsec)	Applies a previously defined crypto map set to an interface.
crypto map local-address	Specifies and names an identifying interface to be used by the crypto map for IPsec traffic.
match address (IPsec)	Specifies an extended access list for a crypto map entry.
set peer (IPsec)	Specifies an IPsec peer in a crypto map entry.
set pfs	Specifies that IPsec should ask for PFS when requesting new security associations for this crypto map entry, or that IPsec requires PFS when receiving requests for new security associations.
set security-association lifetime	Overrides (for a particular crypto map entry) the global lifetime value, which is used when negotiating IPsec security associations.
set transform-set	Specifies which transform sets can be used with the crypto map entry.
show crypto engine accelerator logs	Displays a dynamic crypto map set.
show crypto map (IPsec)	Displays the crypto map configuration.

crypto-engine

To enter the QoS policy map configuration mode for the IPsec VPN module, use the **crypto-engine** command in interface configuration mode.

crypto-engine

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI	Support for this command was introduced.

Usage Guidelines

Once you enter the **crypto-engine** command, the prompt changes to the following:

```
Router(config-crypto-engine)#
```

The following crypto engine configuration commands are available when you enter the **crypto-engine** command:

- **default**—Sets a command to its defaults.
- **exit**—Exit service-flow submode.
- **no**—Negates a command or set its defaults.
- **service-policy output** *policy-map-name*—Configures the service policy by assigning a policy map to the output of an interface.

Examples

The following example shows how to apply the policy map to tunnel egress traffic:

```
Router(config)# interface tunnel1
Router(config-if)# crypto-engine
Router(config-crypto-engine)# service-policy output crypto1
```

Related Commands

Command	Description
show policy-map interface	Displays the statistics and configurations of the QoS policies attached to the tunnel interface.

crypto engine accelerator

Note Effective with Cisco IOS Release 12.3(11)T, this command is replaced by the **crypto engine aim**, **crypto engine em**, **crypto engine nm**, **crypto engine onboard**, and **crypto engine slot** commands. See these commands for more information.

To enable the onboard hardware accelerator of the router for IP security (IPsec) encryption, use the **crypto engine accelerator** command in global configuration mode. To disable the use of the onboard hardware IPsec accelerator, and thereby perform IPsec encryption or decryption in software, use the **no** form of this command.

crypto engine accelerator

no crypto engine accelerator

Syntax Description

This command has no arguments or keywords.

Defaults

The hardware accelerator for IPsec encryption is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced for the Cisco 1700 series router and other Cisco routers that support hardware accelerators for IPsec encryption.
12.1(3)XL	Support was added for the Cisco uBR905 cable access router.
12.2(2)XA	Support was added for the Cisco uBR925 cable access router.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T and implemented for the AIM-VPN/EPII and AIM-VPN/HPII on the following platforms: Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.2(15)ZJ	This command was implemented for the AIM-VPN/BPII on the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, and Cisco 2651XM.
12.3(4)T	The AIM-VPN/BPII was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, and Cisco 2651XM.
12.3(11)T	This command was replaced by the **crypto engine aim**, **crypto engine em**, **crypto engine nm**, **crypto engine onboard**, and **crypto engine slot** commands.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is not normally needed for typical operations because the onboard hardware accelerator of the router is enabled for IPsec encryption by default. The hardware accelerator should not be disabled except on instruction from Cisco Technical Assistance Center (TAC) personnel.

Examples

The following example shows how to disable the onboard hardware accelerator of the router for IPsec encryption. This disabling is normally needed only after the accelerator has been disabled for testing or debugging purposes.

```
Router(config)# no crypto engine accelerator

Warning! all current connections will be torn down.
Do you want to continue? [yes/no]:
```

Related Commands

Command	Description
clear crypto engine accelerator counter	Resets the statistical and error counters for the hardware accelerator to zero.
crypto ca	Defines the parameters for the certification authority used for a session.
crypto cisco	Defines the encryption algorithms and other parameters for a session.
crypto dynamic-map	Creates a dynamic map crypto configuration for a session.
crypto ipsec	Defines the IPSec security associations and transformation sets.
crypto isakmp	Enables and defines the IKE protocol and its parameters.
crypto key	Generates and exchanges keys for a cryptographic session.
crypto map	Creates and modifies a crypto map for a session.
debug crypto engine accelerator control	Displays each control command as it is given to the crypto engine.
debug crypto engine accelerator packet	Displays information about each packet sent for encryption and decryption.
show crypto engine accelerator ring	Displays the contents of command and transmits rings for the crypto engine.
show crypto engine accelerator sa-database	Displays the active (in-use) entries in the crypto engine SA database.
show crypto engine accelerator statistic	Displays the current run-time statistics and error counters for the crypto engine.
show crypto engine brief	Displays a summary of the configuration information for the crypto engine.
show crypto engine configuration	Displays the version and configuration information for the crypto engine.
show crypto engine connections	Displays a list of the current connections maintained by the crypto engine.

crypto engine aim

To reenable an advanced integration module (AIM), use the **crypto engine aim** command in global configuration mode. To disable an AIM encryption module, use the **no** form of this command.

crypto engine aim *aim-slot-number*

no crypto engine aim *aim-slot-number*

Syntax Description

aim-slot-number	Slot number to which an AIM is to be reenabled or disabled.

Defaults

An AIM is neither reenabled nor disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced. This command replaces the **crypto engine accelerator** command.

Usage Guidelines

The **crypto engine accelerator** command will still be usable for a while, but if it is used, only the **crypto engine aim** command will be saved to the running and startup (nonvolatile memory) configuration.

Examples

The following example shows that the AIM in slot 0 is to be reenabled:

```
crypto engine aim 0
```

The following example shows that the AIM in slot 0 is to be disabled:

```
no crypto engine aim 0
```

crypto engine em

To enable the hardware accelerator of an expansion slot for IP security (IPsec) encryption, use the **crypto engine em** command in global configuration mode. To disable the hardware accelerator of the expansion slot, use the **no** form of this command.

crypto engine em *slot-number*

no crypto engine em *slot-number*

Syntax Description

slot-number	Slot number to which the hardware accelerator of the expansion slot is to be enabled or disabled (applies to slots 0 through 3).

Defaults

The hardware accelerator is neither enabled nor disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced. This command replaces the **crypto engine accelerator** command.

Usage Guidelines

The **crypto engine accelerator** command will still be usable for a while, but if it is used, only the **crypto engine em** command will saved to the running and startup (nonvolatile memory) configuration.

Examples

The following example shows that the hardware accelerator of expansion slot 1 is to be enabled:

```
crypto engine em 1
```

The following example shows that the hardware accelerator of expansion slot 1 is to be disabled:

```
no crypto engine em 1
```

crypto engine mode vrf

To enable VRF-Aware mode for the IPSec VPN SPA, use the **crypto engine mode vrf** command in global configuration mode. To disable VRF-aware mode, use the **no** form of this command.

crypto engine mode vrf

no crypto engine mode vrf

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXE2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The VRF-Aware IPSec feature introduces IPSec tunnel mapping to Multiprotocol Label Switching (MPLS) VPNs.

Using the VRF-Aware IPSec feature, you can map IPSec tunnels to VPN routing and forwarding instances (VRFs) using a single public-facing address.

Unlike other IPSec VPN SPA feature configurations, when configuring VRF-Aware features, you do not use the **crypto connect vlan** command.

Examples

The following example shows a VRF-Aware IPSec implementation:

```
ip vrf pepsi
 rd 1000:1
 route-target export 1000:1
 route-target import 1000:1
!
ip vrf coke
 rd 2000:1
 route-target export 2000:1
 route-target import 2000:1

crypto engine mode vrf

interface vlan 100
 ip vrf forwarding pepsi
 ip address 10.2.1.1 255.255.255.0
 crypto engine subslot 3/0
 crypto map map100

interface vlan 200
 ip vrf forwarding coke
 ip address 10.2.1.1 255.255.255.0
 crypto engine subslot 3/0
```

```
 crypto map map200

interface gi1/1 (hidden VLAN 1000)
 ip address 171.1.1.1
 crypto engine subslot 3/0

! BASIC MPLS CONFIGURATION
mpls label protocol ldp
tag-switching tdp router-id Loopback0
mls ip multicast flow-stat-timer 9
no mls flow ip
no mls flow ipv6
!
! CONFIGURE THE INTERFACE CONNECTED TO THE MPLS BACKBONE WITH LABEL/TAG SWITCHING
interface GigabitEthernet2/12
 ip address 20.1.0.34 255.255.255.252
 logging event link-status
 speed nonegotiate
 mpls label protocol ldp
tag-switching ip
```

Related Commands

Command	Description
crypto engine subslot	Assigns an interface VLAN that requires encryption to the IPSec VPN SPA.
ip vrf	Configures a VRF routing table and enters VRF configuration mode.
ip vrf forwarding	Associates a VRF with an interface or subinterface.
vrf	Defines the VRF to which the IPSec tunnel will be mapped.

crypto engine nm

To enable the onboard hardware accelerator of a network module for IP security (IPsec) encryption, use the **crypto engine nm** command in global configuration mode. To disable the accelerator of the network module, use the **no** form of this command.

crypto engine nm *slot-number*

no crypto engine nm *slot-number*

Syntax Description

slot-number	Slot number to which the hardware accelerator of a network module is to be enabled or disabled (applies to slots 0 through 5).

Defaults

The hardware accelerator is neither enabled nor disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced. This command replaces the **crypto engine accelerator** command.

Usage Guidelines

The **crypto engine accelerator** command will still be usable for a while, but if it is used, only the **crypto engine nm** command will saved to the running and startup (nonvolatile memory) configuration.

Examples

The following example shows that the hardware accelerator of the network module in slot 0 is to be enabled:

```
crypto engine nm 0
```

The following example shows that the hardware accelerator of the network module in slot 0 is to be disabled:

```
no crypto engine nm 0
```

crypto engine onboard

To enable the hardware accelerator of an onboard module for IP security (IPsec) encryption, use the **crypto engine onboard** command in global configuration mode. To disable the hardware accelerator of the onboard module, use the **no** form of this command.

crypto engine onboard *slot-number*

no crypto engine onboard *slot-number*

Syntax Description

slot-number	Slot number to which the hardware accelerator of the onboard module is to be enabled or disabled (applies to slots 0 and 1).

Defaults

The hardware accelerator is neither enabled nor disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced. This command replaces the **crypto engine accelerator** command.

Usage Guidelines

The **crypto engine accelerator** command will still be usable for a while, but if it is used, only the **crypto engine onboard** command will saved to the running and startup (nonvolatile memory) configuration.

Examples

The following example shows that the hardware accelerator of the onboard module in slot 1 is to be enabled:

```
crypto engine onboard 1
```

The following example shows that the hardware accelerator of the onboard module in slot 1 is to be disabled:

```
no crypto engine onboard 1
```

crypto engine slot

To reenable the onboard hardware accelerator in a service adapter, use the **crypto engine slot** command in global configuration mode. To disable the hardware accelerator in the service adapter, use the **no** form of this command.

crypto engine slot *slot-number*

no crypto engine slot *slot-number*

Syntax Description

slot-number	Slot number to which the hardware accelerator in a service adapter is to be reenabled or disabled (applies to slots 1 through 6).

Defaults

The hardware accelerator is neither enabled nor disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced. This command replaces the **crypto engine accelerator** command.

Usage Guidelines

The **crypto engine accelerator** command will still be usable for a while, but if it is used, only the **crypto engine slot** command will saved to the running and startup (nonvolatile memory) configuration.

Examples

The following example shows that the hardware accelerator of the service adaptor in slot 2is to be enabled:

```
crypto engine slot 2
```

The following example shows that the hardware accelerator of the service adaptor in slot 2 is to be disabled:

```
no crypto engine slot 2
```

crypto engine slot (interface)

To assign an interface VLAN, Virtual Routing and Forwarding (VRF) tunnel interface, or Front-door VRF (FVRF) interface that requires encryption to the IPSec VPN Shared Port Adapter (SPA), use the **crypto engine slot** command in interface configuration mode. The command usage and syntax varies based on whether you are in crypto-connect mode or VRF mode. In crypto-connect mode, the command is applied to interface VLANs and only the *slot*/*subslot* arguments are specified; in VRF-mode, the command is applied to interface VLANs, tunnel interfaces, or FVRF interfaces and either the **inside** or **outside** keyword must also be specified. To remove the interface, use the corresponding **no** form of this command.

Crypto-Connect Mode Syntax

crypto engine slot *slot*

no crypto engine slot *slot*

VRF Mode Syntax

crypto engine slot *slot* {**inside** | **outside**}

no crypto engine slot *slot* {**inside** | **outside**}

Syntax Description

slot	Chassis slot number where the Cisco 7600 SSC-400 card is located. Refer to the appropriate hardware manual for slot information. For SIPs and SSCs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
inside	(VRF Mode Only) Identifies the interface as an interface VLAN or tunnel interface.
outside	(VRF Mode Only) Identifies the interface as an FVRF interface.

Command Default

No interface is assigned.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRA	This command was introduced into Cisco IOS Release 12.2(33)SRA to support the IPSec VPN SPA on Cisco 7600 series routers and Catalyst 6500 series switches.
12.2(33)SRE	This command was modified. The *subslot* argument was removed.

Usage Guidelines

Usage guidelines vary based on whether you are in crypto-connect mode or VRF mode:

Crypto-Connect Mode Usage Guidelines

With this command, you do not need to explicitly add interface VLANs to the IPSec VPN SPA inside trunk port.

It is strongly recommended that you use the **crypto engine slot** command instead of manually adding and removing VLANs from the inside trunk port.

When you add an interface VLAN to an inside trunk port and that interface VLAN is not already added to another inside trunk port, the crypto engine slot configuration state on the interface VLAN is combined. If the interface VLAN is already added to another inside trunk port, the command is rejected.

You should not try to add all VLANs at one time (If you attempt this, you can recover by manually removing the VLANs from the inside trunk port.)

In crypto-connect mode, the **crypto engine slot** command is used in conjunction with the **crypto connect vlan** command.

In crypto-connect mode, the **crypto engine slot** command is only available for VLANs prior to the VLANs being made interface VLANs by the **crypto connect vlan** command.

The **crypto engine slot** command is rejected if you enter it on a crypto-connected interface VLAN whose current crypto engine slot configuration is different from the subslot specified in the **crypto engine slot** command. To change the crypto engine slot configuration on an interface VLAN, you must ensure that the VLAN is not crypto-connected.

If you change the crypto engine slot configuration on an interface VLAN, any IPSec and IKE SAs that are currently active on that interface VLAN are deleted.

If you enter the **no crypto engine slot** command and the interface VLAN is crypto-connected, the **no crypto engine slot** command is rejected. The **no crypto engine slot** command is allowed only after you enter the **no crypto connect vlan** command, or before you enter the **crypto connect vlan** command.

When you remove an interface VLAN from an inside trunk port and a corresponding crypto engine slot configuration state exists, then that crypto engine slot configuration state is not removed. If you remove a VLAN that has a crypto engine slot configuration state, you need to manually add it back to recover. While in this inconsistent state, any attempt to enter the **no crypto connect vlan** command is rejected.

When you enter the **no crypto connect vlan** command, the interface VLAN status is removed from a VLAN. Any associated crypto engine slot configuration state is not altered.

When you write the configuration or show the configuration, the crypto engine slot configuration state is expressed in the context of the associated interface VLAN. The interface VLAN is also shown as having been added to the appropriate inside trunk port. This is the case even if the configuration was loaded from a legacy (pre-crypto engine slot) configuration file, or if VLANs were manually added instead of being added through the **crypto engine slot** command.

By editing the **crypto engine slot** commands and inside trunk port VLANs, it is possible to produce an inconsistent configuration file.

VRF Mode Usage Guidelines

When configuring an interface VLAN or tunnel interface in VRF mode, the **crypto-engine slot inside** command must be specified.

When configuring an FVRF interface in VRF mode, the **crypto-engine slot outside** command must be specified.

In VRF mode, the **crypto-connect vlan** command is not used.

In Cisco IOS Release 12.2(33)SRE and later releases the *subslot* argument was removed.

Examples

The following crypto-connect mode example shows how to assign VLAN interface 101 to the IPSec VPN SPA in slot 3, subslot 0:

```
Router(config)# interface Vlan101
Router(config-if)# ip address 192.168.101.1 255.255.255.0
Router(config-if)# crypto map cmap
Router(config-if)# crypto engine slot 3/0

Router(config)# interface GigabitEthernet2/1
Router(config-if)# crypto connect Vlan101
```

The following VRF mode example shows how to assign VLAN interface 101 to the IPSec VPN SPA in slot 3, subslot 0:

```
Router(config)# interface Vlan101
Router(config-if)# ip vrf forwarding abc
Router(config-if)# ip address 10.2.1.1 255.255.255.0
Router(config-if)# crypto engine slot 3/0 inside
Router(config-if)# crypto map map100
```

The following VRF mode example shows how to assign Tunnel interface 1 to the IPSec VPN SPA in slot 4, subslot 0:

```
Router(config)# interface Tunnel1
Router(config)# ip vrf forwarding abc
Router(config-if)# ip address 10.1.1.254 255.255.255.0
Router(config-if)# tunnel source 172.1.1.1
Router(config-if)# tunnel destination 100.1.1.1
Router(config-if)# tunnel mode ipsec profile tp
Router(config-if)# crypto engine slot 4/0 inside
```

The following VRF mode example assigns the WAN-side interface GigabitEthernet1/1 to the IPSec VPN SPA in slot 3, subslot 0:

```
Router(config)# interface GigabitEthernet1/1
Router(config-if)# ip address 171.1.1.1 255.255.255.0
Router(config-if)# crypto engine slot 3/0 outside
```

Related Commands

Command	Description
crypto connect vlan	Creates an interface VLAN for an IPSec VPN SPA and enters crypto-connect mode.
crypto map (interface IPSec)	Applies a previously defined crypto map set to an interface.
ip vrf forwarding	Associates a VRF with an interface.
show crypto vlan	Displays the VPN running state for an IPSec VPN SPA.
tunnel vrf	Associates a VRF instance with a specific tunnel interface.

crypto gdoi gm

For group members to change the IP security (IPsec) security association (SA) status, use the **crypto gdoi gm** command in privileged EXEC mode.

crypto gdoi gm group *group-name* {**ipsec direction inbound optional** | **ipsec direction inbound only** | **ipsec direction both**}

Syntax Description

group *group-name*	Name of the group.
ipsec direction inbound optional	Allows a group member to change the IPsec SA status to inbound optional. IPsec SA will accept cipher or plain text or both and will encrypt the packet before forwarding it.
ipsec direction inbound only	Allows a group member to change the IPsec SA status to inbound only. IPsec SA will accept cipher or plain text or both and will forward the packet in clear text.
ipsec direction both	Allows a group member to change the IPsec SA status to both inbound and outbound. IPsec SA will accept only cipher text and will encrypt the packet before forwarding it.

Command Default

If the **sa receive-only** command is specified on the key server, the group member remains in receive-only mode.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(11)T	This command was introduced.
Cisco IOS XE Release 2.3	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

This command is executed on group members. This command and its various keywords aid in testing individual group members and verifies that the group members are encrypting or decrypting traffic. This command and its keywords can be used only after the **sa receive-only** command has been configured on the key server.

The **ipsec direction inbound optional** keyword is used for situations in which all group members have been instructed to install the IPsec SAs as inbound only but for which a group member wants to install the IPsec SAs as inbound optional.

The **ipsec direction inbound only** keyword is used when a group member wants to change a previously set IPsec SA status to inbound only.

The **ipsec direction both** keyword is used when a group member has to change a previously set IPsec SA status to both inbound and outbound. In this setting, the group member accepts only cipher text.

Examples

The following example shows how to determine whether a group member can accept cipher text.

On Group Member 1, configure the following:

```
crypto gdoi gm group groupexample ipsec direction inbound only
```

On Group Member 2, configure the following:

```
crypto gdoi gm group groupexample ipsec direction inbound optional
```

Then Ping Group Member 1.

Group Member 2 will have encrypted the packet and will send an encrypted packet to Group Member 1, which then decrypts that packet. If the traffic is from Group Member 1 to Group Member 2, Group Member 1 will forward the packet in clear text, and Group Member will accept it.

Related Commands

Command	Description
sa receive-only	Specifies that an IPsec SA is to be installed by a group member as "inbound only."

crypto gdoi group

To identify a Group Domain of Interpretation (GDOI) group and enter GDOI group configuration mode, use the **crypto gdoi group** command in global configuration mode. To disable a GDOI group, use the **no** form of this command.

crypto gdoi group {*group-name*}

no crypto gdoi group {*group-name*}

Syntax Description

group-name	Name of the group. The group name is limited to 80 characters.

Command Default

A GDOI group is not defined.

Command Modes

Global configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

There are more options for configuring a group on a key server than there are for configuring a group member. The group is identified by an identity and by the server. If the crypto GDOI group is a group member, the address of the server is specified. If the crypto GDOI group is a key server, "server local" is specified, which indicates that this is the key server.

Examples

The following example shows how to configure a GDOI group for a key server:

```
crypto gdoi group gdoigroupname
 identity number 4444
 server local
```

The following example shows how to configure a GDOI group for a group member:

```
crypto gdoi group gdoigroupname
 identity number 3333
 server address ipv4 10.0.5.2
```

crypto identity

To configure the identity of the router with a given list of distinguished names (DNs) in the certificate of the router, use the **crypto identity** command in global configuration mode. To delete all identity information associated with a list of DNs, use the **no** form of this command.

crypto identity *name*

no crypto identity *name*

Syntax Description

name	Identity of the router, which is associated with the given list of DNs.

Defaults

If this command is not enabled, the IP address is associated with the identity of the router.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(20)T	Support for IPv6 was added.

Usage Guidelines

The **crypto identity** command allows you to configure the identity of a router with a given list of DNs. Thus, when used with the **dn** and **fqdn** commands, you can set restrictions in the router configuration that prevent peers with specific certificates, especially certificates with particular DNs, from having access to selected encrypted interfaces.

Note The identity of the peer must be the same as the identity in the exchanged certificate.

Examples

The following example shows how to configure a DN-based crypto map:

```
! The following is an IPSec crypto map (part of IPSec configuration). It can be used only
! by peers that have been authenticated by DN and if the certificate belongs to BigBiz.
crypto map map-to-bigbiz 10 ipsec-isakmp
 set peer 172.21.114.196
 set transform-set my-transformset
 match address 124
 identity to-bigbiz
!
crypto identity to-bigbiz
 dn ou=BigBiz
!
!
! This crypto map can be used only by peers that have been authenticated by hostname
```

```
! and if the certificate belongs to little.com.
crypto map map-to-little-com 10 ipsec-isakmp
 set peer 172.21.115.119
 set transform-set my-transformset
 match address 125
 identity to-little-com
!
crypto identity to-little-com
 fqdn little.com
!
```

Related Commands

Command	Description
crypto mib ipsec flowmib history failure size	Associates the identity of the router with the DN in the certificate of the router.
fqdn	Associates the identity of the router with the hostname that the peer used to authenticate itself.

crypto ikev2 authorization policy

To configure an IKEv2 client configuration group, use the **crypto ikev2 authorization policy** command in global configuration mode. To remove this command and all associated subcommands from your configuration, use the **no** form of this command.

crypto ikev2 authorization policy *policy-name*

nocrypto ikev2 authorization policy *policy-name*

Syntax Description

policy-name	Group definition that identifies which policy is enforced for users.

Command Default

No IKEv2 client group is configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use the **crypto ikev2 authorization policy** command to specify the group for which a policy profile must be defined and the group policy information that needs to be defined or changed. You may wish to change the group policy on your router if you decide to connect to the client using a group ID that does not match the *policy-name* argument. The authorization policy is referred from the IKEv2 profile using the **aaa authorization group** command where the group name can be directly specified or derived from the remote identities using a name mangler.

If AAA authorization is configured as local, AAA derives the authorization attributes from IKEv2 client configuration group through the callback to crypto component.

After enabling this command, which puts the networking device in IKEv2 group configuration mode, you can specify the characteristics for the group policy using the following commands:

- **dhcp**—Configures an IP address on the remote access client for the Dynamic Host Configuration Protocol (DHCP) to use.
- **dns**—Specifies the primary and secondary Domain Name Service (DNS) servers for the group.
- **netmask**—Subnet mask to be used by the client for local connectivity.
- **pool**—Refers to the IP local pool address used to allocate internal IP addresses to clients.
- **subnet-acl**—Configures split tunneling.
- **wins**—Specifies the primary and secondary Windows Internet Naming Service (WINS) servers for the group.

Examples

The following example shows how the client configuration group is referred from IKEv2 profile using the **aaa authorization group** command where the group name is specified directly. In this example, the policy is enforced for users that matches the group name "abc."

```
aaa new-model
aaa authorization network aaa-group-list default local
!
crypto ikev2 authorization policy
abc
  pool pool1
  dns 198.51.100.1 198.51.100.100
  wins 203.0.113.1 203.0.113.115
  dhcp server 3.3.3.3
  dhcp giaddr 192.0.2.1
  dhcp timeout 10
  netmask 255.255.255.0
  subnet-acl acl-123
!
crypto ikev2 profile profile1
  authentication remote eap
aaa authorization group aaa-group-list abc
!
ip access-list extended acl-123
permit ip 209.165.200.225 0.0.0.31 any
permit ip 209.165.201.1 255.255.255.224 any
```

Related Commands

Command	Description
aaa authorization group	Sets parameters that restrict user access to a network.
dhcp	Configures an IP address for the DHCP to use.
dns	Specifies the primary and secondary DNS servers for the group.
netmask	Specifies the netmask of the subnet address that is assigned to the client.
pool	Defines a local pool address for assigning IP addresses.
subnet-acl	Defines ACL for split tunneling.
wins	Specifies the internal WINS server addresses.

crypto ikev2 certificate-cache

To set the cache size to store certificates, use the **crypto ikev2 certificate-cache** command in global configuration mode. To delete the cache size, use the **no** form of this command.

crypto ikev2 certificate-cache *number-of-certificates*

no crypto ikev2 certificate-cache

Syntax Description

number-of-certificates	The maximum number of certificates that can be stored in the cache.

Command Default

The cache size is not set.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to set the cache to store the maximum number of certificates fetched from the HTTP URLs.

Examples

The following example sets the cache size to store 500 certificates:

```
Router(config)# crypto ikev2 certificate-cache 500
```

Related Commands

Command	Description
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 cookie-challenge

To enable a cookie challenge for Internet Key Exchange Version 2 (IKEv2), use the **crypto ikev2 cookie-challenge** command in global configuration mode. To disable the cookie challenge, use the **no** form of this command.

crypto ikev2 cookie-challenge *number*

no crypto ikev2 cookie-challenge

Syntax Description

number	Enables the IKEv2 cookie challenge when the number of half-open security associations (SAs) crosses the configured number. The range is 1 to 1000.

Command Default

The cookie challenge is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to enable the IKEv2 cookie challenge. A cookie challenge mitigates the effect of a DoS attack when an IKEv2 responder is flooded with session initiation requests from forged IP addresses.

Examples

The following example sets the cookie challenge to 450:

```
Router(config)# crypto ikev2 cookie-challenge 450
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.

Command	Description
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 diagnose

To enable Internet Key Exchange Version 2 (IKEv2) error diagnostics, use the **crypto ikev2 diagnose** command in global configuration mode. To disable the error diagnostics, use the **no** form of this command.

crypto ikev2 diagnose error *number*

no crypto ikev2 diagnose error

Syntax Description

error	Enables the IKEv2 error path tracing.
number	Specifies the maximum number of errors allowed in the exit path entry. The range is 1 to 1000.

Command Default

IKEv2 error diagnostics is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to enable IKEv2 error path tracing and to specify the number of entries in the exit path database. When the number exceeds the specified number, new entries replace the old entries.

Examples

The following example sets the maximum number of entries that can be logged:

```
Router(config)# crypto ikev2 diagnose error 500
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.

Command	Description
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 dpd

To configure Dead Peer Detection (DPD) for Internet Key Exchange Version 2 (IKEv2), use the **crypto ikev2 dpd** command in global configuration mode. To delete DPD, use the **no** form of this command.

crypto ikev2 dpd *interval retry-interval* {**on-demand** | **periodic**}

no crypto ikev2 dpd

Syntax Description

interval	Specifies the keepalive interval in seconds.
retry-interval	Specifies the retry interval in seconds when there is no reply from the peer.
on-demand	Specifies the on-demand mode to send keepalive only in the absence of any incoming data traffic, to check the liveness of the peer before sending any data.
periodic	Specifies the periodic mode to send keepalives regularly at a specified interval.

Command Default

DPD is disabled by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to configure DPD globally for all peers. The DPD configuration in a Internet Key Exchange Version 2 (IKEv2) profile overrides the global DPD configuration.

Examples

The following example shows how to configure the periodic mode for DPD:

```
Router(config)# crypto ikev2 dpd 500 50 periodic
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.

Command	Description
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 fragmentation

To configure Internet Key Exchange Version 2 (IKEv2) fragmentation, use the **crypto ikev2 fragmentation** command in global configuration mode. To disable the fragmentation, use the **no** form of this command.

crypto ikev2 fragmentation mtu *mtu-size*

no crypto ikev2 fragmentation

Syntax Description

mtu *mtu size*	Specifies the maximum transmission unit in bytes. The range is from 68 to 1500 bytes. **Note** The MTU size refers to the IP or UDP encapsulated IKEv2 packets.

Command Default

IKEv2 fragmentation is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to fragment the IKEv2 packets at IKEv2 layer and to avoid fragmentation after encryption.

Examples

The following example shows how to configure IKEv2 fragmentation:

```
Router# enable
Router(config)# crypto ikev2 fragmentation mtu 200
```

crypto ikev2 http-url

To enable lookup based on HTTP URL, use the **crypto ikev2 http-url** command in global configuration mode. To disable the lookup based on HTTP URL, use the **no** form of this command.

crypto ikev2 http-url cert

no crypto ikev2 http-url cert

Syntax Description

cert	Enable certificate lookup based on the HTTP URL.

Command Default

HTTP CERT is enabled by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1.(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to enable certificate lookup based on the HTTP URL. HTTP CERT indicates that the node is capable of looking up certificates based on the URL. This avoids the fragmentation that results when transferring large certificates.

Examples

The following example shows how to configure HTTP CERT:

```
Router(config)# crypto ikev2 http-url cert
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 limit	Defines call admission control for all peers.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 keyring

To configure an Internet Key Exchange version 2 (IKEv2) key ring, use the **crypto ikev2 keyring** command in the global configuration mode. To delete an IKEv2 keyring, use the **no** form of this command.

crypto ikev2 keyring *keyring-name*

no crypto ikev2 keyring *keyring-name*

Syntax Description

keyring-name	Name of the keyring.

Command Default

There is no default key ring.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

IKEv2 keyrings are independent of IKEv1 keyrings. The key differences are as follows:

- IKEv2 keyrings support symmetric and asymmetric preshared keys.
- IKEv2 keyrings do not support Rivest, Shamir and Adleman (RSA) public keys.
- IKEv2 keyrings are specified in the IKEv2 profile and are not looked up, unlike IKEv1 where keys are looked up on receipt of MM1 to negotiate the preshared key authentication method. The authentication method is not negotiated in IKEv2.
- IKEv2 keyrings are not associated with VPN routing and forwarding (VRF) during configuration. The VRF of an IKEv2 keyring is the VRF of the IKEv2 profile that refers the keyring.
- A single keyring can be specified in an IKEv2 profile, unlike an IKEv1 profile, which can specify multiple keyrings.
- A single keyring can be specified in more than one IKEv2 profile, if the same keys are shared across peers matching different profiles.
- An IKEv2 keyring is structured as one or more peer subblocks.

On an IKEv2 initiator, IKEv2 keyring key lookup is performed using the peer's hostname or the address, in that order. Use the **hostname** (ikev2 keyring) and **address** (ikev2 keyring) commands to configure the hostname and address in the IKEv2 keyring peer configuration mode.

On an IKEv2 responder, the key lookup is performed using the peer's IKEv2 identity or the address, in that order. Use the **address** (ikev2 keyring) and **identity** (ikev2 keyring) command to configure the address and identity in IKEv2 keyring peer configuration mode.

Note You cannot configure the same identity in more than one peer.

The best match is only performed for address configurations and a key lookup is performed for the remaining peer identification, including identity address.

Examples

The following example shows how to configure a keyring:

```
Router(config)# crypto ikev2 keyring keyring-1
Router(config-ikev2-keyring)# peer peer1
Router(config-ikev2-keyring-peer)# description example.com
Router(config-ikev2-keyring-peer)# address 0.0.0.0 0.0.0.0
Router(config-ikev2-keyring-peer)# pre-shared-key xyz-key
```

The following example shows how a keyring match is performed. In the example, the key lookup for peer 10.0.0.1 would first match the wildcard key abc-key, then the prefix key abc-key and finally the host key host1-abc-key and the best match host1-abc-key is used.

```
Router(config)# crypto ikev2 keyring keyring-1
Router(config-ikev2-keyring)# peer peer1
Router(config-ikev2-keyring-peer)# description example.com
Router(config-ikev2-keyring-peer)# address 0.0.0.0 0.0.0.0
Router(config-ikev2-keyring-peer)# pre-shared-key xyz-key

Router(config-ikev2-keyring)# peer peer1
Router(config-ikev2-keyring-peer)# description abc.example.com
Router(config-ikev2-keyring-peer)# address 10.0.0.0 255.255.0.0
Router(config-ikev2-keyring-peer)# pre-shared-key abc-key

Router(config-ikev2-keyring)# peer host1
Router(config-ikev2-keyring-peer)# description host1@abc.example.com
Router(config-ikev2-keyring-peer)# address 10.0.0.1
Router(config-ikev2-keyring-peer)# pre-shared-key host1-abc-key
```

In the following example, the key lookup for peer 10.0.0.1 would first match the host key host1-abc-key. Because, this is a specific match, no further lookup is performed.

```
Router(config)# crypto ikev2 keyring keyring-2
Router(config-ikev2-keyring)# peer host1
Router(config-ikev2-keyring-peer)# description host1 in abc.example.com sub-domain
Router(config-ikev2-keyring-peer)# address 10.0.0.1
Router(config-ikev2-keyring-peer)# pre-shared-key host1-abc-key

Router(config-ikev2-keyring)# peer host2
Router(config-ikev2-keyring-peer)# description example domain
Router(config-ikev2-keyring-peer)# address 0.0.0.0 0.0.0.0
Router(config-ikev2-keyring-peer)# pre-shared-key xyz-key
```

Related Commands

Command	Description
address (ikev2 keyring)	Specifies the IPv4 address or the range of the peers in IKEv2 keyring.
description (ikev2 keyring)	Describes an IKEv2 peer or a peer group for the IKEv2 keyring.
hostname (ikev2 keyring)	Specifies the hostname for the peer in the IKEv2 keyring.

Command	Description
identity (ikev2 keyring)	Identifies the peer with IKEv2 types of identity.
peer	Defines a peer or a peer group for the keyring.
pre-shared-key (ikev2 keyring)	Defines a preshared key for the IKEv2 peer.

crypto ikev2 limit

To enable call admission control in Internet Key Exchange Version 2 (IKEv2), use the **crypto ikev2 limit** command in global configuration mode. To disable call admission control, use the **no** form of this command.

crypto ikev2 limit {**max-in-negotiation-sa** | **max-sa**} *limit*

no crypto ikev2 limit {**max-in-negotiation-sa** | **max-sa**}

Syntax Description

max-in-negotiation-sa	Limits the total number of in-negotiation IKEv2 security associations (SAs) on the node.
max-sa	Limits the total number of IKEv2 SAs on the node.

Command Default

There is no configured limit on the number of IKEv2 SAs by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Call admission control limits the in-negotiation and total number of IKEv2 SA on a node.

Note In IKEv2, rekey is not a new security association (SA) unlike in IKEv1. Hence, the rekey SA is not counted.

Examples

The following example shows how to enable call admission control:

```
Router(config)# crypto ikev2 max-in-negotiation-sa limit 5000
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.

Command	Description
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 name mangler

To configure the Internet Key Exchange version 2 (IKEv2) name mangler, use the **crypto ikev2 name mangler** command in global configuration mode. To delete the name mangler, use the **no** form of this command.

crypto ikev2 name mangler *mangler-name*

no crypto ikev2 name mangler *mangler-name*

Syntax Description

mangler-name	IKEv2 mangler name.

Command Default

IKEv2 name mangler is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

The IKEv2 name mangler is used to derive a name for the AAA group or user authorization requests. The name mangler contains multiple statements—one for each identity type. The name mangler is derived from the specified portions of different forms of remote IKE identities or EAP identity. The name mangler is referred in the IKEv2 profile using the **aaa authorization** command.

After enabling this command, which puts the networking device in IKEv2 name mangler configuration mode, you can specify the characteristics for the name mangler using the following commands:

- **dn**—Derives the name from the remote identity of type distinguished name (DN).
- **eap**—Derives the name from remote identities of type Extensible Authentication Protocol (EAP).
- **email**—Derives the name from the remote identity of type e-mail.
- **fqdn**—Derives the name from the remote identity of type Fully Qualified Domain Name (FQDN).

Examples

The following example shows how to define name manglers based on identity of type FQDN:

```
crypto ikev2 name-mangler mangler1
 fqdn domain

crypto ikev2 name-mangler mangler2
 fqdn hostname

crypto ikev2 name-mangler mangler3
 fqdn all
```

The following example shows how to define name manglers based on identity of type e-mail:

```
crypto ikev2 name-mangler mangler1
 email domain

crypto ikev2 name-mangler mangler2
 email username

crypto ikev2 name-mangler mangler3
 email all
```

The following example shows how to define name manglers based on identity of type DN:

```
crypto ikev2 name-mangler mangler2
  DN country

crypto ikev2 name-mangler mangler3
  DN state

crypto ikev2 name-mangler mangler4
  DN organization

crypto ikev2 name-mangler mangler5
  DN organization-unit
```

The following example shows how to define name manglers based on identity of type EAP:

```
crypto ikev2 name-mangler mangler1
  eap all

crypto ikev2 name-mangler mangler2
  eap prefix user123 delimiter @

crypto ikev2 name-mangler mangler3
  eap suffix cisco delimiter

crypto ikev2 name-mangler mangler4
 eap DN common-name
```

Related Commands

Command	Description
dn (IKEv2)	Derives the name from identity of type DN.
eap (IKEv2)	Derives the name from identity of type EAP.
email	Derives the name from identity of type e-mail.
fqdn	Derives the name from identity of type FQDN.

crypto ikev2 nat

To configure Network Address Translation (NAT) keepalive for Internet Key Exchange Version 2 (IKEv2), use the **crypto ikev2 nat** command in global configuration mode. To delete NAT keepalive configuration, use the **no** form of this command.

crypto ikev2 nat keepalive *interval*

no crypto ikev2 nat keepalive *interval*

Syntax Description

keepalive *interval*	Specifies the NAT keepalive interval in seconds.

Command Default

NAT keepalive is disabled by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to configure NAT keepalive globally for all peers. The NAT keepalive configuration specified in the IKEv2 profile overrides the global configuration. NAT keepalive prevents the deletion of NAT translation entries in the absence of any traffic, when NAT is between IKEv2 peers.

Examples

The following example shows how to specify a NAT keepalive interval of 500 seconds:

```
Router(config)# crypto ikev2 nat keepalive 500
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.

Command	Description
crypto ikev2 window	Specifies the IKEv2 window size.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ikev2 policy

To configure an Internet Key Exchange Version 2 (IKEv2) policy, use the **crypto ikev2 policy** command in global configuration mode. To delete a policy, use the **no** form of this command.

crypto ikev2 policy *name*

no crypto ikev2 policy *name*

Syntax Description

name	Name of the IKEv2 policy.

Command Default

A default IKEv2 policy is used only in the absence of any user-defined IKEv2 policy. The default IKEv2 policy will have the default IKEv2 proposal and will match all local addresses in a global VPN Routing and Forwarding (VRF).

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

An IKEv2 policy contains the proposals that are used to negotiate the encryption, integrity, Psuedo-Random Function (PRF) algorithms and Diffie-Hellman (DH) group in SA_INIT exchange. IKEv2 policy can have match statements, which are used as selection criteria to select a policy for negotiation.

An IKEv2 policy must contain at least one proposal to be considered as complete, and can have more proposals and match statements.

A policy can have similar or different match statements. Match statements that are similar are logically ORed and match statements that are different are logically ANDed. There is no precedence between match statements of different types. If there are policies with similar match statements, the first policy configured is selected. If there are policies with overlapping match statements, the policy with the best or most specific match is selected.

A policy is matched as follows:

- If no IKEv2 policy is configured, the default policy is used for negotiating a SA that uses any local address in a global VRF.
- If IKEv2 policies are configured, the policy with the best match is selected.
- If none of the configured policies matches, the SA_INIT exchange does not start.

Examples

The following examples show how to configure a policy and how a policy match is performed:

```
Router(config)# crypto ikev2 policy policy1
Router(config-ikev2-policy)# proposal pro1
Router(config-ikev2-policy)# match fvrf green
Router(config-ikev2-policy)# match address local 10.0.0.1
```

The policy policy1 is selected and proposal pro1 is used for negotiating IKEv2 SA with the local address as 10.0.0.1 and the FVRF as green:

```
Router(config)# crypto ikev2 policy policy1
Router(config-ikev2-policy)# proposal pro1
Router(config-ikev2-policy)# match address local 10.0.0.1
```

The policy policy1 is selected and proposal pro1 is used for negotiation of the IKEv2 SA that is negotiatied with the local address as 10.0.0.1 and the FVRF as global:

```
Router(config)# crypto ikev2 policy policy1
Router(config-ikev2-policy)# proposal pro1
Router(config-ikev2-policy)# match fvrf green
```

The policy policy1 is selected and proposal pro1 is used for negotiation of the IKEv2 SA that is negotiatied with any local address and the FVRF as green.

How a Policy Match Is Performed

The following example shows how a policy is chosen out of two policies:

```
Router(config)# crypto ikev2 policy policy1
Router(config-ikev2-policy)# proposal1
Router(config-ikev2-policy)# match fvrf green

Router(config)# crypto ikev2 policy policy2
Router(config-ikev2-policy)# proposal1
Router(config-ikev2-policy)# match fvrf green
Router(config-ikev2-policy)# match local address 10.0.0.1
```

To negotiate the SA for local address 10.0.0.1 and FVRF as green, policy 2 is selected because policy 2 is the best match:

```
Router(config)# crypto ikev2 policy policy1
Router(config-ikev2-policy)# proposal2
Router(config-ikev2-policy)# match local address 10.0.0.1
Router(config-ikev2-policy)# match fvrf green

Router(config)# crypto ikev2 policy policy2
Router(config-ikev2-policy)# proposal1
Router(config-ikev2-policy)# match fvrf green
Router(config-ikev2-policy)# match local address 10.0.0.1
```

In this case, even though both the policies are the best match, policy1 is selected, because it was configured first.

Related Commands

Command	Description
match (ikev2 policy)	Matches an IKEv2 policy based on the parameters.
proposal	Specifies the proposals that must be used in the IKEv2 policy.
show crypto ikev2 policy	Displays the default or user-defined IKEv2 policy.

crypto ikev2 profile

To configure an Internet Key Exchange Version 2 (IKEv2) profile, use the **crypto ikev2 profile** command in global configuration mode. To delete the profile, use the **no** form of this command.

crypto ikev2 profile *profile-name*

no crypto ikev2 profile *profile-name*

Syntax Description

profile-name	Name of the IKEv2 profile.

Command Default

There is no default IKEv2 profile. However, there are default values for some commands under the profile, such as lifetime.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to define an IKEv2 profile. An IKEv2 profile is a repository of the nonnegotiable parameters of the IKE security associations (SAs) (such as local/remote identities and authentication methods) and the services that will be available to the authenticated peers that match the profile. The following are the characteristics of an IKEv2 profile:

- It must be attached to either a crypto map or an IPsec profile on the IKEv2 initiator and responder.
- It must contain a match identity or match certificate statement; otherwise the profile is considered incomplete and is unused.
- The statements match VRF, local or remote authentication methods are optional.

Table 21 describes the differences between IKEv1 and IKEv2 profiles.

Table 21 Differences between IKEv1 and IKEv2 Profiles

IKEv1	IKEv2
The authentication method is a negotiable parameter and must be specified in the ISAKMP policy.	The authentication method is not a negotiable parameter, can be asymmetric, and must be specified in the profile.
Multiple keyrings can be specified in the profile.	A single keyring can be specified in the profile and is optional also.

The IKEv2 profile applied on the crypto interface must be the same as IKEv2 profile that matches the peer identity received in the IKE_AUTH exchange.

Examples

The following examples show an IKEv2 profile matched on a remote identity and an IKEv2 profile catering to two peers using different authentication method.

IKEv2 Profile Matched on Remote Identity

The following profile caters to peers that identify using fqdn example.com and authenticate with rsa-signature using trustpoint-remote. The local node authenticates with pre-share using keyring-1.

```
Router(config)# crypto ikev2 profile profile2
Router(config-ikev2-profile)# match identity remote fqdn example.com
Router(config-ikev2-profile)# identity local email router2@example.com
Router(config-ikev2-profile)# authentication local pre-share
Router(config-ikev2-profile)# authentication remote rsa-sig
Router(config-ikev2-profile)# keyring keyring-1
Router(config-ikev2-profile)# pki trustpoint trustpoint-remote verify
Router(config-ikev2-profile)# lifetime 300
Router(config-ikev2-profile)# dpd 5 10 on-demand
Router(config-ikev2-profile)# virtual-template 1
```

IKEv2 Profile Catering to Two Peers Using Different Authentication Method

The following profile caters to two peers: user1@example.com that authenticate with pre-share using keyring-1, and user2@example.com authenticates with rsa-signature using trustpoint-remote. However, the local peer authenticates the remote peers with rsa-signature using trustpoint-local.

```
Router(config)# crypto ikev2 profile profile2
Router(config-ikev2-profile)# match identity remote email user1@example.com
Router(config-ikev2-profile)# match identity remote email user2@example.com
Router(config-ikev2-profile)# identity local email router2@abc.com
Router(config-ikev2-profile)# authentication local rsa-sig
Router(config-ikev2-profile)# authentication remote pre-share
Router(config-ikev2-profile)# authentication remote rsa-sig
Router(config-ikev2-profile)# keyring keyring-1
Router(config-ikev2-profile)# pki trustpoint trustpoint-local sign
Router(config-ikev2-profile)# pki trustpoint trustpoint-remote verify
Router(config-ikev2-profile)# lifetime 300
Router(config-ikev2-profile)# dpd 5 10 on-demand
Router(config-ikev2-profile)# virtual-template 1
```

EAP Authentication with External EAP Server

The following example shows how to configure the remote access server using the remote EAP authentication method with an external EAP server:

```
aaa new-model
aaa authentication login aaa-eap-list default group radius
!
crypto ikev2 profile profile2
 authentication remote eap
 aaa authentication eap aaa-eap-list
```

EAP Authentication with Local and External EAP

The following example shows how to configure the remote access server with local and external EAP server using the remote EAP authentication method:

```
aaa new-model
aaa authentication login aaa-eap-list default group radius
aaa authentication login aaa-eap-local-list default group tacacs
```

```
!
crypto ikev2 profile profile2
 authentication remote eap
 authentication remote eap-local
 aaa authentication eap aaa-eap-list
 aaa authentication eap-local aaa-eap-local-list
```

Configuring the Local Policy

This example shows how to configure the AAA authorization for a local group policy:

```
aaa new-model
aaa authorization network aaa-group-list default local
!
 crypto ikev2 client configuration group cisco
  pool addr-pool1
  dns 198.51.100.1 198.51.100.100
  wins 203.0.113.1 203.0.113.115
 !
 crypto ikev2 profile profile1
  authentication remote eap
  aaa authorization group aaa-group-list abc
```

The aaa-group-list specifies that the group authorization is local and that the AAA username is abc. The authorization list name corresponds to the group policy defined in the **crypto ikev2 client configuration group** command.

External AAA-based Group Policy

This example shows how to configure an external AAA-based group policy. The aaa-group-list specifies that the group authorization is RADIUS based. The name mangler derives the group name from the domain part of ID-FQDN, which is abc.

```
 aaa new-model
 aaa authorization network aaa-group-list default group radius
 !
 crypto ikev2 name-mangler mangler1
  fqdn domain
  !
 crypto ikev2 profile profile1
  identity remote fqdn host1.abc
  authentication remote eap
  aaa authorization group aaa-group-list name-mangler mangler1
```

External AAA-based User Policy

This example shows how to configure an external AAA-based group policy. The aaa-user-list specifies that the user authorization is RADIUS based. The name mangler derives the username from the hostname part of ID-FQDN, which is host1.

```
aaa new-model
aaa authorization network aaa-user-list default group radius
!
crypto ikev2 name-mangler mangler2
 fqdn hostname
!
crypto ikev2 profile profile1
 match identity remote fqdn host1.abc
  authentication remote eap
 aaa authorization user aaa-user-list name-mangler mangler2
```

Related Commands

Command	Description
aaa authentication (IKEv2 profile)	Defines the AAA authentication list for EAP authentication.
aaa authorization (IKEv2 profile)	Defines the AAA authorization for a local or group policy.
authentication (IKEv2 profile)	Defines the local and remote authentication methods.
crypto ikev2 keyring	Defines an IKEv2 keyring.
show crypto ikev2 profile	Displays the IKEv2 profile.

crypto ikev2 proposal

To configure an Internet Key Exchange Version 2 (IKEv2) proposal, use the **crypto ikev2 proposal** command in global configuration mode. To delete an IKEv2 proposal, use the **no** form of this command.

crypto ikev2 proposal *name*

no crypto ikev2 proposal *name*

Syntax Description

name	Name of the proposal. The proposals are attached to IKEv2 policies using the **proposal** command.

Command Default

The default IKEv2 proposal is used.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

An IKEv2 proposal is a set of transforms used in the negotiation of IKEv2 SA as part of the IKE_SA_INIT exchange. An IKEv2 proposal is regarded as complete only when it has at least an encryption algorithm, an integrity algorithm and a Diffie-Hellman (DH) group configured. If no proposal is configured and attached to an IKEv2 policy, then the default proposal is used in negotiation. The default proposal is a collection of commonly used algorithms, which are as follows:

```
encryption aes-cbc-128 3des
integrity sha md5
group 5 2
```

The transforms shown translate to the following combinations in the following order of priority:

```
aes-cbc-128, sha, 5
aes-cbc-128, sha, 2
aes-cbc-128, md5, 5
aes-cbc-128, md5, 2
3des, sha, 5
3des, sha, 2
3des, md5, 5
3des, md5, 2
```

Although this command is similar to the **crypto isakmp policy** command, the IKEv2 proposal differs as follows:

- An IKEv2 proposal allows configuration of one or more transforms for each transform type.
- An IKEv2 proposal does not have any associated priority.

Note The IKEv2 proposals must be attached to the IKEv2 policies for using the proposals in negotiation. If a proposal is not configured, then the default IKEv2 proposal is used with the default IKEv2 policy.

When multiple transforms are configured for a transform type, the order of priority is from left to right.

A proposal with multiple transforms for each transform type translates to all possible combinations of transforms. If only a subset of these combinations is required, then they must be configured as individual proposals.

```
Router(config)# crypto ikev2 proposal proposal-1
Router(config-ikev2-proposal)# encryption 3des, aes-cbc-128
Router(config-ikev2-proposal)# integrity sha, md5
Router(config-ikev2-proposal)# group 2
```

For example, the commands shown translates to the following transform combinations:

```
3des, sha, 2
aes-cbc-128, sha, 2
3des, md5, 2
aes-cbc-128, md5, 2
```

To configure the first and last transform combinations, the commands are as follows:

```
Router(config)# crypto ikev2 proposal proposal-1
Router(config-ikev2-proposal)# encryption 3des
Router(config-ikev2-proposal)# integrity sha
Router(config-ikev2-proposal)# group 2

Router(config)# crypto ikev2 proposal proposal-2
Router(config-ikev2-proposal)# encryption aes-cbc-128
Router(config-ikev2-proposal)# integrity md5
Router(config-ikev2-proposal)# group 2
```

Examples

The following examples show how to configure a proposal:

IKEv2 Proposal with One Transform for Each Transform Type

```
Router(config)# crypto ikev2 proposal proposal-1
Router(config-ikev2-proposal)# encryption 3des
Router(config-ikev2-proposal)# integrity sha
Router(config-ikev2-proposal)# group 2
```

IKEv2 Proposal with Multiple Transforms for Each Transform Type

```
Router(config)# crypto ikev2 proposal proposal-2
Router(config-ikev2-proposal)# encryption 3des aes-cbc-128
Router(config-ikev2-proposal)# integrity sha md5
Router(config-ikev2-proposal)# group 2 5
```

The IKEv2 proposal **proposal-2** shown translates to the following prioritized list of transform combinations:

- 3des, sha, 2
- 3des, sha, 5
- 3des, md5, 2
- 3des, md5, 5
- aes-cbc-128, sha, 2

- aes-cbc-128, sha, 5
- aes-cbc-128, md5, 2
- aes-cbc-128, md5, 5

IKEv2 Proposals on the Initiator and Responder

The proposal of the initiator is as follows:

```
Router(config)# crypto ikev2 proposal proposal-1
Router(config-ikev2-proposal)# encryption 3des aes-cbc-128
Router(config-ikev2-proposal)# integrity sha md5
Router(config-ikev2-proposal)# group 2 5
```

The proposal of the responder is as follows:

```
Router(config)# crypto ikev2 proposal proposal-2
Router(config-ikev2-proposal)# encryption aes-cbc-128 3des
Router(config-ikev2-proposal)# integrity md5 sha
Router(config-ikev2-proposal)# group 5 2
```

In the scenario shown, the initiator choice of algorithms is preferred and the selected algorithms are as follows:

```
encryption 3des
integrity sha
group 2
```

Related Commands

Command	Description
encryption (ikev2 proposal)	Specifies the encryption algorithm in an IKEv2 proposal.
group (ikev2 proposal)	Specifies the Diffie-Hellman group identifier in an IKEv2 proposal.
integrity (ikev2 proposal)	Specifies the integrity algorithm in an IKEv2 proposal.
show crypto ikev2 proposal	Displays the parameters for each IKEv2 proposal.

crypto ikev2 window

To configure the Internet Key Exchange Version 2 (IKEv2) window size, use the **crypto ikev2 window** command in global configuration mode. To delete IKEv2 window configuration, use the **no** form of this command.

crypto ikev2 window *window-size*

no crypto ikev2 window

Syntax Description

window-size	Size of the window that can range from 1 to 20.

Command Default

The default window size is 5.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Window size allows multiple IKEv2 request-response pairs in transit. Use this command to specify the IKEv2 window size to have multiple IKEv2 request-response pairs in transit.

Examples

The following example shows how to configure a window size of 10:

```
Router(config)# crypto ikev2 window size 10
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.

Command	Description
crypto ikev2 nat	Defines NAT keepalive globally for all peers.
crypto logging ikev2	Enables IKEv2 syslog messages on a server.

crypto ipsec client ezvpn (global)

To create a Cisco Easy VPN remote configuration and enter the Cisco Easy VPN remote configuration mode, use the **crypto ipsec client ezvpn** command in global configuration mode. To delete the Cisco Easy VPN remote configuration, use the **no** form of this command.

crypto ipsec client ezvpn *name*

no crypto ipsec client ezvpn *name*

Note A separate **crypto ipsec client ezvpn** command in interface configuration mode assigns a Cisco Easy VPN remote configuration to the interface.

Syntax Description

name	Identifies the Cisco Easy VPN remote configuration with a unique, arbitrary name.

Command Default

Newly created Cisco Easy VPN remote configurations default to client mode.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(4)YA	This command was introduced for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(8)YJ	This command was enhanced to enable you to manually establish and terminate an IPsec VPN tunnel on demand for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.3(4)T	The **username** command was added, and the **pee**command was changed so that the command may now be input multiple times.
12.3(7)XR	The **acl** and **backup** commands were added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.3(11)T	The **acl** command was integrated into Cisco IOS Release 12.3(11)T. However, the **backup** command was not integrated into Cisco IOS Release 12.3(11)T.
12.4(2)T	The **virtual-interface** command was added.
12.4(4)T	The **default** keyword was added to the **peer** command, and the **flow allow acl** and **idle-time** commands were added.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11)T	The **nat acl** and **nat allow** commands were added.

Usage Guidelines

The **crypto ipsec client ezvpn** command creates a Cisco Easy VPN remote configuration and then enters the Cisco Easy VPN remote configuration mode, at which point you can enter the following commands:

- **acl** {*acl-name* | *acl-number*}—Specifies multiple subnets in a Virtual Private Network (VPN) tunnel. Up to 50 subnets may be configured.
  - The *acl-name* argument is the name of the access control list (ACL).
  - The *acl-number* argument is the number of the ACL.

Note Use the **acl** command in the Network Extension Mode (NEM) to expand the networks that are being extended. The **permit** statements in the ACL allow you to add additional networks to the list of extended networks. Without an ACL, the VPN only provides connectivity with the directly connected network of the inside interface.

- **backup** {*ezvpn-config-name*} **track** {*tracked-object-number*}—Specifies the Easy VPN configuration that will be activated when the backup is triggered.
  - **backup** {*ezvpn-config-name*}—Specifies the Easy VPN configuration that will be activated when the backup is triggered.
  - **track** {*tracked-object-number*}—Specifies the link to the tracking system so that the Easy VPN state machine can get the notification to trigger the backup.
- **connect** [**auto** | **manual** | **acl**]—Manually establishes and terminates an IP Security (IPsec) tunnel on demand.
  - The **auto** keyword is the default setting, because it was the initial Cisco Easy VPN remote functionality. The IPsec VPN tunnel is automatically connected when the Cisco Easy VPN Remote feature is configured on an interface.
  - The **manual** keyword specifies the manual setting to direct the Cisco Easy VPN remote to wait for a command or application programming interface (API) call before attempting to establish the Cisco Easy VPN remote connection. When the tunnel times out or fails, subsequent connections have to wait for the command to reset to manual or to an API call.
  - The **acl** keyword specifies the ACL-triggered setting, which is used for transactional-based applications and dial backup. Using this option, you can define the "interesting" traffic that triggers the tunnel to be established.
- **default**—Sets the following command to its default values.
- **exit**—Exits the Cisco Easy VPN configuration mode and returns to global configuration mode.
- **flow allow acl** [*name* | *number*]—Restricts the client from sending traffic in clear text when the tunnel is down. The *name* argument is the access list name. The *number* argument is the access list number, which can be 100 through 199.
- **group** *group-name* **key** *group-key*—Specifies the group name and key value for the VPN connection.
- **idletime**—(Optional) Sets the idle time after which an Easy VPN tunnel is brought down.

- **local-address** *interface-name*—Informs the Cisco Easy VPN remote which interface is used to determine the public IP address, which is used to source the tunnel. This command applies only to the Cisco uBR905 and Cisco uBR925 cable access routers.
  - The value of the *interface-name* argument specifies the interface used for tunnel traffic.

  After specifying the local address used to source tunnel traffic, the IP address can be obtained in two ways:
  - The **local-address** command can be used with the **cable-modem dhcp-proxy** {**interface loopback** *number*} command to obtain a public IP address and automatically assign it to the loopback interface.
  - The IP address can be manually assigned to the loopback interface.
- **mode** {**client | network-extension | network extension plus**}—Specifies the VPN mode of operation of the router:
  - The **client** keyword (default) automatically configures the router for Cisco Easy VPN client mode operation, which uses Network Address Translation (NAT) or Peer Address Translation (PAT) address translations. When the Cisco Easy VPN remote configuration is assigned to an interface, the router automatically creates the NAT or PAT and access list configuration needed for the VPN connection.
  - The **network-extension** keyword specifies that the router should become a remote extension of the enterprise network at the other end of the VPN connection. The PCs that are connected to the router typically are assigned an IP address in the address space of the enterprise network.
  - The **network extension plus** keyword is identical to network extension mode with the additional capability of being able to request an IP address via mode configuration and automatically assign it to an available loopback interface. The IPsec security associations (SAs) for this IP address are automatically created by Easy VPN Remote. The IP address is typically used for troubleshooting (using ping, Telnet, and Secure Shell).
- **nat acl** {*acl-name* | *acl-number*}—Enables split-tunneling for the traffic specified by the ACL name or the ACL number.
  - The *acl-name* argument is the name of the ACL.
  - The *acl-number* argument is the number of the ACL.
- nat allow—Allows NAT to be integrated with Cisco Easy VPN.
- **no**—Removes the command or sets it to its default values.
- **peer** {*ipaddress* | *hostname*} [**default**]—Sets the peer IP address or hostname for the VPN connection. A hostname can be specified only when the router has a Domain Name System (DNS) server available for hostname resolution.

  The **peer** command may be input multiple times.

  The **default** keyword defines the given peer as the primary peer. When Phase 1 SA negotiations fail and Easy VPN fails over from the primary peer to the next peer on its backup list and the primary peer is again available, the current connection is torn down and the primary peer is reconnected.
- **username** *name* **password** {**0** | **6**} {*password*}—Allows you to save your extended authentication (Xauth) password locally on the PC. On subsequent authentications, you may activate the save-password tick box on the software client or add the username and password to the Cisco IOS hardware client profile. The setting remains until the save-password attribute is removed from the server group profile.
  - **0** specifies that an unencrypted password will follow.
  - **6** specifies that an encrypted password will follow.

  - *password* specifies an unencrypted (cleartext) user password.

  The save-password option is useful only if the user password is static, that is, it is not a one-time password (OTP), such as a password generated by a token.

- **virtual-interface** [*virtual-template-number*]—Specifies a virtual interface for an Easy VPN remote device. If a virtual template number is specified, the virtual interface is derived from the virtual template that is configured. If a virtual template number is not specified, a generic virtual-access interface of the type tunnel is created. If the creation is successful, Easy VPN makes the virtual-access interface its outside interface (that is, the crypto map and NAT are applied on the virtual-access interface). If the creation is a failure, Easy VPN prints an error message and remains in the IDLE state.

After configuring the Cisco Easy VPN remote configuration, use the **exit** command to exit the Cisco Easy VPN remote configuration mode and return to global configuration mode.

Note You cannot use the **no crypto ipsec client ezvpn** command to delete a Cisco Easy VPN remote configuration that is assigned to an interface. You must remove that Cisco Easy VPN remote configuration from the interface before you can delete the configuration.

Examples

The following example shows a Cisco Easy VPN remote configuration named "telecommuter-client" being created on a Cisco uBR905 or Cisco uBR925 cable access router and being assigned to cable interface 0:

```
Router# configure terminal
Router(config)# crypto ipsec client ezvpn telecommuter-client
Router(config-crypto-ezvpn)# group telecommute-group key secret-telecommute-key
Router(config-crypto-ezvpn)# peer telecommuter-server
Router(config-crypto-ezvpn)# mode client
Router(config-crypto-ezvpn)# exit
Router(config)# interface c0
Router(config-if)# crypto ezvpn telecommuter-client
Router(config-if)# exit
```

Note Specifying the **mode client** option as shown above is optional because this is a default configuration for these options.

The following example shows the Cisco Easy VPN remote configuration named "telecommuter-client" being removed from the interface and then deleted:

```
Router# configure terminal
Router(config)# interface e1
Router(config-if)# no crypto ipsec client ezvpn telecommuter-client
Router(config-if)# exit
Router(config)# no crypto ipsec client ezvpn telecommuter-client
```

The following example shows that a virtual IPsec interface has been configured for the Easy VPN remote device:

```
crypto ipsec client ezvpn EasyVPN1
 virtual-interface 3
```

Related Commands

Command	Description
crypto ipsec client ezvpn (interface)	Assigns a Cisco Easy VPN remote configuration to an interface.

crypto ipsec client ezvpn (interface)

To assign a Cisco Easy Virtual Private Network (VPN) remote configuration to an interface other than a virtual interface, to specify whether the interface is outside or inside, and to configure multiple outside and inside interfaces, use the **crypto ipsec client ezvpn** command in interface configuration mode. To remove the Cisco Easy VPN remote configuration from the interface, use the **no** form of this command.

crypto ipsec client ezvpn *name* [**outside | inside**]

no crypto ipsec client ezvpn *name* [**outside | inside**]

Syntax Description

name	Specifies the Cisco Easy VPN remote configuration to be assigned to the interface. **Note** The interface specified cannot be a virtual interface.
outside	(Optional) Specifies the outside interface of the IP Security (IPsec) client router. You can add up to four outside tunnels for all platforms, one tunnel per outside interface.
inside	(Optional) Specifies the inside interface of the IPsec client router. The Cisco 1700 series has no default inside interface, and any inside interface must be configured. The Cisco 800 series routers and Cisco uBR905 and Cisco uBR925 cable access routers have default inside interfaces. However, you can configure any inside interface and add up to three inside interfaces for all platforms.

Defaults

The default inside interface is the Ethernet interface on Cisco 800 series routers and Cisco uBR905 and Cisco uBR925 cable access routers.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(4)YA	This command was introduced on Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(8)YJ	This command was enhanced to enable you to configure multiple outside and inside interfaces for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

The **crypto ipsec client ezvpn** command assigns a Cisco Easy VPN remote configuration to an interface, enabling the creation of a VPN connection over that interface to the specified VPN peer. If the Cisco Easy VPN remote configuration is configured for the client mode of operation, the router is also automatically configured for network address translation (NAT) or port address translation (PAT) and for an associated access list.

Note The **crypto ipsec client ezvpn** command is not supported on virtual interfaces.

Release 12.2(8)YJ

The **crypto ipsec client ezvpn** command was enhanced to allow you to configure multiple outside and inside interfaces. To configure multiple outside and inside interfaces, you must use the **interface** *interface-name* command to first define the type of interface on the IPsec client router.

- In client mode for the Cisco Easy VPN client, a single security association (SA) connection is used for encrypting and decrypting the traffic coming from all the inside interfaces. In network extension mode, one SA connection is established for each inside interface.
- When a new inside interface is added or an existing one is removed, all established SA connections are deleted and new ones are initiated.
- Configuration information for the default inside interface is shown with the **crypto ipsec client ezvpn name inside** command. All inside interfaces, whether they belong to a tunnel, are listed in interface configuration mode as an inside interface, along with the tunnel name.

Release 12.2(4)YA

The following restrictions apply to the **crypto ipsec client ezvpn** command:

- The Cisco Easy VPN remote feature supports only one tunnel, so the **crypto ipsec client ezvpn** command can be assigned to only one interface. If you attempt to assign it to more than one interface, an error message is displayed. You must use the **no** form of this command to remove the configuration from the first interface before assigning it to the second interface.
- The **crypto ipsec client ezvpn** command should be assigned to the outside interface of the NAT or PAT. This command cannot be used on the inside NAT or PAT interface. On some platforms, the inside and outside interfaces are fixed.

  For example, on Cisco uBR905 and Cisco uBR925 cable access routers, the outside interface is always the cable interface. On Cisco 1700 series routers, the FastEthernet interface defaults to being the inside interface, so attempting to use the **crypto ipsec client ezvpn** command on the FastEthernet interface displays an error message.

Note A separate **crypto ipsec client ezvpn** command exists in global configuration mode that creates a Cisco Easy VPN remote configuration.

You must first use the global configuration version of the **crypto ipsec client ezvpn** command to create a Cisco Easy VPN remote configuration before assigning it to an interface.

Examples

The following example shows a Cisco Easy VPN remote configuration named “telecommuter-client” being assigned to the cable interface on a Cisco uBR905 or a Cisco uBR925 cable access router:

```
Router# configure terminal
Router(config)# interface c0
Router(config-if)# crypto ipsec client ezvpn telecommuter-client
```

```
Router(config-if)# exit
```

The following example first shows an attempt to delete the Cisco Easy VPN remote configuration named "telecommuter-client," but the configuration cannot be deleted because it is still assigned to an interface. The configuration is then removed from the interface and deleted.

```
Router# configure terminal
Router(config)# no crypto ipsec client ezvpn telecommuter-client
Error: crypto map in use by interface; cannot delete
Router(config)# interface e1
Router(config-if)# no crypto ipsec client ezvpn telecommuter-client
Router(config-if)# exit
Router(config)# no crypto ipsec client ezvpn telecommuter-client
```

Related Commands

Command	Description
crypto ipsec client ezvpn (global)	Creates and modifies a Cisco Easy VPN remote configuration.
interface	Configures an interface type.

crypto ipsec client ezvpn connect

To connect to a specified IPSec Virtual Private Network (VPN) tunnel in a manual configuration, use the **crypto ipsec client ezvpn connect** command in privileged EXEC mode. To disable the connection, use the **no** form of this command.

crypto ipsec client ezvpn connect *name*

no crypto ipsec client ezvpn connect *name*

Syntax Description

name	Identifies the IPSec VPN tunnel with a unique, arbitrary name.

Command Modes

Privileged EXEC (#)

12.2(8)YJ	This command was introduced on Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

This command is used with the **connect** [**auto** | **manual** | **acl**] subcommand. After the manual setting is designated, the Cisco Easy VPN remote waits for a command or application programming interface (API) call before attempting to establish the Cisco Easy VPN remote connection.

If the configuration is manual, the tunnel is connected only after the **crypto ipsec client ezvpn connect** *name* command is entered in privileged EXEC mode, and after the **connect** [**auto**] | **manual** subcommand is entered.

Examples

The following example shows how to connect an IPSec VPN tunnel named ISP-tunnel on a Cisco uBR905/uBR925 cable access router:

```
Router# crypto ipsec client ezvpn connect ISP-tunnel
```

Related Commands

Command	Description
connect	Manually establishes and terminates an IPSec VPN tunnel on demand.
crypto ipsec client ezvpn (global)	Creates and modifies a Cisco Easy VPN remote configuration.

crypto ipsec client ezvpn xauth

To respond to a pending Virtual Private Network (VPN) authorization request, use the **crypto ipsec client ezvpn xauth** command in privileged EXEC mode.

crypto ipsec client ezvpn xauth *name*

Syntax Description

name	Identifies the IP Security (IPSec) VPN tunnel with a unique, arbitrary name. This name is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(4)YA	This command was introduced on Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(8)YJ	This command was enhanced to specify an IPSec VPN tunnel for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(8)YJ	This command was enhanced to specify an IPSec VPN tunnel for Cisco 806, Cisco 826, Cisco 827, and Cisco 828 routers; Cisco 1700 series routers; and Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

If the tunnel name is not specified, the authorization request is made on the active tunnel. If there is more than one active tunnel, the command fails with an error requesting that you specify the tunnel name.

When making a VPN connection, individual users might also be required to provide authorization information, such as a username or password. When the remote end requires this information, the router displays a message on the console of the router instructing the user to enter the **crypto ipsec client ezvpn xauth** command. The user then uses command-line interface (CLI) to enter this command and to provide the information requested by the prompts that follow after the command has been entered.

Note If the user does not respond to the authentication notification, the message is repeated every 10 seconds.

Examples

The following example shows an example of the user being prompted to enter the **crypto ipsec client ezvpn xauth** command. The user then enters the requested information and continues.

```
Router#
20:27:39: EZVPN: Pending XAuth Request, Please enter the following command:
20:27:39: EZVPN: crypto ipsec client ezvpn xauth

Router> crypto ipsec client ezvpn xauth
Enter Username and Password: userid
Password: ************
```

Related Commands

Command	Description
crypto ipsec client ezvpn (interface)	Assigns a Cisco Easy VPN Remote configuration to an interface.

crypto ipsec default transform-set

To enable default IP Security (IPsec) transform sets, use the **crypto ipsec default transform-set** command in global configuration mode. To disable the default IPsec transform sets, use the **no** form of this command.

crypto ipsec default transform-set

no crypto ipsec default transform-set

Syntax Description

This command has no arguments or keywords.

Command Default

The default IPsec transform sets are enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(20)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

A default transform set will be used by any crypto map or ipsec profile where no other transform set has been configured if the following is true:

- The default transform sets have not been disabled with the **no crypto ipsec default transform-set** command.
- The crypto engine in use supports the encryption algorithm.

Each default transform set defines both an Encapsulation Security Protocol (ESP) encryption transform type and an ESP authentication transform type as shown in Table 22.

Table 22 Default Transform Sets and Parameters

Default Transform Name	ESP Encryption Transform and Description	ESP Authentication Transform and Description
#$!default_transform_set_0	esp-3des (ESP with the 168-bit Triple Data Encryption Standard [3DES or Triple DES] encryption algorithm)	esp-sha-hmac (ESP with the Secure Hash Algorithm [SHA-1, HMAC variant] authentication algorithm)
#$!default_transform_set_1	esp-aes (ESP with the 128-bit Advanced Encryption Standard [AES] encryption algorithm)	esp-sha-hmac

Examples

The following example displays output from the **show crypto ipsec default transform-set** command when the default transform sets are enabled, the default setting.

```
Router# show crypto ipsec default transform-set

Transform set #$!default_transform_set_1: { esp-aes esp-sha-hmac  }
   will negotiate = { Transport,  },

Transform set #$!default_transform_set_0: { esp-3des esp-sha-hmac  }
   will negotiate = { Transport,  },
```

The following example displays output from the **show crypto ipsec default transform-set** command when the default transform sets have been disabled with the **no crypto ipsec default transform-set** command.

```
Router(config)# no crypto ipsec default transform-set
Router(config)# exit
Router#
Router# show crypto ipsec default transform-set
! There is no output.
Router#
```

The following is example system log message that is generated whenever IPsec security associations (SAs) have negotiated with a default transform set.

```
%CRYPTO-5-IPSEC_DEFAULT_TRANSFORM: Using Default IPSec transform-set
```

Related Commands

Command	Description
show crypto isakmp default policy	Displays the default IKE policies currently in use.

crypto ipsec df-bit (global)

To set the DF bit for the encapsulating header in tunnel mode to all interfaces, use the **crypto ipsec df-bit** command in global configuration mode.

crypto ipsec df-bit [**clear** | **set** | **copy**]

Syntax Description

clear	Outer IP header will have the DF bit cleared, and the router may fragment the packet to add the IP Security (IPSec) encapsulation.
set	Outer IP header will have the DF bit set; however, the router may fragment the packet if the original packet had the DF bit cleared.
copy	The router will look in the original packet for the outer DF bit setting. The **copy** keyword is the default setting.

Defaults

The default is **copy**.

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)T	This command was introduced.

Usage Guidelines

Use the **crypto ipsec df-bit** command in global configuration mode to configure your router to specify the DF bit in an encapsulated header.

You may want use the **clear** setting for the DF bit when encapsulating tunnel mode IPSec traffic so you can send packets larger than the available maximum transmission unit (MTU) size or if you do not know what the available MTU size is.

If this command is enabled without a specified setting, the router will use the **copy** setting as the default.

Examples

The following example shows how to clear the DF bit on all interfaces:

```
crypto ipsec df-bit clear
```

crypto ipsec df-bit (interface)

To set the DF bit for the encapsulating header in tunnel mode to a specific interface, use the **crypto ipsec df-bit** command in interface configuration mode.

crypto ipsec df-bit [**clear** | **set** | **copy**]

Syntax Description

clear	Outer IP header has the DF bit cleared, and the router may fragment the packet to add the IP Security (IPSec) encapsulation.
set	Outer IP header has the DF bit set; however, the router may fragment the packet if the original packet had the DF bit cleared.
copy	The router looks in the original packet for the outer DF bit setting.

Defaults

The default setting is the same as the **crypto ipsec df-bit** command setting in global configuration mode.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(2)T	This command was introduced.

Usage Guidelines

Use the **crypto ipsec df-bit** command in interface configuration mode to configure your router to specify the DF bit in an encapsulated header. This command overrides any existing DF bit global settings.

You may want use the **clear** setting for the DF bit when encapsulating tunnel mode IPSec traffic so you can send packets larger than the available maximum transmission unit (MTU) size or if you do not know what the available MTU size is.

If this command is enabled without a specified setting, the router uses the **crypto ipsec df-bit** command setting in global configuration mode.

Examples

In following example, the router is configured to globally clear the setting for the DF bit and copy the DF bit on the interface named Ethernet0. Thus, all interfaces *except* Ethernet0 allows the router to send packets larger than the available MTU size; Ethernet0 allows the router to fragment the packet.

```

```

crypto ipsec fragmentation (global)

To enable prefragmentation for IP Security (IPSec) Virtual Private Networks (VPNs) on a global basis, use the **crypto ipsec fragmentation** command in global configuration mode. To disable a manually configured command, use the **no** form of this command.

crypto ipsec fragmentation {**before-encryption** | **after-encryption**}

no crypto ipsec fragmentation {**before-encryption** | **after-encryption**}

Syntax Description

before-encryption	Enables prefragmentation for IPSec VPNs. The default is that prefragmentation is enabled.
after-encryption	Disables prefragmentation for IPSec VPNs.

Command Default

If you do not enter this command, prefragmentation is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(11b)E	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **before-encryption** keyword to enable prefragmentation for IPSec VPNs; use the **after-encryption** keyword to disable prefragmentation for IPSec VPNs. This command allows an encrypting router to predetermine the encapsulated packet size from information available in transform sets, which are configured as part of the IPSec security association (SA). If it is predetermined that the packet will exceed the maximum transmission unit (MTU) of the output interface, the packet is fragmented before encryption.

Note This command does not show up in the a running configuration if the default global command is enabled. It shows in the running configuration only when you explicitly enable the command on an interface.

Examples

The following example shows how to globally enable prefragmentation for IPSec VPNs:

```
crypto ipsec fragmentation before-encryption
```

crypto ipsec fragmentation (interface)

To enable prefragmentation for IP Security (IPSec) Virtual Private Networks (VPNs) on an interface, use the **crypto ipsec fragmentation** command in interface configuration mode. To disable a manually configured command, use the **no** form of this command.

crypto ipsec fragmentation {**before-encryption** | **after-encryption**}

no crypto ipsec fragmentation {**before-encryption** | **after-encryption**}

Syntax Description

before-encryption	Enables prefragmentation for IPSec VPNs.
after-encryption	Disables prefragmentation for IPSec VPNs.

Defaults

If no other prefragmentation for IPSec VPNs commands are in the configuration, the router will revert to the default global configuration.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(11b)E	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **before-encryption** keyword to enable prefragmentation for IPSec VPNs per interface; use the **after-encryption** keyword to disable prefragmentation for IPSec VPNs. This command allows an encrypting router to predetermine the encapsulated packet size from information available in transform sets, which are configured as part of the IPSec security association (SA). If it is predetermined that the packet will exceed the maximum transmission unit (MTU) of output interface, the packet is fragmented before encryption.

Examples

The following example shows how to enable prefragmentation for IPSec VPNs on an interface and then how to display the output of the show running configuration command:

Note This command shows in the running configuration only when you explicitly enable it on the interface.

```
Router(config-if)# crypto ipsec fragmentation before-encryption
Router(config-if)# exit
```

```
Router# show running-config

crypto isakmp policy 10
 authentication pre-share
crypto isakmp key abcd123 address 209.165.202.130
!
crypto ipsec transform-set fooprime esp-3des esp-sha-hmac
!
crypto map bar 10 ipsec-isakmp
 set peer 209.165.202.130
 set transform-set fooprime
 match address 102
```

crypto ipsec ipv4-deny

To configure deny address ranges at the global (IPSec VPN SPA) level, use the **crypto ipsec ipv4 deny-policy** command in global configuration mode.

crypto ipsec ipv4-deny {**jump | clear | drop**}

Syntax Description

jump	Causes the search to jump to the beginning of the ACL associated with the next sequence in the crypto map and continues the search when a deny address is hit.
clear	Allows traffic to pass through in the clear (unencrypted) state when a deny address is hit.
drop	Causes traffic to be dropped when a deny address is hit.

Command Modes

The default behavior is **jump**.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXE2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use this command to prevent repeated address ranges from being programmed in the hardware, resulting in more efficient TCAM space utilization.

Specifying a deny address range in an ACL results in “jump” behavior. When a denied address range is hit, it forces the search to “jump” to the beginning of the ACL associated with the next sequence in a crypto map and continue the search.

The **clear** keyword allows a deny address range to be programmed in hardware. The deny addresses are then filtered out for encryption and decryption. If the voice private network (VPN) mode is crypto-connect, when a deny address is hit, the search is stopped and traffic is allowed to pass in the clear (unencrypted) state.

If the VPN mode is VRF mode, the deny address matching traffic is dropped.

If you want to pass clear traffic on an address, you must insert a deny address range for each sequence in a crypto map.

Each permit list of addresses inherits all the deny address ranges specified in the ACL. A deny address range causes the software to do a subtraction of the deny address range from a permit list, and creates multiple permit address ranges that need to be programmed in hardware. This behavior can cause repeated address ranges to be programmed in the hardware for a single deny address range, resulting in multiple permit address ranges in a single ACL.

If you apply the specified keyword **(jump**, **clear**, or **drop**) when crypto maps are already configured on the IPSec VPN SPA, all existing IPSec sessions are temporarily removed and restarted, which impacts traffic on your network.

The number of deny entries that can be specified in an ACL are dependent on the keyword specified:

- **jump**—Supports up to 8 deny entries in an ACL.
- **clear**—Supports up to 1000 deny entries in an ACL.
- **drop**—Supports up to 1000 deny entries in an ACL.

Examples

The following example shows a configuration using the deny-policy **clear** option. In this example, when a deny address is hit, the search will stop and traffic will be allowed to pass in the clear (unencrypted) state:

```
Router(config)# crypto ipsec ipv4-deny clear
```

Related Commands

Command	Description
access-list	Defines a standard or extended IP access list.

crypto ipsec nat-transparency

To enable security parameter index (SPI) matching or User Datagram Protocol (UDP) encapsulation between two Virtual Private Network (VPN) devices, use the **crypto ipsec nat-transparency** command on both devices in global configuration mode. To disable both SPI matching and UDP encapsulation, use the **no** form of this command with each keyword.

crypto ipsec nat-transparency {**spi-matching** | **udp-encaps**}

no crypto ipsec nat-transparency {**spi-matching** | **udp-encaps**}

Syntax Description

spi-matching	Enables SPI matching on both endpoints.
udp-encaps	Enables UDP encapsulation on both endpoints.

Defaults

When this command is entered, UDP encapsulation is enabled by default.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(15)T	The command syntax was modified to add the **spi-matching** keyword.

Usage Guidelines

You can use this command to resolve issues that arise when Network Address Translation (NAT) is configured in an IP Security (IPsec)-aware network. This command has two mutually exclusive options:

- The default option is UDP encapsulation of the IPsec protocols.
- The alternative is to match the inbound SPI to the outbound SPI.

When you enter the **crypto ipsec nat-transparency** command, UDP encapsulation is configured unless you either specifically disable it or configure SPI matching. You can disable both options, but doing so might cause problems if the device you are configuring uses NAT and is part of a VPN.

To disable SPI matching, configure UDP encapsulation or use the **no** form of this command with the keyword **spi-matching**. To disable UDP encapsulation, configure SPI matching or use the **no** form of this command with the keyword **udp-encaps**. To disable both SPI matching and UDP encapsulation, first disable UDP encapsulation, and then disable SPI matching. If you disable both options, the **show running-config** command displays: **no crypto ipsec nat-transparency udp-encaps.**

Examples

The following example enables SPI matching on the endpoint routers:

```
crypto ipsec nat-transparency spi-matching
```

Related Commands

Command	Description
clear ip nat translation	Clears dynamic NAT translations from the translation table.
ip nat	Designates that traffic originating from or destined for the interface is subject to NAT.
ip nat inside destination	Enables NAT of the inside destination address.
ip nat inside source	Enables NAT of the inside source address.
ip nat outside source	Enables NAT of the outside source address.
show ip nat statistics	Displays NAT statistics.
show ip nat translations	Displays active NAT translations.
show crypto isakmp sa detail nat	Displays NAT translations of source and destination addresses.

crypto ipsec optional

To enable IP Security (IPSec) passive mode, use the **crypto ipsec optional** command in global configuration mode. To disable IPSec passive mode, use the **no** form of this command.

crypto ipsec optional

no crypto ipsec optional

Syntax Description

This command has no arguments or keywords.

Defaults

IPSec passive mode is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

Use the **crypto ipsec optional** command to implement an intermediate mode (IPSec passive mode) that allows a router to accept unencrypted and encrypted data. IPSec passive mode is valuable for users who wish to migrate existing networks to IPSec because all routers will continue to interact with routers that encrypt data (that is, that have been upgraded with IPSec) and also with routers that have yet to be upgraded.

After this feature is disabled, all active connections that are sending unencrypted packets are cleared, and a message that reminds the user to enter the **write memory** command is sent.

Note Because a router in IPSec passive mode is insecure, ensure that no routers are accidentally left in this mode after upgrading a network.

Examples

The following example shows how to enable IPSec passive mode:

```
crypto map xauthmap 10 ipsec-isakmp
 set peer 209.165.202.145
 set transform-set xauthtransform
 match address 192
!
crypto ipsec optional
!
interface Ethernet1/0
 ip address 209.165.202.147 255.255.255.224
 crypto map xauthmap
!
access-list 192 permit ip host 209.165.202.147 host 209.165.202.145
```

crypto ipsec optional retry

To adjust the amount of time that a packet can be routed in the clear (unencrypted), use the **crypto ipsec optional retry** command in global configuration mode. To return to the default setting (5 minutes), use the **no** form of this command.

crypto ipsec optional retry *seconds*

no crypto ipsec optional retry *seconds*

Syntax Description

seconds	Time a connection can exist before another attempt is made to establish an encrypted IP Security (IPSec) session. The default value is 5 minutes.

Defaults

5 minutes

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

You must enable the **crypto ipsec optional** command, which enables IPSec passive mode, before you can use this command.

Examples

The following example shows how to enable IPSec passive mode:

```
crypto map xauthmap 10 ipsec-isakmp
 set peer 209.165.202.145
 set transform-set xauthtransform
 match address 192
!
crypto ipsec optional
crypto ipsec optional retry 60
!
interface Ethernet1/0
 ip address 209.165.202.147 255.255.255.224
 crypto map xauthmap
!
access-list 192 permit ip host 209.165.202.147 host 209.165.202.145
```

Related Commands

Command	Description
crypto ipsec optional	Enables IPSec passive mode.

crypto ipsec profile

To define the IP Security (IPsec) parameters that are to be used for IPsec encryption between two IPsec routers and to enter IPsec profile configuration mode, use the **crypto ipsec profile** command in global configuration mode. To delete an IPsec profile, use the **no** form of this command.

crypto ipsec profile *name*

no crypto ipsec profile *name*

Syntax Description

name	Profile name.

Command Default

An IPsec profile is not defined.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.4(4)T	Support for IPv6 was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

An IPsec profile abstracts the IPsec policy settings into a single profile that can be used in other parts of the Cisco IOS configuration.

The IPsec profile shares most of the same commands with the crypto map configuration, but only a subset of the commands are valid in an IPsec profile. Only commands that pertain to an IPsec policy can be issued under an IPsec profile; you cannot specify the IPsec peer address or the access control list (ACL) to match the packets that are to be encrypted.

After this command has been enabled, the following commands can be configured under an IPsec profile:

- **default**—Lists the commands that can be configured under the **crypto ipsec profile** command.
- **description**—Describes the crypto map statement policy.
- **dialer**—Specifies dialer-related commands.
- **redundancy**—Specifies a redundancy group name.
- **set-identity**—Specifies identity restrictions.
- **set isakmp-profile**—Specifies an ISAKMP profile.
- **set pfs**—Specifies perfect forward secrecy (PFS) settings.
- **set security-association**—Defines security association parameters.
- **set-transform-set**—Specifies a list of transform sets in order of priority.

After enabling this command, the only parameter that *must* be defined under the profile is the transform set via the **set transform-set** command.

For more information on transform sets, refer to the section "Defining Transform Sets" in the chapter "Configuring IPSec Network Security" in the *Cisco IOS Security Configuration Guide*.

Examples

The following example shows how to configure a crypto map that uses an IPsec profile:

```
crypto ipsec transform-set cat-transforms esp-des esp-sha-hmac
 mode transport
!
crypto ipsec profile cat-profile
 set transform-set cat-transforms
 set pfs group2
!
interface Tunnel1
 ip address 192.168.1.1 255.255.255.252
 tunnel source FastEthernet2/0
 tunnel destination 10.13.7.67
 tunnel protection ipsec profile cat-profile
```

Related Commands

Command	Description
crypto ipsec transform-set	Defines a transform set.
set pfs	Specifies that IPsec should ask for PFS when requesting new security associations for a crypto map entry.
set transform-set	Specifies which transform sets can be used with the crypto map entry.
tunnel protection	Associates a tunnel interface with an IPsec profile.

crypto ipsec security-association idle-time

To configure the IP Security (IPSec) security association (SA) idle timer, use the **crypto ipsec security-association idle-time** command in global configuration mode or crypto map configuration mode. To inactivate the IPSec SA idle timer, use the **no** form of this command.

crypto ipsec security-association idle-time *seconds*

no crypto ipsec security-association idle-time

Syntax Description

seconds	Time, in seconds, that the idle timer allows an inactive peer to maintain an SA. The range is 60 to 86400 seconds.

Defaults

IPSec SA idle timers are disabled.

Command Modes

Global configuration
Crypto map configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

Use the **crypto ipsec security-association idle-time** command to configure the IPSec SA idle timer. This timer controls the amount of time that an SA will be maintained for an idle peer.

Use the **crypto ipsec security-association lifetime** command to configure global lifetimes for IPSec SAs. There are two lifetimes: a timed lifetime and a traffic-volume lifetime. A security association expires after the first of these lifetimes is reached.

The IPSec SA idle timers are different from the global lifetimes for IPSec SAs. The expiration of the global lifetimes is independent of peer activity. The IPSec SA idle timer allows SAs associated with inactive peers to be deleted before the global lifetime has expired.

If the IPSec SA idle timers are not configured with the **crypto ipsec security-association idle-time** command, only the global lifetimes for IPSec SAs are applied. SAs are maintained until the global timers expire, regardless of peer activity.

Note If the last IPSec SA to a given peer is deleted due to idle timer expiration, the Internet Key Exchange (IKE) SA to that peer will also be deleted.

Release 12.2(33)SRA or later releases
Release 12.2(33)SXH or later releases

In a system using the IPSec VPN SPA with these software releases, the configured value for the *seconds* argument is rounded up to the next multiple of 600 seconds (ten minutes), and the rounded value becomes the polling interval for SA idle detection. Because the SA idle condition must be observed in two successive pollings, the period of inactivity may last up to twice the polling period before the SAs are deleted.

Examples

The following example configures the IPSec SA idle timer to drop SAs for inactive peers after at least 750 seconds:

```
Router# configure terminal
Router(config)# crypto ipsec security-association idle-time 750
```

With Cisco IOS Release 12.2(15)T or later releases, the SA will be deleted after an inactivity period of 750 seconds.

With Cisco IOS Release 12.2(33)SRA or 12.2(33)SXH or later releases, the configured value of 750 seconds will be rounded up to 1200 seconds (the next multiple of 600), which becomes the idle polling interval. The SA will be deleted after two successive idle pollings, resulting in an inactivity period of between 1200 and 2400 seconds before deletion.

Related Commands

Command	Description
clear crypto sa	Deletes IPSec SAs.
crypto ipsec security-association lifetime	Changes global lifetime values used when negotiating IPSec SAs.

crypto ipsec security-association lifetime

To change global lifetime values used when negotiating IPsec security associations, use the **crypto ipsec security-association lifetime** command in global configuration mode. To reset a lifetime to the default value, use the **no** form of this command.

crypto ipsec security-association lifetime {**seconds** *seconds* | **kilobytes** *kilobytes* | **kilobytes disable**}

no crypto ipsec security-association lifetime {**seconds** | **kilobytes** | **kilobytes disable**}

Syntax Description

seconds *seconds*	Specifies the number of seconds a security association will live before expiring. The default is 3600 seconds (one hour).
kilobytes *kilobytes*	Specifies the volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before that security association expires. The default is 4,608,000 kilobytes.
kilobytes disable	Disables the Internet Key Exchange (IKE) rekey based on volume only on the router on which it is configured. • If the **no** form is used with this keyword, lifetime settings switch back to the default settings.

Defaults

3600 seconds (one hour) and 4,608,000 kilobytes (10 megabits per second for one hour).

Command Modes

Global configuration

Command History

Release	Modification
11.3T	This command was introduced.
12.2(13)T	The security association negotiation changed. Prior to Cisco IOS Release 12.2(13)T, the new security association was negotiated either 30 seconds before the **seconds** lifetime expired or when the volume of traffic through the tunnel reached 256 kilobytes less than the **kilobytes** lifetime. Effective with Cisco IOS Release 12.2(13)T, the negotiation is either 30 seconds before the **seconds** lifetime expires or when the volume of traffic through the tunnel reaches 90 percent of the **kilobytes** lifetime.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SXI	The **disable** keyword was added. **Note** This keyword addition is for only Cisco IOS Release 12.2(33)SXI.
15.0(1)M	The **disable** keyword was added.

Usage Guidelines

IPsec security associations use shared secret keys. These keys and their security associations time out together.

Assuming that the particular crypto map entry does not have lifetime values configured, when the router requests new security associations during security association negotiation, it will specify its global lifetime value in the request to the peer; it will use this value as the lifetime of the new security associations. When the router receives a negotiation request from the peer, it will use the smaller of the lifetime value proposed by the peer or the locally configured lifetime value as the lifetime of the new security associations.

There are two lifetimes: a "timed" lifetime and a "traffic-volume" lifetime. The security association expires after the first of these lifetimes is reached.

If you change a global lifetime, the change is only applied when the crypto map entry does not have a lifetime value specified. The change will not be applied to existing security associations, but will be used in subsequent negotiations to establish new security associations. If you want the new settings to take effect sooner, you can clear all or part of the security association database by using the **clear crypto sa** command. Refer to the **clear crypto sa** command for more details.

To change the global timed lifetime, use the **crypto ipsec security-association lifetime seconds** form of the command. The timed lifetime causes the security association to time out after the specified number of seconds have passed.

To change the global traffic-volume lifetime, use the **crypto ipsec security-association lifetime kilobytes** form of the command. The traffic-volume lifetime causes the security association to time out after the specified amount of traffic (in kilobytes) has been protected by the key of the security association.

Shorter lifetimes can make it harder to mount a successful key recovery attack, since the attacker has less data encrypted under the same key to work with. However, shorter lifetimes require more CPU processing time for establishing new security associations.

The lifetime values are ignored for manually established security associations (security associations installed using an **ipsec-manual** crypto map entry).

How The Lifetimes Work

The security association (and corresponding keys) will expire according to whichever occurs sooner, either after the number of seconds has passed (specified by the **seconds** keyword) or after the amount of traffic in kilobytes has passed (specified by the **kilobytes** keyword).

A new security association is negotiated *before* the lifetime threshold of the existing security association is reached, to ensure that a new security association is ready for use when the old one expires. The **seconds** lifetime and the **kilobytes** lifetime each have a jitter mechanism to avoid security association rekey collisions. The new security association is negotiated either (30 plus a random number of) seconds before the **seconds** lifetime expires or when the traffic volume reaches (90 minus a random number of) percent of the **kilobytes** lifetime (whichever occurs first).

If no traffic has passed through the tunnel during the entire life of the security association, a new security association is not negotiated when the lifetime expires. Instead, a new security association will be negotiated only when IPsec sees another packet that should be protected.

Disabling the Volume Lifetime

The **crypto ipsec security-association lifetime kilobytes disable** form of the command disables the volume lifetime. Using this command form should result in a significant improvement in performance and reliability, and this option can be used to reduce packet loss in high traffic environments. It can be used to prevent frequent rekeys that are triggered by reaching the volume lifetimes.

Note The volume lifetime can also be disabled using the **set security-association lifetime kilobytes disable** command.

Examples

The following example shortens both lifetimes, because the administrator feels there is a higher risk that the keys could be compromised. The timed lifetime is shortened to 2700 seconds (45 minutes), and the traffic-volume lifetime is shortened to 2,304,000 kilobytes (10 megabits per second for one half hour).

```
crypto ipsec security-association lifetime seconds 2700
crypto ipsec security-association lifetime kilobytes 2304000
```

The following example shows that the **kilobytes disable** keyword has been used to disable the volume lifetime.

```
crypto ipsec security-association lifetime kilobytes disable
```

Related Commands

Command	Description
set security-association lifetime	Overrides (for a particular crypto map entry) the global lifetime value, which is used when negotiating IPsec security associations.
show crypto ipsec security-association lifetime	Displays the security-association lifetime value configured for a particular crypto map entry.

crypto ipsec security-association replay disable

To disable anti-replay checking globally, use the **crypto ipsec security-association replay disable** command in global configuration mode. To reset the configuration to enable anti-replay checking, use the **no** form of this command.

crypto ipsec security-association replay disable

no crypto ipsec security-association replay disable

Syntax Description

This command has no arguments or keywords.

Defaults

Anti-replay checking is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(18)SXF6	This command was integrated into Cisco IOS Release 12.2(18)SXF6.

Examples

The following example shows that anti-replay checking has been disabled globally:

```
crypto map mymap 10
exit
crypto ipsec security-association replay disable
```

Related Commands

Command	Description
crypto ipsec security-association replay window-size	Sets the size of the SA anti-replay window.

crypto ipsec security-association replay window-size

To set the size of the security association (SA) anti-replay window globally, use the **crypto ipsec security-association replay window-size** command in global configuration mode. To reset the window size to the default of 64, use the **no** form of this command.

crypto ipsec security-association replay window-size [*N*]

no crypto ipsec security-association replay window-size

Syntax Description

N	(Optional) Size of the window. Values can be 64, 128, 256, 512, or 1024. This value becomes the default value. **Note** The window size is significant only if anti-replay checking is enabled.

Defaults

If a window size is not entered, the default is 64.

Command Modes

Global configuration

12.3(14)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(18)SXF6	This command was integrated into Cisco IOS Release 12.2(18)SXF6.

Examples

The following example shows that the size of the SA anti-replay window has been set globally to 128:

```
crypto map mymap 20
exit
crypto ipsec security-association replay window-size 128
```

Related Commands

Command	Description
crypto ipsec security-association replay disable	Disables anti-replay checking.

crypto ipsec server send-update

To send auto-update notifications any time after an Easy VPN connection is "up," use the **crypto ipsec server send-update** command in privileged EXEC mode.

crypto ipsec server send-update {*group-name*}

no crypto ipsec server send-update {*group-name*}

Syntax Description

group-name	Name of group to which to send auto-update notifications.

Command Default

Auto-update notifications are not sent.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(2T)	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

This command is configured on a server. By configuring the command, the auto update notification is sent manually after the tunnel is "up."

Examples

The following example shows that automatic update notifications are to be sent to GroupA:

```
crypto ipsec server send-update GroupA
```

crypto ipsec transform-set

To define a transform set—an acceptable combination of security protocols and algorithms—use the **crypto ipsec transform-set** command in global configuration mode. To delete a transform set, use the **no** form of this command.

crypto ipsec transform-set *transform-set-name transform1* [*transform2*] [*transform3*] [*transform4*]

no crypto ipsec transform-set *transform-set-name*

Syntax Description

transform-set-name	Name of the transform set to create (or modify).
transform1 *transform2* *transform3* *transform4*	Type of transform set. You may specify up to four "transforms": one Authentication Header (AH), one Encapsulating Security Payload (ESP) encryption, one ESP authentication, and one compression. These transforms define the IP Security (IPSec) security protocols and algorithms. Accepted transform values are described in Table 23.

Defaults

No default behavior or values

Command Modes

Global configuration

This command invokes the crypto transform configuration mode.

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(13)T	The following transform set options were added: **esp-aes**, **esp-aes 192**, and **esp-aes 256**.
12.3(7)T	The **esp-seal** transform set option was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(2)T	This command was modified in Cisco IOS Release 15.1(2)T. The **esp-gcm** and **esp-gmac** transforms were added.

Usage Guidelines

A transform set is an acceptable combination of security protocols, algorithms, and other settings to apply to IPSec-protected traffic. During the IPSec security association (SA) negotiation, the peers agree to use a particular transform set when protecting a particular data flow.

You can configure multiple transform sets, and then specify one or more of these transform sets in a crypto map entry. The transform set defined in the crypto map entry is used in the IPSec SA negotiation to protect the data flows specified by the access list of that crypto map entry. During the negotiation, the peers search for a transform set that is the same at both peers. When such a transform set is found, it is selected and will be applied to the protected traffic as part of the IPSec SAs of both peers.

When Internet Key Exchange (IKE) is not used to establish SAs, a single transform set must be used. The transform set is not negotiated.

Before a transform set can be included in a crypto map entry, it must be defined using this command.

A transform set specifies one or two IPSec security protocols (either AH, ESP, or both) and specifies which algorithms to use with the selected security protocol. The AH and ESP IPSec security protocols are described in the section "IPSec Protocols: AH and ESP."

To define a transform set, you specify one to four "transforms"—each transform represents an IPSec security protocol (AH or ESP) plus the algorithm you want to use. When the particular transform set is used during negotiations for IPSec SAs, the entire transform set (the combination of protocols, algorithms, and other settings) must match a transform set at the remote peer.

In a transform set you can specify the AH protocol, the ESP protocol, or both. If you specify an ESP protocol in a transform set, you can specify just an ESP encryption transform set or both an ESP encryption transform set and an ESP authentication transform set.

Table 23 lists the acceptable transform set combination selections for the AH and ESP protocols.

Table 23 Allowed Transform Combinations

Transform Type	Transform	Description
AH Transform (*Pick only one.*)	**ah-md5-hmac**	AH with the MD5 (Message Digest 5) (a Hash-based Message Authentication Code [HMAC] variant) authentication algorithm.
	ah-sha-hmac	AH with the SHA (Secure Hash Algorithm) (an HMAC variant) authentication algorithm.

Table 23 Allowed Transform Combinations (continued)

Transform Type	Transform	Description
ESP Encryption Transform (*Pick only one.*)	**esp-aes**	ESP with the 128-bit Advanced Encryption Standard (AES) encryption algorithim.
	esp-gcm **esp-gmac**	The **esp-gcm** and **esp-gmac** transforms are ESPs with either a 128 or 256 bit encryption algorithm. The default for either of these transforms is 128 bits. **Note** Both the **esp-gcm** and **esp-gmac** transforms cannot be configured together with any other ESP transform within the same crypto IPsec transform set using the **crypto ipsec transform-set** command.
	esp-aes 192	ESP with the 192-bit AES encryption algorithim.
	esp-aes 256	ESP with the 256-bit AES encryption algorithim.
	esp-des	ESP with the 56-bit Data Encryption Standard (DES) encryption algorithm.
	esp-3des	ESP with the 168-bit DES encryption algorithm (3DES or Triple DES).
	esp-null	Null encryption algorithm.
	esp-seal	ESP with the 160-bit SEAL encryption algorithm.
ESP Authentication Transform (*Pick only one.*)	**esp-md5-hmac**	ESP with the MD5 (HMAC variant) authentication algorithm.
	esp-sha-hmac	ESP with the SHA (HMAC variant) authentication algorithm.
IP Compression Transform	**comp-lzs**	IP compression with the Lempel-Ziv-Stac (LZS) algorithm

Examples of acceptable transform set combinations are as follows:

- **ah-md5-hmac**
- **esp-gcm 256**
- **esp-des**
- **esp-3des** and **esp-md5-hmac**
- **ah-sha-hmac** and **esp-des** and **esp-sha-hmac**

- **comp-lzs** and **esp-sha-hmac** and **esp-aes** (In general, the **comp-lzs** transform set can be included with any other legal combination that does not already include the **comp-lzs** transform.)
- esp-seal and esp-md5-hmac

The parser will prevent you from entering invalid combinations; for example, after you specify an AH transform set, it will not allow you to specify another AH transform set for the current transform set.

IPSec Protocols: AH and ESP

Both the AH and ESP protocols implement security services for IPSec.

AH provides data authentication and antireplay services.

ESP provides packet encryption and optional data authentication and antireplay services.

ESP encapsulates the protected data—either a full IP datagram (or only the payload)—with an ESP header and an ESP trailer. AH is embedded in the protected data; it inserts an AH header immediately after the outer IP header and before the inner IP datagram or payload. Traffic that originates and terminates at the IPSec peers can be sent in either tunnel or transport mode; all other traffic is sent in tunnel mode. Tunnel mode encapsulates and protects a full IP datagram, while transport mode encapsulates or protects the payload of an IP datagram. For more information about modes, see the **mode** (IPSec) command description.

The esp-seal Transform

There are three limitations on the use of the **esp-seal** transform set:

- The **esp-seal** transform set can be used only if no crypto accelerators are present. This limitation is present because no current crypto accelerators implement the SEAL encryption transform set, and if a crypto accelerator is present, it will handle all IPSec connections that are negotiated with IKE. If a crypto accelerator is present, the Cisco IOS software will allow the transform set to be configured, but it will warn that it will not be used as long as the crypto accelerator is enabled.
- The **esp-seal** transform set can be used only in conjunction with an authentication transform set, namely one of these: **esp-md5-hmac**, **esp-sha-hmac**, **ah-md5-hmac**, or **ah-sha-hmac**. This limitation is present because SEAL encryption is especially weak when it comes to protecting against modifications of the encrypted packet. Therefore, to prevent such a weakness, an authentication transform set is required. (Authentication transform sets are designed to foil such attacks.) If you attempt to configure an IPSec transform set using SEAL but without an authentication transform set, an error is generated, and the transform set is rejected.
- The **esp-seal** transform set cannot be used with a manually keyed crypto map. This limitation is present because such a configuration would reuse the same keystream for each reboot, which would compromise security. Because of the security issue, such a configuration is prohibited. If you attempt to configure a manually keyed crypto map with a SEAL-based transform set, an error is generated, and the transform set is rejected.

Selecting Appropriate Transform Sets

The following tips may help you select transform sets that are appropriate for your situation:

- If you want to provide data confidentiality, include an ESP encryption transform set.
- If you want to ensure data authentication for the outer IP header as well as the data, include an AH transform set. (Some consider the benefits of outer IP header data integrity to be debatable.)
- If you use an ESP encryption transform set, also consider including an ESP authentication transform set or an AH transform set to provide authentication services for the transform set.

- If you want data authentication (either using ESP or AH), you can choose from the MD5 or SHA (HMAC keyed hash variants) authentication algorithms. The SHA algorithm is generally considered stronger than MD5 but is slower.
- Note that some transform sets might not be supported by the IPSec peer.

Note If a user enters an IPSec transform set that the hardware does not support, a warning message will be displayed immediately after the **crypto ipsec transform-set** command is entered.

- In cases where you need to specify an encryption transform set but do not actually encrypt packets, you can use the **esp-null** transform.

Suggested transform set combinations follow:

- **esp-3des** and **esp-sha-hmac**
- **esp-aes** and **esp-md5-hmac**

The Crypto Transform Configuration Mode

After you issue the **crypto ipsec transform-set** command, you are put into the crypto transform configuration mode. While in this mode, you can change the mode to tunnel or transport. (These are optional changes.) After you have made these changes, type **exit** to return to global configuration mode. For more information about these optional changes, see the **match address** (IPSec) and **mode** (IPSec) command descriptions.

Changing Existing Transform Sets

If one or more transform sets are specified in the **crypto ipsec transform-set** command for an existing transform set, the specified transform sets will replace the existing transform sets for that transform set.

If you change a transform set definition, the change is only applied to crypto map entries that reference the transform set. The change will not be applied to existing SAs but will be used in subsequent negotiations to establish new SAs. If you want the new settings to take effect sooner, you can clear all or part of the SA database by using the **clear crypto sa** command.

Examples

The following example defines two transform sets. The first transform set will be used with an IPSec peer that supports the newer ESP and AH protocols. The second transform set will be used with an IPSec peer that supports only the older transforms.

```
Router (config)# crypto ipsec transform-set newer esp-3des esp-sha-hmac
Router (config)# crypto ipsec transform-set older ah-rfc-1828 esp-rfc1829
```

The following example is a sample warning message that is displayed when a user enters an IPSec transform set that the hardware does not support:

```
Router (config)# crypto ipsec transform transform-1 esp-aes 256 esp-md5
WARNING:encryption hardware does not support transform
esp-aes 256 within IPSec transform transform-1
```

The following output example shows that SEAL encryption has been correctly configured with an authentication transform set:

```
Router (config)# crypto ipsec transform-set seal esp-seal esp-sha-hmac
```

The following example is a warning message that is displayed when SEAL encryption has been configured with a crypto accelerator present:

```
Router (config)# show running-config
```

```
crypto ipsec transform-set seal esp-seal esp-sha-hmac
! Disabled because transform not supported by encryption hardware
```

The following example is an error message that is displayed when SEAL encryption has been configured without an authentication transform set:

```
Router (config)# crypto ipsec transform seal esp-seal
ERROR: Transform requires either ESP or AH authentication.
```

The following example is an error message that is displayed when SEAL encryption has been configured within a manually keyed crypto map:

```
Router (config)# crypto map green 10 ipsec-manual
%Note: This new crypto map will remain disabled until a peer
        and a valid access list have been configured.
Router (config-crypto-map)# set transform seal
ERROR: transform seal illegal for a manual crypto map.
```

Related Commands

Command	Description
clear crypto sa	Deletes IPSec security associations.
crypto ipsec transform-set	Defines a transform set—an acceptable combination of security protocols and algorithms.
match address	Specifies an extended access list for a crypto map entry.
mode (IPSec)	Changes the mode for a transform set.
set transform-set	Specifies which transform sets can be used with the crypto map entry.
show crypto ipsec transform-set	Displays the configured transform sets.

crypto isakmp aggressive-mode disable

To block all Internet Security Association and Key Management Protocol (ISAKMP) aggressive mode requests to and from a device, use the **crypto isakmp aggressive-mode disable** command in global configuration mode. To disable the blocking, use the **no** form of this command.

crypto isakmp aggressive-mode disable

no crypto isakmp aggressive-mode disable

Syntax Description

This command has no arguments or keywords.

Defaults

If this command is not configured, Cisco IOS software will attempt to process all incoming ISAKMP aggressive mode security association (SA) connections. In addition, if the device has been configured with the **crypto isakmp peer address** and the **set aggressive-mode password** or **set aggressive-mode client-endpoint** commands, the device will initiate aggressive mode if this command is not configured.

Command Modes

Global configuration

Command History

Release	Modification
12.3(1)	This command was introduced on all Cisco IOS platforms that support IP Security (IPSec).

Usage Guidelines

If you configure this command, all aggressive mode requests to the device and all aggressive mode requests made by the device are blocked, regardless of the ISAKMP authentication type (preshared keys or Rivest, Shamir, and Adelman [RSA] signatures).

If a request is made by or to the device for aggressive mode, the following syslog notification is sent:

```
Unable to initiate or respond to Aggressive Mode while disabled
```

Note This command will prevent Easy Virtual Private Network (Easy VPN) clients from connecting if they are using preshared keys because Easy VPN clients (hardware and software) use aggressive mode.

Examples

The following example shows that all aggressive mode requests to and from a device are blocked:

```
Router (config)# crypto isakmp aggressive-mode disable
```

crypto isakmp client configuration address-pool local

To configure the IP address local pool to reference Internet Key Exchange (IKE) on your router, use the **crypto isakmp client configuration address-pool local** command in global configuration mode. To restore the default value, use the **no** form of this command.

crypto isakmp client configuration address-pool local *pool-name*

no crypto isakmp client configuration address-pool local

Syntax Description

pool-name	Specifies the name of a local address pool.

Defaults

IP address local pools do not reference IKE.

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XE	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS release 12.0(7)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example references IP address local pools to IKE on your router, with “ire” as the *pool-name*:

```
crypto isakmp client configuration address-pool local ire
```

Related Commands

Command	Description
ip local pool	Configures a local pool of IP addresses to be used when a remote peer connects to a point-to-point interface.

crypto isakmp client configuration browser-proxy

To configure browser-proxy parameters for an Easy VPN remote device and to enter ISAKMP browser proxy configuration mode, use the **crypto isakmp client configuration browser-proxy** command in global configuration mode. To disable the browser-proxy parameters, use the **no** form of this command.

crypto isakmp client configuration browser-proxy {*browser-proxy-name*}

no crypto isakmp client configuration browser-proxy {*browser-proxy-name*}

Syntax Description

browser-proxy-name	Name of the browser proxy.

Command Default

Browser-proxy parameters are not set.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

While specifying the proxy server, the proxy IP address and port number are separated with a colon. The proxy exception list is a semicolon-delimited string of IP addresses.

After enabling this command, you may specify the following subcommand:

- **proxy**—Configures proxy parameters for your Easy VPN remote device (see the **proxy** command for more information about this command and the acceptable parameters).

Examples

The following example shows various browser-proxy parameter settings for a browser proxy named "bproxy":

```
crypto isakmp client configuration browser-proxy bproxy
 proxy auto-detect

crypto isakmp client configuration browser-proxy bproxy
 proxy none

crypto isakmp client configuration browser-proxy bproxy
 proxy server 10.1.1.1:2000
 proxy exception-list 10.2.2.*,www.*org
 proxy by-pass-local
```

Related Commands

Command	Description
proxy	Configures proxy parameters for an Easy VPN remote device.

crypto isakmp client configuration group

To specify to which group a policy profile will be defined and to enter crypto ISAKMP group configuration mode, use the **crypto isakmp client configuration group** command in global configuration mode. To remove this command and all associated subcommands from your configuration, use the **no** form of this command.

crypto isakmp client configuration group {*group-name* | **default**}

no crypto isakmp client configuration group

Syntax Description

group-name	Group definition that identifies which policy is enforced for users.
default	Policy that is enforced for all users who do not offer a group name that matches a *group-name* argument. The **default** keyword can only be configured locally.

Defaults

No default behavior or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.3(2)T	The **access-restrict**, **firewall are-u-there**, **group-lock**, **include-local-lan**, and **save-password** commands were added. These commands are added during Mode Configuration. In addition, this command was modified so that output for this command will show that the preshared key is either encrypted or unencrypted.
12.3(4)T	The **backup-gateway**, **max-logins**, **max-users,** and **pfs** commands were added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.4(2)T	The **browser-proxy** command was added.
12.4(6)T	The **firewall policy** command was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(9)T	The **crypto aaa attribute list**, **dhcp server,** and **dhcp timeout** commands were added.
12.4(11)T	The **dhcp giaddr** command was added.

Usage Guidelines

Use the **crypto isakmp client configuration group** command to specify group policy information that needs to be defined or changed. You may wish to change the group policy on your router if you decide to connect to the client using a group ID that does not match the *group-name* argument.

After enabling this command, which puts you in Internet Security Association Key Management Protocol (ISAKMP) group configuration mode, you can specify characteristics for the group policy using the following commands:

- **access-restrict**—Ties a particular Virtual Private Network (VPN) group to a specific interface for access to the Cisco IOS gateway and the services it protects.
- **acl**—Configures split tunneling.
- **auto-update client**—Configures auto upgrade.
- **backup-gateway**—Configures a server to "push down" a list of backup gateways to the client. These gateways are tried in order in the case of a failure of the previous gateway. The gateways may be specified using IP addresses or host names.
- **banner**—Specifies a mode configuration banner.
- **browser-proxy**—Applies a browser-proxy map to a group.
- **configuration url**—Specifies on a server the URL an Easy VPN remote device must use to get a configuration in a Mode Configuration Exchange.
- **configuration version**—Specifies on a server the version a Cisco Easy VPN remote device must use to get a particular configuration in a Mode Configuration Exchange.
- **crypto aaa attribute list**—Defines a AAA attribute list of per-user attributes on a local Easy VPN server.
- **dhcp giaddr**—Configures an IP address on the Easy VPN server for the Dynamic Host Configuration Protocol (DHCP) to use. The DHCP server uses the giaddr keyword to determine the scope for the client IP address assignment. If the giaddr keyword is not configured, the Easy VPN server must be configured with a loopback interface to communicate with the DHCP server, and the IP address on the loopback interface determines the scope for the client IP address assignment.
- **dhcp server**—Configures multiple DHCP server entries.
- **dhcp timeout**—Controls the wait time before the next DHCP server on the list is tried.
- **dns**—Specifies the primary and secondary Domain Name Service (DNS) servers for the group.
- **domain**—Specifies group domain membership.
- **firewall are-u-there—**Adds the Firewall-Are-U-There attribute to the server group if your PC is running the Black Ice or Zone Alarm personal firewalls.
- **firewall policy**—Specifies the CPP firewall policy push name for the crypto ISAKMP client configuration group on a local AAA server.
- **group-lock**—Use if preshared key authentication is used with Internet Key Exchange (IKE). Allows you to enter your extended authentication (Xauth) username. The group delimiter is compared against the group identifier sent during IKE aggressive mode.
- **include-local-lan—**Configures the Include-Local-LAN attribute to allow a nonsplit-tunneling connection to access the local subnetwork at the same time as the client.
- **key**—Specifies the IKE preshared key when defining group policy information for Mode Configuration push.
- **max-logins**—Limits the number of simultaneous logins for users in a specific user group.
- **max-users**—Limits the number of connections to a specific server group.
- **netmask**—Subnet mask to be used by the client for local connectivity.

- **pfs**—Configures a server to notify the client of the central-site policy regarding whether PFS is required for any IPsec SA. Because the client device does not have a user interface option to enable or disable PFS negotiation, the server will notify the client device of the central site policy via this parameter. The Diffie-Hellman (D-H) group that is proposed for PFS will be the same that was negotiated in Phase 1 of the IKE negotiation.
- **pool**—Refers to the IP local pool address used to allocate internal IP addresses to clients.
- **save-password**—Saves your Xauth password locally on your PC.
- **split-dns**—Specifies a list of domain names that must be tunneled or resolved to the private network.
- **wins**—Specifies the primary and secondary Windows Internet Naming Service (WINS) servers for the group.

Output for the **crypto isakmp client configuration group** command (using the **key** subcommand) will show that the preshared key is either encrypted or unencrypted. An output example for an unencrypted preshared key would be as follows:

```
crypto isakmp client configuration group key test
```

An output example for a type 6 encrypted preshared key would be as follows:

```
crypto isakmp client configuration group
 key 6 JK_JHZPeJV_XFZTKCQFYAAB
```

Session Monitoring and Limiting for Easy VPN Clients

It is possible to mimic the functionality provided by some RADIUS servers for limiting the number of connections to a specific server group and also for limiting the number of simultaneous logins for users in that group.

To limit the number of connections to a specific server group, use the **max-users** subcommand. To limit the number of simultaneous logins for users in the server group, use the **max-logins** subcommand.

The following example shows the RADIUS attribute-value (AV) pairs for the maximum users and maximum logins parameters:

```
ipsec:max-users=1000
ipsec:max-logins=1
```

The **max-users** and **max-logins** commands can be enabled together or individually to control the usage of resources by any groups or individuals.

If you use a RADIUS server, such as a CiscoSecure access control server (ACS), it is recommended that you enable this session control on the RADIUS server if the functionality is provided. In this way, usage can be controlled across a number of servers by one central repository. When enabling this feature on the router itself, only connections to groups on that specific device are monitored, and load-sharing scenarios are not accurately accounted for.

Examples

The following example shows how to define group policy information for Mode Configuration push. In this example, the first group name is “cisco” and the second group name is “default.” Thus, the default policy will be enforced for all users who do not offer a group name that matches “cisco.”

```
crypto isakmp client configuration group cisco
 key cisco
 dns 10.2.2.2 10.2.2.3
 wins 10.6.6.6
 domain cisco.com
 pool fred
 acl 199
```

```
!
crypto isakmp client configuration group default
 key cisco
 dns 10.2.2.2 10.3.2.3
 pool fred
 acl 199
```

Related Commands

Command	Description
access-restrict	Ties a particular VPN group to a specific interface for access to the Cisco IOS gateway and the services it protects.
acl	Configures split tunneling.
backup-gateway	Configures a server to "push down" a list of backup gateways to the client.
browser-proxy	Applies browser-proxy parameter settings to a group.
crypto isakmp keepalive	Adds the Firewall-Are-U-There attribute to the server group if your PC is running the Black Ice or Zone Alarm personal firewalls.
dns	Specifies the primary and secondary DNS servers.
domain (isakmp-group)	Specifies the DNS domain to which a group belongs.
firewall are-u-there	Adds the Firewall-Are-U-There attribute to the server group if your PC is running the Black Ice or Zone Alarm personal firewalls.
firewall policy	Specifies the CPP firewall policy push name for the crypto ISAKMP client configuration group on a local AAA server.
group-lock	Allows you to enter your Xauth username, including the group name, when preshared key authentication is used with IKE.
include-local-lan	Configures the Include-Local-LAN attribute to allow a nonsplit-tunneling connection to access the local subnetwork at the same time as the client.
key (isakmp-group)	Specifies the IKE preshared key for Group-Policy attribute definition.
max-logins	Limits the number of simultaneous logins for users in a specific server group.
max-users	Limits the number of connections to a specific server group.
pool (isakmp-group)	Defines a local pool address.
save-password	Saves your Xauth password locally on your PC.
set aggressive-mode client-endpoint	Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration.

crypto isakmp client firewall

To define the Central Policy Push (CPP) firewall policypush on a server, use the **crypto isakmp client firewall** command in global configuration mode. To remove the CPP that was configured, use the **no** form of this command.

crypto isakmp client firewall {*policy-name*} {**required** | **optional**} {*firewall-type*}

nocrypto isakmp client firewall {*policy-name*} {**required** | **optional}** {*firewall-type*}

Syntax Description

policy-name	Uniquely identifies a policy. A policy name can be associated with an Easy VPN client group configuration on the server (local group configuration) or on the authentication, authorization, and accounting (AAA) server.
required	Policy is mandatory. If the CPP policy is defined as mandatory and is included in the Easy VPN server configuration, the tunnel setup is allowed only if the Cisco VPN Client confirms this policy. If the policy is not confirmed, the tunnel is terminated.
optional	Policy is optional. If the CPP policy is defined as optional and is included in the Easy VPN server configuration, the tunnel setup continues even if the Cisco VPN Client does not confirm the defined policy.
firewall-type	Type of firewall. See Table 24 for a list of acceptable firewall types.

Command Default

CPP is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Table 24 lists firewall types that may be used for the *firewall-type* argument.

Table 24 Acceptable Firewall Types

Firewall Type
Cisco-Integrated-firewall (central-policy-push)
Cisco-Security-Agent (check-presence)
Zonelabs-Zonealarm (both)
Zonelabs-ZonealarmPro (both)

Examples

The following example defines the CPP policy name as “hw-client-g-cpp.” The “Cisco-Security-Agent” policy type is mandatory. The CPP inbound list is “192” and the outbound list is “sample”:

```
crypto isakmp client firewall hw-client-g-cpp required Cisco-Security-Agent
 policy central-policy-push access-list in 192
 policy central-policy-push access-list out sample
 policy check-presence
```

Related Commands

Command	Description
policy	Specifies the CPP policy.

crypto isakmp default policy

To enable default policies for Internet Security Association and Key Management Protocol (ISAKMP) protection suite, use the **crypto isakmp default policy** command in global configuration mode. To disable the default IKE policies, use the **no** form of this command.

crypto isakmp default policy

no crypto isakmp default policy

Syntax Description

This command has no arguments or keywords.

Command Default

The default ISAKMP policies are enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(20)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

If you have neither manually configured ISAKMP policies with the **crypto isakmp policy** command nor issued the **no crypto isakmp default policy** command, IPsec will use the default ISAKMP policies to negotiate IKE proposals. There are eight default ISAKMP default policies supported (see Table 25). The default ISAKMP policies define the following policy set parameters:

- The priority, 65507–65514, where 65507 is the highest priority and 65514 is the lowest priority.
- The authentication method, Rivest, Shamir, and Adelman (RSA) or preshared keys (PSK).
- The encryption method, Advanced Encryption Standard (AES) or Triple Data Encryption Standard (3DES).
- The hash function, Secure Hash Algorithm (SHA-1) or Message-Digest algorithm 5 (MD5).
- The Diffie-Hellman (DH) group specification DH2 or DH5.
  - DH2 specifies the 768-bit Diffie-Hellman group.
  - DH5 specifies the 1536-bit Diffie-Hellman group.

Table 25 Default ISAKMP Policies

Priority	Authentication	Encryption	Hash	Diffie-Hellman
65507	RSA	AES	SHA	DH5
65508	PSK	AES	SHA	DH5
65509	RSA	AES	MD5	DH5

Table 25 Default ISAKMP Policies (continued)

Priority	Authentication	Encryption	Hash	Diffie-Hellman
65510	PSK	AES	MD5	DH5
65511	RSA	3DES	SHA	DH2
65512	PSK	3DES	SHA	DH2
65513	RSA	3DES	MD5	DH2
65514	PSK	3DES	MD5	DH2

Examples

The following example disables the default ISAKMP policies and shows the resulting output of the **show crypto isakmp default policy** command, which is blank:

```
Router# configure terminal
Router(config)# no crypto isakmp default policy
Router(config)# exit
Router# show crypto isakmp default policy
Router#
!There is no output since the default IKE policies have been disabled.
```

The following example enables the default ISAKMP policies and displays the resulting output of the **show crypto isakmp default policy** command. The default policies are displayed because there are no user configured policies, and the default policies have not been disabled.

```
Router# configure terminal
Router(config)# crypto isakmp default policy
Router(config)# exit
Router# show crypto isakmp default policy

Related Commands

Command	Description
show crypto isakmp default policy	Displays the default ISAKMP policies currently in use.

crypto isakmp enable

To globally enable Internet Key Exchange (IKE) for your peer router, use the **crypto isakmp enable** command in global configuration mode. To disable IKE for the peer, use the **no** form of this command.

crypto isakmp enable

no crypto isakmp enable

Syntax Description

This command has no arguments or keywords.

Defaults

IKE is enabled.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

IKE is enabled by default. IKE does not have to be enabled for individual interfaces, but is enabled globally for all interfaces at the router.

If you do not want IKE to be used for your IPSec implementation, you can disable IKE for all your IP Security peers. If you disable IKE for one peer, you must disable it for all IPSec peers.

If you disable IKE, you will have to make these concessions at the peers:

- You must manually specify all the IPSec security associations (SAs) in the crypto maps at the peers. (Crypto map configuration is described in the chapter "Configuring IPSec Network Security" in the *Cisco IOS Security Configuration Guide*.)
- The IPSec SAs of the peers will never time out for a given IPSec session.
- During IPSec sessions between the peers, the encryption keys will never change.
- Anti-replay services will not be available between the peers.
- Certification authority (CA) support cannot be used.

Note Effective with Cisco IOS Release 12.3(2)T, a device is prevented from responding to Internet Security Association and Key Management Protocol (ISAKMP) by default unless there is a crypto map applied to an interface or if Easy VPN is configured.

Examples

The following example disables IKE at one peer. (The same command should be issued for all remote peers.)

```
no crypto isakmp enable
```

crypto isakmp fragmentation

To enable fragmentation of large Internet Key Exchange (IKE) packets into a series of smaller IKE packets to avoid fragmentation at the User Datagram Protocol (UDP) layer, use the **crypto isakmp fragmentation** command in global configuration mode. To disable fragmentation, use the **no** form of this command.

crypto isakmp fragmentation

no crypto isakmp fragmentation

Syntax Description

This command has no arguments or keywords.

Command Default

Fragmentation is not allowed.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T7	This command was introduced.

Usage Guidelines

Do not configure IKE fragmentation on a Cisco IOS router with Cisco Easy VPN Client versions 5.01 through 5.03. Versions earlier than version 5.01 and version 5.04 or a later release should be all right.

Note The **crypto isakmp fragmentation** command is only applicable when the IOS Router is acting as an Easy VPN server and the remote peer is a Cisco IPsec VPN client.

Examples

The following example shows that fragmentation has been enabled:

```
crypto isakmp fragmentation

crypto isakmp policy 1
  encryption 3des
crypto isakmp profile ezvpn-SW
  match group frag-clients
  vrf frags
```

crypto isakmp identity

To define the ISAKMP identity used by the router when participating in the Internet Key Exchange (IKE) protocol, use the **crypto isakmp identity** command in global configuration mode. To reset the ISAKMP identity to the default value (address), use the **no** form of this command.

crypto isakmp identity {**address** | **dn** | **hostname**}

no crypto isakmp identity

Syntax Description

address	Sets the ISAKMP identity to the IP address of the interface that is used to communicate to the remote peer during IKE negotiations.
dn	Sets the ISAKMP identity to the distinguished name (DN) of the router certificate.
hostname	Sets the ISAKMP identity to the host name concatenated with the domain name (for example, myhost.example.com).

Command Default

The IP address is used for the ISAKMP identity.

Command Modes

Global configuration

Command History

Release	Modification
11.3T	This command was introduced.
12.4(4)T	Support for IPv6 was added.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to specify an ISAKMP identity either by IP address, DN or host name. An ISAKMP identity is set whenever you specify preshared keys or RSA signature authentication.

The **address** keyword is typically used when only one interface (and therefore only one IP address) will be used by the peer for IKE negotiations, and the IP address is known.

The **dn** keyword should be used if the DN of a router certificate is to be specified and chosen as the ISAKMP identity during IKE processing. The **dn** keyword is used only for certificate-based authentication.

The **hostname** keyword should be used if more than one interface on the peer might be used for IKE negotiations, or if the interface's IP address is unknown (such as with dynamically assigned IP addresses).

As a general rule, you should set all peers' identities in the same way, either by IP address or by host name.

Examples

The following example uses preshared keys at two peers and sets both their ISAKMP identities to the IP address.

At the local peer (at 10.0.0.1) the ISAKMP identity is set and the preshared key is specified:

```
crypto isakmp identity address
crypto isakmp key sharedkeystring address 192.168.1.33
```

At the remote peer (at 192.168.1.33) the ISAKMP identity is set and the same preshared key is specified:

```
crypto isakmp identity address
crypto isakmp key sharedkeystring address 10.0.0.1
```

Note In the preceding example if the **crypto isakmp identity** command had not been performed, the ISAKMP identities would have still been set to IP address, the default identity.

The following example uses preshared keys at two peers and sets both their ISAKMP identities to the hostname.

At the local peer the ISAKMP identity is set and the preshared key is specified:

```
crypto isakmp identity hostname
crypto isakmp key sharedkeystring hostname RemoteRouter.example.com
ip host RemoteRouter.example.com 192.168.0.1
```

At the remote peer the ISAKMP identity is set and the same preshared key is specified:

```
crypto isakmp identity hostname
crypto isakmp key sharedkeystring hostname LocalRouter.example.com
ip host LocalRouter.example.com 10.0.0.1 10.0.0.2
```

In the example, hostnames are used for the peers' identities because the local peer has two interfaces that might be used during an IKE negotiation.

In the example the IP addresses are also mapped to the hostnames; this mapping is not necessary if the routers' hostnames are already mapped in DNS.

Related Commands

Command	Description
crypto ipsec security-association lifetime	Specifies the authentication method within an IKE policy.
crypto isakmp key	Configures a preshared authentication key.

crypto isakmp invalid-spi-recovery

To initiate the Internet Key Exchange (IKE) security association (SA) to notify the receiving IP Security (IPSec) peer that there is an "Invalid SPI" error, use the **crypto isakmp invalid-spi-recovery** command in global configuration mode. To disable the notification process, use the **no** form of this command.

crypto isakmp invalid-spi-recovery

no crypto isakmp invalid-spi-recovery

Syntax Description

This command has no arguments or keywords.

Defaults

The IKE notification process is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

This command allows you to configure your router so that when an invalid security parameter index error (shown as "Invalid SPI") occurs, an IKE SA is initiated. The "IKE" module, which serves as a checkpoint in the IPSec session, recognizes the "Invalid SPI" situation. The IKE module then sends an "Invalid Error" message to the packet-receiving peer so that synchronization of the security association databases (SADBs) of the two peers can be attempted. As soon as the SADBs are resynchronized, packets are no longer dropped.

Note SPI recovery initiates a new IKE SA only for static peers.

Caution Using this command to initiate an IKE SA to notify an IPSec peer of an "Invalid SPI" error can result in a denial-of-service (DoS) attack.

Examples

The following example shows that the IKE module process has been initiated to notify the receiving peer that there is an "Invalid SPI" error:

```
Router (config)# crypto isakmp invalid-spi-recovery
```

crypto isakmp keepalive

To allow the gateway to send dead peer detection (DPD) keepalive messages to the peer, use the **crypto isakmp keepalive** command in global configuration mode. To disable keepalives, use the **no** form of this command.

crypto isakmp keepalive *seconds* [*retry-seconds*] [**periodic | on-demand**]

no crypto isakmp keepalive *seconds* [*retry-seconds*] [**periodic | on-demand**]

Syntax Description

seconds	When the **periodic** keyword is used, this argument is the number of seconds between DPD messages; the range is from 10 to 3600 seconds. When the **on-demand** keyword is used, this argument is the number of seconds during which traffic is not received from the peer before DPD retry messages are sent if there is data (IPSec) traffic to send; the range is from 10 to 3600 seconds. **Note** If you do not specify a time interval, an error message appears.
retry-seconds	(Optional) Number of seconds between DPD retry messages if the DPD retry message is missed by the peer; the range is from 2 to 60 seconds. Once 1 DPD message is missed by the peer, the router moves to a more aggressive state and sends the DPD retry message at the faster retry interval, which is the number of seconds between DPD retries if the DPD message is missed by the peer. The default DPD retry message is sent every 2 seconds. Five aggressive DPD retry messages can be missed before the tunnel is marked as down. **Note** To configure DPD with IPsec High Availability (HA), the recommendation is to use a value other than the default (which is 2 seconds). A keepalive timer of 10 seconds with 5 retries seems to work well with HA because of the time that it takes for the router to get into active mode.
periodic	(Optional) DPD messages are sent at regular intervals.
on-demand	(Optional) The default behavior. DPD retries are sent on demand. **Note** Because this option is the default, the **on-demand** keyword does not appear in configuration output.

Command Default

No DPD messages are sent.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.3(7)T	The **periodic** and **on-demand** keywords were added.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

Use the **crypto isakmp keepalive** command to enable the gateway to send DPD messages to the peer. DPD is a keepalives scheme that allows the router to query the liveliness of its Internet Key Exchange (IKE) peer.

Use the **periodic** keyword to configure your router so that DPD messages are "forced" at regular intervals. This forced approach results in earlier detection of dead peers than with the on-demand approach. If you do not configure the periodic option, the router defaults to the on-demand approach.

Note When the **crypto isakmp keepalive** command is configured, the Cisco IOS software negotiates the use of Cisco IOS keepalives or DPD, depending on which protocol the peer supports.

Note Cisco IOS VPN Client connections are not supported if you configure the **crypto isakmp keepalive** command with the **periodic** keyword on a Cisco IOS device.

Examples

The following example shows how to configure DPD messages to be sent every 60 seconds and a DPD retry message every 3 seconds between retries if the peer does not respond one time:

```
crypto isakmp keepalive 60 3
```

The 60 indicates that a keepalive or DPD message is sent every 60 seconds. Once a DPD message is missed by the peer, the router moves to a more aggressive state, sending DPD retry messages every 3 seconds. After 5 aggressive DPD retries, the tunnel is marked as down.

In this example, if the router has sent a DPD message at time *x* and has not received a response within *x* + 60, then the DPD retry is sent again at *x* + 60 and then aggressively at time intervals of *x* + 63, *x* + 66, *x* + 69, and *x* + 72. At *x* + 75, a decision is made by the router to bring down the tunnel and DELETE payload is sent to the peer. The DPD retry message is not sent at *x* + 75 and only DELETE payload is sent. Therefore, the number of aggressive DPD retry messages that can be missed before marking the tunnel as down is 5 (sent at intervals *x* + 60, *x* + 63, *x*+66, *x* + 69, and *x* + 72).

The following example shows that periodic DPD messages are to be sent at intervals of 10 seconds:

```
crypto isakmp keepalive 10 periodic
```

The following example shows that the above periodic behavior is being disabled:

```
crypto isakmp keepalive 10 on-demand
```

The following example shows that DPD has been configured with IPsec HA. The number of seconds between DPD messages is 10, and the number of seconds between DPD retries is 5. DPD messages are to be sent at regular intervals.

```
crypto isakmp keepalive 10 5 periodic
```

Related Commands

Command	Description
acl	Configures split tunneling.

crypto isakmp key

To configure a preshared authentication key, use the **crypto isakmp key** command in global configuration mode. To delete a preshared authentication key, use the **no** form of this command.

crypto isakmp key *enc-type-digit keystring* {**address** *peer-address* [*mask*] | **ipv6** *ipv6-address/ipv6-prefix* | **hostname** *hostname*} [**no-xauth**]

no crypto isakmp key *enc-type-digit keystring* {**address** *peer-address* [*mask*] | **ipv6** *ipv6-address/ipv6-prefix* | **hostname** *hostname*} [**no-xauth**]

Syntax Description

enc-type-digit	Specifies whether the password to be used is encrypted or unencrypted. • 0—Specifies that an unencrypted password follows. • 6—Specifies that an encrypted password follows.
keystring	Specifies the preshared key. Use any combination of alphanumeric or special characters up to 128 bytes. Special characters include the following: !?"#$%&'()*+,-./:;<=>@[\]^_`~. (Type "CTRL-V" before the "?" symbol to avoid invoking help.) This preshared key must be identical at both peers.
address	Use this keyword if the remote peer Internet Security Association Key Management Protocol (ISAKMP) identity was set with its IP or IPv6 address. The *peer-address* argument specifies the IP or IPv6 address of the remote peer.
peer-address	Specifies the IP address of the remote peer.
mask	(Optional) Specifies the subnet address of the remote peer. (The argument can be used only if the remote peer ISAKMP identity was set with its IP address.)
ipv6	Specifies that an IPv6 address of a remote peer will be used.
ipv6-address	IPv6 address of the remote peer. This argument must be in the form documented in RFC 2373 where the address is specified in hexadecimal using 16-bit values between colons.
ipv6-prefix	IPv6 prefix of the remote peer.
hostname *hostname*	Fully qualified domain name (FQDN) of the peer. The **hostname** keyword and *hostname* argument are not supported by IPv6.
no-xauth	(Optional) Use this keyword if router-to-router IP Security (IPSec) is on the same crypto map as a Virtual Private Network (VPN)-client-to-Cisco-IOS IPSec. This keyword prevents the router from prompting the peer for extended authentication (Xauth) information (username and password).

Command Default

There is no default preshared authentication key.

Command Modes

Global configuration

Command History

Release	Modification
11.3T	This command was introduced.
12.1(1)T	The *mask* argument was added.
12.2(4)T	The **no-xauth** keyword was added.
12.3(2)T	This command was modified so that output shows that the preshared key is either encrypted or unencrypted.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.4(4)T	The **ipv6** keyword and the *ipv6-address* and *ipv6-prefix* arguments were added.

Usage Guidelines

You must use this command to configure a key whenever you specify preshared keys in an Internet Key Exchange (IKE) policy; you must enable this command at both peers.

If an IKE policy includes preshared keys as the authentication method, these preshared keys must be configured at both peers—otherwise the policy cannot be used (the policy will not be submitted for matching by the IKE process). The **crypto isakmp key** command is the second task required to configure the preshared keys at the peers. (The first task is accomplished using the **crypto isakmp identity** command.)

Use the **address** keyword if the remote peer ISAKMP identity was set with its IP address.

With the **address** keyword, you can also use the *mask* argument to indicate the remote peer ISAKMP identity will be established using the preshared key only. If the *mask* argument is used, preshared keys are no longer restricted between two users.

Note If you specify *mask*, you must use a subnet address. (The subnet address 0.0.0.0 is not recommended because it encourages group preshared keys, which allow all peers to have the same group key, thereby reducing the security of your user authentication.)

When using IKE main mode, preshared keys are indexed by IP address only because the identity payload has not yet been received. This means that the hostname keyword in the identity statement is not used to look up a preshared key and will be used only when sending and processing the identity payloads later in the main mode exchange. The identity keyword can be used when preshared keys are used with IKE aggressive mode, and keys may be indexed by identity types other than IP address as the identity payload is received in the first IKE aggressive mode packet.

If **crypto isakmp identity hostname** is configured as identity, the preshared key *must* be configured with the peer's IP address for the process to work when using IKE in main mode.

Use the **no-xauth** keyword to prevent the router from prompting the peer for Xauth information (username and password). This keyword disables Xauth for static IPSec peers. The **no-xauth** keyword should be enabled when configuring the preshared key for router-to-router IPSec—not VPN-client-to-Cisco-IOS IPSec.

Output for the **crypto isakmp key** command will show that the preshared key is either encrypted or unencrypted. An output example for an unencrypted preshared key would be as follows:

```
crypto isakmp key test123 address 10.1.0.1
```

An output example for a type 6 encrypted preshared key would be as follows:

```
crypto isakmp key 6 RHZE[JACMUI\bcbTdELISAAB address 10.1.0.1
```

Examples

In the following example, the remote peer "RemoteRouter" specifies an ISAKMP identity by address:

```
crypto isakmp identity address
```

Now, the preshared key must be specified at each peer.

In the following example, the local peer specifies the preshared key and designates the remote peer by its IP address and a mask:

```
crypto isakmp key 0 sharedkeystring address 172.21.230.33  255.255.255.255
```

In the following example for IPv6, the peer specifies the preshared key and designates the remote peer with an IPv6 address:

```
crypto isakmp key 0 my-preshare-key-0 address ipv6 3ffe:1001::2/128
```

Related Commandsl

Command	Description
crypto ipsec security-association lifetime	Specifies the authentication method within an IKE policy.
crypto isakmp identity	Defines the identity the router uses when participating in the IKE protocol.
ip host	Defines a static host name-to-address mapping in the host cache.

crypto isakmp nat keepalive

To allow an IP Security (IPSec) node to send Network Address Translation (NAT) keepalive packets, use the **crypto isakmp nat keepalive** command in global configuration mode. To disable NAT keepalive packets, use the **no** form of this command.

crypto isakmp nat keepalive *seconds*

no crypto isakmp nat keepalive

Syntax Description

seconds	Number of seconds between keepalive packets; the range is between 5 and 3600 seconds.

Defaults

NAT keepalive packets are not sent.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

The **crypto isakmp nat keepalive** command allows users to keep the dynamic NAT mapping alive during a connection between two peers. A NAT keepalive beat is sent if IPSec does not send or receive a packet within a specified time period.

If this command is enabled, users should ensure that the idle value is shorter than than the NAT mapping expiration time.

Note When the timer is modified, it is modified for every Internet Security Association Key Management Protocol (ISAKMP) security association (SA) when the keepalive for that SA is sent based on the existing timer.

Note A five-percent jitter mechanism value is applied to the timer to avoid security association rekey collisions. If there are many peer routers, and the timer is configured too low, then the router can experience high CPU usage.

Examples

The following example shows how to enable NAT keepalives to be sent every 20 seconds:

```
crypto isakmp policy 1
 authentication pre-share
crypto isakmp key 1234 address 209.165.202.130
crypto isakmp nat keepalive 20
!
```

```
crypto ipsec transform-set t2 esp-des esp-sha-hmac
no crypto engine accelerator
!
crypto map test2 10 ipsec-isakmp
 set peer 209.165.202.130
 set transform-set t2
 match address 101
```

crypto isakmp peer

To enable an IP Security (IPSec) peer for Internet Key Exchange (IKE) querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode, use the **crypto isakmp peer** command in global configuration mode. To disable this functionality, use the **no** form of this command.

crypto isakmp peer {**address** {*ipv4-address* | **ipv6** *ipv6-address*} | **hostname** *fqdn-hostname*}

no crypto isakmp peer {**address** {*ipv4-address* | **ipv6** *ipv6-address*} | **hostname** *fqdn-hostname*}

Syntax Description

address *ip-address*	Address of the peer router.
ipv4-address	IPv4 address of the peer router.
ipv6 *ipv6-address*	IPv6 address of the peer router.
hostname	Hostname of the peer router.
fqdn-hostname	Fully qualified domain name (FQDN) of the peer router.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(15)T	The **vrf** keyword and *fvrf-name* argument were added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.4(4)T	The **ipv6** keyword and *ipv6-address* argument were added.

Usage Guidelines

After enabling this command, you can use the **set aggressive-mode client-endpoint** and **set aggressive-mode password** commands to specify RADIUS tunnel attributes in the Internet Security Association and Key Management Protocol (ISAKMP) peer policy for IPSec peers.

Instead of keeping your preshared keys on the hub router, you can scale your preshared keys by storing and retrieving them from an AAA server. The preshared keys are stored in the AAA server as Internet Engineering Task Force (IETF) RADIUS tunnel attributes and are retrieved when a user tries to "speak" to the hub router. The hub router retrieves the preshared key from the AAA server and the spokes (the users) initiate aggressive mode to the hub by using the preshared key that is specified in the ISAKMP peer policy as a RADIUS tunnel attribute.

Examples

The following example shows how to initiate aggressive mode using RADIUS tunnel attributes:

```
crypto isakmp peer ip-address 209.165.200.230 vrf vpn1
 set aggressive-mode client-endpoint user-fqdn user@cisco.com
 set aggressive-mode password cisco123
```

Related Commands

Command	Description
crypto map isakmp authorization list	Enables IKE querying of AAA for tunnel attributes in aggressive mode.
set aggressive-mode client-endpoint	Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration.
set aggressive-mode password	Specifies the Tunnel-Password attribute within an ISAKMP peer configuration.

crypto isakmp policy

To define an Internet Key Exchange (IKE) policy, use the **crypto isakmp policy** command in global configuration mode. To delete an IKE policy, use the **no** form of this command.

crypto isakmp policy *priority*

no crypto isakmp policy *priority*

Syntax Description

priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 10,000, with 1 being the highest priority and 10,000 the lowest.

Command Default

Default IKE policies are in use.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.3T	This command was introduced.
12.4(4)T	Support for IPv6 was added.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(20)T	The command default was modified. Support for eight default IKE (ISAKMP) policies was added.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

IKE policies define a set of parameters to be used during the IKE negotiation. Use this command to specify the parameters to be used during an IKE negotiation. (These parameters are used to create the IKE security association [SA].)

This command invokes the Internet Security Association Key Management Protocol (ISAKMP) policy configuration (config-isakmp) command mode. While in the ISAKMP policy configuration command mode, some of the commands for which you can specify parameters are as follows:

- **authentication**; default = RSA signatures
- **encryption (IKE policy)**; default = 56-bit DES-CBC
- **group (IKE policy)**; default = 768-bit Diffie-Hellman
- **hash (IKE policy)**; default = SHA-1
- **lifetime (IKE policy)**; default = 86,400 seconds (one day)

If you do not specify any given parameter, the default value will be used for that parameter.

To exit the config-isakmp command mode, type **exit**.

You can configure multiple IKE policies on each peer participating in IPsec. When the IKE negotiation begins, it tries to find a common policy configured on both peers, starting with the highest priority policies as specified on the remote peer.

Examples

The following example shows how to manually configure two policies for the peer:

```
crypto isakmp policy 15
 hash md5
 authentication rsa-sig
 group 2
 lifetime 5000
crypto isakmp policy 20
 authentication pre-share
 lifetime 10000
```

The above configuration results in the following policies:

```
Router# show crypto isakmp policy

Protection suite priority 15
    encryption algorithm:DES - Data Encryption Standard (56 bit keys)
    hash algorithm:Message Digest 5
    authentication method:Rivest-Shamir-Adleman Signature
    Diffie-Hellman Group:#2 (1024 bit)
    lifetime:5000 seconds, no volume limit
Protection suite priority 20
    encryption algorithm:DES - Data Encryption Standard (56 bit keys)
    hash algorithm:Secure Hash Standard
    authentication method:preshared Key
    Diffie-Hellman Group:#1 (768 bit)
    lifetime:10000 seconds, no volume limit
Default protection suite
    encryption algorithm:DES - Data Encryption Standard (56 bit keys)
    hash algorithm:Secure Hash Standard
    authentication method:Rivest-Shamir-Adleman Signature
    Diffie-Hellman Group:#1 (768 bit)
    lifetime:86400 seconds, no volume limit
```

The following sample output from the **show crypto isakmp policy** command displays the default IKE policies when the manually configured IKE policies with priorities 15 and 20 have been removed.

```
Router(config)# no crypto isakmp policy 15
Router(config)# no crypto isakmp policy 20
Router(config)# exit
R1# show crypto isakmp policy

Default IKE policy
Protection suite of priority 65507
        encryption algorithm:   AES - Advanced Encryption Standard (128 bit key.

        hash algorithm:         Message Digest 5
        authentication method:  Pre-Shared Key
        Diffie-Hellman group:   #2 (1024 bit)
        lifetime:               86400 seconds, no volume limit
```

Related Commands

Command	Description
encryption (IKE policy)	Specifies the encryption algorithm within an IKE policy.
group (IKE policy)	Specifies the Diffie-Hellman group identifier within an IKE policy.
hash (IKE policy)	Specifies the hash algorithm within an IKE policy.
lifetime (IKE policy)	Specifies the lifetime of an IKE SA.
show crypto isakmp default policy	Displays the default IKE (ISAKMP) policies currently in use.
show crypto isakmp policy	Displays the parameters for each IKE policy.

crypto isakmp profile

To define an Internet Security Association and Key Management Protocol (ISAKMP) profile and to audit IP security (IPsec) user sessions, use the **crypto isakmp profile** command in global configuration mode. To delete a crypto ISAKMP profile, use the **no** form of this command.

crypto isakmp profile *profile-name* [**accounting** *aaa-list*]

no crypto isakmp profile *profile-name* [**accounting** *aaa-list*]

Syntax Description

profile-name	Name of the user profile. To associate a user profile with the RADIUS server, the user profile name must be identified.
accounting *aaa-list*	(Optional) Name of a client accounting list.

Command Defaults

No profile exists if the command is not used.

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.4(2)T	Support for dynamic virtual tunnel interfaces was added.
12.4(4)T	Support for IPv6 was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 2.1	This command was introduced on Cisco ASR 1000 Series Routers.

Usage Guidelines

Defining an ISAKMP Profile

An ISAKMP profile can be viewed as a repository of Phase 1 and Phase 1.5 commands for a set of peers. The Phase 1 configuration includes commands to configure such things as keepalive, identity matching, and the authorization list. The Phase 1.5 configuration includes commands to configure such things as extended authentication (Xauth) and mode configuration.

The peers are mapped to an ISAKMP profile when their identities are matched (as given in the identification [ID] payload of the Internet Key Exchange [IKE]) against the identities defined in the ISAKMP profile. To uniquely map to an ISAKMP profile, no two ISAKMP profiles should match the same identity. If the peer identity is matched in two ISAKMP profiles, the configuration is invalid. Also, there must be at least one **match identity** command defined in the ISAKMP profile for it to be complete.

After enabling this command and entering ISAKMP profile configuration mode, you can configure the following commands:

- **accounting**—Enables authentication, authorization, and accounting (AAA) accounting.
- **ca trust-point**—Specifies certificate authorities.
- **client**—Specifies client configuration settings.

- **default**—Lists subcommands for the **crypto isakmp profile** command.
- **description**—Specifies a description of this profile.
- **initiate mode**—Initiates a mode.
- **isakmp authorization**—ISAKMP authorization parameters.
- **keepalive**—Sets a keepalive interval.
- **keyring**—Specifies a keyring.
- **local-address**—Specifies the interface to use as the local address of this ISAKMP profile.
- **match**—Matches the values of the peer.
- **qos-group**—Applies a quality of service (QoS) policy class map for this profile.
- **self-identity**—Specifies the identity.
- **virtual-template**—Specifies the virtual template for the dynamic interface.
- **vrf**—Specifies the Virtual Private Network routing and forwarding (VRF) instance to which the profile is related.

Auditing IPSec User Sessions

Use this command to audit multiple user sessions that are terminating on the IPSec gateway.

Note The **crypto isakmp profile** command and the **crypto map (global IPSec)** command are mutually exclusive. If a profile is present (the **crypto isakmp profile** command has been used), with no accounting configured but with the global command present (the **crypto isakmp profile** command without the **accounting** keyword), accounting will occur using the attributes in the global command.

Dynamic Virtual Tunnel Interfaces

Support for dynamic virtual tunnel interfaces allows for the virtual profile to be mapped into a specified virtual template.

Examples

ISAKAMP Profile Matching Peer Identities Example

The following example shows how to define an ISAKMP profile and match the peer identities:

```
crypto isakmp profile vpnprofile
 match identity address 10.76.11.53
```

ISAKAMP Profile with Accounting Example

The following accounting example shows that an ISAKMP profile is configured:

```
aaa new-model
!
!
aaa authentication login cisco-client group radius
aaa authorization network cisco-client group radius
aaa accounting network acc start-stop broadcast group radius
aaa session-id common
!
crypto isakmp profile cisco
vrf cisco
match identity group cclient
 client authentication list cisco-client
```

```
 isakmp authorization list cisco-client
 client configuration address respond
 accounting acc
!
crypto dynamic-map dynamic 1
 set transform-set aswan
 set isakmp-profile cisco
 reverse-route
!
!
radius-server host 172.16.1.4 auth-port 1645 acct-port 1646
radius-server key nsite
```

Related Commands

Command	Description
crypto map (global IPsec)	Enters crypto map configuration mode and creates or modifies a crypto map entry, creates a crypto profile that provides a template for configuration of dynamically created crypto maps, or configures a client accounting list.
debug crypto isakmp	Displays messages about IKE events.
match identity	Matches an identity from a peer in an ISAKMP profile.
tunnel protection	Associates a tunnel interface with an IP Security (IPsec) profile.
virtual template	Specifies which virtual template to be used to clone virtual access interfaces.

crypto key decrypt rsa

To delete the encrypted RSA key and leave only the unencrypted key on the running router, use the **crypto key decrypt rsa** command in global configuration mode.

crypto key decrypt [**write**] **rsa** [**name** *key-name*] **passphrase** *passphrase*

Syntax Description

write	(Optional) Clear text (unencrypted) key is immediately written to NvRAM. If the **write** keyword is not issued, the configuration must be manually written to NvRAM; otherwise, the key will remain encrypted the next time the router is reloaded.
name *key-name*	(Optional) Name of the RSA key pair that is to be decrypted.
passphrase *passphrase*	Passphrase that is used to decrypt the RSA key. The passphrase must match the passphrase that was specified via the **crypto key encrypt rsa** command.

Defaults

The private key running on the router is encrypted.

Command Modes

Global configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.

Usage Guidelines

Use the **crypto key decrypt rsa** command to store the decrypted private key in NvRAM the next time NvRAM is written (which is immediately if the **write** keyword is issed).

Examples

The following example shows how to decrypt the RSA key “pki1-72a.cisco.com”:

```
Router(config)# crypto key decrypt write rsa name pki1-72a.cisco.com passphrase cisco1234
```

Related Commands

Command	Description
crypto key encrypt rsa	Encrypts the RSA private key.
show crypto key mypubkey rsa	Displays the RSA public keys of your router.

crypto key encrypt rsa

To encrypt the RSA private key, use the **crypto key encrypt rsa** command in global configuration mode.

crypto key encrypt [**write**] **rsa** [**name** *key-name*] **passphrase** *passphrase*

Syntax Description

write	(Optional) Router configuration is immediately written to NVRAM. If the **write** keyword is not issued, the configuration must be manually written to NvRAM; otherwise, the encrypted key will be lost next time the router is reloaded.
name *key-name*	(Optional) Name of the RSA key pair that is to be encrypted. If a key name is not specified, the default key name, *routername.domainname*, is used.
passphrase *passphrase*	Passphrase that is used to encrypt the RSA key. To access the RSA key pair, the passphrase must be specified.

Defaults

RSA keys are not encrypted.

Command Modes

Global configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.

Usage Guidelines

The private key is encrypted (protected) via the specified passphrase. After the key is protected, it may continue to be used by the router; that is Internet Key Exchange (IKE) tunnels and encrypted key export attempts should continue to work because the key remains "unlocked."

To lock the key, which can be used to disable the router, issue the **crypto key lock rsa** privileged EXEC command. (When you lock the encrypted key, all functions which use the locked key are disabled.)

Examples

The following example shows how to encrypt the RSA key "pki1-72a.cisco.com." Thereafter, the **show crypto key mypubkey rsa** command is issued to verify that the RSA key is encrypted and unlocked.

```
Router(config)# crypto key encrypt rsa name pki1-72a.cisco.com passphrase cisco1234
Router(config)# exit
Router# show crypto key mypubkey rsa
```

```

Command	Description
crypto key decrypt rsa	Deletes the encrypted RSA key and leaves only the unencrypted key on the running router.
crypto key lock rsa	Locks the RSA private key in a router.
show crypto key mypubkey rsa	Displays the RSA public keys of your router.

crypto key export rsa pem

To export Rivest, Shamir, and Adelman (RSA) keys in privacy-enhanced mail (PEM)-formatted files, use the **crypto key export rsa pem** command in global configuration mode.

crypto key export rsa *key-label* **pem** {**terminal** | **url** *url*} {**3des** | **des**} *passphrase*

Syntax Description

rsa *key-label*	Name of the RSA key pair that will be exported. The *key-label* argument must match the key pair name that was specified via the **crypto key generate rsa** command.
terminal	RSA key pair will be displayed in PEM format on the console terminal.
url *url*	URL of the file system where your router should export the RSA key pair.
3des	Export the RSA key pair using the Triple Data Encryption Standard (3DES) encryption algorithm.
des	Export the RSA key pair using the DES encryption algorithm.
passphrase	Passphrase that is used to encrypt the PEM file for import. **Note** The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

The **crypto key export rsa pem** command allows you to export RSA key pairs in PEM-formatted files. The PEM files can then be imported back into a Cisco IOS router or other public key infrastructure (PKI) applications.

Note Before you can export a RSA key pair in a PEM file, ensure that the RSA key pair is exportable. To generate an exportable RSA key pair, issue the **crypto key generate rsa** command and specify the **exportable** keyword.

Examples

The following example shows how to generate, export, bring the key back (import), and verify the status of the RSA key pair “mycs”:

```
! Generate the key pair
!
Router(config)# crypto key generate rsa general-purpose label mycs exportable
```

```
The name for the keys will be: mycs
Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose
Keys. Choosing a key modulus greater than 512 may take a few minutes.

How many bits in the modulus [512]: 1024
% Generating 1024 bit RSA keys ...[OK]
!
! Archive the key pair to a remote location, and use a good password.
!
Router(config)# crypto key export rsa mycs pem url nvram: 3des PASSWORD
% Key name: mycs
Usage: General Purpose Key
Exporting public key...
Destination filename [mycs.pub]?
Writing file to nvram:mycs.pub
Exporting private key...
Destination filename [mycs.prv]?
Writing file to nvram:mycs.prv
!
! Import the key as a different name.
!
Router(config)# crypto key import rsa mycs2 pem url nvram:mycs PASSWORD
% Importing public key or certificate PEM file...
Source filename [mycs.pub]?
Reading file from nvram:mycs.pub
% Importing private key PEM file...
Source filename [mycs.prv]?
Reading file from nvram:mycs.prv% Key pair import succeeded.
!
! After the key has been imported, it is no longer exportable.
!
! Verify the status of the key.
!
Router# show crypto key mypubkey rsa

% Key pair was generated at: 18:04:56 GMT Jun 6 2003

Related Commands

Command	Description
crypto key generate rsa	Generates RSA key pairs.
crypto key import rsa pem	Imports RSA keys in PEM-formatted files.

crypto key generate ec keysize

To generate Elliptic Curve (EC) key pairs, use the **crypto key generate ec keysize** command in global configuration mode.

crypto key generate ec keysize [**256** | **384**] [**label** *key-label*]

no crypto key generate ec keysize

Syntax Description

256	Specifies a 256-bit keysize.
384	Specifies a 384-bit keysize.
label *key-label*	(Optional) Specifies the name that is used for the EC key pair when they are being exported. If a key label is not specified, the fully qualified domain name (FQDN) of the router is used.

Command Default

The EC key pairs do not exist.

Command Modes

Global configuration

Command History

Release	Modification
15.1(2)T	This command was introduced.

Usage Guidelines

Use this command to generate EC key pairs for your Cisco device (such as a router).

Examples

The following example generates a 256-bit EC key pair with the label “Router_1_Key”.

```
Router(config)# crypto key generate ec keysize 256 label Router_1_Key
```

Related Commands

Command	Description
copy	Copies any file from a source to a destination, use the copy command in privileged EXEC mode.
crypto key generate rsa	Generates RSA keys.
crypto key storage	Sets the default storage location for RSA key pairs.
debug crypto engine	Displays debug messages about crypto engines.
hostname	Specifies or modifies the hostname for the network server.

Command	Description
ip domain-name	Defines a default domain name to complete unqualified hostnames (names without a dotted-decimal domain name).
show crypto key mypubkey rsa	Displays the RSA public keys of your router.
show crypto pki certificates	Displays information about your PKI certificate, certification authority, and any registration authority certificates.

crypto key generate rsa

To generate Rivest, Shamir, and Adelman (RSA) key pairs, use the **crypto key generate rsa** command in global configuration mode.

crypto key generate rsa [**general-keys | usage-keys | signature | encryption**] [**label** *key-label*] [**exportable**] [**modulus** *modulus-size*] [**storage** *devicename***:**][**redundancy**][**on** *devicename***:**]

Syntax Description

general-keys	(Optional) Specifies that a general-purpose key pair will be generated, which is the default.
usage-keys	(Optional) Specifies that two RSA special-usage key pairs, one encryption pair and one signature pair, will be generated.
signature	(Optional) Specifies that the RSA public key generated will be a signature special usage key.
encryption	(Optional) Specifies that the RSA public key generated will be an encryption special usage key.
label *key-label*	(Optional) Specifies the name that is used for an RSA key pair when they are being exported. If a key label is not specified, the fully qualified domain name (FQDN) of the router is used.
exportable	(Optional) Specifies that the RSA key pair can be exported to another Cisco device, such as a router.
modulus *modulus-size*	(Optional) Specifies the IP size of the key modulus. By default, the modulus of a certification authority (CA) key is 1024 bits. The recommended modulus for a CA key is 2048 bits. The range of a CA key modulus is from 350 to 4096 bits. **Note** Effective with Cisco IOS XE Release 2.4 and Cisco IOS Release 15.1(1)T, the maximum key size was expanded to 4096 bits for private key operations. The maximum for private key operations prior to these releases was 2048 bits.
storage *devicename***:**	(Optional) Specifies the key storage location. The name of the storage device is followed by a colon (:).
redundancy	(Optional) Specifies that the key should be synchronized to the standby CA.
on *devicename***:**	(Optional) Specifies that the RSA key pair will be created on the specified device, including a Universal Serial Bus (USB) token, local disk, or NVRAM. The name of the device is followed by a colon (:). Keys created on a USB token must be 2048 bits or less.

Command Default

RSA key pairs do not exist.

Command Modes

Global configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(8)T	The *key-label* argument was added.
12.2(15)T	The **exportable** keyword was added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.4(4)T	The **storage** keyword and *devicename***:** argument were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11)T	The **storage** keyword and *devicename***:** argument were implemented on the Cisco 7200VXR NPE-G2 platform. The **signature**, **encryption** and **on** keywords and *devicename***:** argument were added.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.
XE 2.4	The maximum RSA key size was expanded from 2048 to 4096 bits for private key operations.
15.0(1)M	This command was modified. The **redundancy** keyword was introduced.
15.1(1)T	This command was modified. The range value for the **modulus** keyword value is extended from 360 to 2048 bits to 360 to 4096 bits.

Usage Guidelines

Use this command to generate RSA key pairs for your Cisco device (such as a router).

RSA keys are generated in pairs—one public RSA key and one private RSA key.

If your router already has RSA keys when you issue this command, you will be warned and prompted to replace the existing keys with new keys.

Note Before issuing this command, ensure that your router has a hostname and IP domain name configured (with the **hostname** and **ip domain-name** commands). You will be unable to complete the **crypto key generate rsa** command without a hostname and IP domain name. (This situation is not true when you generate only a named key pair.)

Note Secure Shell (SSH) may generate an additional RSA key pair if you generate a key pair on a router having no RSA keys. The additional key pair is used only by SSH and will have a name such as {*router_FQDN*}.server. For example, if a router name is "router1.cisco.com," the key name is "router1.cisco.com.server."

This command is not saved in the router configuration; however, the RSA keys generated by this command are saved in the private configuration in NVRAM (which is never displayed to the user or backed up to another device) the next time the configuration is written to NVRAM.

Note If the configuration is not saved to NVRAM, the generated keys are lost on the next reload of the router.

There are two mutually exclusive types of RSA key pairs: special-usage keys and general-purpose keys. When you generate RSA key pairs, you will be prompted to select either special-usage keys or general-purpose keys.

Special-Usage Keys

If you generate special-usage keys, two pairs of RSA keys will be generated. One pair will be used with any Internet Key Exchange (IKE) policy that specifies RSA signatures as the authentication method, and the other pair will be used with any IKE policy that specifies RSA encrypted keys as the authentication method.

A CA is used only with IKE policies specifying RSA signatures, not with IKE policies specifying RSA-encrypted nonces. (However, you could specify more than one IKE policy and have RSA signatures specified in one policy and RSA-encrypted nonces in another policy.)

If you plan to have both types of RSA authentication methods in your IKE policies, you may prefer to generate special-usage keys. With special-usage keys, each key is not unnecessarily exposed. (Without special-usage keys, one key is used for both authentication methods, increasing the exposure of that key.)

General-Purpose Keys

If you generate general-purpose keys, only one pair of RSA keys will be generated. This pair will be used with IKE policies specifying either RSA signatures or RSA encrypted keys. Therefore, a general-purpose key pair might get used more frequently than a special-usage key pair.

Named Key Pairs

If you generate a named key pair using the *key-label* argument, you must also specify the **usage-keys** keyword or the **general-keys** keyword. Named key pairs allow you to have multiple RSA key pairs, enabling the Cisco IOS software to maintain a different key pair for each identity certificate.

Modulus Length

When you generate RSA keys, you will be prompted to enter a modulus length. The longer the modulus, the stronger the security. However a longer modules takes longer to generate (see Table 26 for sample times) and takes longer to use.

Table 26 Sample Times by Modulus Length to Generate RSA Keys

Router	360 bits	512 bits	1024 bits	2048 bits (maximum)
Cisco 2500	11 seconds	20 seconds	4 minutes, 38 seconds	More than 1 hour
Cisco 4700	Less than 1 second	1 second	4 seconds	50 seconds

Cisco IOS software does not support a modulus greater than 4096 bits. A length of less than 512 bits is normally not recommended. In certain situations, the shorter modulus may not function properly with IKE, so we recommend using a minimum modulus of 2048 bits.

Note As of Cisco IOS Release 12.4(11)T, peer *public* RSA key modulus values up to 4096 bits are automatically supported.

The largest private RSA key modulus is 4096 bits. Therefore, the largest RSA private key a router may generate or import is 4096 bits. However, RFC 2409 restricts the private key size to 2048 bits or less for RSA encryption.

The recommended modulus for a CA is 2048 bits; the recommended modulus for a client is 2048 bits.

Additional limitations may apply when RSA keys are generated by cryptographic hardware. For example, when RSA keys are generated by the Cisco VPN Services Port Adapter (VSPA), the RSA key modulus must be a minimum of 384 bits and must be a multiple of 64.

Specifying a Storage Location for RSA Keys

When you issue the **crypto key generate rsa** command with the **storage** *devicename***:** keyword and argument, the RSA keys will be stored on the specified device. This location will supersede any **crypto key storage** command settings.

Specifying a Device for RSA Key Generation

As of Cisco IOS Release 12.4(11)T and later releases, you may specify the device where RSA keys are generated. Devices supported include NVRAM, local disks, and USB tokens. If your router has a USB token configured and available, the USB token can be used as cryptographic device in addition to a storage device. Using a USB token as a cryptographic device allows RSA operations such as key generation, signing, and authentication of credentials to be performed on the token. The private key never leaves the USB token and is not exportable. The public key is exportable.

RSA keys may be generated on a configured and available USB token, by the use of the **on** *devicename***:** keyword and argument. Keys that reside on a USB token are saved to persistent token storage when they are generated. The number of keys that can be generated on a USB token is limited by the space available. If you attempt to generate keys on a USB token and it is full you will receive the following message:

```
% Error in generating keys:no available resources
```

Key deletion will remove the keys stored on the token from persistent storage immediately. (Keys that do not reside on a token are saved to or deleted from nontoken storage locations when the **copy** or similar command is issued.)

For information on configuring a USB token, see "Storing PKI Credentials" chapter in the *Cisco IOS Security Configuration Guide*, Release 12.4T. For information on using on-token RSA credentials, see the "Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment" chapter in the *Cisco IOS Security Configuration Guide*, Release 12.4T.

Specifying RSA Key Redundancy Generation on a Device

You can specify redundancy for existing keys only if they are exportable.

Examples

The following example generates a general-usage 1024-bit RSA key pair on a USB token with the label "ms2" with crypto engine debugging messages shown:

```
Router(config)# crypto key generate rsa label ms2 modulus 2048 on usbtoken0:

The name for the keys will be: ms2
% The key modulus size is 2048 bits
% Generating 1024 bit RSA keys, keys will be on-token, non-exportable...
Jan 7 02:41:40.895: crypto_engine: Generate public/private keypair [OK]
Jan 7 02:44:09.623: crypto_engine: Create signature
Jan 7 02:44:10.467: crypto_engine: Verify signature
Jan 7 02:44:10.467: CryptoEngine0: CRYPTO_ISA_RSA_CREATE_PUBKEY(hw)(ipsec)
Jan 7 02:44:10.467: CryptoEngine0: CRYPTO_ISA_RSA_PUB_DECRYPT(hw)(ipsec)
```

Now, the on-token keys labeled “ms2” may be used for enrollment.

The following example generates special-usage RSA keys:

```
Router(config)# crypto key generate rsa usage-keys

The name for the keys will be: myrouter.example.com

Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys.
Choosing a key modulus greater than 512 may take a few minutes.
How many bits in the modulus[512]? <return>
Generating RSA keys.... [OK].

Choose the size of the key modulus in the range of 360 to 2048 for your Encryption Keys.
Choosing a key modulus greater than 512 may take a few minutes.
How many bits in the modulus[512]? <return>
Generating RSA keys.... [OK].
```

The following example generates general-purpose RSA keys:

Note You cannot generate both special-usage and general-purpose keys; you can generate only one or the other.

```
Router(config)# crypto key generate rsa general-keys

The name for the keys will be: myrouter.example.com

Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose
Keys. Choosing a key modulus greater than 512 may take a few minutes.
How many bits in the modulus[512]? <return>
Generating RSA keys.... [OK].
```

The following example generates the general-purpose RSA key pair “exampleCAkeys”:

```
crypto key generate rsa general-keys label exampleCAkeys
crypto ca trustpoint exampleCAkeys
 enroll url http://exampleCAkeys/certsrv/mscep/mscep.dll
 rsakeypair exampleCAkeys 1024 1024
```

The following example specifies the RSA key storage location of “usbtoken0:” for “tokenkey1”:

```
crypto key generate rsa general-keys label tokenkey1 storage usbtoken0:
```

The following example specifies the **redundancy** keyword:

```
Router(config)# crypto key generate rsa label MYKEYS redundancy

The name for the keys will be: MYKEYS
Choose the size of the key modulus in the range of 360 to 2048 for your
  General Purpose Keys. Choosing a key modulus greater than 512 may take
  a few minutes.

How many bits in the modulus [512]:
% Generating 512 bit RSA keys, keys will be non-exportable with redundancy...[OK]
```

Related Commands

Command	Description
copy	Copies any file from a source to a destination, use the copy command in privileged EXEC mode.
crypto key storage	Sets the default storage location for RSA key pairs.
debug crypto engine	Displays debug messages about crypto engines.
hostname	Specifies or modifies the hostname for the network server.
ip domain-name	Defines a default domain name to complete unqualified hostnames (names without a dotted-decimal domain name).
show crypto key mypubkey rsa	Displays the RSA public keys of your router.
show crypto pki certificates	Displays information about your PKI certificate, certification authority, and any registration authority certificates.

crypto key import rsa pem

To import Rivest, Shamir, and Adelman (RSA) keys in privacy-enhanced mail (PEM)-formatted files, use the **crypto key import rsa pem** command in global configuration mode.

crypto key import rsa *key-label* **pem** [**usage-keys | signature | encryption | general-purpose**] {**storage | terminal** [*passphrase*] **| url** *url*} [**exportable**] [**on** *devicename***:**]

Syntax Description

key-label	Name of the RSA key pair that is imported to the device. The *key-label* argument must match the key pair name that was specified through the **crypto key generate rsa** command.
usage-keys	(Optional) Specifies that two RSA special usage key pairs, one encryption pair and one signature pair, are imported.
signature	(Optional) Specifies that RSA signature keys are imported.
encryption	(Optional) Specifies that RSA encryption keys are imported.
general-purpose	(Optional) Specifies a General Purpose Key.
storage	Stores the key on the specified device.
terminal	Specifies the certificates and RSA key pairs are manually imported to the console terminal.
passphrase	Passphrase that is used to encrypt the PEM file for import. **Note** The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.
url *url*	URL of the file system where the router should import certificates and RSA key pairs.
exportable	(Optional) Specifies that the imported RSA key pair can be exported to another Cisco device such as a router.
on *devicename***:**	(Optional) Specifies that the imported RSA key pair is created on the specified device. Devices supported include local disks, NVRAM, and USB tokens. The name of the device is followed by a colon (:). Keys created on a USB token have a maximum size of 1024-bits.

Command Default

RSA general-purpose key pair type is expected for import.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(4)T	This command was introduced.

Release	Modification
12.4(11)T	This command was modified. The **signature**, **encryption**, and **on** keywords and *devicename***:** argument were added.
15.0(1)M	This command was modified. The **terminal** keyword and *passphrase* argument were added.

Usage Guidelines

The **crypto key import rsa pem** command allows RSA key pairs to be imported into PEM-formatted files. The files can be previously exported from another Cisco IOS router or generated by other public key infrastructure (PKI) applications.

As of Cisco IOS Release 12.4(11)T and later releases, the device can be specified for where RSA keys are generated. Devices supported include NVRAM, local disks and USB tokens. If the router has a USB token configured and available, the USB token can be used as cryptographic device in addition to a storage device. Using a USB token as a cryptographic device allows RSA operations such as key generation, signing and authentication of credentials to be performed on the token. The private key never leaves the USB token and is not exportable. The public key is exportable.

RSA keys may be imported to a configured and available USB token by using the **on** *devicename***:** keyword and argument. Keys that reside on a USB token, or on-token keys, are saved to persistent token storage when they are imported. Key deletion removes the on-token keys from persistent storage immediately. (Keys that do not reside on a token are saved to or deleted from nontoken storage locations when the **write memory** or similar command is issued.)

If the device, on which the RSA key is to be imported, does not have enough space for this key, then a message appears saying that the importation of the key has failed.

For information on configuring a USB token, see "Storing PKI Credentials" module. For information on using on-token RSA credentials, see "Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment" module.

Examples

The following example shows that an encryption key has been imported successfully to a configured and available USB token, shown with crypto engine and crypto PKI transaction debugging messages:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# crypto key import rsa label encryption on usbtoken0 url nvram:e password
% Importing public Encryption key or certificate PEM file...
filename [e-encr.pub]?
Reading file from nvram:e-encr.pub
% Importing private Encryption key PEM file...
Source filename [e-encr.prv]?
Reading file from nvram:e-encr.prv
% Key pair import succeeded.
```

The following example shows how to generate, export, import, and verify the status of the RSA key pair "mycs":

```
! Generate the key pair
!
Router(config)# crypto key generate rsa general-purpose label mycs exportable
The name for the keys will be: mycs
Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose
Keys. Choosing a key modulus greater than 512 may take a few minutes.

How many bits in the modulus [512]: 1024
```

```
% Generating 1024 bit RSA keys ...[OK]
!
! Archive the key pair to a remote location, and use a good password.
!
Router(config)# crypto key export rsa mycs pem url nvram: 3des PASSWORD
% Key name: mycs
Usage: General Purpose Key
Exporting public key...
Destination filename [mycs.pub]?
Writing file to nvram:mycs.pub
Exporting private key...
Destination filename [mycs.prv]?
Writing file to nvram:mycs.prv
!
! Import the key as a different name.
!
Router(config)# crypto key import rsa mycs2 pem url nvram:mycs PASSWORD
% Importing public key or certificate PEM file...
Source filename [mycs.pub]?
Reading file from nvram:mycs.pub
% Importing private key PEM file...
Source filename [mycs.prv]?
Reading file from nvram:mycs.prv% Key pair import succeeded.
!
! After the key has been imported, it is no longer exportable.
!
! Verify the status of the key.
!
Router# show crypto key mypubkey rsa

% Key pair was generated at: 18:04:56 GMT Jun 6 2003

Related Commands

Command	Description
crypto key export pem	Exports RSA keys in PEM-formatted files.
crypto key generate rsa	Generates RSA key pairs.

crypto key lock rsa

To lock the RSA private key in a router, use the **crypto key lock rsa** command in privileged EXEC mode.

crypto key lock rsa [**name** *key-name*] [**all**] [**passphrase** [*passphrase*]]

Syntax Description

name *key-name*	(Optional) Specifies the name of the RSA key pair that is to be locked. The name must match the name that was specified via the **crypto key encrypt rsa** command.
all	(Optional) Locks all the encrypted keys.
passphrase *passphrase*	(Optional) Specifies the passphrase that is used to lock the RSA key. The passphrase must match the passphrase that was specified via the **crypto key encrypt rsa** command.

Defaults

RSA keys are encrypted, but not locked.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **all** keyword was added.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

When the **crypto key lock rsa** command is issued, the unencrypted copy of the key is deleted. Because the private key is not available, all RSA operations will fail.

This command affects only the "run-time" access to the key; that is, it does not affect the key that is stored in NVRAM.

Examples

The following example shows how to lock the key "pki1-72a.cisco.com." Thereafter, the **show crypto key mypubkey rsa** command is issued to verify that the key is protected (encrypted) and locked.

```
Router# crypto key lock rsa name pki1-72a.cisco.com passphrase cisco1234
!
Router# show crypto key mypubkey rsa

% Key pair was generated at:20:29:41 GMT Jun 20 2003
Key name:pki1-72a.cisco.com
Usage:General Purpose Key
*** The key is protected and LOCKED. ***
Key is exportable.
```

```
Key Data:
305C300D 06092A86 4886F70D 01010105 00034B00 30480241 00D7808D C5FF14AC
0D2B55AC 5D199F2F 7CB4B355 C555E07B 6D0DECBE 4519B1F0 75B12D6F 902D6E9F
B6FDAD8D 654EF851 5701D5D7 EDA047ED 9A2A619D 5639DF18 EB020301 0001
```

Related Commands

Command	Description
crypto key encrypt rsa	Encrypts the RSA private key.
crypto key unlock rsa	Unlocks the RSA private key in a router.
show crypto key mypubkey rsa	Displays the RSA public keys of your router.

crypto key move rsa

To move an existing Cisco IOS generated Rivest, Shamir, and Adelman (RSA) key pair from one storage location to another storage location, use the **crypto key move rsa** command in global configuration mode.

crypto key move rsa *keylabel* [**non-exportable**] [**on** | **storage**] [**redundancy***routername*] *location*

Syntax Description

keylabel	Specifies name of the existing RSA key pair.
non-exportable	(Optional) Specifies that the RSA key pair cannot be exported once the key pair is moved to the eToken device.
on	(Optional) Specifies that the RSA key pair will be placed on a configured USB token and stored in the PIN protected flash portion of the USB token. Any subsequent RSA operations will be performed on the USB token.
storage	(Optional) Specifies that the RSA key pair will be stored on the specified device, for example a smart card. The key pair will be loaded back into Cisco IOS for any subsequent RSA operations.
location	Identifies the storage location where the RSA key pair will be moved.
redundancy	(Optional) Specifies that the key should be synchronized to the standby CA.

Command Default

The RSA key pair remains stored on the current device.

Command Modes

Global configuration

Command History

Release	Modification
12.4(15)T	This command was introduced.
15.0(1)M	This command was modified. The **redundancy** keyword was introduced.

Usage Guidelines

When an existing RSA key pair is generated in Cisco IOS, stored on a USB token, and used for an enrollment, it may be necessary to move those existing RSA key pairs to an alternate location for permanent storage.

Generating the key on the router and moving it to the token requires less than a minute. Generating a key on the token using the **on** keyword could require 5 to 10 minutes and is dependent on hardware key generation routines available on the USB token.

Using the **crypto key move rsa** command allows the storage location of a newly generated key to be changed if the **storage** keyword or **on** keyword was not specified when the key was first generated and the key has not yet been written out to a storage location. You can always move an exportable key.

Note If you make the key nonexportable by issuing the **non-exportable** keyword, the key cannot be made exportable again. Also, once you specify the **on** keyword with the target device, either to move an existing key or during key generation, the command cannot be undone.

Examples

The following example moves an existing RSA key pair to a configured and available USB token, "tokenA," as a nonexportable key pair stored in the PIN protected flash portion of the designated USB token:

```
crypto key move rsa keypairname non-exportable on tokenA
```

Related Commands

Command	Description
binary file	Specifies the binary file location on the registrar and the destination binary file location on the petitioner.
template file	Specifies the source template file location on the registrar and the destination template file location on the petitioner.

crypto key pubkey-chain rsa

To enter public key configuration mode (so you can manually specify other devices' RSA public keys), use the **crypto key pubkey-chain rsa** command in global configuration mode.

crypto key pubkey-chain rsa

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to enter public key chain configuration mode. Use this command when you need to manually specify other IPSec peers' RSA public keys. You need to specify other peers' keys when you configure RSA encrypted nonces as the authentication method in an Internet Key Exchange policy at your peer router.

Examples

The following example specifies the RSA public keys of two other IPSec peers. The remote peers use their IP address as their identity.

```
Router(config)# crypto key pubkey-chain rsa
Router(config-pubkey-chain)# addressed-key 10.5.5.1
Router(config-pubkey-key)# key-string
Router(config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973
Router(config-pubkey)# 2DD50A37 C4F4B0FD 9DADE748 429618D5
Router(config-pubkey)# 18242BA3 2EDFBDD3 4296142A DDF7D3D8
Router(config-pubkey)# 08407685 2F2190A0 0B43F1BD 9A8A26DB
Router(config-pubkey)# 07953829 791FCDE9 A98420F0 6A82045B
Router(config-pubkey)# 90288A26 DBC64468 7789F76E EE21
Router(config-pubkey)# quit
Router(config-pubkey-key)# exit
Router(config-pubkey-chain)# addressed-key 10.1.1.2
Router(config-pubkey-key)# key-string
Router(config-pubkey)# 0738BC7A 2BC3E9F0 679B00FE 53987BCC
Router(config-pubkey)# 01030201 42DD06AF E228D24C 458AD228
Router(config-pubkey)# 58BB5DDD F4836401 2A2D7163 219F882E
Router(config-pubkey)# 64CE69D4 B583748A 241BED0F 6E7F2F16
Router(config-pubkey)# 0DE0986E DF02031F 4B0B0912 F68200C4
```

```
Router(config-pubkey)# C625C389 0BFF3321 A2598935 C1B1
Router(config-pubkey)# quit
Router(config-pubkey-key)# exit
Router(config-pubkey-chain)# exit
Router(config)#
```

Related Commands

Command	Description
address	Specifies the IP address of the remote RSA public key of the remote peer you will manually configure.
addressed-key	Specifies the RSA public key of the peer you will manually configure.
key-string (IKE)	Specifies the RSA public key of a remote peer.
named-key	Specifies which peer RSA public key you will manually configure.
show crypto key pubkey-chain rsa	Displays peer RSA public keys stored on your router.

crypto key storage

To set the default storage location for newly created Rivest, Shamir, and Adelman (RSA) key pairs, use the **crypto key storage** command in global configuration mode. To store keys on the most recently logged-in USB token (or on NVRAM if there is no token), use the **no** form of this command.

crypto key storage *device*:

no crypto key storage *device*:

Syntax Description

device:	Name of the device where the RSA key pairs will be stored by default.

Command Default

RSA key pairs are stored on NVRAM.

Command Modes

Global configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

You may specify a default storage location, other than NVRAM, for newly created USB token RSA keys. The storage location specified by the **crypto key generate rsa** command for RSA keys will override the location specified by the **crypto key storage** command. The name of the designated device is followed by a colon (:).

Regardless of configuration settings, existing keys will be stored on the devices from where they were originally loaded.

Note The USB token must be logged into the router for the RSA keys to be read or written.

Examples

The following example shows how to store new keys in NVRAM by default, regardless of where the token is inserted:

```
crypto key storage nvram:
```

The following example shows how to store new keys on usbtoken0: by default:

```
crypto key storage usbtoken0:
```

The following example shows how to store new keys on most recently logged-in token, or on NVRAM if there is no token:

```
no crypto key storage
```

Related Commands

Command	Description
crypto key generate rsa	Generates RSA key pairs and specifies RSA key storage location (other than the default location).
crypto pki token user-pin	Creates a PIN that automatically allows the router to log into the USB token at router startup.

crypto key unlock rsa

To unlock the RSA private key in a router, use the **crypto key unlock rsa** command in privileged EXEC mode.

crypto key unlock rsa [**name** *key-name*] [**all**] [**passphrase** [*passphrase*]]

Syntax Description

name *key-name*	(Optional) Specifies the name of the RSA key pair that is to be unlocked. The name must match the name that was specified via the **crypto key encrypt rsa** command.
all	(Optional) Unlocks all the locked key pairs.
passphrase *passphrase*	(Optional) Specifies the passphrase that is used to unlock the RSA key. The passphrase must match the passphrase that was specified via the **crypto key encrypt rsa** command.

Defaults

The encrypted private key is locked.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **all** keyword was added.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

When a router with an encrypted RSA key (via the **crypto key encrypt rsa** command) initially boots up, the key does not exist in plain text and is therefore considered to be locked. Because the private key is not available, all RSA operations will fail. After you unlock the private key, RSA operations will function again.

This command affects only the “run-time” access to the key; that is, it does not affect the key that is stored in NVRAM.

Examples

The following example shows how to unlock the key “pki1-72a.cisco.com”:

```
Router# crypto key unlock rsa name pki1-72a.cisco.com passphrase cisco1234
```

Related Commands

Command	Description
crypto key encrypt rsa	Encrypts the RSA private key.
crypto key lock rsa	Locks the RSA private key in a router.
show crypto key mypubkey rsa	Displays the RSA public keys of your router.

crypto key zeroize pubkey-chain

To delete the remote peer's public key from the cache, use the **crypto key zeroize pubkey-chain** command in global configuration mode.

crypto key zeroize pubkey-chain [*index*]

Syntax Description

index	(Optional) Specifies an index entry to be deleted. If no index entry is specified, then all the index entries are deleted. The acceptable range of index entries is from 1 to 65535.

Defaults

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

This command is used is used to delete the peer router's public keys in order to help debug signature verification problems in IKEv1 and IKEv2. Keys are cached by default with the lifetime of the certificate revocation list (CRL) associated with the trustpoint.

Examples

The following example deletes all public key index entries:

```
Router# configure terminal
Router(config)# crypto key zeroize pubkey-chain
```

Related Commands

Command	Description
crypto key zeroize rsa	Deletes RSA key pairs from the router.

crypto key zeroize rsa

To delete all RSA keys from your router, use the **crypto key zeroize rsa** command in global configuration mode.

crypto key zeroize rsa [*key-pair-label*]

Syntax Description

key-pair-label	(Optional) Specifies the name of the key pair that router will delete.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(8)T	The *key-pair-label* argument was added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command deletes all Rivest, Shamir, and Adelman (RSA) keys that were previously generated by your router unless you include the *key-pair-label* argument, which will delete only the specified RSA key pair. If you issue this command, you must also perform two additional tasks for each trustpoint that is associated with the key pair that was deleted:

- Ask the certification authority (CA) administrator to revoke your router's certificates at the CA; you must supply the challenge password you created when you originally obtained the router's certificates using the **crypto ca enroll** command.
- Manually remove the router's certificates from the configuration by removing the configured trustpoint (using the **no crypto ca trustpoint** *name* command.)

Note This command cannot be undone (after you save your configuration), and after RSA keys have been deleted, you cannot use certificates or the CA or participate in certificate exchanges with other IP Security (IPSec) peers unless you reconfigure CA interoperability by regenerating RSA keys, getting the CA's certificate, and requesting your own certificate again.

This command is not saved to the configuration.

Examples

The following example deletes the general-purpose RSA key pair that was previously generated for the router. After deleting the RSA key pair, the administrator contacts the CA administrator and requests that the certificate of the router be revoked. The administrator then deletes the certificate of the router from the configuration.

```
crypto key zeroize rsa
crypto ca certificate chain
 no certificate
```

Related Commands

Command	Description
certificate	Adds certificates manually.
crypto ca certificate chain	Enters the certificate chain configuration mode.
crypto ca trustpoint	Declares the CA that your router should use.
show crypto ca timers	Specifies which key pair to associate with the certificate.

crypto keyring

To define a crypto keyring to be used during Internet Key Exchange (IKE) authentication, use the **crypto keyring** command in global configuration mode. To remove the keyring, use the **no** form of this command.

crypto keyring *keyring-name* [**vrf** *fvrf-name*]

no crypto keyring *keyring-name* [**vrf** *fvrf-name*]

Syntax Description

keyring-name	Name of the crypto keyring.
vrf *fvrf-name*	(Optional) Front door virtual routing and forwarding (FVRF) name to which the keyring will be referenced. The *fvrf-name* must match the FVRF name that was defined during virtual routing and forwarding (VRF) configuration. The **vrf** keyword and *fvrf-name* argument are not supported by IPv6.

Command Default

All the Internet Security Association and Key Management Protocol (ISAKMP) keys that were defined in the global configuration are part of the default global keyring.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.4(4)T	Support for IPv6 was added.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
Cisco IOS XE Release 2.1	This command was introduced on Cisco ASR 1000 Series Routers.

Usage Guidelines

A keyring is a repository of preshared and Rivest, Shamir, and Adelman (RSA) public keys. The keyring is used in the ISAKMP profile configuration mode. The ISAKMP profile successfully completes authentication of peers if the peer keys are defined in the keyring that is attached to this profile.

Examples

The following example shows that a keyring and its usage have been defined:

```
crypto keyring vpnkeys
  pre-shared-key address 10.72.23.11 key vpnsecret
crypto isakmp profile vpnprofile
  keyring vpnkeys
```

Related Commands

Command	Description
pre-shared-key	Defines a preshared key to be used for IKE authentication.

crypto logging ezvpn

To enable Easy VPN syslog messages on a server, use the **crypto logging ezvpn** command in global configuration mode. To disable syslog messages on the server, use the **no** form of this command.

crypto logging ezvpn [**group** *group-name*]

no crypto logging ezvpn [**group** *group-name*]

Syntax Description

group *group-name*	(Optional) Group name. If a group name is not provided, syslog messages are enabled for all Easy VPN connections to the server. If a group name is provided, syslog messages are enabled only for that particular group.

Command Default

Syslog messages are not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Examples

The following configuration shows that syslog messages are to be displayed for group_1.

```
crypto logging ezvpn group group_1
```

The following is an example of a typical Easy VPN syslog message:

```
timestamp: %CRYPTO-6-VPN_TUNNEL_STATUS: (Server)  <event message>  User=<username>
Group=<groupname>  Client_public_addr=<ip_addr> Server_public_addr=<ip addr>
```

The following is an example of an authentication-passed event Easy VPN syslog message:

```
Jul 25 23:33:06.847: %CRYPTO-6-VPN_TUNNEL_STATUS: (Server)  Authentication PASS
ED  User=blue Group=Cisco1760group  Client_public_addr=10.20.20.1
Server_public_addr=10.20.20.2
```

The following is an example of a “Group does not exist” Easy VPN syslog message:

```
*Jun 30 18:02:58.107: %CRYPTO-6-VPN_TUNNEL_STATUS: Group: group_1 does not exist
```

crypto logging ikev2

To enable Internet Key Exchange Version 2 (IKEv2) syslog messages, use the **crypto logging ikev2** command in global configuration mode. To disable syslog messages, use the **no** form of this command.

crypto logging ikev2

no crypto logging ikev2

Syntax Description

This command has no keywords or arguments.

Command Default

IKEv2 syslog messages are not enabled.

Command Modes

Global configuration (config)

Command Historyb

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Examples

The following configuration shows how to enable IKEv2 syslog messages:

```
Router(config)# crypto logging ikev2
```

Related Commands

Command	Description
crypto ikev2 certificate-cache	Specifies the cache size to store certificates fetched from HTTP URLs.
crypto ikev2 cookie-challenge	Enables IKEv2 cookie challenge.
crypto ikev2 diagnose error	Enables IKEv2 error diagnosis.
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 http-url cert	Enables HTTP CERT support.
crypto ikev2 limit	Defines call admission control for all peers.
crypto ikev2 nat	Defines NAT keepalive globally for all peers.
crypto ikev2 window	Specifies the IKEv2 window size.

crypto logging session

To generate crypto logging messages, use the **crypto logging session** command in global configuration mode. To disable logging messages, use the **no** form of this command.

crypto logging session

no crypto logging session

Syntax Description

session	Generates the log of active or up sessions, and inactive or down sessions.

Command Default

Crypto logging messages are not generated.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

Crypto logging messages allow users to receive notification for every crypto EZVPN group or session that is made on their device.

Examples

The following example shows how to enable crypto logging syslog messages for all the sessions:

```
Router(config)# crypto logging session
```

Related Commands

Command	Description
crypto logging ezvpn	Enables Easy VPN syslog messages on a server.
show logging	Displays the state of system logging and the contents of the standard system logging buffer.

crypto map (global IPsec)

To enter crypto map configuration mode and create or modify a crypto map entry, to create a crypto profile that provides a template for configuration of dynamically created crypto maps, or to configure a client accounting list, use the **crypto map** command in global configuration mode. To delete a crypto map entry, profile, or set, use the **no** form of this command.

crypto map [**ipv6**] *map-name seq-num* [**ipsec-manual**]

crypto map [**ipv6**] *map-name seq-num* [**ipsec-isakmp** [**dynamic** *dynamic-map-name* | **discover** | **profile** *profile-name*]]

no crypto map [**ipv6**] *map-name* [*seq-num*]

crypto map [**ipv6**] *map-name* **client accounting list** *aaalist*

no crypto map [**ipv6**] *map-name* [**client accounting list**]

crypto map *map-name seq num* [**gdoi**]

no crypto map *map-name* [*seq-num*]

Syntax Description

ipv6	(Optional) Specifies an IPv6 crypto map. For IPv4 crypto maps, use the command without this keyword. **Note** IPv6 addresses are not supported on dynamic crypto maps.
map-name	Identifies the crypto map set.
seq-num	Sequence number you assign to the crypto map entry. See additional explanation for using this argument in the "Usage Guidelines" section.
ipsec-manual	(Optional) Indicates that Internet Key Exchange (IKE) will not be used to establish the IP Security (IPsec) security associations (SAs) for protecting the traffic specified by this crypto map entry. **Note** The **ipsec-manual** keyword is not supported by the virtual private network Shared Port Adapter (VPN SPA) beginning with Cisco IOS Release 12.2(33)SXH5 or 12.2(33)SXI1. If the **ipsec-manual** keyword is entered for images after those releases, the following error message appears beneath the keyword entry line: "Manually-keyed crypto map configuration is not supported by the current crypto engine."
ipsec-isakmp	(Optional) Indicates that IKE will be used to establish the IPsec for protecting the traffic specified by this crypto map entry.
dynamic	(Optional) Specifies that this crypto map entry must reference a preexisting dynamic crypto map. **Note** Dynamic crypto maps are policy templates used in processing negotiation requests from a peer IPsec device. If you use this keyword, none of the crypto map configuration commands will be available.
dynamic-map-name	(Optional) Name of the dynamic crypto map set that should be used as the policy template.
discover	(Optional) Enables peer discovery. By default, peer discovery is disabled.

profile	(Optional) Designates a crypto map as a configuration template. The security configurations of this crypto map will be cloned as new crypto maps are created dynamically on demand.
profile-name	(Optional) Name of the crypto profile being created.
client accounting list	Designates a client accounting list.
aaalist	(Optional) AAA list name.
gdoi	(Optional) Indicates that the key management mechanism is Group Domain of Interpretation (GDOI).

Command Default

No crypto maps exist.
Peer discovery is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.2	This command was introduced.
11.3T	The following keywords and arguments were added: • **ipsec-manual** • **ipsec-isakmp** • **dynamic** • *dynamic-map-name*
12.0(5)T	The **discover** keyword was added to support Tunnel Endpoint Discovery (TED).
12.2(4)T	The **profile** *profile-name* keyword-argument pair was added to allow the generation of a crypto map profile that is cloned to create dynamically created crypto maps on demand.
12.2(11)T	This command was implemented on the Cisco 1760, Cisco AS5300, Cisco AS5400, and Cisco AS5800 platforms.
12.2(15)T	The **client accounting list** *aaalist* keyword-argument pair was added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB without support for the **gdoi** keyword.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH5, 12.2(33)SXI1	The **ipsec-manual** keyword is not supported by the VPN SPA beginning with Cisco IOS Release 12.2(33)SXH5 or 12.2(33)SXI1.
12.4(6)T	The **gdoi** keyword was added.
Cisco IOS XE 2.1	This command was implemented on Cisco ASR 1000 series routers.
15.1(4) M	This command was modified. The **ipv6** keyword was added.

Usage Guidelines

Use this command to create a new crypto map entry or profile. Use the **crypto map ipv6** *map-name seq-num* command without any keyword to modify an existing IPv6 crypto map entry or profile. For IPv4 crypto maps, use the **crypto map** *map-name seq-num* command without any keyword to modify the existing crypto map entry or profile.

After a crypto map entry is created, you cannot change the parameters specified at the global configuration level because these parameters determine the configuration commands that are valid at the crypto map level. For example, after a map entry has been created using the **ipsec-isakmp** keyword, you cannot change it to the option specified by the **ipsec-manual** keyword; you must delete and reenter the map entry.

After you define crypto map entries, you can assign the crypto map set to interfaces using the **crypto map** (interface IPsec) command.

Crypto Map Functions

Crypto maps provide two functions: filtering and classifying the traffic to be protected and defining the policy to be applied to that traffic. The first affects the flow of traffic on an interface; the second affects the negotiation performed (via IKE) on behalf of that traffic.

IPsec crypto maps define the following:

- What traffic should be protected
- To which IPsec peers the protected traffic can be forwarded—these are the peers with which an SA can be established
- Which transform sets are acceptable for use with the protected traffic
- How keys and SAs should be used or managed (or what the keys are, if IKE is not used)

Multiple Crypto Map Entries with the Same Map Name Form a Crypto Map Set

A crypto map set is a collection of crypto map entries, each with a different *seq-num* argument but the same *map-name* argument. Therefore, for an interface, you could have certain traffic forwarded to one IPsec peer with specified security applied to that traffic and other traffic forwarded to the same or different IPsec peer with different IPsec security applied. To accomplish differential forwarding, you would create two crypto maps, each with the same *map-name* argument but different *seq-num* argument. Crypto profiles must have unique names within a crypto map set.

Note If a deny statement (which specifies the conditions under which a packet cannot pass the access control list) in an access control list belongs to a crypto map in a crypto map set, the IPsec logic causes a jump to the next crypto map in the crypto map set, hoping for a better possible match. VPN Service Adapter (VSA) hardware has a restriction of 14 jumps.

Sequence Numbers

The number you assign to the *seq-num* argument should not be arbitrary. This number is used to rank multiple crypto map entries within a crypto map set. Within a crypto map set, a crypto map entry with a lower *seq-num* is evaluated before a map entry with a higher *seq-num*; that is, the map entry with the lower number has a higher priority.

For example, assume that a crypto map set contains three crypto map entries: mymap 10, mymap 20, and mymap 30. The crypto map set named "mymap" is applied to serial interface 0. When traffic passes through serial interface 0, traffic is evaluated first for mymap 10. If the traffic matches any access list permit statement entry in the extended access list in mymap 10, the traffic will be processed according to the information defined in mymap 10 (which includes establishing IPsec SAs when necessary). If the

traffic does not match the mymap 10 access list, the traffic will be evaluated for mymap 20, and then mymap 30, until the traffic matches a permit entry in a map entry. (If the traffic does not match a permit entry in any crypto map entry, it will be forwarded without any IPsec security.)

Dynamic Crypto Maps

Refer to the "Usage Guidelines" section of the **crypto dynamic-map** command for a discussion on dynamic crypto maps.

Crypto map entries that reference dynamic map sets should be the lowest priority map entries, allowing inbound SA negotiation requests to try to match the static maps first. If the request does not match any of the static maps, it will be evaluated against the dynamic map set.

If a crypto map entry references a dynamic crypto map set, make it the lowest priority map entry by giving it the highest *seq-num* value of all the map entries in a crypto map set.

Create dynamic crypto map entries using the **crypto dynamic-map** command. After you create a dynamic crypto map set, add the dynamic crypto map set to a static crypto map set with the **crypto map** (global IPsec) command using the **dynamic** keyword.

Note IPv6 keywords are not supported on dynamic crypto maps.

TED

Tunnel Endpoint Discovery (TED) is an enhancement to the IPsec feature. Defining a dynamic crypto map allows you to dynamically determine an IPsec peer; however, only the receiving router has this ability. With TED, the initiating router can dynamically determine an IPsec peer for secure IPsec communications.

Dynamic TED helps to simplify the IPsec configuration on individual routers within a large network. Each node has a simple configuration that defines the local network that the router is protecting and the IPsec transforms that are required.

Note TED helps only in discovering peers; otherwise, TED does not function any differently from normal IPsec. Thus, TED does not improve the scalability of IPsec (in terms of performance or the number of peers or tunnels).

Crypto Map Profiles

Crypto map profiles are created using the **profile** *profile-name* keyword and argument combination. Crypto map profiles are used as configuration templates for dynamically creating crypto maps on demand for use with the L2TP Security feature. The relevant SAs in the crypto map profile will be cloned and used to protect IP traffic on the L2TP tunnel.

Note The **set peer** and **match address** commands are ignored by crypto profiles and should not be configured in the crypto map definition.

Examples

The following example shows the minimum required crypto map configuration when IKE will be used to establish the SAs:

```
crypto map mymap 10 ipsec-isakmp
 match address 101
 set transform-set my_t_set1
```

```
 set peer 10.0.0.1
```

The following example shows the minimum required IPv6 crypto map configuration when IKE will be used to establish the SAs:

```
crypto map ipv6 CM_V6 10 ipsec-isakmp
 match address ACL_IPV6_1
  set peer 2001:DB8:0:ABCD::1
```

The following example shows the minimum required crypto map configuration when the SAs are manually established:

```
crypto transform-set someset ah-md5-hmac esp-des
crypto map mymap 10 ipsec-manual
 match address 102
 set transform-set someset
 set peer 10.0.0.5
 set session-key inbound ah 256 98765432109876549876543210987654
 set session-key outbound ah 256 fedcbafedcbafedcfedcbafedcbafedc
 set session-key inbound esp 256 cipher 0123456789012345
 set session-key outbound esp 256 cipher abcdefabcdefabcd
```

The following example shows the minimum required IPv6 crypto map configuration when the SAs are manually established:

```
crypto map ipv6 CM_V6 ipsec-manual
 match address ACL_V6_2
 set transform-set someset
 set peer 2001:DB8:0:ABCD::1
 set session-key inbound ah 256 98765432109876549876543210987654
 set session-key outbound ah 256 fedcbafedcbafedcfedcbafedcbafedc
 set session-key inbound esp 256 cipher 0123456789012345
 set session-key outbound esp 256 cipher abcdefabcdefabcd
```

The following example shows how to configure an IPsec crypto map set that includes a reference to a dynamic crypto map set.

Crypto map “mymap 10” allows SAs to be established between the router and either or both the remote IPsec peers for traffic matching access list 101. Crypto map “mymap 20” allows either of the two transform sets to be negotiated with the remote peer for traffic matching access list 102.

Crypto map entry “mymap 30” references the dynamic crypto map set “mydynamicmap,” which can be used to process inbound SA negotiation requests that do not match “mymap” entries 10 or 20. In this case, if the peer specifies a transform set that matches one of the transform sets specified in “mydynamicmap,” for a flow permitted by the access list 103, IPsec will accept the request and set up SAs with the remote peer without previously knowing about the remote peer. If the request is accepted, the resulting SAs (and temporary crypto map entry) are established according to the settings specified by the remote peer.

The access list associated with “mydynamicmap 10” is also used as a filter. Inbound packets that match any access list permit statement in this list are dropped for not being IPsec protected. (The same is true for access lists associated with static crypto maps entries.) Outbound packets that match a permit statement without an existing corresponding IPsec SA are also dropped.

```
crypto map mymap 10 ipsec-isakmp
 match address 101
 set transform-set my_t_set1
 set peer 10.0.0.1
 set peer 10.0.0.2
crypto map mymap 20 ipsec-isakmp
 match address 102
 set transform-set my_t_set1 my_t_set2
```

```
 set peer 10.0.0.3
crypto map mymap 30 ipsec-isakmp dynamic mydynamicmap
!
crypto dynamic-map mydynamicmap 10
 match address 103
 set transform-set my_t_set1 my_t_set2 my_t_set3
```

The following example shows how to configure TED on a Cisco router:

```
crypto map testtag 10 ipsec-isakmp dynamic dmap discover
```

The following example shows how to configure a crypto profile to be used as a template for dynamically created crypto maps when IPsec is used to protect an L2TP tunnel:

```
crypto map l2tpsec 10 ipsec-isakmp profile l2tp
```

The following example shows how to configure a crypto map for a GDOI group member:

```
crypto map diffint 10 gdoi
 set group diffint
```

Related Commands

Command	Description
crypto dynamic-map	Creates a dynamic crypto map entry and enters crypto map configuration command mode.
crypto isakmp profile	Audits IPsec user sessions.
crypto map (interface IPSec)	Applies a previously defined crypto map set to an interface.
crypto map local-address	Specifies and names an identifying interface to be used by the crypto map for IPsec traffic.
match address (IPSec)	Specifies an extended access list for a crypto map entry.
set peer (IPsec)	Specifies an IPsec peer in a crypto map entry.
set pfs	Specifies that IPsec should ask for PFS when requesting new SAs for this crypto map entry, or that IPsec requires PFS when receiving requests for new SAs.
set session-key	Specifies the IPsec session keys within a crypto map entry.
set transform-set	Specifies which transform sets can be used with the crypto map entry.
show crypto map (IPsec)	Displays the crypto map configuration.

crypto map (interface IPsec)

To apply a previously defined crypto map set to an interface, use the **crypto map** command in interface configuration mode. To remove the crypto map set from the interface, use the **no** form of this command.

crypto map *map-name* [**redundancy** *standby-group-name* [**stateful**]]

no crypto map [*map-name*] [**redundancy** *standby-group-name* [**stateful**]]

Syntax Description

map-name	Name that identifies the crypto map set. This is the name assigned when the crypto map was created. When the **no** form of the command is used, this argument is optional. Any value supplied for the argument is ignored.
redundancy	(Optional) Defines a backup IP security (IPsec) peer. Both routers in the standby group are defined by the redundancy *standby-group-name* argument and share the same virtual IP address.
standby-group-name	(Optional) Refers to the name of the standby group as defined by Hot Standby Router Protocol (HSRP) standby commands.
stateful	(Optional) Enables IPsec stateful failover for the crypto map.

Defaults

No crypto maps are assigned to interfaces.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.2	This command was introduced.
12.1(9)E	This command was modified. The **redundancy** keyword and *standby-group-name* argument were added.
12.2(8)T	This command was modified. The **redundancy** keyword and *standby-group-name* argument were added.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5800 platforms.
12.2(9)YE	This command was modified. The **redundancy** keyword and *standby-group-name* argument were added.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.3(11)T	This command was modified. The **stateful** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to assign a crypto map set to an interface. You must assign a crypto map set to an interface before that interface can provide IPsec services. Only one crypto map set can be assigned to an interface. If multiple crypto map entries have the same map name but a different sequence number, they are considered to be part of the same set and will all be applied to the interface. The crypto map entry that has the lowest sequence number is considered the highest priority and will be evaluated first. A single crypto map set can contain a combination of **ipsec-isakmp** and **ipsec-manual crypto map** entries.

Note A crypto map applied to a loopback interface is not supported.

The standby name must be configured on all devices in the standby group, and the standby address must be configured on at least one member of the group. If the standby name is removed from the router, the IPSec security associations (SAs) will be deleted. If the standby name is added again, regardless of whether the same name or a different name is used, the crypto map (using the **redundancy** option) will have to be reapplied to the interface.

Note A virtual IP address must be configured in the standby group to enable either stateless or stateful redundancy.

The **stateful** keyword enables stateful failover of The Internet Key Exchange (IKE) and IPsec sessions. Stateful Switchover (SSO) must also be configured for IPsec stateful failover to operate correctly.

Note A crypto map cannot be applied to a tunnel interface. If you try to apply the tunnel interface to a crypto map, an error message is displayed as follows: `crypto map is configured on tunnel interface. Currently only Group Domain of Interpretation (GDOI) crypto map is supported on tunnel interface`.

Examples

The following example shows how to connect all remote Virtual Private Network (VPN) gateways to the router via 192.168.0.3::

```
crypto map mymap 1 ipsec-isakmp
 set peer 10.1.1.1
 reverse-route
 set transform-set esp-3des-sha
 match address 102

Interface FastEthernet 0/0
 ip address 192.168.0.2 255.255.255.0
 standby name group1
 standby ip 192.168.0.3
 crypto map mymap redundancy group1

access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

The crypto map on the interface binds this standby address as the local tunnel endpoint for all instances of mymap and, at the same time, ensures that stateless HSRP failover is facilitated between an active and standby device that belongs to the same standby group, named group1.

Reverse route injection (RRI) is also enabled to provide the ability for only the *active* device in the HSRP group to be advertising itself to inside devices as the next hop VPN gateway to the remote proxies. If a failover occurs, routes are deleted on the former active device and created on the new active device.

The following example shows how to configure IPSec stateful failover on the crypto map named to-per-outside:

```
crypto map to-peer-outside 10 ipsec-isakmp
 set peer 209.165.200.225
 set transform-set trans1
 match address peer-outside

interface Ethernet0/0
 ip address 209.165.201.1 255.255.255.224
 standby 1 ip 209.165.201.3
 standby 1 preempt
 standby 1 name HA-out
 standby 1 track Ethernet1/0
 crypto map to-peer-outside redundancy HA-out stateful
```

Related Commands

Command	Description
crypto map (global IPsec)	Creates or modifies a crypto map entry and enters the crypto map configuration mode.
crypto map local-address	Specifies and names an identifying interface to be used by the crypto map for IPsec traffic.
redundancy inter-device	Configures redundancy and enters inter-device configuration mode.
show crypto map (IPsec)	Displays the crypto map configuration.
standby ip	Assigns an IP address that is to be shared among the members of the HSRP group and owned by the primary IP address.
standby name	Assigns a user-defined group name to the HSRP redundancy group.

crypto map (Xauth)

To configure Internet Key Exchange (IKE) extended authentication (Xauth) on a router, use the **crypto map** command in global configuration mode. To restore the default value, use the **no** form of this command.

crypto map [**ipv6**] *map-name* **client authentication list** *list-name*

no crypto map [**ipv6**] *map-name* [**client authentication list**]

Syntax Description

ipv6	(Optional) Specifies an IPv6 crypto map. For IPv4 crypto maps, use the command without this keyword.
map-name	Name you assign to the crypto map set.
client authentication list	Designates an extended user authentication method.
list-name	Character string used to name the list of authentication methods activated when a user logs in. The list name must match the list name defined during AAA configuration.

Defaults

Xauth is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(4)M	This command was modified. The **ipv6** keyword was added.

Usage Guidelines

Before configuring Xauth, you should complete the following tasks:

- Set up an authentication list using AAA commands.
- Configure an IP Security transform.
- Configure a crypto map.
- Configure Internet Security Association Key Management Protocol (ISAKMP) policy.

After enabling Xauth, you should apply the crypto map on which Xauth is configured to the router interface.

Examples

The following example shows how to configure user authentication (a list of authentication methods called *xauthlist*) on an existing static crypto map called *xauthmap*:

```
crypto map xauthmap client authentication list xauthlist
```

The following example shows how to configure user authentication (a list of authentication methods called *CM_V6list)* on an existing static IPv6 crypto map called *CM_V6*:

```
crypto map ipv6 CM_V6 client authentication list CM_V6list
```

The following example shows how to configure user authentication (a list of authentication methods called *xauthlist*) on a dynamic crypto map called *xauthdynamic* that has been applied to a static crypto map called *xauthmap*:

```
crypto map xauthmap client authentication list xauthlist
crypto map xauthmap 10 ipsec-isakmp dynamic xauthdynamic
```

Related Commands

Command	Description
aaa authentication login	Sets AAA authentication at login.
crypto ipsec transform-set	Defines a transform set, which is an acceptable combination of security protocols and algorithms, and enters crypto transform configuration mode.
crypto isakmp key	Configures a preshared authentication key.
crypto isakmp policy	Defines an IKE policy, and enters ISAKMP policy configuration mode.
crypto map (global configuration)	Creates or modifies a crypto map entry, and enters the crypto map configuration mode.
interface	Enters the interface configuration mode.

crypto map client configuration address

To configure IKE Mode Configuration on your router, use the **crypto map client configuration address** command in global configuration mode. To disable IKE Mode Configuration, use the **no** form of this command.

crypto map *tag* **client configuration address** [**initiate** | **respond**]

no crypto map *tag* **client configuration address**

Syntax Description

tag	The name that identifies the crypto map.
initiate	(Optional) A keyword that indicates the router will attempt to set IP addresses for each peer.
respond	(Optional) A keyword that indicates the router will accept requests for IP addresses from any requesting peer.

Defaults

IKE Mode Configuration is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XE	This command was introduced.
12.0(7)T	This command was implemented in Cisco IOS release 12.0(7)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

At the time of this publication, this feature is an IETF draft with limited support. Therefore this feature was not designed to enable the configuration mode for every IKE connection by default.

Examples

The following examples configure IKE Mode Configuration on your router:

```
crypto map dyn client configuration address initiate
crypto map dyn client configuration address respond
```

Related Commands

Command	Description
crypto map (global)	Creates or modifies a crypto map entry and enters the crypto map configuration mode

crypto map gdoi fail-close

To specify that the crypto map is to work in fail-close mode, use the **crypto map gdoi fail-close** command in global configuration mode. To disable fail-close mode, use the no form of this command.

crypto map *map-number* **gdoi fail-close**

no crypto map *map-number* **gdoi fail-close**

Syntax Description

This command has no arguments or keywords.

Command Default

Crypto map is not in fail-close mode.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Examples

The following example shows that fail-close mode has been activated, and unencrypted traffic from access list 102 is allowed before the group member is registered:

```
crypto map map1 gdoi fail-close
 match address 102
 activate
crypto map map1 10 gdoi
 set group ks1_group
 match address 101
!
access-list 101 deny ip 10.0.1.0 0.0.0.255 10.0.1.0 0.0.0.255
access-list 102 deny tcp any eq telnet any
```

crypto map (isakmp)

To enable Internet Key Exchange (IKE) querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode, use the **crypto map** command in global configuration mode. To restore the default value, use the **no** form of this command.

crypto map [**ipv6**] *map-name* **isakmp authorization list** *list-name*

no crypto map [**ipv6**] *map-name* [**isakmp authorization list**]

Syntax Description

ipv6	(Optional) Specifies an IPv6 crypto map. For IPv4 crypto maps, use the command without this keyword.
map-name	Name you assign to the crypto map set.
isakmp authorization list	Specifies the Internet Security Association Key Management Protocol (ISAKMP) configuration settings and authorization parameters.
list-name	Character string used to name the list of authorization methods activated when a user logs in. The list name must match the list name defined during AAA configuration.

Defaults

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(4)M	This command was modified. The **ipv6** keyword was added.

Usage Guidelines

Use this command to enable key lookup from an AAA server.

Preshared keys deployed in a large-scale Virtual Private Network (VPN) without a certification authority, with dynamic IP addresses, are accessed during aggression mode of IKE negotiation through an AAA server. Thus, users have their own key, which is stored on an external AAA server. This allows for the central management of the user database, linking it to an existing database and allowing all users to have their own unique and secure pre-shared keys.

Before configuring this command, you should perform the following tasks:

- Set up an authorization list using AAA commands.
- Configure an IPsec transform.
- Configure a crypto map.

- Configure an ISAKMP policy using IPsec and IKE commands.

After enabling this command, you should apply the previously defined crypto map to the interface.

Examples

The following example shows how to configure the **crypto map** command for IPv4 crypto maps:

```
crypto map ikessaaamap isakmp authorization list ikessaaalist
crypto map ikessaaamap 10 ipsec-isakmp dynamic ikessaaadyn
```

The following example shows how to configure the **crypto map** command for IPv6 crypto maps:

```
crypto map ipv6 CM_V6 isakmp authorization list aaa
crypto map ipv6 CM_V6 10 ipsec-isakmp dynamic aaadyn
```

Related Commands

Command	Description
aaa authorization	Sets parameters that restrict a user's network access.
crypto ipsec transform-set	Defines a transform set, which is an acceptable combination of security protocols and algorithms, and enters crypto transform configuration mode.
crypto isakmp key	Configures a preshared authentication key.
crypto isakmp policy	Defines an IKE policy and enters ISAKMP policy configuration mode.
crypto map (global configuration)	Creates or modifies a crypto map entry and enters the crypto map configuration mode.
interface	Enters interface configuration mode.

crypto map isakmp-profile

To configure an Internet Security Association and Key Management Protocol (ISAKMP) profile on a crypto map, use the **crypto map isakmp-profile** command in global configuration mode. To restore the default values on the crypto map, use the **no** form of this command.

crypto map *map-name* **isakmp-profile** *isakmp-profile-name*

no crypto map *map-name* **isakmp-profile** *isakmp-profile-name*

Syntax Description

map-name	Name assigned to the crypto map set.
isakmp-profile-name	Character string used to name the ISAKMP profile that is used during an Internet Key Exchange (IKE) Phase 1 and Phase 1.5 exchange. The *isakmp-profile-name* must match the ISAKMP profile name that was defined during the ISAKMP profile configuration.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

This command describes the ISAKMP profile to use to start the IKE exchange. Before configuring this command, you must set up the ISAKMP profile.

Examples

The following example shows that an ISAKMP profile is configured on a crypto map:

```
crypto map vpnmap isakmp-profile vpnprofile
```

Related Commands

Command	Description
crypto ipsec transform-set	Defines a transform set—an acceptable combination of security protocols and algorithms.
crypto map (global)	Creates or modifies a crypto map entry.

crypto map local-address

To specify and name an identifying interface to be used by the crypto map for IPSec traffic, use the **crypto map local-address** command in global configuration mode. To remove this command from the configuration, use the **no** form of this command.

crypto map *map-name* **local-address** *interface-id*

no crypto map *map-name* **local-address**

Syntax Description

map-name	Name that identifies the crypto map set. This is the name assigned when the crypto map was created.
interface-id	The identifying interface that should be used by the router to identify itself to remote peers. If Internet Key Exchange is enabled and you are using a certification authority (CA) to obtain certificates, this should be the interface with the address specified in the CA certificates.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you apply the same crypto map to two interfaces and do not use this command, two separate security associations (with different local IP addresses) could be established to the same peer for similar traffic. If you are using the second interface as redundant to the first interface, it could be preferable to have a single security association (with a single local IP address) created for traffic sharing the two interfaces. Having a single security association decreases overhead and makes administration simpler.

This command allows a peer to establish a single security association (and use a single local IP address) that is shared by the two redundant interfaces.

If applying the same crypto map set to more than one interface, the default behavior is as follows:

- Each interface will have its own security association database.
- The IP address of the local interface will be used as the local address for IPSec traffic originating from/destined to that interface.

However, if you use a local-address for that crypto map set, it has multiple effects:

- Only one IPSec security association database will be established and shared for traffic through both interfaces.
- The IP address of the specified interface will be used as the local address for IPSec (and IKE) traffic originating from or destined to that interface.

One suggestion is to use a loopback interface as the referenced local address interface, because the loopback interface never goes down.

Examples

The following example assigns crypto map set "mymap" to the S0 interface and to the S1 interface. When traffic passes through either S0 or S1, the traffic will be evaluated against the all the crypto maps in the "mymap" set. When traffic through either interface matches an access list in one of the "mymap" crypto maps, a security association will be established. This same security association will then apply to both S0 and S1 traffic that matches the originally matched IPSec access list. The local address that IPSec will use on both interfaces will be the IP address of interface loopback0.

```
interface S0
 crypto map mymap

interface S1
 crypto map mymap

crypto map mymap local-address loopback0
```

Related Commands

Command	Description
crypto map (interface IPSec)	Applies a previously defined crypto map set to an interface.

crypto map redundancy replay-interval

To modify the interval at which inbound and outbound replay updates are passed from an active device to a standby device, use the **crypto map redundancy replay-interval** command in global configuration mode. To return to the default functionality, use the **no** form of this command.

crypto map *map-name* **redundancy replay-interval inbound** *in-value* **outbound** *out-value*

no crypto map *map-name* **redundancy replay-interval inbound** *in-value* **outbound** *out-value*

Syntax Description

map-name	Name that identifies the crypto map set. This is the name assigned when the crypto map was created.
inbound *in-value*	Number of inbound packets that are processed before an anti-replay update is sent from the active router to the standby router.
outbound *out-value*	Number of outbound packets that are processed before an anti-replay update is sent from the active router to the standby router.

Defaults

inbound *in-value*: one update every 1,000 packets

outbound *out-value*: one update every 100,000 packets

Command Modes

Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

Note This command can be used only in conjunction with IPSec stateful failover on a crypto map.

Stateful failover enables a router to continue processing and forwarding packets after a planned or unplanned outage occurs; that is, a backup (secondary) router automatically takes over the tasks of the active (primary) router if the active router loses connectivity for any reason.

The **crypto map redundancy replay-interval** command allows you to modify the interval in which an IP redundancy-enabled crypto map sends anti-replay updates from the active router to the standby router.

Examples

The following example shows how to enable replay checking for the crypto map “to-peer-outside” and enable IPSec stateful failover:

```
crypto map to-peer-outside redundancy replay-interval inbound 1000 outbound 10000
crypto map to-peer-outside 10 ipsec-isakmp
 set peer 209.165.200.225
 set transform-set trans1
```

```
 match address peer-outside
!
interface Ethernet0/0
 ip address 209.165.201.1 255.255.255.224
 standby 1 ip 209.165.201.3
 standby 1 preempt
 standby 1 name HA-out
 standby 1 track Ethernet1/0
 crypto map to-peer-outside redundancy HA-out stateful
```

crypto mib ipsec flowmib history failure size

To change the size of the IP Security (IPSec) MIB failure history table, use the **crypto mib ipsec flowmib history failure size** command in global configuration mode.

crypto mib ipsec flowmib history failure size *number*

Syntax Description

number	Size of the failure history table.

Defaults

If this command is not used, the default table size is 200.

Command Modes

Global configuration

Command History

Release	Modification
12.1(4)E	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **crypto mib ipsec flowmib history failure size** command to change the size of a failure history table. If you do not configure the size of a failure history table, the default of 200 will be implemented.

A failure history table stores the reason for tunnel failure and the time failure occurred. A failure history table can be used as a simple method to distinguish between a normal and an abnormal tunnel termination. That is, if a tunnel entry in the tunnel history table has no associated failure record, the tunnel must have terminated normally. However, every failure does not correspond to a tunnel. Supported setup failures are recorded in the failure table, but a history table is not associated because a tunnel was never set up.

Examples

The following example shows the size of a failure history table configured to be 140:

```
crypto mib ipsec flowmib history failure size 140
```

Related Commands

Command	Description
crypto mib ipsec flowmib history tunnel size	Changes the size of the IPSec tunnel history table.
show crypto mib ipsec flowmib history failure size	Displays the size of the IPSec failure history table.

crypto mib ipsec flowmib history tunnel size

To change the size of the IP Security (IPSec) tunnel history table, use the **crypto mib ipsec flowmib history tunnel size** command in global configuration mode.

crypto mib ipsec flowmib history tunnel size *number*

Syntax Description

number	Size of the tunnel history table.

Defaults

The default table size is 200.

Command Modes

Global configuration

Command History

Release	Modification
12.1(4)E	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **crypto mib ipsec flowmib history tunnel size** command to change the size of a tunnel history table. If you do not configure the size of a tunnel history table, the default of 200 will be implemented.

A tunnel history table stores the attribute and statistics records, which contain the attributes and the last snapshot of the traffic statistics of a given tunnel. A tunnel history table accompanies a failure table, so you can display the complete history of a given tunnel. However, a tunnel history table does not accompany every failure table because every failure does not correspond to a tunnel. Thus, supported setup failures are recorded in the failure table, but an associated history table is not recorded because a tunnel was never set up.

As an optimization, a tunnel endpoint table can be combined with a tunnel history table. However, if a tunnel endpoint table is combined, all three tables (the failure history table, tunnel history table, and the endpoint table) must remain the same size even though the MIB allows each table to be distinct.

Examples

The following example shows the size of a tunnel history table configured to be 130:

```
crypto mib ipsec flowmib history tunnel size 130
```

Related Commands

Command	Description
crypto mib ipsec flowmib history failure size	Changes the size of the IPSec failure history table.
show crypto mib ipsec flowmib history tunnel size	Displays the size of the IPSec tunnel history table.

crypto pki authenticate

To authenticate the certification authority (CA) (by getting the certificate of the CA), use the **crypto pki authenticate** command in global configuration mode.

crypto pki authenticate *name*

Syntax Description

name	The name of the CA. This is the same name used when the CA was declared with the **crypto ca identity** command.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3T	The **crypto ca authenticate** command was introduced.
12.3(7)T	This command replaced the **crypto ca authenticate** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

This command is required when you initially configure CA support at your router.

This command authenticates the CA to your router by obtaining the self-signed certificate of the CA that contains the public key of the CA. Because the CA signs its own certificate, you should manually authenticate the public key of the CA by contacting the CA administrator when you enter this command.

If you are using Router Advertisements (RA) mode (using the **enrollment** command) when you issue the **crypto pki authenticate** command, then registration authority signing and encryption certificates will be returned from the CA and the CA certificate.

This command is not saved to the router configuration. However. the public keys embedded in the received CA (and RA) certificates are saved to the configuration as part of the Rivest, Shamir, and Adelman (RSA) public key record (called the "RSA public key chain").

Note If the CA does not respond by a timeout period after this command is issued, the terminal control will be returned so that it remains available. If this happens, you must reenter the command. Cisco IOS software will not recognize CA certificate expiration dates set for beyond the year 2049. If the validity period of the CA certificate is set to expire after the year 2049, the following error message will be displayed when authentication with the CA server is attempted:

```
error retrieving certificate :incomplete chain
```

If you receive an error message similar to this one, check the expiration date of your CA certificate. If the expiration date of your CA certificate is set after the year 2049, you must reduce the expiration date by a year or more.

Examples

In the following example, the router requests the certificate of the CA. The CA sends its certificate and the router prompts the administrator to verify the certificate of the CA by checking the CA certificate's fingerprint. The CA administrator can also view the CA certificate's fingerprint, so you should compare what the CA administrator sees to what the router displays on the screen. If the fingerprint on the router's screen matches the fingerprint viewed by the CA administrator, you should accept the certificate as valid.

```
Router(config)# crypto pki authenticate myca

Certificate has the following attributes:
Fingerprint: 0123 4567 89AB CDEF 0123
Do you accept this certificate? [yes/no] y#
```

Related Commands

Command	Description
debug crypto pki transactions	Displays debug messages for the trace of interaction (message type) between the CA and the router.
enrollment	Specifies the enrollment parameters of your CA.
show crypto pki certificates	Displays information about your certificate, the certificate of the CA, and any RA certificates.

crypto pki benchmark

To start or stop benchmarking data for Public Key Infrastructure (PKI) performance monitoring and optimization, use the **crypto pki benchmark** command in privileged EXEC mode.

crypto pki benchmark {**start** *limit* [**wrap**] | **stop**}

Syntax Description

start *limit*	Enables PKI benchmarking. The *limit* argument states the number of records from 0 to 9990 that can be stored for the benchmarking session. A limit of 0 indicates an unlimited number of records can be stored.
wrap	(Optional) Specifies a continuous flow of records. Once the maximum number of records is gathered, they are released and a new set of records is generated. If the **wrap** keyword is not specified, then benchmarking stops once the limit for the maximum number of records has been reached.
stop	Terminates PKI benchmarking data collection.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use the **crypto pki benchmark start** command to start the collection of PKI benchmarking performance monitoring and optimization data. Use the **crypto pki benchmark stop** command to stop the collection of the PKI benchmarking performance monitoring and optimization data.

Use the **show crypto pki benchmarks** command to view the collection data.

Use the **clear crypto pki benchmarks** command to clear the PKI benchmarking performance monitoring and optimization data and release all memory associated with this data.

The IOS PKI Performance Monitoring and Optimization feature enables you to collect the following types of PKI performance data:

- Time to validate entire certificate chain.
- Time to verify each certificate.
- Time to check revocation status for each certificate.
- Time to fetch certificate revocation list (CRL) database for each fetch location.
- Time to fetch Simple Certificate Enrollment Protocol (SCEP) method capabilities to retrieve the CRL.
- Time to process each CRL.
- Time to process the Online Certificate Status Protocol (OCSP) response. OCSP is a certificate revocation mechanism.
- Time to fetch Authentication, Authorization, and Accounting (AAA).

- CRL size.
- Validation result.
- Validation Bypass (pubkey cached).
- Method used to fetch a CRL.
- PKI session identifier.
- Crypto engine used (hardware, software, etoken).

Examples

The following example starts PKI benchmarking data and collects 20 records. Once 20 records are collected, they are released and a new set of 20 records is generated.

```
Router# crypto pki benchmark start 20 wrap
```

Related Commands

Command	Description
clear crypto pki benchmarks	Clears PKI benchmarking performance monitoring and optimization data and releases all memory associated with this data.
show crypto pki benchmarks	Displays benchmarking data for PKI performance monitoring and optimization that was collected.

crypto pki cert validate

To determine if a trustpoint has been successfully authenticated, a certificate has been requested and granted, and if the certificate is currently valid, use the **crypto pki cert validate** command in global configuration mode.

crypto pki cert validate *trustpoint*

Syntax Description

trustpoint	The trustpoint to be validated.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced. Also, effective with Cisco IOS Release 12.3(8)T, this command replaced the **crypto ca cert validate** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **crypto pki cert validate** command validates the router's own certificate for a given trustpoint. Use this command as a sanity check after enrollment to verify that the trustpoint is properly authenticated, a certificate has been requested and granted for the trustpoint, and that the certificate is currently valid. A certificate is valid if it is signed by the trustpoint certification authority (CA), not expired, and so on.

Examples

The following examples show the possible output from the **crypto pki cert validate** command:

```
Router(config)# crypto pki cert validate ka

Validation Failed: trustpoint not found for ka

Router(config)# crypto pki cert validate ka

Validation Failed: can't get local certificate chain

Router(config)# crypto pki cert validate ka

Certificate chain has 2 certificates.
Certificate chain for ka is valid

Router(config)# crypto pki cert validate ka
```

```
Certificate chain has 2 certificates.
Validation Error: no certs on chain

Router(config)# crypto pki cert validate ka

Certificate chain has 2 certificates.
Validation Error: unspecified error
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the certification authority that the router should use.
show crypto pki trustpoints	Displays the trustpoints that are configured in the router.

crypto pki certificate chain

To enter the certificate chain configuration mode, use the **crypto pki certificate chain** command in global configuration mode.

crypto pki certificate chain *name*

Syntax Description

name	Specifies the name of the certificate authority (CA). The name must match that which was declared for the CA using the **crypto pki trustpoint** command.

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	The **crypto ca certificate chain** command was introduced.
12.3(7)T	This command replaced the **crypto ca certificate chain** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.4(2)T	The command output was modified to distinguish the current active certificate and the rollover certificate in the certificate chain.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command puts you into certificate chain configuration mode. When you are in certificate chain configuration mode, you can delete certificates using the **certificate** command.

You need to be in certificate chain configuration mode to delete certificates.

Examples

The following example deletes the router's certificate. In this example, the router had a general-purpose RSA key pair with one corresponding certificate. The show command is used to determine the serial number of the certificate to be deleted.

```
Router# show crypto pki certificates

Certificate
  Subject Name
    Name: myrouter.example.com
    IP Address: 10.0.0.1
  Status: Available
  Certificate Serial Number: 0123456789ABCDEF0123456789ABCDEF
  Key Usage: General Purpose

CA Certificate
  Status: Available
  Certificate Serial Number: 3051DF7123BEE31B8341DFE4B3A338E5F
  Key Usage: Not Set
```

```
Router# configure terminal
Router(config)# crypto pki certificate chain myca
Router(config-cert-chain)# no certificate 0123456789ABCDEF0123456789ABCDEF
% Are you sure you want to remove the certificate [yes/no]? yes
% Be sure to ask the CA administrator to revoke this certificate.
Router(config-cert-chain)# exit
```

The following example shows a certificate chain with an active CA certificate and a shadow, or rollover, certificate:

```
Router# configure terminal
Router(config)# crypto pki certificate chain myca

certificate 06

certificate ca 01

certificate rollover 0B
 ! This is the peer's shadow PKI certificate.

certificate rollover ca 0A
! This is the CA shadow PKI certificate
```

This example shows how the certificate chain is rewritten when rollover actually happens:

```
Router# configure terminal
Router(config)# crypto pki certificate chain myca

 certificate 0B
 certificate ca 0A
```

Related Commands

Command	Description
certificate	Adds certificates manually.

crypto pki certificate map

To define certificate-based access control lists (ACLs), use the **crypto pki certificate map** command in ca-certificate-map configuration mode. To remove the certificate-based ACLs, use the **no** form of this command.

crypto pki certificate map *label sequence-number*

no crypto pki certificate map *label sequence-number*

Syntax Description

label	A user-specified label that is referenced within the **crypto pki trustpoint** command.
sequence-number	A number that orders the ACLs with the same label. ACLs with the same label are processed from lowest to highest sequence number. When an ACL is matched, processing stops with a successful result.

Defaults

None

Command Modes

Ca-certificate-map configuration (ca-certificate-map)

Command History

Release	Modification
12.2(15)T	The **crypto ca certificate map** command was introduced.
12.3(7)T	This command replaced the **crypto ca certificate map** command.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.4(9)T	The **serial-number** field name was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

Issuing this command places the router in ca-certificate-map configuration mode where you can specify several certificate fields together with their matching criteria. The general form of these fields is as follows:

```
field-name match-criteria match-value
```

The *field-name* field in the above example is one of the certificate fields. Field names are similar to the names used in the ITU-T X.509 standard. The *field-name* is a special field that matches any subject name or related name field in the certificate, such as the **alt-subject-name, subject-name**, and **unstructured-subject-name** fields.

- **alt-subject-name**—Case-insensitive string.
- **expires-on**—Date field in the format dd mm yyyy hh:mm:ss or mmm dd yyyy hh:mm:ss.
- **issuer-name**—Case-insensitive string.
- **name**—Case-insensitive string.

- **serial-number**—Case-insensitive string.
- **subject-name**—Case-insensitive string.
- **unstructured-subject-name**—Case-insensitive string.
- **valid-start**—Date field in the format dd MM. yyy hh:mm:ss or mmm dd yyyy hh:mm:ss.

Note The time portion is optional in both the **expires-on** date and **valid-start** field and defaults to 00:00:00 if not specified. The time is interpreted according to the time zone offset configured for the router. The string **utc** can be appended to the date and time when they are configured as Universal Time, Coordinated (UTC) rather than local time.

The *match-criteria* field in the example is one of the following logical operators:

- **eq**—equal (valid for name and date fields)
- **ne**—not equal (valid for name and date fields)
- **co**—contains (valid only for name fields)
- **nc**—does not contain (valid only for name fields)
- **lt**—less than (valid only for date fields)
- **ge**—greater than or equal to (valid only for date fields)

The *match-value* field is a case-insensitive string or a date.

Examples

The following example shows how to configure a certificate-based ACL that will allow any certificate issued by Company to an entity within the company.com domain. The label is Company, and the sequence is 10.

```
crypto pki certificate map Company 10
 issuer-name co Company
 unstructured-subject-name co company.com
```

The following example accepts any certificate issued by Company for an entity with DIAL or organizationUnit component ou=WAN. This certificate-based ACL consists of two separate ACLs tied together with the common label Group. Because the check for DIAL has a lower sequence number, it is performed first. Note that the string “DIAL” can occur anywhere in the subjectName field of the certificate, but the string WAN must be in the organizationUnit component.

```
crypto pki certificate map Group 10
 issuer-name co Company
 subject-name co DIAL
crypto pki certificate map Group 20
 issuer-name co Company
 subject-name co ou=WAN
```

Case is ignored in string comparisons; therefore, DIAL in the previous example will match dial, DIAL, Dial, and so on. Also note that the component identifiers (o=, ou=, cn=, and so on) are not required unless it is desirable that the string to be matched occurs in a specific component of the name. (Refer to the ITU-T security standards for more information about certificate fields and components such as ou=.)

If a component identifier is specified in the match string, the exact string, including the component identifier, must appear in the certificate. This requirement can present a problem if more than one component identifier is included in the match string. For example, “ou=WAN,o=Company” will not match a certificate with the string “ou=WAN,ou=Engineering,o=Company” because the “ou=Engineering” string separates the two desired component identifiers.

To match both “ou=WAN” and “o=Company” in a certificate while ignoring other component identifiers, you could use this certificate map:

```
crypto pki certificate map Group 10
 subject-name co ou=WAN
 subject-name co o=Company
```

Any space character proceeding or following the equal sign (=) character in component identifiers is ignored. Therefore “o=Company” in the proceeding example will match “o = Company,” “o =Company,” and so on.

The following example shows a CA map file used to certificate serial number session control:

```
crypto pki trustpoint CA1
  enrollment url http://CA1
  ip-address FastEthernet0/0
  crl query ldap://CA1_ldap
  revocation-check crl
  match certificate crl-map1

  crypto pki certificate map crl-map1 1
  serial-number ne 489d
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.

crypto pki certificate query (ca-trustpoint)

To specify that certificates should not be stored locally but retrieved from a certification authority (CA) trustpoint, use the **crypto pki certificate query** command in ca-trustpoint configuration mode. To cause certificates to be stored locally per trustpoint, use the **no** form of this command.

crypto pki certificate query

no crypto pki certificate query

Syntax Description

This command has no arguments or keywords.

Defaults

CA trustpoints are stored locally in the router's NVRAM.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(8)T	The **crypto ca certificate query (ca-trustpoint)** command was introduced.
12.3(7)T	This command replaced the **crypto ca certificate query (ca-trustpoint)** command.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Normally, certain certificates are stored locally in the router's NVRAM, and each certificate uses a moderate amount of memory. To save NVRAM space, you can use this command to put the router into query mode, preventing certificates from being stored locally; instead, they are retrieved from a specified CA trustpoint when needed. This will save NVRAM space but could result in a slight performance impact.

The **crypto pki certificate query** command is a subcommand for each trustpoint; thus, this command can be disabled on a per-trustpoint basis.

Before you can configure this command, you must enable the **crypto pki trustpoint** command, which puts you in ca-trustpoint configuration mode.

Note This command deprecates the **crypto ca certificate query** command in global configuration mode. Although you can still enter the global configuration command, the configuration mode and command will be written back as ca-trustpoint.

Examples

The following example shows how to prevent certificates and certificate revocation lists (CRLs) from being stored locally on the router; instead, they are retrieved from the "ka" trustpoint when needed.

```
crypto pki trustpoint ka
 .
 .
 .
 crypto pki certificate query
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.

crypto pki certificate storage

To specify the local storage location for public key infrastructure (PKI) credentials, use the **crypto pki certificate storage** command in global configuration mode. To restore the default behavior, that is to store PKI credentials to NVRAM, use the **no** form of this command.

crypto pki certificate storage *location-name*

no crypto pki certificate storage

Syntax Description

location-name	Name of the local storage device. • Default is NVRAM.

Defaults

NVRAM is the default local storage location if this command is not issued.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

All Cisco platforms support NVRAM and flash local storage. Depending on your platform, you may have other supported local storage options including bootflash, slot, disk, USB flash, or USB token.

During run time, you can specify what active local storage device you would like to use to store PKI credentials. You must have the following system requirements before you can specify PKI credentials local storage location:

- A Cisco IOS Release 12.4(2)T PKI-enabled image or a later image
- A platform that supports storing PKI credentials as separate files
- A configuration that contains at least one certificate
- An accessible local file system

When using a local storage device to store PKI data, the following restrictions are applicable:

- Only local file systems may be used. An error message will be displayed if a remote file system is selected, and the command will not take effect.
- A subdirectory may be specified if supported by the local file system. NVRAM does not support subdirectories.
- Settings will take effect only when the running configuration is saved to the startup configuration.

If the keys are generated on the etoken, then the default storage loaction for the certificates is the etoken

for the device certificates. The CA certificates are stored in NVRAM. This allows for the credentials(keysa nd certificates) to be stored together on the removable media by default.

Examples

The following configuration example shows how to store certificates to the certs subdirectory. The certs subdirectory does not exist and is automatically created.

```
Router# dir nvram:

 114  -rw-        4687                    <no date>  startup-config
 115  ----        5545                    <no date>  private-config
 116  -rw-        4687                    <no date>  underlying-config
   1  ----          34                    <no date>  persistent-data
   3  -rw-         707                    <no date>  ioscaroot#7401CA.cer

Command	Description
show crypto pki certificates storage	Displays the current PKI certificate storage location.

crypto pki crl cache

To set the maximum amount of volatile memory used to cache certificate revocation lists (CRLs), use the **crypto pki crl cache** command in privileged EXEC mode. To restore the default value, use the **no** form of this command.

crypto pki crl cache *cache-size*

no crypto pki crl cache *cache-size*

Syntax Description

cache-size	The maximum CRL cache size in kilobytes. • The default value is 512 kilobytes. The value specified must be an integer. Specifying a cache size of zero disables CRL caching.

Command Default

The default CRL cache size is set to 512 kilobytes.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(20)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

The CRL cache is a global cache that holds all CRLs downloaded by the router regardless of the trustpoint configuration. The impact on router memory depends upon the CRL cache size configured by the administrator. Configuring the CRL cache size allows the amount of memory used for the CRL cache to be reduced (for instance, if low memory conditions exist) or to be increased for better performance (for instance, when a large number of CRLs are being processed).

If the **crypto pki crl cache** command is issued, regardless of the CRL cache size value set, the CRL cache size will be included in the configuration. Issuing the **no crypto pki crl cache** command will remove the CRL cache size from the configuration.

When a CRL is stored in the CRL cache, it is condensed at least one-fifth of its original size. Therefore, more CRLs can be stored in the CRL cache than would be expected based on the CRL size before being cached.

Note To configure CRL caching for a given trustpoint, you may issue either the **crl-cache none** or **crl cache delete-after** command. To disable caching of CRLs for a given trustpoint, use the **crl-cache none** command. To set a maximum age for CRLs in the cache for a given trustpoint, use the **crl cache delete-after** command.

Examples

The following example sets the maximum CRL cache size to 2048 kilobytes and then shows sample output of the **show crypto pki crls** command:

```
Router# crypto pki crl cache 2048
Router# show crypto pki crls

     CRL Issuer Name:
           cn=ioscs,l=Anytown,c=US
           LastUpdate: 02:53:41 GMT Mar 6 2007
           NextUpdate: 02:53:41 GMT Mar 13 2007
           Retrieved from CRL Distribution Point:
                ** CDP Not Published - Retrieved via SCEP
     CRL DER is 475 bytes
     CRL is stored in parsed CRL cache
     Parsed CRL cache current size is 1705 bytes
     Parsed CRL cache maximum size is 2048 bytes
```

Related Commands

Command	Description
crl cache delete-after	Deletes a CRL from the cache after the specified number of minutes.
crl cache none	Disables caching of all CRLs.
crypto pki crl request	Requests that a new CRL be obtained immediately from the CA.
show crypto pki crls	Displays the current CRL on the router.

crypto pki crl request

To request that a new certificate revocation list (CRL) be obtained immediately from the certification authority, use the **crypto pki crl request** command in global configuration mode.

crypto pki crl request *name*

Syntax Description

name	Specifies the name of the CA. This is the same name used when the CA was declared with the **crypto pki trustpoint** command.

Defaults

Normally, the router requests a new CRL when it is verifying a certificate and there is no CRL cached.

Command Modes

Global configuration

Command History

Release	Modification
11.3 T	The **crypto ca crl request** command was introduced.
12.3(7)T	This command replaced the **crypto ca crl request** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

A CRL lists all the certificates of the network device that have been revoked. Revoked certificates will not be honored by your router; therefore, any IPSec device with a revoked certificate cannot exchange IP Security traffic with your router.

The first time your router receives a certificate from a peer, it will download a CRL from the CA. Your router then checks the CRL to make sure the certificate of the peer has not been revoked. (If the certificate appears on the CRL, it will not accept the certificate and will not authenticate the peer.)

A CRL can be reused with subsequent certificates until the CRL expires. If your router receives the certificate of a peer after the applicable CRL has expired, it will download the new CRL.

If your router has a CRL which has not yet expired, but you suspect that the contents of the CRL are out of date, use the **crypto pki crl request** command to request that the latest CRL be immediately downloaded to replace the old CRL.

This command is not saved to the configuration.

Note This command should be used only after the trustpoint is enrolled.

Examples

The following example immediately downloads the latest CRL to your router:

```
crypto pki crl request
```

crypto pki enroll

To obtain the certificates for your router from the certificate authority (CA), use the **crypto pki enroll** command in global configuration mode. To delete a current enrollment request, use the **no** form of this command.

crypto pki enroll *name*

no crypto pki enroll *name*

Syntax Description

name	The name of the CA. Use the same name as when you declared the CA using the **crypto pki trustpoint** command.

Defaults

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.3T	The **crypto ca enroll** command was introduced.
12.3(7)T	This command replaced the **crypto ca enroll** command.
12.3(14)T	The command was modified to include self-signed certificate information.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

This command requests certificates from the CA for all of your router's Rivest, Shamir, and Adelmen (RSA) key pairs. This task is also known as enrolling with the CA. (Technically, enrolling and obtaining certificates are two separate events, but they both occur when this command is issued.)

Your router needs a signed certificate from the CA for each RSA key pairs of your router; if you previously generated general-purpose keys, this command obtains the one certificate corresponding to the one general-purpose RSA key pair. If you previously generated special-usage keys, this command obtains two certificates corresponding to each of the special-usage RSA key pairs.

If you already have a certificate for your keys you are prompted to remove the existing certificate first. (You can remove existing certificates with the **no certificate** command.)

The **crypto pki enroll** command is not saved in the router configuration.

Note If your router reboots after you issue the **crypto pki enroll** command but before you receive the certificates, you must reissue the command.

Note If you are using a Secure Shell (SSH) service, you should set up specific RSA key pairs (different private keys) for the trustpoint and the SSH service. (If the Public Key Infrastructure [PKI] and the SSH infrastructure share the same default RSA key pair, a temporary disruption of SSH service could occur. The RSA key pair could become invalid or change because of the CA system, in which case you would not be able to log in using SSH. You could receive the following error message: "key changed, possible security problem.")

Responding to Prompts

When you issue the **crypto pki enroll** command, you are prompted a number of times.

You are prompted to create a challenge password. This password can be up to 80 characters in length. This password is necessary in the event that you ever need to revoke your router's certificates. When you ask the CA administrator to revoke your certificate, you must supply this challenge password as a protection against fraudulent or mistaken revocation requests.

Note This password is not stored anywhere, so you need to remember this password.

If you lose the password, the CA administrator may still be able to revoke the router's certificate but will require further manual authentication of the router administrator identity.

You are also prompted to indicate whether your router's serial number should be included in the obtained certificate. The serial number is not used by IP Security (IPsec) or Internet Key Exchange, but may be used by the CA to either authenticate certificates or to later associate a certificate with a particular router. (Note that the serial number stored is the serial number of the internal board, not the one on the enclosure.) Ask your CA administrator if serial numbers should be included. If you are in doubt, include the serial number.

Normally, you would not include the IP address because the IP address binds the certificate more tightly to a specific entity. Also, if the router is moved, you would need to issue a new certificate. A router has multiple IP addresses, any of which might be used with IPsec.

If you indicate that the IP address should be included, you will then be prompted to specify the interface of the IP address. This interface should correspond to the interface that you apply your crypto map set to. If you apply crypto map sets to more than one interface, specify the interface that you name in the **crypto map local-address** command.

Examples

In the following example, a router with a general-purpose RSA key pair requests a certificate from the CA. When the router displays the certificate fingerprint, the administrator verifies this number by calling the CA administrator, which checks the number. The fingerprint is correct, so the router administrator accepts the certificate.

There can be a delay between when the router administrator sends the request and when the certificate is actually received by the router. The amount of delay depends on the CA method of operation.

```
Router(config)# crypto pki enroll myca
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this
   password to the CA Administrator in order to revoke your certificate.
   For security reasons your password will not be saved in the configuration.
   Please make a note of it.

Password: <mypassword>
```

```
Re-enter password: <mypassword>

% The subject name in the certificate will be: myrouter.example.com
% Include the router serial number in the subject name? [yes/no]: yes
% The serial number in the certificate will be: 03433678
% Include an IP address in the subject name [yes/no]? yes
Interface: ethernet0/0
Request certificate from CA [yes/no]? yes
% Certificate request sent to Certificate Authority
% The certificate request fingerprint will be displayed.
% The 'show crypto pki certificates' command will also show the fingerprint.
```

Some time later, the router receives the certificate from the CA and displays the following confirmation message:

```
Router(config)#   Fingerprint: 01234567 89ABCDEF FEDCBA98 75543210

%CRYPTO-6-CERTRET: Certificate received from Certificate Authority

Router(config)#
```

If necessary, the router administrator can verify the displayed fingerprint with the CA administrator.

If there is a problem with the certificate request and the certificate is not granted, the following message is displayed on the console instead:

```
%CRYPTO-6-CERTREJ: Certificate enrollment request was rejected by Certificate Authority
```

The subject name in the certificate is automatically assigned to be the same as the RSA key pair's name. In the example, the RSA key pair was named "myrouter.example.com." (The router assigned this name.)

Requesting certificates for a router with special-usage keys would be the same as in the previous example, except that two certificates would have been returned by the CA. When the router received the two certificates, the router would have displayed the same confirmation message:

```
%CRYPTO-6-CERTRET: Certificate received from Certificate Authority
```

Related Commands

Command	Description
crypto map local address	Specifies and names an identifying interface to be used by the crypto map for IPsec traffic.
debug crypto pki messages	Displays debug messages for the details of the interaction (message dump) between the CA and the router.
debug crypto pki transactions	Displays debug messages for the trace of interaction (message type) between the CA and the router.
show crypto pki certificates	Displays information about your certificate, the certificate of the CA, and any RA certificates.

crypto pki export pem

To export certificates and Rivest, Shamir, and Adelman (RSA) keys that are associated with a trustpoint in a privacy-enhanced mail (PEM)-formatted file, use the **crypto pki export pem** command in global configuration mode.

crypto pki export *trustpoint* **pem** {**terminal** | **url** *url*} {**3des** | **des**} *passphrase* [**rollover**]

Syntax Description

trustpoint	Name of the trustpoint that the associated certificate and RSA key pair will export. The *trustpoint* argument must match the name that was specified via the **crypto pki trustpoint** command.
terminal	Certificate and RSA key pair that will be displayed in PEM format on the console terminal.
url *url*	URL of the file system where your router should export the certificate and RSA key pairs.
3des	Export the trustpoint using the Triple Data Encryption Standard (3DES) encryption algorithm.
des	Export the trustpoint using the DES encryption algorithm.
passphrase	Passphrase that is used to encrypt the PEM file for import. **Note** The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.
rollover	(Optional) Export certificate authority (CA) shadow, or rollover, certificate.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)T	The **crypto ca export pem** command was introduced.
12.3(7)T	This command replaced the **crypto ca export pem** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.4(2)T	The **rollover** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **crypto pki export pem** command allows you to export certificate and RSA key pairs in PEM-formatted files. The PEM files can then be imported back into the Cisco IOS router (via the **crypto pki import pem** command) or other public key infrastructure (PKI) applications.

Examples

The following example shows how to generate and export the RSA key pair "aaa" and certificates of the router in PEM files that are associated with the trustpoint "mycs":

```
Router(config)# crypto key generate rsa general-keys label aaa exportable
The name for the keys will be:aaa
Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose
Keys. Choosing a key modulus greater than 512 may take a few minutes.
!
How many bits in the modulus [512]:
% Generating 512 bit RSA keys ...[OK]
!
Router(config)# crypto pki trustpoint mycs
Router(ca-trustpoint)# enrollment url http://mycs
Router(ca-trustpoint)# rsakeypair aaa
Router(ca-trustpoint)# exit
Router(config)# crypto pki authenticate mycs
Certificate has the following attributes:
Fingerprint:C21514AC 12815946 09F635ED FBB6CF31
% Do you accept this certificate? [yes/no]:y
Trustpoint CA certificate accepted.
!
Router(config)# crypto pki enroll mycs
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this password to the CA
Administrator in order to revoke your certificate.
For security reasons your password will not be saved in the configuration.
Please make a note of it.

Password:
Re-enter password:

% The fully-qualified domain name in the certificate will be:Router
% The subject name in the certificate will be:bizarro.cisco.com
% Include the router serial number in the subject name? [yes/no]:n
% Include an IP address in the subject name? [no]:n
Request certificate from CA? [yes/no]:y
% Certificate request sent to Certificate Authority
% The certificate request fingerprint will be displayed.
% The 'show crypto ca certificate' command will also show the fingerprint.

Router(config)# Fingerprint: 8DA777BC 08477073 A5BE2403 812DD157

00:29:11:%CRYPTO-6-CERTRET:Certificate received from Certificate Authority

Related Commands

Command	Description
crypto pki import pem	Imports certificates and RSA keys to a trustpoint from PEM-formatted files.
crypto pki trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of a CA.

crypto pki export pkcs12

To export Rivest, Shamir, and Adelman (RSA) keys within a PKCS12 file at a specified location, use the **crypto pki export pkcs12** command in global configuration mode.

crypto pki export *trustpointname* **pkcs12** *destination url passphrase*

Syntax Description

trustpointname	Name of the trustpoint who issues the certificate that a user is going to export. When you export the PKCS12 file, the trustpoint name is the RSA key name.
destination url	Location of the PKCS12 file to which a user wants to import the RSA key pair.
passphrase	Passphrase that is used to encrypt the PKCS12 file for export.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	The **crypto ca export pkcs12** command was introduced.
12.3(7)T	This command replaced the **crypto ca export pkcs12** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **crypto pki export pkcs12** command creates a PKCS 12 file that contains an RSA key pair. The PKCS12 file, along with a certificate authority (CA), is exported to the location that you specify with the destination URL. If you decide not to import the file to another router, you must delete the file.

Security Measures

Keep the PKCS12 file stored in a secure place with restricted access.

An RSA keypair is more secure than a passphrase because the private key in the key pair is not known by multiple parties. When you export an RSA key pair to a PKCS#12 file, the RSA key pair now is only as secure as the passphrase.

To create a good passphrase, be sure to include numbers, as well as both lowercase and uppercase letters. Avoid publicizing the passphrase by mentioning it in e-mail or cell phone communications because the information could be accessed by an unauthorized user.

Examples

The following example exports an RSA key pair with a trustpoint name “mytp” to a Flash file:

```
Router(config)# crypto pki export mytp pkcs12 flash:myexport mycompany
```

Related Commands

Command	Description
crypto pki import pkcs12	Imports RSA keys.

crypto pki import

To import a certificate manually via TFTP or as a cut-and-paste at the terminal, use the **crypto pki import** command in global configuration mode.

crypto pki import *name* **certificate**

Syntax Description

name **certificate**	Name of the certification authority (CA). This name is the same name used when the CA was declared with the **crypto pki trustpoint** command.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	The **crypto ca import** command was introduced.
12.3(7)T	This command replaced the **crypto ca import** command.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

You must enter the **crypto pki import** command twice if usage keys (signature and encryption keys) are used. The first time the command is entered, one of the certificates is pasted into the router; the second time the command is entered, the other certificate is pasted into the router. (It does not matter which certificate is pasted first.)

Examples

The following example shows how to import a certificate via cut-and-paste. In this example, the CA trustpoint is "MS."

```
crypto pki trustpoint MS
 enroll terminal
 crypto pki authenticate MS
!
crypto pki enroll MS
crypto pki import MS certificate
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of your CA.
enrollment terminal	Specifies manual cut-and-paste certificate enrollment.

crypto pki import pem

To import certificates and Rivest, Shamir, and Adelman (RSA) keys to a trustpoint from privacy-enhanced mail (PEM)-formatted files, use the **crypto pki import pem** command in global configuration mode.

crypto pki import *trustpoint* **pem** [**usage-keys**] {**terminal** | **url** *url*} [**exportable**] *passphrase*

Syntax Description

trustpoint	Name of the trustpoint that is associated with the imported certificates and RSA key pairs. The *trustpoint* argument must match the name that was specified via the **crypto pki trustpoint** command.
usage-keys	(Optional) Specifies that two RSA special usage key pairs will be imported (that is, one encryption pair and one signature pair), instead of one general-purpose key pair.
terminal	Certificates and RSA key pairs will be manually imported from the console terminal.
url *url*	URL of the file system where your router should import the certificates and RSA key pairs.
exportable	(Optional) Specifies that the imported RSA key pair can be exported again to another Cisco device such as a router.
passphrase	Passphrase that is used to encrypt the PEM file for import. **Note** The passphrase can be any phrase that is at least eight characters in length; it can include spaces and punctuation, excluding the question mark (?), which has special meaning to the Cisco IOS parser.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)T	The **crypto ca import pem** command was introduced.
12.3(7)T	This command replaced the **crypto ca import pem** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **crypto pki import pem** command allows you import certificates and RSA key pairs in PEM-formatted files. The files can be previously exported from another router or generated from other public key infrastructure (PKI) applications.

Examples

The following example shows how to import PEM files to trustpoint “ggg” via TFTP:

```
Router(config)# crypto pki import ggg pem url tftp://10.1.1.2/johndoe/msca cisco1234

% Importing CA certificate...
Address or name of remote host [10.1.1.2]?
Destination filename [johndoe/msca.ca]?
Reading file from tftp://10.1.1.2/johndoe/msca.ca
Loading johndoe/msca.ca from 10.1.1.2 (via Ethernet0):!
[OK - 1082 bytes]

% Importing private key PEM file...
Address or name of remote host [10.1.1.2]?
Destination filename [johndoe/msca.prv]?
Reading file from tftp://10.1.1.2/johndoe/msca.prv
Loading johndoe/msca.prv from 10.1.1.2 (via Ethernet0):!
[OK - 573 bytes]

% Importing  certificate PEM file...
Address or name of remote host [10.1.1.2]?
Destination filename [johndoe/msca.crt]?
Reading file from tftp://10.1.1.2/johndoe/msca.crt
Loading johndoe/msca.crt from 10.1.1.2 (via Ethernet0):!
[OK - 1289 bytes]
% PEM files import succeeded.
Router(config)#
```

Related Commands

Command	Description
crypto pki export pem	Exports certificates and RSA keys that are associated with a trustpoint in a PEM-formatted file.
crypto pki trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of a CA.

crypto pki import pkcs12

To import Rivest, Shamir, and Adelman (RSA) keys, use the **crypto pki import pkcs12** command in global configuration mode.

crypto pki import *trustpointname* **pkcs12** *source url passphrase*

Syntax Description

trustpointname	Name of the trustpoint who issues the certificate that a user is going to export or import. When importing, the trustpoint name will become the RSA key name.
source url	The location of the PKCS12 file to which a user wants to export the RSA key pair.
passphrase	Passphrase that must be entered to undo encryption when the RSA keys are imported.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T	The **crypto ca import pkcs12** command was introduced.
12.3(7)T	This command replaced the **crypto ca import pkcs12** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

When you enter the **crypto pki import pkcs12** command, a ke pair and a trustpoint are generated. If you then decide you want to remove the key pair and trustpoint that were generated, enter the **crypto key zeroize rsa** command to zeroize the key pair and enter the **no crypto pki trustpoint** command to remove the trustpoint.

Note After you import RSA keys to a target router, you cannot export those keys from the target router to another router.

Examples

In the following example, an RSA key pair that has been associated with the trustpoint “forward” is to be imported:

```
Router(config)# crypto pki import forward pkcs12 flash:myexport mycompany
```

Related Commands

Command	Description
crypto pki export pkcs12	Exports RSA keys.
crypto pki trustpoint	Declares the CA that your router should use.
crypto key zeroize rsa	Deletes all RSA keys from your router.

crypto pki profile enrollment

To define an enrollment profile, use the **crypto pki profile enrollment** command in global configuration mode. To delete all information associated with this enrollment profile, use the **no** form of this command.

crypto pki profile enrollment *label*

no crypto pki profile enrollment *label*

Syntax Description

label	Name for the enrollment profile; the enrollment profile name must match the name specified in the **enrollment profile** command.

Defaults

An enrollment profile does not exist.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(7)T	This command replaced the **crypto ca profile enrollment** command.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Before entering this command, you must specify a named enrollment profile using the **enrollment profile** in ca-trustpoint configuration mode.

After entering the **crypto pki profile enrollment** command, you can use any of the following commands to define the profile parameters:

- **authentication command**—Specifies the HTTP command that is sent to the certification authority (CA) for authentication.
- **authentication terminal**—Specifies manual cut-and-paste certificate authentication requests.
- **authentication url**—Specifies the URL of the CA server to which to send authentication requests.
- **enrollment command**—Specifies the HTTP command that is sent to the CA for enrollment.
- **enrollment terminal**—Specifies manual cut-and-paste certificate enrollment.
- **enrollment url**—Specifies the URL of the CA server to which to send enrollment requests.
- **parameter**—Specifies parameters for an enrollment profile. This command can be used only if the **authentication command** or the **enrollment command** is used.

Note The **authentication url**, **enrollment url**, **authentication terminal**, and **enrollment terminal** commands allow you to specify different methods for certificate authentication and enrollment, such as TFTP authentication and manual enrollment.

Examples

The following example shows how to define the enrollment profile named "E" and associated profile parameters:

```
crypto pki trustpoint Entrust
  enrollment profile E
  serial

crypto pki profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the PKI trustpoint that your router should use.
enrollment profile	Specifies that an enrollment profile can be used for certificate authentication and enrollment.

crypto pki server

To enable a Cisco IOS certificate server and enter certificate server configuration mode or to immediately generate shadow certification authority (CA) credentials, use the **crypto pki server** command in global configuration mode. To disable a certificate server (which is the default functionality), use the **no** form of this command.

crypto pki server *cs-label* [**rollover** [**cancel**] [**request pkcs10 terminal**]] [**redundancy**] [**show**] [**serial-number** *serial-number*]

no crypto pki server *cs-label*

Syntax Description

cs-label	Name of the certificate server. **Note** The certificate server name should not exceed 13 characters.
rollover	(Optional) Immediately generates a shadow CA certificate. **Note** If the **auto-enroll** command has been issued with the **regenerate** keyword, shadow keys will also be generated. **Note** If the shadow certificate and keys are already present this command will fail.
cancel	(Optional) Deletes the exiting shadow CA certificate when used with the **rollover** keyword. Shadow keys will also be deleted if they exist.
request pkcs10 terminal	(Optional) Exports CA shadow certificate. Also exports shadow keys if they exist.
redundancy	(Optional) Synchronizes the server configuration with that of the standby CA.
show	(Optional) Displays the current configuration of the server being configured.
serial-number *serial-number*	(Optional) Specifies the next serial number to be issued, and updates the serial-number file.

Defaults

A certificate server is not enabled; the automatic CA certificate rollover process is not initiated.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.4(2)T	The **rollover**, **cancel**, and **request pkcs10 terminal** keywords were introduced to support automated CA certificate rollover functionality.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.0(1)M	This command was modified. The **redundancy**, **show**, and **serial-number** keywords were added.

Usage Guidelines

A certificate server allows you to more easily deploy public key infrastructure (PKI) by defining default behavior, which limits user interface complexity. To define the functionality of the certificate server, you can use any of the following certificate server configuration mode commands:

- **database (certificate server)**—Requires a username or password to be issued when accessing a database storage location.
- **database level**—Controls what type of data is stored in the certificate enrollment database.
- **database url**—Specifies the location where all database entries for the certificate server will be written out.
- **grant automatic**—Specifies automatic certificate enrollment.

Note This command can be used for testing and building simple networks; however, it is recommended that you do not issue this command if your network is generally accessible.

- **issuer-name**—Specifies the distinguished name (DN) as the CA issuer name for the certificate server.
- **lifetime (certificate server)**—Specifies the lifetime of the CA or a certificate.
- **lifetime crl**—Defines the lifetime of the certificate revocation list (CRL) that is used by the certificate server.
- **shutdown**—Allows a certificate server to be disabled without removing the configuration.

Note All of these commands are optional; thus, any basic certificate server functionality that is not specified via the command-line interface (CLI) will use the default value.

Automated CA Certificate Rollover

CAs and their clients, have certificates with expiration dates that have to be reissued when the current certificate is about to expire. CAs also have key pairs used to sign client certificates. When the CA certificate is expiring it must generate a new certificate and possibly a new key pair. This process, called rollover, allows for continuous operation of the network while clients and the certificate server are switching from an expiring CA certificate to a new CA certificate.

Examples

The following example shows how to enable the certificate server “mycertserver”:

```
Router(config)# ip http server
Router(config)# crypto pki server mycertserver
Router(cs-server)# database url tftp://mytftp/johndoe/mycertserver
```

The following example shows how to disable the certificate server “mycertserver”:

```
Router(config)# no crypto pki server mycertserver
% This will stop the Certificate Server process and delete the server
  configuration
Are you sure you want to do this? [yes/no]: yes
% Do you also want to remove the associated trustpoint and
  signing certificate and key? [yes/no]: no
% Certificate Server Process stopped
```

The following example shows a shadow client certificate request from a terminal:

```
Router# crypto pki server mycs rollover request pkcs10 terminal

% Enter Base64 encoded or PEM formatted PKCS10 enrollment request.

% End with a blank line or "quit" on a line by itself.

-----BEGIN CERTIFICATE REQUEST-----

The following example shows the **redundancy**, **show**, and **serial-number** keywords in the **crypto pki server** command.

```
Router(config)#crypto pki server MYCA
Router(cs-server)#grant auto
Router(cs-server)#redundancy
Router(cs-server)#serial-number 0x4c
Router(cs-server)#show
 redundancy
 serial-number 0x4C
 grant auto
end
```

Related Commands

Command	Description
crypto pki server info requests	Displays all outstanding certificate enrollment requests.
ip http server	Enables an HTTP server on your network.

crypto pki server grant

To grant all or certain simple certificate enrollment protocol (SCEP) requests, use the **crypto pki server grant** command in privileged EXEC mode.

crypto pki server *cs-label* **grant** {**all** | *req-id*}

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.
all	All certificate enrollment requests are granted.
req-id	ID associated with a specific enrollment request in the enrollment request database. Use the **crypto pki server info requests** command to display the ID.

Defaults

If this command is not issued, the certificate server keeps the requests in a pending state.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

After you enable the **crypto pki server grant** command, your certificate server will immediately grant all specified certificate requests. Certificate requests that are not granted will expire after the time that was specified using the **lifetime enrollment-request** command.

Examples

The following example shows to grant all manual enrollment requests for the certificate server "mycs":

```
Router# crypto pki server mycs grant all
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto pki server reject	Rejects all or certain SCEP requests.

crypto pki server info crl

Note Effective with Cisco IOS Release 12.4(20)T, the **crypto pki server info crl** command is replaced by the **show crypto pki server crl** command. See the **show crypto pki server crl** command for more information.

To display information regarding the status of the current certificate revocation list (CRL), use the **crypto pki server info crl** command in privileged EXEC mode.

crypto pki server *cs-label* **info crl**

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.

Defaults

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.4(20)T	This command was replaced by the **show crypto pki server crl** command.

Usage Guidelines

CRLs are issued once every specified time period via the **lifetime crl** command. It is the responsibility of the network administrator to ensure that the CRL is available from the location that is specified via the **cdp-url** command. To access information, such as the lifetime and location of the CRL, use the **crypto pki server info crl** command.

Examples

The following example shows how to access CRL information for the certificate server “mycs”:

```
Router# crypto pki server mycs info crl
```

Related Commands

Command	Description
cdp-url	Specifies a CDP to be used in certificates that are issued by the certificate server.
crypto pki server	Enables a Cisco IOS certificate server and enter certificate server configuration mode.
lifetime crl	Defines the lifetime of the CRL that is used by the certificate server.

crypto pki server info requests

Note Effective with Cisco IOS Release 12.4(20)T, the **crypto pki server info requests** command is replaced by the **show crypto pki server requests** command. See the **show crypto pki server requests** command for more information.

To display all outstanding certificate enrollment requests, use the **crypto pki server info requests** command in privileged EXEC mode.

crypto pki server *cs-label* **info requests**

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.

Defaults

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.4(2)T	The command output was modified to include shadow CA certificate information.
12.4(20)T	This command was replaced by the **show crypto pki server requests** command.

Usage Guidelines

A certificate enrollment request functions as follows:

- The certificate server receives the enrollment request from an end user, and the following actions occur:
  - A request entry is created in the enrollment request database with the initial state. (See the **show pki server** command for a complete list of certificate enrollment request states.)
  - The certificate server refers to the command-line interface (CLI) configuration (or the default behavior any time a parameter is not specified) to determine the authorization of the request. Thereafter, the state of the enrollment request is updated in the enrollment request database.
- At each Simple Certificate Enrollment Protocol (SCEP) query for a response, the certificate server examines the current request and performs one of the following actions:
  - Responds to the end user with a “pending” or “denied” state.
  - Forwards to the request to the certification authority (CA) core, where it will generate and sign the appropriate certificate, store the certificate in the enrollment request database, and return the request to the built-in certificate server SCEP server, who will reply to the end user with the certificate on the next SCEP request.

If the connection of the client has closed, the certificate server will wait for client user to request another certificate.

All enrollment requests transitions through the certificate enrollment states that are defined in Table 27.

Table 27 Certificate Enrollment Request State Descriptions

Certificate Enrollment State	Description
initial	The request has been created by the SCEP server.
authorized	The certificate server has authorized the request.
malformed	The certificate server has determined that the request is invalid for cryptographic reasons.
denied	The certificate server has denied the request for policy reasons.
pending	The enrollment request must be manually accepted by the network administrator.
granted	The CA core has generated the appropriate certificate for the certificate request.

Examples

The following example shows output for the certificate server "certsrv1," which has a pending certificate enrollment request:

```
Router# crypto pki server certsrv1 info requests

   Enrollment Request Database:
   ReqID  State      Fingerprint                      SubjectName
   --------------------------------------------------------------
   1      pending    0A71820219260E526D250ECC59857C2D serialNumber=2326115A+hostname=831.
```

The following example shows the output for shadow PKI certificate info requests:

```
Router# crypto pki server mycs info requests

Enrollment Request Database:

RA certificate requests:

  ReqID  State      Fingerprint                      SubjectName

--------------------------------------------------------------
RA rollover certificate requests:

  ReqID  State      Fingerprint                      SubjectName

  --------------------------------------------------------------

Router certificates requests:

  ReqID  State      Fingerprint                      SubjectName

--------------------------------------------------------------

1      pending    A426AF07FE3A4BB69062E0E47198E5BF hostname=client

  Router rollover certificates requests:
```

```
ReqID  State      Fingerprint                      SubjectName

--------------------------------------------------------------

2      pending    B69062E0E47198E5BFA426AF07FE3A4B hostname=client
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters PKI configuration mode.

crypto pki server password generate

To generate a password for simple certificate enrollment protocol (SCEP) requests that can be used only one time, use the **crypto pki server password generate** command in privileged EXEC mode.

crypto pki server *cs-label* **password generate** [*minutes*]

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.
minutes	(Optional) Length of time, in minutes, that the password is valid. Valid times range from 1 to 1440 minutes. The default value is 60 minutes.

Defaults

If this command is not enabled, no password is created.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

SCEP, which is the only supported enrollment protocol, supports two client authentication mechanisms—manual and preshared key. Manual enrollment requires the administrator at the certification authority (CA) server to specifically authorize the enrollment requests; enrollment using preshared keys allows the administrator to preauthorize enrollment requests by generating a one-time password.

Note Only one password is valid at a time; if a second password is generated, the previous password is no longer valid.

Examples

The following example shows how to generate a one-time password that is valid for 75 minutes for the certificate server “mycs”:

```
Router# crypto pki server mycs password generate 75
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.

crypto pki server reject

To reject all or certain Simple Certificate Enrollment Protocol (SCEP) requests, use the **crypto pki server reject** command in privileged EXEC mode.

crypto pki server *cs-label* **reject** {**all** | *req-id*}

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.
all	All certificate enrollment requests are rejected.
req-id	ID associated with a specific enrollment request in enrollment request database. Use the **crypto pki server info requests** command to display the ID.

Defaults

If this command is not issued, the certificate server keeps the requests in a pending state.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

After you enable the **crypto pki server reject** command, your certificate server will immediately reject all certificate requests.

SCEP, which is the only supported enrollment protocol, supports two client authentication mechanisms—manual and preshared key. Manual enrollment requires the administrator at the certification authority (CA) server to specifically authorize the enrollment requests. The administrator can become overloaded if there are numerous enrollment requests. Thus, the **crypto pki server reject** command can be reduce user interaction by automatically rejecting all or specific enrollment requests.

Examples

The following example shows how reject all manual enrollment requests for the certificate server "mycs":

```
Router# crypto pki server mycs reject all
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto pki server grant	Grants all or certain SCEP requests.
crypto pki server info requests	Displays all outstanding certificate enrollment requests.

crypto pki server remove

To remove enrollment requests that are in the certificate server Enrollment Request Database, use the **crypto pki server remove** command in privileged EXEC mode . This command does not have a **no** form.

crypto pki server *cs-label* **remove** {**all** | *req-id*}

Syntax Description

cs-label	Name of the certificate server.
all	Removes all enrollment requests.
req-id	Removes the specified enrollment request.

Defaults

Enrollment requests will remain in the certificate server database.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

After the certificate server receives an enrollment request, it can leave the request in pending, reject it, or grant it. Before this command was added, the request would be left in the Enrollment Request Database for 1 hour until the client polled the certficiate server for the result of the request. This command allows you to remove individual or all requests from the database, especially useful if the client leaves and never polls the certificate server.

In addition, the use of this command also allows the server to be returned to a clean slate with respect to the keys and transaction IDs. Thus, it is a useful command to use during troubleshooting with a Simple Certificate Enrollment Protocol (SCEP) client that may be behaving badly.

Examples

The following example shows that all enrollment requests are to be removed from the certificate server:

```
Router# enable
 Router# crypto pki server server1 remove all
```

Related Commands

Command	Description
crypto pki server info request	Displays all outstanding enrollment requests.

crypto pki server request pkcs10

To manually add a certificate request to the request database, use the **crypto pki server request pkcs10** command in privileged EXEC mode.

crypto pki server *cs-label* **request pkcs10** {*url* | **scep** | **terminal**} [**base64** | **pem** | **hex** [*transaction-id* [*nonce* [*request-id*]]]]

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified through the **crypto pki server** command.
url	URL of the file systems from which the certificate server should retrieve the PKCS10 enrollment request and to which it should post the granted certificate. **Note** The request filename should have a ".req" extension and the granted certificate file name will have a ".crt" extension (see the URL example in the section "Examples" below).
scep	Specifies the certificate is returned using Secure Certificate Enrollment Protocol (SCEP) request.
terminal	Certificate requests is manually pasted from the console terminal, and the granted certificate is displayed on the console.
base64	(Optional) Specifies the certificate is returned *without* privacy-enhanced mail (PEM) headers, regardless of whether PEM headers were used in the request.
pem	(Optional) Specifies the certificate is returned *with* PEM headers automatically added to the certificate after the certificate is granted, regardless of whether PEM headers were used in the request.
hex	(Optional) Specifies the certificate is returned in hexadecimal. Pending requests will also be synchronized with the standby certificate server in hexadecimal.
transaction-id	(Optional) Transaction ID in hexadecimal format.
nonce	(Optional) Nonce word in hexadecimal format. (Nonce words frequently arise through the combination of an existing word with a familiar prefix or suffix, in order to meet a particular need)
request-id	(Optional) Request ID. Valid values are from 1 to 999.

Command Default

None

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.3(11)T	This command was modified. The **pem** keyword was added.

Release	Modification
12.4(6)T	This command was modified. The **base64** keyword was added.
15.0(1)M	This command was modified. The **scep** and **hex** keywords and *transaction-id*, *nonce*, and *request-id* arguments were added. Command accepts the PKCS10 certificate and the signing certificate in hexadecimal as well as in base64 encoding.
15.1(1)T	This command was modified. The prompt for entering a certificate in hex mode has changed from config-pubkey to config-pki-hexmode.

Usage Guidelines

Use the **crypto pki server request pkcs10** command to manually add a base64-encoded, PEM-formatted, or hexadecimal-encoded PKCS10 certificate enrollment request. This command is especially useful when the client does not have a network connection with the certificate server so that it can do Simple Certificate Enrollment Protocol (SCEP) enrollment. After the certificate is granted, the certificate will be displayed on the console terminal using base64 encoding if the **terminal** keyword is specified, or it will be sent to the file system that is specified using the *url* argument.

The *url* argument allows you to specify or change the location in which the certificate server retrieves the new certificate request and posts the granted certificate.

Examples

The following example shows how to manually add a base64-encoded certificate request with PEM boundaries to the request database:

```
Router# crypto pki server mycs request pkcs10 terminal pem

% Enter Base64 encoded or PEM formatted PKCS10 enrollment request.
% End with a blank line or "quit" on a line by itself.
-----BEGIN CERTIFICATE REQUEST-----

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto pki server grant	Grants all or certain SCEP requests.
show crypto pki server	Displays the current state and configuration of a certificate server.

crypto pki server revoke

To revoke a certificate on the basis of its serial number, use the **crypto pki server revoke** command in privileged EXEC mode.

crypto pki server *cs-label* **revoke** *certificate-serial-number*

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.
certificate-serial-number	Serial number of the certificate that is to be revoked. The serial number can be a hexadecimal number with the prefix "0x" (for example, 0x4c) or a decimal number (for example, 76).

Defaults

Certificates are revoked on the basis of their name.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.
15.0(1)M	The command was modified to remove the serial-number check against the last-issued serial number.

Usage Guidelines

When a new certificate revocation list (CRL) is issued, the certificate server obtains the previous CRL, makes the appropriate changes, and resigns the new CRL. A new CRL is issued after a certificate is revoked from the CLI. If this process negatively affects router performance, the **crypto pki server revoke** command can be used to revoke a list or range of certificates.

Note In Cisco IOS Release 15.0(1)M, the serial number to be revoked is not compared with the last-issued serial number.

Note A new CRL cannot be issued unless the current CRL is revoked or changed.

Examples

The following examples show how to revoke a certificate with the serial number 76 (for example, 0x4c in hexidecimal) from the certificate server "mycs":

```
Router# crypto pki server mycs revoke 76
Router# crypto pki server mycs revoke 0x4c
```

Related Commands

Command	Description
cdp-url	Specifies that CDP should be used in the certificates that are issued by the certificate server.
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.

crypto pki server start

To enable a Cisco IOS certificate server, use the **crypto pki server start** command in privileged EXEC mode. To disable a certificate server, use the **crypto pki server stop** command.

crypto pki server *servername* **start**

Syntax Description

servername	Name of the certificate server. **Note** The certificate server name must not exceed 13 characters.

Command Default

The certificate server is disabled.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Using the **crypto pki server start** command is the same as using the **no shut** command in DSP configuration mode.

Examples

The following example shows how to enable a certificate server on a router:

```
Router# crypto pki server MYCA start
%Some server settings cannot be changed after CA certificate generation.
% Please enter a passphrase to protect the private key
% or type Return to exit
Password:

Re-enter password:

% Certificate Server enabled.
```

Related Commands

Command	Description
crypto pki server stop	Disables a Cisco IOS certificate server.
show crypto pki server	Displays the current state and configuration of a certificate server.

crypto pki server stop

To disable a Cisco IOS certificate server, use the **crypto pki server stop** command in privileged EXEC mode.

crypto pki server *servername* **stop**

Syntax Description

servername	Name of the certificate server.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Using the **crypto pki server stop** command is the same as using the **shutdown** command in DSP configuration mode.

Examples

The following example shows how to disable a certificate server:

```
Router# crypto pki server MYCA stop
Certificate server 'shut' event has been queued for processing.
```

Related Commands

Command	Description
crypto pki server start	Enables a Cisco IOS certificate server.
show crypto pki server	Displays the current state and configuration of a certificate server.

crypto pki server trim

To trim certificates from the certificate revocation list (CRL), use the **crypto pki server trim** command in privileged EXEC mode.

crypto pki server [*cs-label*] **trim** {**expired** [*start-number* [*end-number*] [**verbose**]] | **generate expired-list** [*start-number end-number*] [**url** *url*] | **url** *url* [**verbose**]}

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified using the **crypto pki server** command.
expired	Specifies that the expired certificates are to be trimmed from the CRL.
start-number	The beginning of the certificate serial number range to check and trim from the CRL if the certificate has expired.
end-number	(Optional) The ending number of the certificate serial number range to check and trim from the CRL if the certificate has expired.
verbose	Displays information about the action taken on the certificates checked in the CRL.
generate	Generates information about CRL trimming.
expired-list	Generates information about trimmed expired certificates.
url *url*	Specifies the location of the expired certificate list, which contains a list of certificate serial numbers to be trimmed from the CRL.

Command Default

All certificates in the specified certificate server database will be searched to locate and to trim expired certificates.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(20)T	This command was introduced.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **generate** keyword was added.

Usage Guidelines

This command trims expired certificates from the CRL. Only certificates that are expired and have accurate and complete information in the certificate database can be trimmed from the database.

Depending on the size and location of the certificate database, searching the database for expired certificates may be a time-consuming process. Depending on your environment, you may choose one of three methods to search and to trim your CRL:

- Search the entire certificate database.

  This is usually the most time-consuming and resource-consuming method.

- Specify a range of certificate serial numbers to search.

If a large number of certificates are in your certificate database or if your certificate database is stored at a remote location (for example, TFTP or Secure Copy [SCP]) you may limit the range of certificates to search by specifying both the starting and ending certificate serial numbers. If no starting and ending certificate serial numbers are specified, the entire certificate database will be searched and all expired certificates will be trimmed.

- Use an input list to specify the expired certificates to be trimmed from the CRL.

  This is the most scalable method because it divides the process into two steps: searching the certificate database for expired certificates and trimming the CRL. An input file listing expired certificate serial numbers may be generated using a Perl script or similar program, manually, or by issuing the **crypto pki server trim generate expired-list** command. The input list must follow the format as shown:

```
# CRL Trimming file generated on 01/31/2008
version=1
35
37
```

  Lines that begin with a pound sign (#) are inserted comments. The second line contains a version string indicating the file type. Each remaining line (in this example lines 35 and 37) contains a certificate serial number indicating one certificate to be removed from the CRL.

Examples

The following example shows how to check and trim the CRL of all expired certificates in the certificate database for the certificate server “mycs”:

```
Router# crypto pki server mycs trim expired
```

The following example shows how to check and trim the CRL of expired certificates within the certificate serial number range 0x1–0x3 in the certificate database for the certificate server “mycs”. The result is the same as generating and using an input file of expired certificate serial numbers, as shown in the next example.

```
Router# crypto pki server mycs trim expired 0x1 end 0x3
```

The following example shows how to generate a list of expired certificate serial numbers, store the list on an HTTP server, then use the resulting list to trim the CRL of all expired certificates for the certificate server “mycs”:

```
Router# crypto pki server mycs trim generate expired-list 0x1 0x3 url
http://databaselocation/expired-certs.1st

Router# crypto pki server mycs trim url http://databaselocation/expired-certs.1st
```

The following example shows how to check and trim the CRL for only one certificate serial number in the certificate database for the certificate server “mycs.” If the certificate with the serial number 45 has expired, it will be trimmed from the CRL.

```
Router# crypto pki server mycs trim expired 0x2
```

The following example shows how to trim the CRL of all expired certificates for the certificate server “mycs” and display the resulting action taken for each certificate serial number:

```
Router# crypto pki server mycs trim expired verbose

Certificate 2: Expired. Removed from CRL.
Certificate F4240: Expired. Removed from CRL.
```

```
Certificate 4593: Not Removed.
Certificate 1234: Not Removed.
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto pki server trim generate expired-list	Generates a list of expired certificates in the CRL.

crypto pki server trim generate expired-list

To generate a list of expired certificates in the current certificate revocation list (CRL), use the **crypto pki server trim generate expired-list** command in privileged EXEC mode.

crypto pki server *cs-label* **trim generate expired-list** [**start** *number* **end** *number*] [**url** *url*]

Syntax Description

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.
start *number*	(Optional) The first certificate serial number from which to begin searching the CRL for expired certificates. To locate expired certificates within a range *both* the starting certificate serial number and the ending certificate serial number must be specified.
end *number*	(Optional) The last certificate serial number that will be checked when searching the CRL for a range of expired certificates.
url *url*	(Optional) Specifies the location where the resulting list of expired certificates will be stored.

Command Default

All certificates in the specified certificate server database will be searched to locate expired certificates.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

This command generates a list of expired certificates that are in the CRL for the specified certificate server. The resulting list of expired certificates may be used as input to the **crypto pki server trim** command to remove the listed certificates from the CRL resulting in trimming, or revoking, the expired certificates.

Only certificates that have accurate and complete information in the certificate database can be automatically added to the list of expired certificates and later trimmed from the database. Only CRL entries for expired certificates can be trimmed.

If there are a large number of certificates in your certificate database or if your certificate database is stored at a remote location, for example TFTP or SCP, you may limit the range of certificates to search by specifying *both* the starting and ending certificate serial numbers. If no starting and ending certificate serial numbers are specified, the entire certificate database will be searched and all expired certificates will be added to the expired certificates list.

A URL may be specified to save the list of expired certificates to a specified location. If no URL is specified, the list of expired certificates will be printed on your terminal. The list may then be cut and pasted to a file.

Examples

The following example shows both how to generate a list of expired certificates within the certificate serial number range 34–38 in the certificate database for the certificate server "mycs" and how to save the resulting list to an HTTP location:

```
Router# crypto pki server mycs trim generate expired-list start 34 end 38 url
http://databaselocation/expired-certs.1st
```

The following example shows the resulting list of expired certificates in the file expired-certs.1st:

```
# CRL Trimming file generated on 01/31/2008
version=1
35
37
```

Lines that begin with a pound sign (#) are inserted comments. The second line contains a version string indicating the file type. Each remaining line, in this example lines 35 and 37, contains a certificate serial number indicating one certificate to be removed from the CRL.

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto pki server trim	Trims certificates from the certificate revocation list.

crypto pki server unrevoke

To recover a revoked certificate, that is to remove a certificate from the certificate revocation list (CRL), use the **crypto pki server unrevoke** command in privileged EXEC mode.

crypto pki server *cs-label* **unrevoke** *certificate-serial-number*

Syntax Descriptions

cs-label	Name of the certificate server. The name must match the name specified via the **crypto pki server** command.
certificate-serial-number	Serial number of the certificate that is to be recovered. The serial number can be a hexadecimal number with the prefix "0x" (for example, 0x4c) or a decimal number (for example, 76).

Command Default

None.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

If a certificate is erroneously revoked, either the client has to reenroll in the PKI or the administrator may recover the revoked certificate by issuing the **crypto pki server unrevoke** command. This command removes a certificate, specified by its serial number, from the CRL. The CRL is then resigned and can be republished.

Examples

The following examples show how to unrevoke a certificate with the serial number 76, or 0x4c in hexidecimal, from the certificate server "mycs":

```
Router# crypto pki server mycs unrevoke 76
Router# crypto pki server mycs unrevoke 0x4c
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
cyrpto pki server revoke	Revokes a certificate based on its serial number.

crypto pki token change-pin

To change the user PIN on the USB eToken, use the **crypto pki token change-pin** command in privileged EXEC mode.

crypto pki token *token-name* [**admin**] **change-pin** [*pin*]

Syntax Description

token-name	Name of USB token specified via the **crypto pki token login** command.
admin	(Optional) The router will change the administrative PIN on the USB token. If this keyword is not issued, the router will change the user pin.
pin	(Optional) User PIN required to access the etoken.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

If you want to change the administrative PIN on the token, you must be logged into the eToken as an admin via the **crypto pki token admin login** command.

After the user PIN has been changed, you must reset the login failure count to zero (via the **crypto pki token max-retries** command). The maximum number of allowable login failures is set (by default) to 15.

Examples

The following example shows that the user PIN was changed to 1234:

```
crypto pki token usbtoken0 admin login 5678
crypto pki token usbtoken0 change-pin 1234
```

Related Commands

Command	Description
crypto pki token login	Logs into the USB eToken.
crypto pki token max-retries	Sets the maximum number of allowed failed login attempts.

crypto pki token encrypted-user-pin

To encrypt a USB token PIN that is stored in private NVRAM, use the **crypto pki token encrypted-user-pin** command in global configuration mode. To decrypt the token's PIN, use the **no** form of this command.

crypto pki token {*token-name* | **default**} **encrypted-user-pin** [**write**] [**passphrase** *passphrase*]

no crypto pki token {*token-name* | **default**} **encrypted-user-pin** [**write**] [**passphrase** *passphrase*]

Syntax Description

token-name	Name of the token that will have its PIN encrypted.
default	Configures default values for tokens.
write	(Optional) Writes to memory immediately after the passphrase is entered. This keyword saves the running configuration to NVRAM.
passphrase *passphrase*	(Optional) Enables noninteractive command-line interface (CLI). If you do not issue this keyword, you will automatically be prompted for the passphrase. **Tip** Noninteractive CLI is provided for instances where users will not be responding to prompts, for example in scripts, configuration tools, or other automated processes. If you are issuing this command from the console, it is recommended that you use the interactive CLI to help protect against observation from unauthorized persons.

Command Default

The PIN stored in private NVRAM is not encrypted.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco IOS Release 12.4(11)T and implemented on 7200VXR NPE-G2 platform.
15.0(1)M	This command was modified earlier than Cisco IOS Release 15.0(1)M. The **default** keyword was added.

Usage Guidelines

After the token's PIN is encrypted with the **crypto pki token encrypted-user-pin** command, no action is taken when you insert the token into the router. The user must log in to the router and enter the passphrase to decrypt the PIN before the router can use the PIN to log in to the token.

After the PIN has been successfully decrypted, the router will execute the configuration commands from the token at privilege level 15.

Tip It is recommended that you create a passphrase different from the token's PIN.

Also, the user should log in to the token as a "normal user" (a privilege level 1 user), so the user cannot access commands that can alter the configuration of the router.

Examples

The following example shows the configuration of a user PIN and the encryption of that user PIN:

```
! Configure the user PIN.
Router(config)# crypto pki token usbtoken0: user-pin
Enter password:
!
! Now, the user PIN can be encrypted.
!
Router(config)# crypto pki token usbtoken0: encrypted-user-pin
 Enter passphrase:
Router(config)# exit
Router#
Router# show running config
.
.
.
     crypto pki token usbtoken0 user-pin *encrypted*
.
.
.
```

Related Commands

Command	Description
crypto pki token user-pin	Creates a PIN that automatically allows the router to log in to the USB token at router startup.
privilege	Configures a new privilege level for users and associates commands with that privilege level.

crypto pki token label

To set or change the name of a USB token label, use the **crypto pki token label** command in global configuration mode.

crypto pki token *device*: **label** *token-label*

Syntax Description

device:	Location or name of the USB device.
token-label	Specifies the label, or name, of the USB token. • *token-label* may be up to 31 alphanumeric characters in length, including dashes and underscores.

Command Default

No label is set. The USB token is known by its factory name.

Command Modes

Global configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

After you have logged in your USB token to the router, you may want to change the factory default label. Changing the default factory name to a unique name is useful when configuring multiple USB tokens for automatic login, secondary configuration files, or other token specific settings.

Note Either the device name or label may be used to specify the USB token.

If using the device name, it is followed by a colon, ":".

Examples

The following example shows how to change the USB token label from the "oldlabel" to "newlabel" after the token has been logged in. The router will not use the "newlabel" until the next time the token is inserted or the router is reloaded:

```
Router#
Router# configure terminal
Router(config)# crypto pki token oldlabel label newlabel
  Token label changed.
```

Related Commands

Command	Description
crypto pki token user-pin	Creates a PIN that automatically allows the router to log into the USB token at router startup.

crypto pki token lock

To lock the token, use the **crypto pki token lock** command in privileged EXEC mode.

crypto pki token *token-name* **lock** [**user-pin**] [**passphrase** *passphrase*]

Syntax Description

token-name	Name of the token that is to be locked.
user-pin	(Optional) Specifies the USB token PIN if set.
passphrase *passphrase*	(Optional) Enables the noninteractive command-line interface (CLI). If you do not issue this keyword, you will automatically be prompted for the passphrase. **Tip** The noninteractive CLI is provided for instances where users will not be responding to prompts, for example in scripts, configuration tools, or other automated processes. If you are issuing this command from the console, it is recommended that you use the interactive CLI to help protect against observation from unauthorized persons.

Command Default

The token is not locked.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

After you have locked a token with the **crypto pki token lock** command, all Rivest, Shamir, and Adelman (RSA) keys that have been loaded from the token will be deleted and, if configured, the secondary "unconfig" file will run with full privileges.

Examples

The following example shows how to reload a router, unlock the PIN, and then lock the PIN again:

```
Router> enable
 Password:
Router# crypto pki token usbtoken0: unlock
 Token eToken is usbtoken0
!
Enter passphrase:
Token login to usbtoken0(eToken) successful
Router#
Sep 20 22:31:13.128: %CRYPTO-6-TOKENLOGIN: Cryptographic Token eToken
Login Successful
```

```
Router# crypto pki token usbtoken0: lock
```

Related Commands

Command	Description
crypto pki token name secondary unconfig file	Specifies a secondary “unconfig” file.
crypto pki token unlock	Unlocks the token and decrypts the PIN that is stored in private NVRAM.

crypto pki token login

To log into the USB eToken, use the **crypto pki token login** command in privileged EXEC mode.

crypto pki token *token-name* [**admin**] **login** [*pin*]

Syntax Description

token-name	Name of USB eToken.
admin	(Optional) The router will attempt to log into the token as an administrator. If this keyword is not issued, the router will attempt to log into the token as a user. **Note** If you want to change the PIN via the **crypto pki token change-pin** command, you must issue this keyword.
pin	(Optional) User PIN required to access the token. If a user PIN is not specified, the default PIN, 1234567890, is used.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

This command allows you to manually log into a USB eToken. To automatically log into an eToken, issue the **crypto pki token user-pin** command, which allows you to create a PIN for automatic login.

Examples

The following example shows how to log into the USB eToken manually:

```
crypto pki token usbtoken0:login 1234567890
```

Related Commands

Command	Description
crypto pki token logout	Logs the router out of the USB eToken.

crypto pki token logout

To log the router out of the USB eToken, use the **crypto pki token logout** command in privileged EXEC mode.

crypto pki token *token-name* **logout**

Syntax Description

token-name	Name of USB eToken specified via the **crypto pki token login** command.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

If you want to save any data to the USB eToken, you must log back into the eToken.

Examples

The following example shows how to successfully log out of a USB eToken:

```
crypto pki token usbtoken0:logout
Token eToken is usbtoken0

Token logout from usbtoken0(eToken) successful
*Jan 28 05:46:59.544:%CRYPTO-6-TOKENLOGOUT:Cryptographic Token eToken Logout Successful
```

Related Commands

Command	Description
crypto pki token login	Logs into the USB eToken.

crypto pki token max-retries

To set the maximum number of allowed failed login attempts, use the **crypto pki token max-retries** command in global configuration mode. To return to the default functionality (which is 15 failed login attempts), use the **no** form of this command.

crypto pki token {*token-name* | **default**} **max-retries** [*number*]

no crypto pki token {*token-name* | **default**} **max-retries** [*number*]

Syntax Description

token-name	Name of USB token that the router will log into.
default	Default value is to be used.
number	(Optional) Number of consecutive failed login attempts the router will allow before locking out the user. Available range: 0 to 15. Default value is 15.

Defaults

15 failed login attempts are allowed

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

After the user PIN is changed via the **crypto pki token change-pin command**, the login failure count is automatically reset to 15; however, it is recommended that the login failure count be set to zero.

Examples

The following example shows how to change the allowed maximum number of failed login attempts to 20:

```
crypto pki token usbtoken0 max-retries 20
```

Related Commands

Command	Description
crypto pki token change-pin	Changes the user PIN number on the USB eToken.
crypto pki token login	Logs into the USB eToken.

crypto pki token removal timeout

To set the time interval that the router waits before removing the Rivest, Shamir, and Adelman (RSA) keys that are stored in the eToken, use the **crypto pki token removal timeout** command in global configuration mode. To return to the default functionality (which is no timeout), use the **no** form of this command.

crypto pki token {*token-name* | **default**} **removal timeout** [*seconds*]

no crypto pki token {*token-name* | **default**} **removal timeout** [*seconds*]

Syntax Description

token-name	Name of USB eToken that is being removed from the router.
default	Default value, which is automatic RSA key removal, is to be used.
seconds	(Optional) Time interval, in seconds, that the router waits before removing the RSA keys and tearing down IP Security (IPSec) tunnels associated with the specified eToken. Available range: 0 to 480. **Note** If a time interval is not specified, all RSA keys and associated tunnels are immediately torn down after the eToken is removed from the router.

Defaults

The default timeout is zero, which causes the RSA keys to be removed automatically after the eToken is removed from the router. The default appears in the running configuration as:

```
crypto pki token default removal timeout 0
```

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

After the eToken is removed from the router, you can clear from your router any RSA keys that were obtained from the eToken; all IPSec tunnels that used those RSA keys for authentication are also torn down. Both the keys and tunnels are immediately cleared unless otherwise specified via the **crypto pki token removal timeout** command.

Although the RSA keys remain on the eToken, they can only be accessed with the correct PIN. Too many unsuccessful attempts to log into the eToken will disable the PIN and any further login attempts will be refused.

Note The **no** version of this command does not remove RSA keys from the router. To immediately remove RSA keys from the router, set the timeout value to zero.

Examples

The following example shows how to set the time that the router will wait before removing the RSA keys that are stored in the eToken after the eToken has been removed from the router:

```
crypto pki token usbtoken0 removal timeout 60
```

Related Commands

Command	Description
crypto pki token logout	Logs the router out of the USB token.
crypto pki token max-retries	Sets the maximum number of allowed failed login attempts.

crypto pki token secondary config

To merge a specified file with the running configuration after the eToken is logged in to the router, use the **crypto pki token secondary config** command in global configuration mode. To remove the specified file, use **no** form of the command.

crypto pki token {*token-name* | **default**} **secondary config** [*file*]

no crypto pki token {*token-name* | **default**} **secondary config** [*file*]

Syntax Description

token-name	Name of USB eToken that will have its running configuration merged with the secondary configuration file.
default	Sets the default values for tokens.
file	(Optional) Name of the file that will be merged with the running configuration. **Note** The filename is relative to the eToken, so the name should not include a device name such as "usbtoken0:."

Command Default

A secondary configuration file does not exist.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.
15.0(1)M	This command was modified earlier than Cisco IOS Release 15.0(1)M. The **default** keyword was added.

Usage Guidelines

Use the **crypto pki token secondary config** command if you want to merge, not overwrite, a file with the running configuration on the router. The secondary configuration is processed after the eToken is logged in to the router.

Examples

The following example shows how to merge the secondary configuration file "CONFIG1.CFG" with the current running configuration:

```
Router# configure terminal
Router(config)# crypto pki token default secondary config CONFIG1.CFG
```

Related Commands

Command	Description
crypto pki token login	Logs in to the USB eToken.
crypto pki token user-pin	Creates a PIN that automatically allows the router to log into the USB eToken at router startup.

crypto pki token secondary unconfig

To specify a secondary "unconfig" file and its location for a USB token, use the **crypto pki token secondary unconfig** command in global configuration mode. To remove secondary configuration elements from the running configuration, use the **no** form of this command.

crypto pki token {*token-name* | **default**} **secondary unconfig** [*file*]

no crypto pki token {*token-name* | **default**} **secondary unconfig** [*file*]

Syntax Description

token-name	Name of the token that is to be unlocked.
default	Configures default values for tokens.
file	(Optional) Name and location of the secondary configuration file.

Command Default

Secondary "unconfig" file will not be processed.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.
15.0(1)M	This command was modified earlier than Cisco IOS Release 15.0(1)M. The **default** keyword was added.

Usage Guidelines

Configuration files that exist on a USB token are called secondary configuration files. If you create and configure a secondary configuration file, it is executed after the token is logged in. The existence of a secondary configuration file is determined by the presence of a secondary configuration file option in the Cisco IOS configuration stored in NVRAM.

When the token is removed, logged out, or the removal timer (if set) expires, a separate "unconfig" file is processed to remove all secondary configuration elements from the running configuration. Secondary configuration and secondary "unconfig" files are executed at privilege level 15 and are not dependent on the level of the user logged in.

Examples

The following example shows a how a secondary "unconfig" file might be used to remove secondary configuration elements from the running config. For example, a secondary configuration file might be used to set up a public key infrastructure (PKI) trustpoint. A corresponding "unconfig" file, named mysecondaryunconfigfile.cfg, might contain the following command:

```
no crypto pki trustpoint token-tp
```

If the token were removed and the following commands executed, the trustpoint and associated certificates would be removed from the router's running configuration:

```
Router# configure terminal
Router(config)# no crypto pki token mytoken secondary unconfig mysecondaryunconfigfile.cfg
```

Related Commands

Command	Description
crypto pki token secondary config	Merges a specified secondary configuration file with the running configuration after the USB token is logged in to the router.
crypto pki token user-pin	Creates a PIN that automatically allows the router to log in to the USB token at router startup.

crypto pki token unlock

To unlock the token and decrypt the PIN that is stored in private NVRAM, use the **crypto pki token unlock** command in privileged EXEC mode.

crypto pki token *token-name* **unlock** [**user-pin**] [**passphrase** *passphrase*]

Syntax Description

token-name	Name of the token that is to be unlocked.
user-pin	(Optional) Specifies the USB token PIN if set.
passphrase *passphrase*	(Optional) Enables the noninteractive command-line interface (CLI). If you do not issue this keyword, you will automatically be prompted for the passphrase. **Tip** The noninteractive CLI is provided for instances where users will not be responding to prompts, for example in scripts, configuration tools, or other automated processes. **Note** If you are issuing this command from the console, it is recommended that you use the interactive CLI to help protect against observation from unauthorized persons.

Command Default

USB token is not unlocked, or decrypted.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(4)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.

Usage Guidelines

After you unlock a token via the **crypto pki token unlock** command, the Cisco IOS software will treat the token as if it is automatically logged into the router. Any Rivest, Shamir, and Adelman (RSA) keys on the token are loaded onto the router and the secondary configuration file on the token is executed (if a secondary configuration file has been configured by the user). Secondary configuration files are executed with full user privileges.

Examples

The following example shows the configuration and encryption of a user PIN and then that the router is reloading and the user PIN is being unlocked.

```
! Configuring the user PIN

Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# crypto pki token usbtoken0: user-pin
     Enter password:
```

```
! Encrypt the user PIN

Router (config)# crypto pki token usbtoken0: encrypted-user-pin
     Enter passphrase:
Router(config)# exit
Router#
Sep 20 21:51:38.076: %SYS-5-CONFIG_I: Configured from console by console
!

Router# show running-config
.
.
.
crypto pki token usbtoken0 user-pin *encrypted*
.
.
.

! Reloading the router.
!
Router> enable
 Password:
!
! Decrypting the user pin.
!
Router# crypto pki token usbtoken0: unlock
 Token eToken is usbtoken0
!
Enter passphrase:
Token login to usbtoken0(eToken) successful
Router#
Sep 20 22:31:13.128: %CRYPTO-6-TOKENLOGIN: Cryptographic Token eToken
Login Successful
```

Related Commands

Command	Description
crypto pki token user-pin	Creates a PIN that automatically allows the router to log into the USB token at router startup.

crypto pki token user-pin

To create a PIN that automatically allows the router to log in to the USB eToken at router startup, use the **crypto pki token user-pin** command in global configuration mode. To remove the stored PIN from the configuration, use the **no** form of this command.

crypto pki token {*token-name* | **default**} **user-pin** [*pin*] [*token-pin*]

no crypto pki token {*token-name* | **default**} **user-pin** [*pin*] [*token-pin*]

Syntax Description

token-name	Name of USB eToken that the router will log in to.
default	Sets the default values for tokens.
user-pin	Specifies the PIN to access token.
pin	(Optional) User PIN required to log in to the eToken. The PINs are stored in private NVRAM. If a user PIN is not specified, the default PIN, 1234567890, will be used.
token-pin	(Optional) Token PIN name.

Command Default

If this command is not issued, the router cannot access the eToken.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(11)T	This command was integrated into the Cisco 7200VXR NPE-G2 platform.
15.0(1)M	This command was modified earlier than Cisco IOS Release 15.0(1)M. The **default** keyword was added.

Usage Guidelines

After the eToken is plugged into the router, the router will use the specified PIN (or the default PIN if no PIN is specified) to automatically log in as the user.

Examples

The following example shows how to access the eToken via the user PIN “12345”:

```
crypto pki token usbtoken0 user-pin 12345
```

Related Commands

Command	Description
crypto pki login	Logs in to the USB eToken.
crypto pki token logout	Logs the router out of the USB eToken.

crypto pki trustpoint

To declare the trustpoint that your router should use, use the **crypto pki trustpoint** command in global configuration mode. To delete all identity information and certificates associated with the trustpoint, use the **no** form of this command.

crypto pki trustpoint *name* **redundancy**

no crypto pki trustpoint *name*

Syntax Description

name	Creates a name for the trustpoint. (If you previously declared the trustpoint and just want to update its characteristics, specify the name you previously created.)
redundancy	(Optional) Specifies that the key, and any certificates associated with it, should be synchronized to the standby certificate authority (CA).

Defaults

Your router does not recognize any trustpoints until you declare a trustpoint using this command.

Your router uses unique identifiers during communication with Online Certificate Status Protocol (OCSP) servers, as configured in your network.

Command Modes

Global configuration

Command History

Release	Modification
12.2(8)T	The **crypto ca trustpoint** command was added.
12.2(15)T	The **match certificate** subcommand was introduced.
12.3(7)T	This command replaced the **crypto ca trustpoint** command. You can still enter the **crypto ca trusted-root** or **crypto ca trustpoint** command, but the command will be written in the configuration as "crypto pki trustpoint."
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.3(14)T	The **enrollment selfsigned** subcommand was introduced.
12.4(4)T	The **ocsp disable-nonce** subcommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.0(1)M	This command was modified. The **redundancy** keyword was introduced.

Usage Guidelines

Declaring Truspoints

Use the **crypto pki trustpoint** command to declare a trustpoint, which can be a self-signed root certificate authority (CA) or a subordinate CA. Issuing the **crypto pki trustpoint** command puts you in ca-trustpoint configuration mode.

You can specify characteristics for the trustpoint using the following subcommands:

- **crl**—Queries the certificate revocation list (CRL) to ensure that the certificate of the peer has not been revoked.

- **default (ca-trustpoint)**—Resets the value of ca-trustpoint configuration mode subcommands to their defaults.
- **enrollment**—Specifies enrollment parameters (optional).
- **enrollment http-proxy**—Accesses the CA by HTTP through the proxy server.
- **enrollment selfsigned**—Specifies self-signed enrollment (optional).
- **match certificate**—Associates a certificate-based access control list (ACL) defined with the **crypto ca certificate map** command.
- **ocsp disable-nonce**—Specifies that your router will not send unique identifiers, or nonces, during OCSP communications
- **primary**—Assigns a specified trustpoint as the primary trustpoint of the router.
- **root**—Defines the TFTP to get the CA certificate and specifies both a name for the server and a name for the file that will store the CA certificate.

Specifying Use of Unique Identifiers

When using OCSP as your revocation method, unique identifiers, or nonces, are sent by default during peer communications with the OCSP server. The use of unique identifiers during OCSP server communications enables more secure and reliable communications. However, not all OCSP servers support the use of unique dentures, see your OCSP manual for more information. To disable the use of unique identifiers during OCSP communications, use the **ocsp disable-nonce** subcommand.

Examples

The following example shows how to declare the CA named *ka* and specify enrollment and CRL parameters:

```
crypto pki trustpoint ka
 enrollment url http://kahului:80
```

The following example shows a certificate-based ACL with the label Group defined in a **crypto pki certificate map** command and included in the **match certificate** subcommand of the **crypto pki trustpoint** command:

```
crypto pki certificate map Group 10
 subject-name co ou=WAN
 subject-name co o=Cisco
!
crypto pki trustpoint pki1
 match certificate Group
```

The following example shows a self-signed certificate being designated for a trustpoint named local using the **enrollment selfsigned** subcommand of the **crypto pki trustpoint** command:

```
crypto pki trustpoint local
 enrollment selfsigned
```

The following example shows the unique identifier being disabled for OCSP communications for a previously created trustpoint named *ts*:

```
crypto pki trustpoint ts
 ocsp disable-nonce
```

The following example shows the **redundancy** keyword specified in the **crypto pki trustpoint** command:

```
Router(config)#crypto pki trustpoint mytp
Router(ca-trustpoint)#redundancy
Router(ca-trustpoint)#show
```

```
 redundancy
 revocation-check crl
end
```

Related Commands

Command	Description
crl	Queries the CRL to ensure that the certificate of the peer has not been revoked.
default (ca-trustpoint)	Resets the value of a ca-trustpoint configuration subcommand to its default.
enrollment	Specifies the enrollment parameters of your CA.
enrollment http-proxy	Accesses the CA by HTTP through the proxy server.
primary	Assigns a specified trustpoint as the primary trustpoint of the router.
root	Obtains the CA certificate via TFTP.

crypto provisioning petitioner

To configure a device to become an easy secure device provisioning (SDP) petitioner and enter tti-petitioner configuration mode, use the **crypto provisioning petitioner** command in global configuration mode. To disable petitioner support, use the **no** form of this command.

crypto provisioning petitioner

no crypto provisioning petitioner

Syntax Description

This command has no arguments or keywords.

Defaults

A device (with a crypto image) is configured to be an SDP petitioner.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	The **crypto wui tti petitioner** command was introduced.
12.3(14)T	This command replaced the **crypto wui tti petitioner** command.

Usage Guidelines

SDP uses Trusted Transitive Introduction (TTI) to easily deploy public key infrastructure (PKI) between two end devices. TTI, which is a communication protocol that provides a bidirectional introduction between two end entities, involves the following three entities:

- Introducer—A mutually trusted device that introduces the petitioner to the registrar. The introducer can be a device user, such as a system administrator.
- Petitioner—A new device that is joined to the secure domain.
- Registrar—A server that authorizes the petitioner. The registrar can be a certificate server.

Note Because the petitioner is enabled by default on the device, you only have to issue the **crypto provisioning petitioner** command if you have previously disabled the petitioner or if you want to use an existing trustpoint instead of the automatically generated trustpoint.

Examples

After the SDP exchange is complete, the petitioner will automatically enroll with the registrar and obtain a certificate. The following sample output from the **show running-config** command shows an automatically generated configuration at the petitioner.

Note The petitioner will not have any TTI-specific configuration in the beginning except that the IP HTTP server will be turned on and the Domain Name System (DNS) server needs to be properly configured.)

```
crypto pki trustpoint tti
! Enrollment url contains the registrar CS details
 enrollment url http://pki1-36a.cisco.com:80
 revocation-check crl
 rsakeypair tti 1024
 auto-enroll 70
```

Related Commands

Command	Description
crypto provisioning registrar	Configures a device to become an SDP registrar and enters tti-registrar configuration mode.
trustpoint (tti-petitioner)	Specifies the trustpoint that is to be associated with the TTI exchange between the SDP petitioner and the SDP registrar.

crypto provisioning registrar

To configure a device to become an easy secure device provisioning (SDP) registrar and enter tti-registrar configuration mode, use the **crypto provisioning registrar** command in global configuration mode. To disable registrar support, use the **no** form of this command.

crypto provisioning registrar

no crypto provisioning registrar

Syntax Description

This command has no arguments or keywords.

Defaults

The registrar is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	The **crypto wui tti registrar** command was introduced.
12.3(14)T	This command replaced the **crypto wui tti registrar** command.

Usage Guidelines

SDP uses Trusted Transitive Introduction (TTI) to easily deploy public key infrastructure (PKI) between two end devices. TTI, which is a communication protocol that provides a bidirectional introduction between two end entities, involves the following three entities:

- Introducer—A mutually trusted device that introduces the petitioner to the registrar. The introducer can be a device user, such as a system administrator.
- Petitioner—A new device that is joined to the secure domain.
- Registrar—A server that authorizes the petitioner.

Although any device that contains a crypto image can be the registrar, it is recommended that the registrar be either a Cisco IOS certificate server registration authority (RA) or a Cisco IOS certificate server root.

Examples

The following sample output from the **show running-config** command verifies that the certificate server "cs1" was configured and associated with the TTI exchange between the registrar and petitioner:

```
crypto pki server cs1
 issuer-name CN = ioscs,L = Santa Cruz,C =US
 lifetime crl 336
 lifetime certificate 730
!
crypto pki trustpoint pki-36a
 enrollment url http://pki-36a:80
 ip-address FastEthernet0/0
 revocation-check none
!
```

```
crypto pki trustpoint cs1
 revocation-check crl
 rsakeypair cs1
!
!
crypto pki certificate chain pki-36a

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto provisioning petitioner	Configures a device to become an SDP petitioner and enters tti-petitioner configuration mode.

crypto wui tti petitioner

Note This command was replaced by the **crypto provisioning petitioner** command effective with Cisco IOS Release 12.3(14)T.

To configure a device to become an easy secure device deployment (EzSDD) petitioner and enter tti-petitioner configuration mode, use the **crypto wui tti petitioner** command in global configuration mode. To disable petitioner support, use the **no** form of this command.

crypto wui tti petitioner

no crypto wui tti petitioner

Syntax Description

This command has no arguments or keywords.

Defaults

A device (with a crypto image) is configured to be an EzSDD petitioner.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

EzSDD uses Trusted Transitive Introduction (TTI) to easily deploy public key infrastructure (PKI) between two end devices. TTI, which is a communication protocol that provides a bidirectional introduction between two end entities, involves the following three entities:

- Introducer—A mutually trusted device that introduces the petitioner to the registrar. The introducer can be a device user, such as a system administrator.
- Petitioner—A new device that is joined to the secure domain.
- Registrar—A server that authorizes the petitioner. The registrar can be a certificate server.

Note Because the petitioner is enabled by default on the device, you only have to issue the **crypto wui tti petitioner** command if you have previously disabled the petitioner or if you want to use an existing trustpoint instead of the automatically generated trustpoint.

Examples

After the EzSDD exchange is complete, the petitioner will automatically enroll with the registrar and obtain a certificate. The following sample output from the **show running-config** command shows an automatically generated configuration at the petitioner. (Note that petitioner will not have any TTI-specific configuration in the beginning except that the http server will be turned on and the Domain Name System (DNS) server needs to be properly configured.)

```
crypto pki trustpoint tti
! Enrollment url contains the registrar CS details
 enrollment url http://pki1-36a.cisco.com:80
 revocation-check crl
 rsakeypair tti 1024
 auto-enroll 70
```

Related Commands

Command	Description
crypto wui tti registrar	Configures a device to become an EzSDD registrar and enters tti-registrar configuration mode.
trustpoint (tti-petitioner)	Specifies the trustpoint that is to be associated with the TTI exchange between the EzSDD petitioner and the EzSDD registrar.

crypto wui tti registrar

Note This command was replaced by the **crypto provisioning registrar** command effective with Cisco IOS Release 12.3(14)T.

To configure a device to become an easy secure device deployment (EzSDD) registrar and enter tti-registrar configuration mode, use the **crypto wui tti registrar** command in global configuration mode. To disable registrar support, use the **no** form of this command.

crypto wui tti registrar

no crypto wui tti registrar

Syntax Description

This command has no arguments or keywords.

Defaults

The registrar is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

EzSDD uses Trusted Transitive Introduction (TTI) to easily deploy public key infrastructure (PKI) between two end devices. TTI, which is a communication protocol that provides a bidirectional introduction between two end entities, involves the following three entities:

- Introducer—A mutually trusted device that introduces the petitioner to the registrar. The introducer can be a device user, such as a system administrator.
- Petitioner—A new device that is joined to the secure domain.
- Registrar—A server that authorizes the petitioner.

Although any device that contains a crypto image can be the registrar, it is recommended that the registrar be either a Cisco IOS certificate server registration authority (RA) or a Cisco IOS certificate server root.

Examples

The following sample output from the **show running-config** command verifies that the certificate server "cs1" was configured and associated with the TTI exchange between the registrar and petitioner:

```
crypto pki server cs1
 issuer-name CN = ioscs,L = Santa Cruz,C =US
 lifetime crl 336
 lifetime certificate 730
!
crypto pki trustpoint pki-36a
```

```
 enrollment url http://pki-36a:80
 ip-address FastEthernet0/0
 revocation-check none
!

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
crypto wui tti petitioner	Configures a device to become an EzSDD petitioner and enters tti-petitioner configuration mode.

crypto xauth

To configure crypto Extended Authentication (xauth) parameters globally on a per-interface basis, use the **crypto xauth** command in global configuration mode. To disable the xauth parameters, use the **no** form of this command.

crypto xauth *interface-name interface-number*

no crypto xauth *interface-name interface-number*

Syntax Description

interface-name	Name of the interface.
interface-number	Number of the related interface. Each interface has a related range of numbers. For example, the asynchronous interface has a range of interface numbers from 1 to 5 and the BVI interface has a range of interface numbers from 1 to 255.

Command Default

Crypto xauth parameters are not configured on any interface.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS 15.0(1)M.

Usage Guidelines

This command is mainly used on responders.

This command is used to disable the negotiation of xauth capabilities during proposals for a session that is terminating on a specific interface.

The **no crypto xauth** command enables the negotiation of xauth capabilities.

Examples

The following example shows how to enable crypto xauth parameters globally on a per-interface basis:

```
Router> enable
Router# configure terminal
Router(config)# crypto xauth fastethernet 0/1
```

The following example shows how the **no crypto xauth** command uses the nonvolatile generation (NVGEN) process to perform a configuration state retrieval operation when you specify the **show run** command:

```
Router> enable
Router# configure terminal
Router(config)# no crypto xauth fastethernet 0/1

Router# show run
archive
 log config
```

```
  hidekeys
!
redundancy
!
!
!
no crypto xauth Ethernet0/0
```

Related Commands

Command	Description
crypto key decrypt rsa	Deletes the encrypted RSA key and leaves only the unencrypted key on the running router.

csd enable

To enable Cisco Secure Desktop (CSD) support for SSL VPN sessions, use the **csd enable** command in webvpn context configuration mode. To remove CSD support from the SSL VPN context configuration, use the **no** form of this command.

csd enable

no csd enable

Syntax Description

This command has no keywords or arguments.

Command Default

CSD support is not enabled.

Command Modes

Webvpn context configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

The CSD software installation package must be present in a local file system, such as flash memory, and it must be cached for distribution to end users (remote PC or networking device). The **webvpn install** command is used to install the software installation package to the distribution cache.

Examples

The following example enables CSD support for SSL VPN sessions:

```
Router(config)# webvpn install csd flash:/securedesktop_3_1_0_9.pkg
SSLVPN Package Cisco-Secure-Desktop : installed successfully
Router(config)# webvpn context context1
Router(config-webvpn-context)# csd enable
```

Related Commands

Command	Description
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.
webvpn install	Installs a CSD or SSL VPN client package file to a SSL VPN gateway for distribution to end users.

ctcp port

To set the port number for Cisco Tunneling Control Protocol (cTCP) encapsulation for Easy VPN, use the **ctcp port** command in crypto ipsec client ezvpn configuration mode. To disable the port that was configured, use the **no** form of this command.

ctcp port *port-number*

no ctcp port

Syntax Description

port-number	Port number. Value = 1 through 65535.

Command Default

If a port is not specified, the default port is the port on which the cTCP server listens.

Command Modes

Crypto ipsec client ezvpn configuration (config-crypto-ezvpn)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

This command is used only on the Easy VPN remote device.

Examples

The following example shows that the cTCP port number has been set to 10:

```
Router (config)# crypto ipsec client ezvpn client1
Router (config-crypto-ezvpn)# ctcp port 10
```

Related Commands

Command	Description
crypto ctcp	Configures cTCP encapsulation for Easy VPN.

ctype

To preauthenticate calls on the basis of the call type, use the **ctype** command in AAA preauthentication configuration mode. To remove the **ctype** command from your configuration, use the **no** form of this command.

ctype [**if-avail | required**] [**accept-stop**] [**password** *password*] [**digital | speech | v.110 | v.120**]

no ctype [**if-avail | required**] [**accept-stop**] [**password** *password*] [**digital | speech | v.110 | v.120**]

Syntax Description

if-avail	(Optional) Implies that if the switch provides the data, RADIUS must be reachable and must accept the string in order for preauthentication to pass. If the switch does not provide the data, preauthentication passes.
required	(Optional) Implies that the switch must provide the associated data, that RADIUS must be reachable, and that RADIUS must accept the string in order for preauthentication to pass. If these three conditions are not met, preauthentication fails.
accept-stop	(Optional) Prevents subsequent preauthentication elements such as **clid** or **dnis** from being tried once preauthentication has succeeded for a call element.
password *password*	(Optional) Defines the password for the preauthentication element.
digital	(Optional) Specifies “digital” as the call type for preauthentication.
speech	(Optional) Specifies “speech” as the call type for preauthentication.
v.110	(Optional) Specifies “v.110” as the call type for preauthentication.
v.120	(Optional) Specifies “v.120” as the call type for preauthentication.

Defaults

The **if-avail** and **required** keywords are mutually exclusive. If the **if-avail** keyword is not configured, the preauthentication setting defaults to **required**.

The default password string is cisco.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You may configure more than one of the AAA preauthentication commands (**clid**, **ctype**, **dnis**) to set conditions for preauthentication. The sequence of the command configuration decides the sequence of the preauthentication conditions. For example, if you configure **dnis**, then **clid**, then **ctype**, in this order, then this is the order of the conditions considered in the preauthentication process.

In addition to using the preauthentication commands to configure preauthentication on the Cisco router, you must set up the preauthentication profiles on the RADIUS server.

Set up the RADIUS preauthentication profile with the call type string as the username and with the password that is defined in the **ctype** command as the password. Table 28 shows the call types that you may use in the preauthentication profile.

Table 28 Preauthentication Call Types

Call Type String	ISDN Bearer Capabilities
digital	Unrestricted digital, restricted digital.
speech	Speech, 3.1 kHz audio, 7 kHz audio.
v.110	Anything with V.110 user information layer.
v.120	Anything with V.120 user information layer.

Examples

The following example specifies that incoming calls be preauthenticated on the basis of the call type:

```
aaa preauth
 group radius
 ctype required
```

Related Commands

Command	Description
clid	Preauthenticates calls on the basis of the CLID number.
dnis (RADIUS)	Preauthenticates calls on the basis of the DNIS number.
dnis bypass (AAA preauthentication configuration)	Specifies a group of DNIS numbers that will be bypassed for preauthentication.
group (RADIUS)	Specifies the AAA RADIUS server group to use for preauthentication.

data

To configure the data interface type and number for a redundancy group, use the **data** command in redundancy application group configuration mode**.** To remove the configuration, use the **no** form of this command.

data *interface-type interface-number*

no data *interface-type interface-number*

Syntax Description

interface-type	Interface type.
interface-number	Interface number.

Command Default

No data interface is configured.

Command Modes

Redundancy application group configuration (config-red-app-grp)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced.

Usage Guidelines

Use the **data** command to configure the data interface. The data interface can be the same physical interface as the control interface.

Examples

The following example shows how to configure the data Gigabit Ethernet interface for group1:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# application redundancy
Router(config-red-app)# group 1
Router(config-red-app-grp)# data GigabitEthernet 0/0/0
```

Related Commands

Command	Description
application redundancy	Enters redundancy application configuration mode.
authentication	Configures clear text authentication and MD5 authentication for a redundancy group.
control	Configures the control interface type and number for a redundancy group.
group(firewall)	Enters redundancy application group configuration mode.
name	Configures the redundancy group with a name.

Command	Description
preempt	Enables preemption on the redundancy group.
protocol	Defines a protocol instance in a redundancy group.

database archive

To set the certification authority (CA) certificate and CA key archive format—and the password—to encrypt this CA certificate and CA key archive file, use the **database archive** command in certificate server configuration mode. To disable the autoarchive feature, use the **no** form of this command.

database archive {**pkcs12** | **pem**} [**password** *password*]

no database archive {**pkcs12** | **pem**} [**password** *password*]

Syntax Description

pkcs12	Export as a PKCS12 file. The default is PKCS12.
pem	Export as a privacy-enhanced mail (PEM) file.
password *password*	(Optional) Password to encrypt the CA certificate and CA key. The password must be at least eight characters. If a password is not specified, you will be prompted for the password after the **no shutdown** command has been issued for the first time. When the password is entered, it will be encrypted.

Defaults

The archive format is PKCS (that is, the CA certificate and CA key are exported into a PKCS12 file, and you will be prompted for the password when the certificate server is turned on the first time).

Command Modes

Certificate server configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

Use this command to configure the autoarchive format for the CA certificate and CA key. The archive can later be used to restore your certificate server.

If autoarchiving is not explicitly turned off when the certificate server is first enabled (using the **no shutdown** command), the CA certificate and CA key will be archived automatically, applying the following rule:

- The CA key must be (1) manually generated and marked “exportable” or (2) automatically generated by the certificate server (it will be marked nonexportable).

Note It is strongly recommended that if the password is included in the configuration to suppress the prompt after the **no shutdown** command, the password should be removed from the configuration after the archiving is finished.

Examples

The following example shows that certificate server autoarchiving has been enabled. The CA certificate and CA key format has been set to PEM, and the password has been set as cisco123.

```
Router (config)# crypto pki server myserver
Router (cs-server)# database archive pem password cisco123
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server.

database level

To control what type of data is stored in the certificate enrollment database, use the **database level** command in certificate server configuration mode. To return to the default functionality, use the **no** form of this command.

database level {**minimal** | **names** | **complete**}

no database level {**minimal** | **names** | **complete**}

Syntax Description

minimal	Enough information is stored only to continue issuing new certificates without conflict. This is the default functionality.
names	The serial number and subject name of each certificate are stored in the database, providing enough information for the administrator to find and revoke and particular certificate, if necessary.
complete	Each issued certificate is written to the database. If this keyword is used, you should enable the **database url** command; see "Usage Guidelines" for more information.

Defaults

minimal

Command Modes

Certificate server configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

The **database level** command is used to describe the database of certificates and certification authority (CA) states. After the user downgrades the database level, the old data stays the same and the new data is logged at the new level.

minimum Level

The *ca-label*.ser file is always available. It contains the previously issued certificate's serial number, which is always 1. If the .ser file is unavailable and the CA server has a self-signed certificate in the local configuration, the CA server will refuse to issue new certificates.

The file format is as follows:

```
last_serial = serial-number
```

names Level

The *serial-number*.cnm file, which is written for each issued certificate, contains the "human readable decoded subject name" of the issued certificate and the "der encoded" values. This file can also include a certificate expiration date and the current status. (The **minimum** level files are also written out.)

The file format is as follows:

```
subjectname_der = <base64 encoded der value>
subjectname_str = <human readable decode subjectname>
expiration = <expiration date>
status = valid | revoked
```

complete Level

The *serial-number*.cer file, which is written for each issued certificate, is the binary certificate without additional encoding. (The **minimum** and **names** level files are also written out.)

The **complete** level produces a large amount of information, so you may want to store all database entries on an external TFTP server via the **database url** command unless your router does one of the following:

- Issues only a small number of certificates
- Has a local file system that is designed to support a large number of write operations and has sufficient storage for the certificates that are being issued

Examples

The following example shows how configure a minimum database to be stored on the local system:

```
Router#(config) ip http server
Router#(config) crypto pki server myserver
Router#(cs-server) database level minimum
Router#(cs-server) database url nvram:
Router#(cs-server) issuer-name CN = ipsec_cs,L = Santa Cruz,C = US
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters PKI configuration mode.
database url	Specifies the location where all database entries for the certificate server will be written out.

database url

To specify the location where database entries for the certificate server (CS) will be stored or published, use the **database url** command in certificate server configuration mode. To return to the default location, use the **no** form of this command.

Storing Files to a Primary Location

database url *root-url*

Storing Critical CS Files to a Specific Location

database url [{**cnm** | **crl** | **crt** | **p12** | **pem** | **ser**}] *root-url* [**username** *username*] [**password** [*encrypt-type*] *password*]

no database url [{**cnm** | **crl** | **crt** | **p12** | **pem** | **ser**}] *root-url* [**username** *username*] [**password** [*encrypt-type*] *password*]

Publishing Noncritical CS Files to a Specific Location

database url {**cnm** | **crl** | **crt**} **publish** *root-url* [**username** *username*][**password** [*encrypt-type*] *password*]

no database url {**cnm** | **crl** | **crt**} **publish** *root-url* [**username** *username*][**password** [*encrypt-type*] *password*]

Syntax Description

root-url	Location where database entries will be written out. The URL can be any URL that is supported by the Cisco IOS file system (IFS).
cnm	(Optional) Specifies the certificate name and expiration file to be stored or published to a specific location.
crl	(Optional) Specifies the DER-encoded certificate revocation list to be stored or published to a specific location
crt	(Optional) Specifies the DER-encoded certificate files to be stored or published to a specific location.
p12	(Optional) Specifies the CS certificate and key archive file in PKCS12 format to be stored to a specific location.
pem	(Optional) Specifies the CS certificate and key archive file in privacy-enhanced mail format to be stored to a specific location.
ser	(Optional) Specifies the current serial number to be stored to a specific location.
publish	Specifies that the files will be made available to a published location.
username *username*	(Optional) When prompted, a username will be used to access a storage location.

password *password*	(Optional) When prompted, a password will be used to access a storage location.
encrypt-type	(Optional) Type of encryption to be used for the password. If no password type is specified the password is sent as clear text. • Default is 0; specifies that the password entered will be encrypted. • 7; specifies that the password entered is already encrypted.

Defaults

The default file storage location is flash.

No default file publish location is specified.

Command Modes

Certificate server configuration (cs-server)

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.4(4)T	This command was modified. The following keywords and arguments were added **cnm**, **crl**, **crt**, **p12**, **pem**, **ser**, **publish, username** *username***,** *encrypt-type* and **password** *password*.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.

Usage Guidelines

After you create a certificate server via the **crypto pki server** command, use the **database url** command if you want to specify a combined list of all the certificates that have been issued and the current command revocation list (CRL). The CRL is written to the certificate enrollment database as *ca-label*.crl (where *ca-label* is the name of the certificate server).

Note Although issuing the **database url** command is not required, it is recommended. Unless your router has a local file system that is designed for a large number of write operations and has sufficient storage for the certificates that are issued, you should issue this command.

Cisco IOS File System

The router uses any file system that is supported by your version of Cisco IOS software (such as TFTP, FTP, flash, and NVRAM) to send a certificate request and to receive the issued certificate. A user may wish to enable IFS certificate enrollment when his or her certification authority (CA) does not support Simple Certificate Enrollment Protocol (SCEP).

Specifying CS Storage and Publication Location by File Type

The CS allows the flexibility to store different critical file types to specific storage locations and publish non-critical files to the same or alternate locations. When choosing storage locations consider the file security needed and server performance. For instance, serial number files (.ser) and archive files (.p12 or .pem) might have greater security restrictions than the general certificates storage location (.crt) or the name file storage location (.cnm). Performance of your certificate server may be affected by the storage location(s) you choose, for example, reading from a network location would likely take more time than reading directly from a router's local storage device.

Examples

The following example shows how to configure all database entries to be written out to a TFTP server:

```
Router#(config) ip http server
Router#(config) crypto pki server myserver
Router#(cs-server) database level complete
Router#(cs-server) database url tftp://mytftp
```

The following example shows the configuration of a primary storage location for critical files, a specific storage location for the critical file serial number file, the main CS database file, and a password protected file publication location for the CRL file:

```
Router(config)# crypto pki server mycs
Router(cs-server)# database url ftp://cs-db.company.com
!
% Server database url was changed. You need to move the
% existing database to the new location.
!
Router(cs-server)# database url ser nvram:
Router(cs-server)# database url crl publish ftp://crl.company.com username myname password
mypassword
Router(cs-server)# end
```

The following show output displays the specified primary storage location and critical file storage locations specified:

```
Router# show

Sep  3 20:19:34.216: %SYS-5-CONFIG_I: Configured from console by user on console
Router# show crypto pki server

Certificate Server mycs:
     Status: disabled
     Server's configuration is unlocked  (enter "no shut" to lock it)
     Issuer name: CN=mycs
     CA cert fingerprint: -Not found-
     Granting mode is: manual
     Last certificate issued serial number: 0x0
     CA certificate expiration timer: 00:00:00 GMT Jan 1 1970
     CRL not present.
     Current primary storage dir: ftp://cs-db.company.com
     Current storage dir for .ser files: nvram:
     Database Level: Minimum - no cert data written to storage
Router#
```

The following show output displays all storage and publication locations. The serial number file (.ser) is stored in NVRAM. The CRL file will be published to ftp://crl.company.com with a username and password. All other critical files will be stored to the primary location, ftp://cs-db.company.com.

```
Router# show running-config

   section crypto pki server
   crypto pki server mycs shutdown database url ftp://cs-db.company.com
   database url crl publish ftp://crl.company.com username myname password 7
12141C0713181F13253920
   database url ser nvram:
Router#
```

Verifying the Database URL

To ensure that the specified URL is working correctly, configure the **database url** command before you issue the **no shutdown** command on the certificate server for the first time. If the URL is broken, you will see output as follows:

```
Router(config)# crypto pki server mycs
Router(cs-server)# database url ftp://myftpserver
Router(cs-server)# no shutdown
% Once you start the server, you can no longer change some of
% the configuration.
Are you sure you want to do this? [yes/no]: yes
Translating "myftpserver"
% There was a problem reading the file 'mycs.ser' from certificate storage.
% Please verify storage accessibility and enable the server again.

% Failed to generate CA certificate - 0xFFFFFFFF
% The Certificate Server has been disabled.
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters PKI server configuration mode.
database level	Controls what type of data is stored in the database.
database username	Requires a username or password to be issued when accessing the primary database storage location.

database username

To require a username or password to be issued when accessing the primary database location, use the **database username** command in certificate server configuration mode. To return to the default value, use the **no** form of this command.

database username *username* [**password** [*encr-type*] *password*]

no database username *username* [**password** [*encr-type*] *password*]

Syntax Description

username	When prompted, a username will be used to access a storage location.
password *password*	(Optional) When prompted, a password will be used to access a storage location.
encr-type	(Optional) Type of encryption to be used for the password. If no password encryption type is specified, the password is sent as clear text. • Default is 0; specifies that the password entered will be encrypted. • 7; specifies the password entered is already encrypted.

Defaults

No username or password will be used to access the primary database storage location.

Command Modes

Certificate server configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.4(4)T	The command name was changed from **database** (certificate server) to **database username**.

Usage Guidelines

All information stored in the remote database is public: there are no private keys stored in the database location. Using a password helps to protect against a potential attacker who can change the contents of the .ser or .crl file. If the contents of the files are changed, the certificate server may shut down, refusing to either issue new certificates or respond to Simple Certificate Enrollment Protocol (SCEP) requests until the files are restored.

It is good security practice to protect all information exchanges with the database server using IP Security (IPsec). To protect your information, use a remote database to obtain the appropriate certificates and setup the necessary IPsec connections to protect all future access to the database server.

Examples

The following example shows how to specify the username “mystorage” when the primary storage location is on an external TFTP server:

```
Router (config)# ip http server
Router (config)# crypto pki server myserver
Router (cs-server)# database level complete
```

```
Router (cs-server)# database url tftp://mytftp
Router (cs-server)# database username mystorage
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters PKI server configuration mode.
database level	Controls what type of data is stored in the database.
database url	Specifies the primary storage location for the certificate server.

deadtime (server-group configuration)

To configure deadtime within the context of RADIUS server groups, use the **deadtime** command in server group configuration mode. To set deadtime to 0, use the **no** form of this command.

deadtime *minutes*

no deadtime

Syntax Description

minutes	Length of time, in minutes, for which a RADIUS server is skipped over by transaction requests, up to a maximum of 1440 minutes (24 hours).

Defaults

Deadtime is set to 0.

Command Modes

Server-group configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to configure the deadtime value of any RADIUS server group. The value of deadtime set in the server groups will override the server that is configured globally. If deadtime is omitted from the server group configuration, the value will be inherited from the master list. If the server group is not configured, the default value (0) will apply to all servers in the group.

When the RADIUS Server Is Marked As Dead

For Cisco IOS versions prior to 12.2(13.7)T, the RADIUS server will be marked as dead if a transaction is transmitted for the configured number of retransmits and a valid response is not received from the server within the configured timeout for any of the RADIUS packet transmissions.

For Cisco IOS versions 12.2(13.7)T and later, the RADIUS server will be marked as dead if both of the following conditions are met:

1. A valid response has not been received from the RADIUS server for any outstanding transaction for at least the timeout period that is used to determine whether to retransmit to that server, and
2. Across all transactions being sent to the RADIUS server, at least the requisite number of retransmits +1 (for the initial transmission) have been sent consecutively without receiving a valid response from the server with the requisite timeout.

Examples

The following example specifies a one-minute deadtime for RADIUS server group group1 once it has failed to respond to authentication requests:

```
aaa group server radius group1
 server 10.1.1.1 auth-port 1645 acct-port 1646
 server 10.2.2.2 auth-port 2000 acct-port 2001
 deadtime 1
```

Related Commands

Command	Description
radius-server deadtime	Sets the deadtime value globally.

default (ca-trustpoint)

To reset the value of a ca-trustpoint configuration subcommand to its default, use the **default** command in ca-trustpoint configuration mode.

default *command-name*

Syntax Description

command-name	Ca-trustpoint configuration subcommand.

Defaults

No default behavior or values.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(8)T	The command mode was changed from **default (ca-root)** to **default (ca-trustpoint)** to support the **crypto ca trustpoint** command and all related subcommands.
12.2(18)SXD	The **default (ca-root)** command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	The **default (ca-root)** command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Before you can configure this command, you must enable the **crypto ca trustpoint** command, which enters ca-trustpoint configuration mode.

Use this command to reset the value of a ca-trustpoint configuration mode subcommand to its default.

Note The **crypto ca trustpoint** command deprecates the **crypto ca identity** and **crypto ca trusted-root** commands and all related subcommands (all ca-identity and trusted-root configuration mode commands). If you enter a ca-identity or trusted-root subcommand, the configuration mode and command will be written back as ca-trustpoint.

Examples

The following example shows how to remove the **crl optional** command from your configuration; the default of **crl optional** is off.

```
default crl optional
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.

default-group-policy

To associate a policy group with a SSL VPN context configuration, use the **default-group-policy** command in webvpn context configuration mode. To remove the policy group from the webvpn context configuration, use the **no** form of this command.

default-group-policy *name*

no default-group-policy

Syntax Description

name	Name of the policy configured with the **policy group** command.

Command Default

A policy group is not associated with a SSL VPN context configuration.

Command Modes

Webvpn context configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

The **policy group** command is first configured to define policy group configuration parameters. This command is configured to attach the policy group to the SSL VPN context when multiple policy groups are defined under the context. This policy will be used as the default unless an authentication, authorization, and accounting (AAA) server pushes an attribute that specifically requests another group policy.

Examples

The following example configures policy group ONE as the default policy group:

```
Router(config)# webvpn context context1
Router(config-webvpn-context)# policy-group ONE
Router(config-webvpn-group)# exit
Router(config-webvpn-context)# policy-group TWO
Router(config-webvpn-group)# exit
Router(config-webvpn-context)# default-group-policy ONE
```

Related Commands

Command	Description
policy group	Enters webvpn group policy configuration mode to configure a policy group.
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.

deny

To set conditions in a named IP access list or object group access control list (OGACL) that will deny packets, use the **deny** configuration command in the appropriate configuration mode. To remove a deny condition from an IP access list or OGACL, use the **no** form of this command.

deny *protocol* {{*source-addr source-wildcard*} | **object-group** *object-group-name* | **any** | **host** {*address* | *name*}} {*destination-addr destination-wildcard*} | **object-group** *object-group-name* | **any** | **host** {*address* | *name*}}

deny {**tcp** | **udp**} {{*source-addr source-wildcard*} | **object-group** *source-addr-group-name* | **any** | **host** {*address* | *name*} {*destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *srcport-groupname*} {**object-group** *dest-addr-groupname* | *destination* | *destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *destport-groupname*} [**dscp** *type*] [**fragments**] [**option** *option*] [**precedence** *precedence*] [**log**] [**log-input**] [**time-range** *time-range-name*] [**tos** *tos*]]}

no deny *protocol* {{*source-addr source-wildcard*} | **object-group** *object-group-name* | **any** | **host** {*address* | *name*}} {*destination-addr destination-wildcard*} | **object-group** *object-group-name* | **any** | **host** {*address* | *name*}}

no deny {**tcp** | **udp**} {{*source-addr source-wildcard*} | **object-group** *source-addr-group-name* | **any** | **host** {*address* | *name*} {*destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *srcport-groupname*} {**object-group** *dest-addr-groupname* | *destination* | *destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *destport-groupname*} [**dscp** *type*] [**fragments**] [**option** *option*] [**precedence** *precedence*] [**log**] [**log-input**] [**time-range** *time-range-name*] [**tos** *tos*]]}

Syntax Description

protocol	Name or number of a protocol; valid values are **eigrp**, **gre**, **icmp**, **igmp**, **igrp**, **ip**, **ipinip**, **nos**, **ospf**, **tcp**, or **udp**, or an integer in the range 0 to 255 representing an IP protocol number. To match any Internet protocol (including Internet Control Message Protocol (ICMP), TCP, and User Datagram Protocol (UDP), use the keyword **ip**. See the "Usage Guidelines" section for additional qualifiers.
source-addr	Number of the network or host from which the packet is being sent in a 32-bit quantity in four-part, dotted-decimal format.
source-wildcard	Wildcard bits to be applied to source in four-part, dotted-decimal format. Place ones in the bit positions you want to ignore.
object-group *object-group-name*	Specifies the source or destination name of the object group.
any	Specifies any source or any destination host as an abbreviation for the *source-addr* or *destination-addr* value and the *source-wildcard* or *destination-wildcard* value of 0.0.0.0 255.255.255.255.
host *address*	Specifies the source or destination address of a single host.
host *name*	Specifies the source or destination name of a single host.
tcp	Specifies the TCP protocol.
udp	Specifies the UDP protocol.

object-group *source-addr-group-name*	Specifies the source address group name.
destination-addr	Number of the network or host to which the packet is being sent in a 32-bit quantity in four-part, dotted-decimal format.
destination-wildcard	Wildcard bits to be applied to the destination in a 32-bit quantity in four-part, dotted-decimal format. Place ones in the bit positions you want to ignore.
eq *port*	Matches only packets on a given port number; see the "Usage Guidelines" section for valid values.
gt *port*	Matches only the packets with a greater port number; see the "Usage Guidelines" section for valid values.
lt *port*	Matches only the packets with a lower port number; see the "Usage Guidelines" section for valid values.
neq *port*	Matches only the packets that are not on a given port number; see the "Usage Guidelines" section for valid values.
portgroup *srcport-group-name*	Specifies the source port object group name.
object-group *dest-addr-group-name*	Specifies the destination address group name.
portgroup *destport-group-name*	Specifies the destination port object group name.
dscp *type*	(Optional) Matches the packets with the given Differentiated Services Code Point (DSCP) value; see the "Usage Guidelines" section for valid values.
fragments	(Optional) Applies the access list entry to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.
option *option*	(Optional) Matches the packets with the given IP options value number; see the "Usage Guidelines" section for valid values.
precedence *precedence*	(Optional) Specifies the precedence filtering level for packets; valid values are a number from 0 to 7 or by a name. See the "Usage Guidelines" section for a list of valid names.

object-group *source-addr-group-name*	Specifies the source address group name.
destination-addr	Number of the network or host to which the packet is being sent in a 32-bit quantity in four-part, dotted-decimal format.
destination-wildcard	Wildcard bits to be applied to the destination in a 32-bit quantity in four-part, dotted-decimal format. Place ones in the bit positions you want to ignore.
eq *port*	Matches only packets on a given port number; see the "Usage Guidelines" section for valid values.
gt *port*	Matches only the packets with a greater port number; see the "Usage Guidelines" section for valid values.
lt *port*	Matches only the packets with a lower port number; see the "Usage Guidelines" section for valid values.
neq *port*	Matches only the packets that are not on a given port number; see the "Usage Guidelines" section for valid values.
portgroup *srcport-group-name*	Specifies the source port object group name.
object-group *dest-addr-group-name*	Specifies the destination address group name.
portgroup *destport-group-name*	Specifies the destination port object group name.
dscp *type*	(Optional) Matches the packets with the given Differentiated Services Code Point (DSCP) value; see the "Usage Guidelines" section for valid values.
fragments	(Optional) Applies the access list entry to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.
option *option*	(Optional) Matches the packets with the given IP options value number; see the "Usage Guidelines" section for valid values.
precedence *precedence*	(Optional) Specifies the precedence filtering level for packets; valid values are a number from 0 to 7 or by a name. See the "Usage Guidelines" section for a list of valid names.

log	(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the **logging console** command.) The message for a standard list includes the access list number, whether the packet was permitted or denied, the source address, and the number of packets. The message for an extended list includes the access list number; whether the packet was permitted or denied; the protocol; whether the protocol was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. For both standard and extended lists, the message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval. The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from reloading because of too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.
log-input	(Optional) Matches the log against this entry, including the input interface.
time-range *time-range-name*	(Optional) Specifies a time-range entry name.
tos *tos*	(Optional) Specifies the service filtering level for packets; valid values are a number from 0 to 15 or by a name as listed in the "Usage Guidelines" section of the **access-list** (IP extended) command.
option *option*	(Optional) Matches packets with the IP options value; see the "Usage Guidelines" section for the valid values.
fragments	(Optional) Applies the access list entry to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List or OGACL Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.

Command Default

There is no specific condition under which a packet is denied passing the access list.

Command Modes

Standard access-list configuration (config-std-nacl)
Extended access-list configuration (config-ext-nacl)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

Use this command following the **ip access-list** command to specify conditions under which a packet cannot pass the access list.

The **portgroup** keyword appears only when you configure an extended ACL.

The *address* or *object-group-name* value is created using the **object-group** command.

The **object-group** *object-group-name* keyword and argument allow you to create logical groups of users (or servers), which you can use to define access policy using ACLs. For example, with one ACL entry you can permit the object group named engineering to access all engineering servers. Otherwise, you would need one ACL entry for every person in the engineering group.

If the operator is positioned after the *source-addr* and *source-wildcard* values, it must match the source port.

If the operator is positioned after the *destination-addr* and *destination-wildcard* values, it must match the destination port.

If you are entering the port number of a TCP or UDP port, you can enter the decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the "Usage Guidelines" section of the **access-list** (IP extended) command. TCP port names can be used only when filtering TCP. UDP port names can be used only when filtering UDP.

The valid values for the **dscp** *type* keyword and argument are as follows:

- **0** to **63**—Differentiated services code point value.
- **af11**—Match packets with AF11 dscp (001010).
- **af12**—Match packets with AF12 dscp (001100).
- **af13**—Match packets with AF13 dscp (001110).
- **af21**—Match packets with AF21 dscp (010010).
- **af22**—Match packets with AF22 dscp (010100).
- **af23**—Matches the patches with the AF23 dscp (010110).
- **af31**—Matches the patches with the AF31 dscp (011010).
- **af32**—Matches the patches with the AF32 dscp (011100).
- **af33**—Matches the patches with the AF33 dscp (011110).
- **af41**—Matches the patches with the AF41 dscp (100010).
- **af42**—Matches the patches with the AF42 dscp (100100).
- **af43**—Matches the patches with the AF43 dscp (100110).
- **cs1**—Matches the patches with the CS1 (precedence 1) dscp (001000).
- **cs2**—Matches the patches with the CS2 (precedence 2) dscp (010000).
- **cs3**—Matches the patches with the CS3 (precedence 3) dscp (011000).
- **cs4**—Matches the patches with the CS4 (precedence 4) dscp (100000).
- **cs5**—Matches the patches with the CS5 (precedence 5) dscp (101000).
- **cs6**—Matches the patches with the CS6 (precedence 6) dscp (110000).
- **cs7**—Matches the patches with the CS7 (precedence 7) dscp (111000).
- **default**—Matches the patches with the default dscp (000000).
- **ef**—Matches the patches with the EF dscp (101110).

The valid values for the **eq** *port* keyword and argument are as follows:

- **0** to **65535**—Port number.
- **bgp**—Border Gateway Protocol (179).
- **chargen**—Character generator (19).
- **cmd**—Remote commands (rcmd, 514).
- **daytime**—Daytime (13).
- **discard**—Discard (9).
- **domain**—Domain Name Service (53).
- **echo**—Echo (7).
- **exec**—Exec (rsh, 512).
- **finger**—Finger (79).
- **ftp**—File Transfer Protocol (21).
- **ftp-data**—FTP data connections (20).
- **gopher**—Gopher (70).
- **hostname**—NIC hostname server (101).
- **ident**—Ident Protocol (113).
- **irc**—Internet Relay Chat (194).
- **klogin**—Kerberos login (543).
- **kshell**—Kerberos shell (544).
- **login**—Login (rlogin, 513).
- **lpd**—Printer service (515).
- **nntp**—Network News Transport Protocol (119).
- **pim-auto-rp**—PIM Auto-RP (496).
- **pop2**—Post Office Protocol v2 (109).
- **pop3**—Post Office Protocol v3 (110).
- **smtp**—Simple Mail Transport Protocol (25).
- **sunrpc**—Sun Remote Procedure Call (111).
- **syslog**—Syslog (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **telnet**—Telnet (23).
- **time**—Time (37).
- **uucp**—Unix-to-Unix Copy Program (540).
- **whois**—Nicname (43).
- **www**—World Wide Web (HTTP, 80).

The valid values for the **gt** *port* keyword and argument are as follows:

- **0**-**65535**—Port number.
- **biff**—Biff (mail notification, comsat, 512).
- **bootpc**—Bootstrap Protocol (BOOTP) client (68).

- **bootps**—Bootstrap Protocol (BOOTP) server (67).
- **discard**—Discard (9).
- **dnsix**—DNSIX security protocol auditing (195).
- **domain**—Domain Name Service (DNS, 53).
- **echo**—Echo (7).
- **isakmp**—Internet Security Association and Key Management Protocol (500).
- **mobile-ip**—Mobile IP registration (434).
- **nameserver**—IEN116 name service (obsolete, 42).
- **netbios-dgm**—NetBios datagram service (138).
- **netbios-ns**—NetBios name service (137).
- **netbios-ss**—NetBios session service (139).
- **non500-isakmp**—Internet Security Association and Key Management Protocol (4500).
- **ntp**—Network Time Protocol (123).
- **pim-auto-rp**—PIM Auto-RP (496).
- **rip**—Routing Information Protocol (router, in.routed, 520).
- **snmp**—Simple Network Management Protocol (161).
- **snmptrap**—SNMP Traps (162).
- **sunrpc**—Sun Remote Procedure Call (111).
- **syslog**—System Logger (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **tftp**—Trivial File Transfer Protocol (69).
- **time**—Time (37).
- **who**—Who service (rwho, 513).
- **xdmcp**—X Display Manager Control Protocol (177).

The valid values for the **lt** *port* keyword and argument are as follows:

- **0-65535**—Port number.
- **biff**—Biff (mail notification, comsat, 512).
- **bootpc**—Bootstrap Protocol (BOOTP) client (68).
- **bootps**—Bootstrap Protocol (BOOTP) server (67).
- **discard**—Discard (9).
- **dnsix**—DNSIX security protocol auditing (195).
- **domain**—Domain Name Service (DNS, 53).
- **echo**—Echo (7).
- **isakmp**—Internet Security Association and Key Management Protocol (500).
- **mobile-ip**—Mobile IP registration (434).
- **nameserver**—IEN116 name service (obsolete, 42).
- **netbios-dgm**—NetBios datagram service (138).

- **netbios-ns**—NetBios name service (137).
- **netbios-ss**—NetBios session service (139).
- **non500-isakmp**—Internet Security Association and Key Management Protocol (4500).
- **ntp**—Network Time Protocol (123).
- **pim-auto-rp**—PIM Auto-RP (496).
- **rip**—Routing Information Protocol (router, in.routed, 520).
- **snmp**—Simple Network Management Protocol (161).
- **snmptrap**—SNMP Traps (162).
- **sunrpc**—Sun Remote Procedure Call (111).
- **syslog**—System Logger (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **tftp**—Trivial File Transfer Protocol (69).
- **time**—Time (37).
- **who**—Who service (rwho, 513).
- **xdmcp**—X Display Manager Control Protocol (177).

The valid values for the **neg** *port* keyword and argument are as follows:

- **0** to **65535**—Port number.
- **biff**—Biff (mail notification, comsat, 512).
- **bootpc**—Bootstrap Protocol (BOOTP) client (68).
- **bootps**—Bootstrap Protocol (BOOTP) server (67).
- **discard**—Discard (9).
- **dnsix**—DNSIX security protocol auditing (195).
- **domain**—Domain Name Service (DNS, 53).
- **echo**—Echo (7).
- **isakmp**—Internet Security Association and Key Management Protocol (500).
- **mobile-ip**—Mobile IP registration (434).
- **nameserver**—IEN116 name service (obsolete, 42).
- **netbios-dgm**—NetBios datagram service (138).
- **netbios-ns**—NetBios name service (137).
- **netbios-ss**—NetBios session service (139).
- **non500-isakmp**—Internet Security Association and Key Management Protocol (4500).
- **ntp**—Network Time Protocol (123).
- **pim-auto-rp**—PIM Auto-RP (496).
- **rip**—Routing Information Protocol (router, in.routed, 520).
- **snmp**—Simple Network Management Protocol (161).
- **snmptrap**—SNMP Traps (162).
- **sunrpc**—Sun Remote Procedure Call (111).

- **syslog**—System Logger (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **tftp**—Trivial File Transfer Protocol (69).
- **time**—Time (37).
- **who**—Who service (rwho, 513).
- **xdmcp**—X Display Manager Control Protocol (177).

The valid values for the **option** *option* keyword and argument are as follows:

- **0** to **255**—IP Options value.
- **add-ext**—Matches the packets with Address Extension Option (147).
- **any-options**—Matches the packets with ANY Option.
- **com-security**—Matches the packets with Commercial Security Option (134).
- **dps**—Matches the packets with Dynamic Packet State Option (151).
- **encode**—Matches the packets with Encode Option (15).
- **eool**—Matches the packets with End of Options (0).
- **ext-ip**—Matches the packets with the Extended IP Option (145).
- **ext-security**—Matches the packets with the Extended Security Option (133).
- **finn**—Matches the packets with the Experimental Flow Control Option (205).
  - **imitd**—Matches the packets with IMI Traffic Desriptor Option (144).
  - **lsr**—Matches the packets with Loose Source Route Option (131).
  - **match-all**—Matches the packets if all specified flags are present.
  - **match-any**—Matches the packets if any specified flag is present.
  - **mtup**—Matches the packets with MTU Probe Option (11).
  - **mtur**—Matches the packets with MTU Reply Option (12).
  - **no-op**—Matches the packets with No Operation Option (1).
  - **psh**—Match the packets on the PSH bit.
  - **nsapa**—Matches the packets with NSAP Addresses Option (150).
  - **reflect**—Creates reflexive access list entry.
  - **record-route**—Matches the packets with Record Route Option (7).
  - **rst**—Matches the packets on the RST bit.
  - **router-alert**—Matches the packets with Router Alert Option (148).
  - **sdb**—Matches the packets with Selective Directed Broadcast Option (149).
  - **security**—Matches the packets with Basic Security Option (130).
  - **ssr**—Matches the packets with Strict Source Routing Option (137).
  - **stream-id**—Matches the packets with Stream ID Option (136).
  - **syn**—Match the packets on the SYN bit.
- **timestamp**—Matches the packets with the Time Stamp Option (68).
- **traceroute**—Matches the packets with the Trace Route Option (82).

- **ump**—Matches the packets with the Upstream Multicast Packet Option (152).
- **visa**—Matches the packets with the Experimental Access Control Option (142).
- **zsu**—Matches the packets with the Experimental Measurement Option (10).

The valid values for the **tos** *value* keyword and argument are as follows:

- **0** to **15**—Type of service value.
- **max-reliability**—Matches the packets with the maximum reliable ToS (2).
- **max-throughput**—Matches the packets with the maximum throughput ToS (4).
- **min-delay**—Matches the packets with the minimum delay ToS (8).
- **min-monetary-cost**—Matches packets with the minimum monetary cost ToS (1).
- **normal**—Matches the packets with the normal ToS (0).

Access List or OGACL Processing of Fragments

The behavior of access-list entries regarding the use or lack of the **fragments** keyword are summarized in Table 29:

Table 29 Access list or OGACL Processing of Fragments

If the Access-List Entry Has...	Then...
...no **fragments** keyword (the default behavior), and assuming all of the access-list entry information matches,	For an access-list entry containing only Layer 3 information: • The entry is applied to nonfragmented packets, initial fragments, and noninitial fragments. For an access list entry containing Layer 3 and Layer 4 information: • The entry is applied to nonfragmented packets and initial fragments: – If the entry is a **permit** statement, the packet or fragment is permitted. – If the entry is a **deny** statement, the packet or fragment is denied. • The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and – If the entry is a **permit** statement, the noninitial fragment is permitted. – If the entry is a **deny** statement, the next access-list entry is processed. **Note** The **deny** statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.
...the **fragments** keyword, and assuming all of the access-list entry information matches,	**Note** The access-list entry is applied only to noninitial fragments. The **fragments** keyword cannot be configured for an access-list entry that contains any Layer 4 information.

Be aware that you should not simply add the **fragments** keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the **fragments** keyword. Therefore, you may need two access list entries for every **deny** entry. The first **deny** entry of the pair will not include the **fragments** keyword, and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases where there are multiple **deny** access-list entries for the same host but with different Layer 4 ports, a single **deny** access-list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

Note The **fragments** keyword cannot solve all cases involving access lists and IP fragments.

Fragments and Policy Routing

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address**s command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the **fragments** keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

The **portgroup** *srcport-groupname or* **portgroup** *destport-groupname* keywords and arguments allow you to create an object group based on a source or destination group.

Examples

The following example creates an access list that denies all TCP packets:

```
Router> enable
Router# configure terminal
Router(config)# ip access-list extended my_ogacl_policy
Router(config-ext-nacl)# deny tcp any any
Router(config-ext-nacl)# exit
Router(config)# exit
```

Related Commands

Command	Description
ip access-group	Applies an ACL or OGACL to an interface or a service policy map.
ip access-list	Defines an IP access list or OGACL by name or number.
object-group network	Defines network object groups for use in OGACLs.
object-group service	Defines service object groups for use in OGACLs.
permit	Sets conditions in a named IP access list or OGACL that will permit packets.
show ip access-list	Displays the contents of IP access lists or OGACLs.
show object-group	Displays information about object groups that are configured.

deny (Catalyst 6500 series switches)

To set conditions for a named access list, use the **deny** configuration command in access-list configuration mode. To remove a deny condition from an access list, use the **no** form of this command.

deny *protocol* {{*source-addr source-wildcard*} | **addrgroup** *object-group-name* | **any** | **host** {*address* | *name*}} {*destination-addr destination-wildcard*} | **addrgroup** *object-group-name* | **any** | **host** {*address* | *name*}}

deny {**tcp** | **udp**} {{*source-addr source-wildcard*} | **addrgroup** *source-addr-group-name* | **any** | **host** {*address* | *name*} {*destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *srcport-groupname*} {**addrgroup** *dest-addr-groupname* | *destination* | *destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *destport-groupname*} [**dscp** *type*] [**fragments**] [**option** *option*] [**precedence** *precedence*] [**log**] [**log-input**] [**time-range** *time-range-name*] [**tos** *tos*]]}

no deny *protocol* {{*source-addr source-wildcard*} | **addrgroup** *object-group-name* | **any** | **host** {*address* | *name*}} {*destination-addr destination-wildcard*} | **addrgroup** *object-group-name* | **any** | **host** {*address* | *name*}}

no deny {**tcp** | **udp**} {{*source-addr source-wildcard*} | **addrgroup** *source-addr-group-name* | **any** | **host** {*address* | *name*} {*destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *srcport-groupname*} {**addrgroup** *dest-addr-groupname* | *destination* | *destination-addr destination-wildcard* | **any** | **eq** *port* | **gt** *port* | **host** {*address* | *name*} | **lt** *port* | **neq** *port* | **portgroup** *destport-groupname*} [**dscp** *type*] [**fragments**] [**option** *option*] [**precedence** *precedence*] [**log**] [**log-input**] [**time-range** *time-range-name*] [**tos** *tos*]]}

Syntax Description

protocol	Name or number of a protocol; valid values are **eigrp**, **gre**, **icmp**, **igmp**, **igrp**, **ip**, **ipinip**, **nos**, **ospf**, **tcp**, or **udp**, or an integer in the range 0 to 255 representing an IP protocol number. To match any Internet protocol (including Internet Control Message Protocol (ICMP), TCP, and User Datagram Protocol (UDP), use the keyword **ip**. See the "Usage Guidelines" section for additional qualifiers.
source-addr	Number of the network or host from which the packet is being sent in a 32-bit quantity in four-part, dotted-decimal format.
source-wildcard	Wildcard bits to be applied to source in four-part, dotted-decimal format. Place ones in the bit positions you want to ignore.
addrgroup *object-group-name*	Specifies the source or destination name of the object group.
any	Specifies any source or any destination host as an abbreviation for the *source-addr* or *destination-addr* value and the *source-wildcard* or *destination-wildcard* value of 0.0.0.0 255.255.255.255.
host *address*	Specifies the source or destination address of a single host.
host *name*	Specifies the source or destination name of a single host.
tcp	Specifies the TCP protocol.
udp	Specifies the UDP protocol.

addrgroup *source-addr-group-name*	Specifies the source address group name.
destination-addr	Number of the network or host to which the packet is being sent in a 32-bit quantity in four-part, dotted-decimal format.
destination-wildcard	Wildcard bits to be applied to the destination in a 32-bit quantity in four-part, dotted-decimal format. Place ones in the bit positions you want to ignore.
eq *port*	Matches only packets on a given port number; see the "Usage Guidelines" section for valid values.
gt *port*	Matches only the packets with a greater port number; see the "Usage Guidelines" section for valid values.
lt *port*	Matches only the packets with a lower port number; see the "Usage Guidelines" section for valid values.
neq *port*	Matches only the packets that are not on a given port number; see the "Usage Guidelines" section for valid values.
portgroup *srcport-group-name*	Specifies the source port object group name.
addrgroup *dest-addr-group-name*	Specifies the destination address group name.
portgroup *destport-group-name*	Specifies the destination port object group name.
dscp *type*	(Optional) Matches the packets with the given Differentiated Services Code Point (DSCP) value; see the "Usage Guidelines" section for valid values.
fragments	(Optional) Applies the access list entry to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.
option *option*	(Optional) Matches the packets with the given IP options value number; see the "Usage Guidelines" section for valid values.
precedence *precedence*	(Optional) Specifies the precedence filtering level for packets; valid values are a number from 0 to 7 or by a name. See the "Usage Guidelines" sectionfor a list of valid names.

log	(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the **logging console** command.) The message for a standard list includes the access list number, whether the packet was permitted or denied, the source address, and the number of packets. The message for an extended list includes the access list number; whether the packet was permitted or denied; the protocol; whether the protocol was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. For both standard and extended lists, the message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval. The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from reloading due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.
log-input	(Optional) Matches the log against this entry, including the input interface.
time-range *time-range-name*	(Optional) Specifies a time-range entry name.
tos *tos*	(Optional) Specifies the service filtering level for packets; valid values are a number from 0 to 15 or by a name as listed in the "Usage Guidelines" section of the **access-list** (IP extended) command.
option *option*	(Optional) Matches packets with the IP options value; see the "Usage Guidelines" section for the valid values.
fragments	(Optional) Applies the access list entry to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.

Command Default

There is no specific condition under which a packet is denied passing the named access list.

Command Modes

Access-list configuration (config-ext-nacl)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.

Usage Guidelines

Use this command following the **ip access-list** command to specify conditions under which a packet cannot pass the named access list.

The **portgroup** keyword appears only when you configure an extended ACL

The *address* or *object-group-name* value is created using the **object-group** command.

The **addrgroup** *object-group-name* keyword and argument allow you to create logical groups of users (or servers), which you can use to define access policy using ACLs. For example, with one ACL entry you can permit the object group named engineering to access all engineering servers. Otherwise, you would need one ACL entry for every person in the engineering group.

If the operator is positioned after the *source-addr* and *source-wildcard* values, it must match the source port.

If the operator is positioned after the *destination-addr* and *destination-wildcard* values, it must match the destination port.

If you are entering the port number of a TCP or UDP port, you can enter the decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the "Usage Guidelines" section of the **access-list** (IP extended) command. TCP port names can be used only when filtering TCP. UDP port names can be used only when filtering UDP.

The valid values for the **dscp** *type* keyword and argument are as follows:

- **0** to **63**—Differentiated services code point value.
- **af11**—Match packets with AF11 dscp (001010).
- **af12**—Match packets with AF12 dscp (001100).
- **af13**—Match packets with AF13 dscp (001110).
- **af21**—Match packets with AF21 dscp (010010).
- **af22**—Match packets with AF22 dscp (010100).
- **af23**—Matches the patches with the AF23 dscp (010110).
- **af31**—Matches the patches with the AF31 dscp (011010).
- **af32**—Matches the patches with the AF32 dscp (011100).
- **af33**—Matches the patches with the AF33 dscp (011110).
- **af41**—Matches the patches with the AF41 dscp (100010).
- **af42**—Matches the patches with the AF42 dscp (100100).
- **af43**—Matches the patches with the AF43 dscp (100110).
- **cs1**—Matches the patches with the CS1(precedence 1) dscp (001000).
- **cs2**—Matches the patches with the CS2(precedence 2) dscp (010000).
- **cs3**—Matches the patches with the CS3(precedence 3) dscp (011000).
- **cs4**—Matches the patches with the CS4(precedence 4) dscp (100000).
- **cs5**—Matches the patches with the CS5(precedence 5) dscp (101000).
- **cs6**—Matches the patches with the CS6(precedence 6) dscp (110000).
- **cs7**—Matches the patches with the CS7(precedence 7) dscp (111000).
- **default**—Matches the patches with the default dscp (000000).
- **ef**—Matches the patches with the EF dscp (101110).

The valid values for the **eq** *port* keyword and argument are as follows:

- **0** to **65535**—Port number.
- **bgp**—Border Gateway Protocol (179).

- **chargen**—Character generator (19).
- **cmd**—Remote commands (rcmd, 514).
- **daytime**—Daytime (13).
- **discard**—Discard (9).
- **domain**—Domain Name Service (53).
- **echo**—Echo (7).
- **exec**—Exec (rsh, 512).
- **finger**—Finger (79).
- **ftp**—File Transfer Protocol (21).
- **ftp-data**—FTP data connections (20).
- **gopher**—Gopher (70).
- **hostname**—NIC hostname server (101).
- **ident**—Ident Protocol (113).
- **irc**—Internet Relay Chat (194).
- **klogin**—Kerberos login (543).
- **kshell**—Kerberos shell (544).
- **login**—Login (rlogin, 513).
- **lpd**—Printer service (515).
- **nntp**—Network News Transport Protocol (119).
- **pim-auto-rp**—PIM Auto-RP (496).
- **pop2**—Post Office Protocol v2 (109).
- **pop3**—Post Office Protocol v3 (110).
- **smtp**—Simple Mail Transport Protocol (25).
- **sunrpc**—Sun Remote Procedure Call (111).
- **syslog**—Syslog (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **telnet**—Telnet (23).
- **time**—Time (37).
- **uucp**—Unix-to-Unix Copy Program (540).
- **whois**—Nicname (43).
- **www**—World Wide Web (HTTP, 80).

The valid values for the **gt** *port* keyword and argument are as follows:

- **0-65535**—Port number.
- **biff**—Biff (mail notification, comsat, 512).
- **bootpc**—Bootstrap Protocol (BOOTP) client (68).
- **bootps**—Bootstrap Protocol (BOOTP) server (67).
- **discard**—Discard (9).

- **dnsix**—DNSIX security protocol auditing (195).
- **domain**—Domain Name Service (DNS, 53).
- **echo**—Echo (7).
- **isakmp**—Internet Security Association and Key Management Protocol (500).
- **mobile-ip**—Mobile IP registration (434).
- **nameserver**—IEN116 name service (obsolete, 42).
- **netbios-dgm**—NetBios datagram service (138).
- **netbios-ns**—NetBios name service (137).
- **netbios-ss**—NetBios session service (139).
- **non500-isakmp**—Internet Security Association and Key Management Protocol (4500).
- **ntp**—Network Time Protocol (123).
- **pim-auto-rp**—PIM Auto-RP (496).
- **rip**—Routing Information Protocol (router, in.routed, 520).
- **snmp**—Simple Network Management Protocol (161).
- **snmptrap**—SNMP Traps (162).
- **sunrpc**—Sun Remote Procedure Call (111).
- **syslog**—System Logger (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **tftp**—Trivial File Transfer Protocol (69).
- **time**—Time (37).
- **who**—Who service (rwho, 513).
- **xdmcp**—X Display Manager Control Protocol (177).

The valid values for the **lt** *port* keyword and argument are as follows:

- **0**-**65535**—Port number.
- **biff**—Biff (mail notification, comsat, 512).
- **bootpc**—Bootstrap Protocol (BOOTP) client (68).
- **bootps**—Bootstrap Protocol (BOOTP) server (67).
- **discard**—Discard (9).
- **dnsix**—DNSIX security protocol auditing (195).
- **domain**—Domain Name Service (DNS, 53).
- **echo**—Echo (7).
- **isakmp**—Internet Security Association and Key Management Protocol (500).
- **mobile-ip**—Mobile IP registration (434).
- **nameserver**—IEN116 name service (obsolete, 42).
- **netbios-dgm**—NetBios datagram service (138).
- **netbios-ns**—NetBios name service (137).
- **netbios-ss**—NetBios session service (139).

- **non500-isakmp**—Internet Security Association and Key Management Protocol (4500).
- **ntp**—Network Time Protocol (123).
- **pim-auto-rp**—PIM Auto-RP (496).
- **rip**—Routing Information Protocol (router, in.routed, 520).
- **snmp**—Simple Network Management Protocol (161).
- **snmptrap**—SNMP Traps (162).
- sunrpc—Sun Remote Procedure Call (111).
- **syslog**—System Logger (514).
- **tacacs**—TAC Access Control System (49).
- **talk**—Talk (517).
- **tftp**—Trivial File Transfer Protocol (69).
- **time**—Time (37).
- **who**—Who service (rwho, 513).
- **xdmcp**—X Display Manager Control Protocol (177).

The valid values for the **neg** *port* keyword and argument are as follows:

- **0** to **65535**—Port number.
- **biff**—Biff (mail notification, comsat, 512).
- **bootpc**—Bootstrap Protocol (BOOTP) client (68).
- **bootps**—Bootstrap Protocol (BOOTP) server (67).
- **discard**—Discard (9).
- **dnsix**—DNSIX security protocol auditing (195).
- **domain**—Domain Name Service (DNS, 53).
- **echo**—Echo (7).
- **isakmp**—Internet Security Association and Key Management Protocol (500).
- **mobile-ip**—Mobile IP registration (434).
- **nameserver**—IEN116 name service (obsolete, 42).
- **netbios-dgm**—NetBios datagram service (138).
- **netbios-ns**—NetBios name service (137).
- **netbios-ss**—NetBios session service (139).
- **non500-isakmp**—Internet Security Association and Key Management Protoc (4500).
- **ntp**—Network Time Protocol (123).
- **pim-auto-rp**—PIM Auto-RP (496).
- **rip**—Routing Information Protocol (router, in.routed, 520).
- **snmp**—Simple Network Management Protocol (161).
- **snmptrap**—SNMP Traps (162).
- **sunrpc**—Sun Remote Procedure Call (111).
- **syslog**—System Logger (514).
- **tacacs**—TAC Access Control System (49).

- **talk**—Talk (517).
- **tftp**—Trivial File Transfer Protocol (69).
- **time**—Time (37).
- **who**—Who service (rwho, 513).
- **xdmcp**—X Display Manager Control Protocol (177).

The valid values for the **option** *option* keyword and argument are as follows:

- **0** to **255**—IP Options value.
- **add-ext**—Matches the packets with Address Extension Option (147).
- **any-options**—Matches the packets with ANY Option.
- **com-security**—Matches the packets with Commercial Security Option (134).
- **dps**—Matches the packets with Dynamic Packet State Option (151).
- **encode**—Matches the packets with Encode Option (15).
- **eool**—Matches the packets with End of Options (0).
- **ext-ip**—Matches the packets with the Extended IP Option (145).
- **ext-security**—Matches the packets with the Extended Security Option (133).
- **finn**—Matches the packets with the Experimental Flow Control Option (205).
  - **imitd**—Matches the packets with IMI Traffic Desriptor Option (144).
  - **lsr**—Matches the packets with Loose Source Route Option (131).
  - **match-all**—Matches the packets if all specified flags are present.
  - **match-any**—Matches the packets if any specified flag is present.
  - **mtup**—Matches the packets with MTU Probe Option (11).
  - **mtur**—Matches the packets with MTU Reply Option (12).
  - **no-op**—Matches the packets with No Operation Option (1).
  - **psh**—Match the packets on the PSH bit.
  - **nsapa**—Matches the packets with NSAP Addresses Option (150).
  - **reflect**—Creates reflexive access list entry.
  - **record-route**—Matches the packets with Record Route Option (7).
  - **rst**—Matches the packets on the RST bit.
  - **router-alert**—Matches the packets with Router Alert Option (148).
  - **sdb**—Matches the packets with Selective Directed Broadcast Option (149).
  - **security**—Matches the packets with Basic Security Option (130).
  - **ssr**—Matches the packets with Strict Source Routing Option (137).
  - **stream-id**—Matches the packets with Stream ID Option (136).
  - **syn**—Match the packets on the SYN bit.
- **timestamp**—Matches the packets with the Time Stamp Option (68).
- **traceroute**—Matches the packets with the Trace Route Option (82).
- **ump**—Matches the packets with the Upstream Multicast Packet Option (152).
- **visa**—Matches the packets with the Experimental Access Control Option (142).

- **zsu**—Matches the packets with the Experimental Measurement Option (10).

The valid values for the **tos** *value* keyword and argument are as follows:

- **0** to **15**—Type of service value.
- **max-reliability**—Matches the packets with the maximum reliable ToS (2).
- **max-throughput**—Matches the packets with the maximum throughput ToS (4).
- **min-delay**—Matches the packets with the minimum delay ToS (8).
- **min-monetary-cost**—Matches packets with the minimum monetary cost ToS (1).
- **normal**—Matches the packets with the normal ToS (0).

Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the **fragments** keyword are summarized in Table 29:

Table 30 Access list Processing of Fragments

If the Access-List Entry Has...	Then...
...no **fragments** keyword (the default behavior), and assuming all of the access-list entry information matches,	For an access-list entry containing only Layer 3 information: • The entry is applied to nonfragmented packets, initial fragments, and noninitial fragments. For an access list entry containing Layer 3 and Layer 4 information: • The entry is applied to nonfragmented packets and initial fragments: – If the entry is a **permit** statement, the packet or fragment is permitted. – If the entry is a **deny** statement, the packet or fragment is denied. • The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and – If the entry is a **permit** statement, the noninitial fragment is permitted. – If the entry is a **deny** statement, the next access-list entry is processed. **Note** The **deny** statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.
...the **fragments** keyword, and assuming all of the access-list entry information matches,	**Note** The access-list entry is applied only to noninitial fragments.The **fragments** keyword cannot be configured for an access-list entry that contains any Layer 4 information.

Be aware that you should not simply add the **fragments** keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the **fragments** keyword. Therefore, you may need two access list entries for every **deny** entry. The first **deny** entry of the pair will not include the **fragments** keyword, and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases where there are multiple **deny** access-list entries for the same host but with different Layer 4 ports, a single **deny** access-list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

Note The **fragments** keyword cannot solve all cases involving access lists and IP fragments.

Fragments and Policy Routing

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address** command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the **fragments** keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

The **portgroup** *srcport-groupname or* **portgroup** *destport-groupname* keywords and arguments allow you to create an object group based on a source or destination group.

Examples

The following example creates an access list that denies all TCP packets:

```
Router(config)# ip access-list extended my-pbacl-policy
Router(config-ext-nacl)# deny tcp any any
Router(config-ext-nacl)# exit
Router(config)# exit
```

Related Commands

Command	Description
ip access-group	Controls access to an interface.
ip access-list	Defines an IP access list by name.
logging console	Limits messages logged to the console based on severity.
object-group	Defines object groups to optimize your configuration
permit (Catalyst 6500 series switches)	Sets conditions for a named IP access list.
show ip access-lists	Displays the contents of all current IP access lists.

deny (IP)

To set conditions in a named IP access list that will deny packets, use the **deny** command in access list configuration mode. To remove a deny condition from an access list, use the **no** form of this command.

[*sequence-number*] **deny** *source* [*source-wildcard*]

[*sequence-number*] **deny** *protocol source source-wildcard destination destination-wildcard* [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]

no *sequence-number*

no deny *source* [*source-wildcard*]

no deny *protocol source source-wildcard destination destination-wildcard*

Internet Control Message Protocol (ICMP)

[*sequence-number*] **deny icmp** *source source-wildcard destination destination-wildcard* [*icmp-type* [*icmp-code*] | *icmp-message*] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]

Internet Group Management Protocol (IGMP)

[*sequence-number*] **deny igmp** *source source-wildcard destination destination-wildcard* [*igmp-type*] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]

Transmission Control Protocol (TCP)

[*sequence-number*] **deny tcp** *source source-wildcard* [*operator port* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**established** | {**match-any** | **match-all**} {**+** | **-**} *flag-name*] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]

User Datagram Protocol (UDP)

[*sequence-number*] **deny udp** *source source-wildcard* [*operator port* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]

Syntax Description

sequence-number	(Optional) Sequence number assigned to the deny statement. The sequence number causes the system to insert the statement in that numbered position in the access list.
source	Number of the network or host from which the packet is being sent. There are three alternative ways to specify the source: • Use a 32-bit quantity in four-part dotted-decimal format. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *source* as an abbreviation for a *source* and *source-wildcard* of *source* 0.0.0.0.
source-wildcard	Wildcard bits to be applied to the source. There are three alternative ways to specify the source wildcard: • Use a 32-bit quantity in four-part dotted-decimal format. Place 1s in the bit positions that you want to ignore. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *source* as an abbreviation for a *source* and *source-wildcard* of *source* 0.0.0.0.
protocol	Name or number of an Internet protocol. The *protocol* argument can be one of the keywords **eigrp**, **gre**, **icmp**, **igmp**, **ip**, **ipinip**, **nos**, **ospf**, **tcp**, or **udp**, or an integer in the range from 0 to 255 representing an Internet protocol number. To match any Internet protocol (including ICMP, TCP, and UDP), use the **ip** keyword. **Note** When the **icmp**, **igmp**, **tcp,** and **udp** keywords are entered, they must be followed with the specific command syntax that is shown for the ICMP, IGMP, TCP, and UDP forms of the **deny** command.
icmp	Denies only ICMP packets. When you enter the **icmp** keyword, you must use the specific command syntax shown for the ICMP form of the **deny** command.
igmp	Denies only IGMP packets. When you enter the **igmp** keyword, you must use the specific command syntax shown for the IGMP form of the **deny** command.
tcp	Denies only TCP packets. When you enter the **tcp** keyword, you must use the specific command syntax shown for the TCP form of the **deny** command.
udp	Denies only UDP packets. When you enter the **udp** keyword, you must use the specific command syntax shown for the UDP form of the **deny** command.
destination	Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination: • Use a 32-bit quantity in four-part dotted-decimal format. • Use the **any** keyword as an abbreviation for the *destination* and *destination-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *destination* as an abbreviation for a *destination* and *destination-wildcard* of *destination* 0.0.0.0.

destination-wildcard	Wildcard bits to be applied to the destination. There are three alternative ways to specify the destination wildcard: • Use a 32-bit quantity in four-part dotted-decimal format. Place 1s in the bit positions that you want to ignore. • Use the **any** keyword as an abbreviation for a *destination* and *destination-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *destination* as an abbreviation for a *destination* and *destination-wildcard* of *destination* 0.0.0.0.
option *option-name*	(Optional) Packets can be filtered by IP Options, as specified by a number from 0 to 255 or by the corresponding IP Option name, as listed in Table 31 in the "Usage Guidelines" section.
precedence *precedence*	(Optional) Packets can be filtered by precedence level, as specified by a number from 0 to 7 or by a name.
tos *tos*	(Optional) Packets can be filtered by type of service (ToS) level, as specified by a number from 0 to 15, or by a name as listed in the "Usage Guidelines" section of the **access-list** (IP extended) command.
ttl *operator value*	(Optional) Compares the TTL value in the packet to the TTL value specified in this **deny** statement. • The *operator* can be **lt** (less than), **gt** (greater than), **eq** (equal), **neq** (not equal), or **range** (inclusive range). • The *value* can range from 0 to 255. • If the operator is **range**, specify two values separated by a space. • For Release 12.0S, if the operator is **eq** or **neq**, only one TTL value can be specified. • For all other releases, if the operator is **eq** or **neq**, as many as 10 TTL values can be specified, separated by a space. If the TTL in the packet matches just one of the possibly 10 values, the entry is considered to be matched.
log	(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the **logging console** command.)
time-range *time-range-name*	(Optional) Name of the time range that applies to this **deny** statement. The name of the time range and its restrictions are specified by the **time-range** and **absolute** or **periodic** commands, respectively.
fragments	(Optional) The access list entry applies to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.
icmp-type	(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.
icmp-code	(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.

icmp-message	(Optional) ICMP packets can be filtered by an ICMP message type name or an ICMP message type and code name. The possible names are listed in the "Usage Guidelines" section of the **access-list** (IP extended) command.
igmp-type	(Optional) IGMP packets can be filtered by IGMP message type or message name. A message type is a number from 0 to 15. IGMP message names are listed in the "Usage Guidelines" section of the **access-list** (IP extended) command.
operator	(Optional) Compares source or destination ports. Operators include **lt** (less than), **gt** (greater than), **eq** (equal), **neq** (not equal), and **range** (inclusive range). If the operator is positioned after the *source* and *source-wildcard* arguments, it must match the source port. If the operator is positioned after the *destination* and *destination-wildcard* arguments, it must match the destination port. The **range** operator requires two port numbers. Up to ten port numbers can be entered for the **eq** (equal) and **neq** (not equal) operators. All other operators require one port number.
port	(Optional) The decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the "Usage Guidelines" section of the **access-list** (IP extended) command. TCP port names can be used only when filtering TCP. UDP port names can be used only when filtering UDP.
established	(Optional) For the TCP protocol only: Indicates an established connection. A match occurs if the TCP datagram has the ACK or RST bit set. The nonmatching case is that of the initial TCP datagram to form a connection. **Note** The **established** keyword can be used only with the old command-line interface (CLI) format. To use the new CLI format, you must use the **match-any** or **match-all** keywords followed by the **+** or **-** keywords and *flag-name* argument.
{**match-any** | **match-all**}	(Optional) For the TCP protocol only: A match occurs if the TCP datagram has certain TCP flags set or not set. You use the **match-any** keyword to allow a match to occur if any of the specified TCP flags are present, or you can use the **match-all** keyword to allow a match to occur only if all of the specified TCP flags are present. You must follow the **match-any** and **match-all** keywords with the **+** or **-** keyword and the *flag-name* argument to match on one or more TCP flags.
{**+** | **-**} *flag-name*	(Optional) For the TCP protocol only: The **+** keyword allows IP packets if their TCP headers contain the TCP flags that are specified by the *flag-name* argument. The **-** keyword filters out IP packets that do not contain the TCP flags specified by the *flag-name* argument. You must follow the **+** and **-** keywords with the *flag-name* argument. TCP flag names can be used only when filtering TCP. Flag names for the TCP flags are as follows: **urg**, **ack**, **psh**, **rst**, **syn**, and **fin**.

Defaults

There are no specific conditions under which a packet is denied passing the named access list.

Command Modes Access list configuration

Command History

Release	Modification
11.2	This command was introduced.
12.0(1)T	The **time-range** *time-range-name* keyword and argument were added.
12.0(11)	The **fragments** keyword was added.
12.2(13)T	The **igrp** keyword was removed because the IGRP protocol is no longer available in Cisco IOS software.
12.2(14)S	The *sequence-number* argument was added.
12.2(15)T	The *sequence-number* argument was added.
12.3(4)T	The **option** *option-name* keyword and argument were added. The **match-any**, **match-all, +**, and **-** keywords and the *flag-name* argument were added.
12.3(7)T	Command functionality was modified to allow up to ten port numbers to be added after the **eq** and **neq** operators so that an access list entry can be created with noncontiguous ports.
12.4(2)T	The **ttl** *operator value* keyword and arguments were added.
12.2(27)SBC	This command was integrated into Cisco IOS Release 12.2(27)SBC.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines Use this command following the **ip access-list** command to specify conditions under which a packet cannot pass the named access list.

The **time-range** keyword allows you to identify a time range by name. The **time-range**, **absolute**, and **periodic** commands specify when this **deny** statement is in effect.

log Keyword

A log message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval.

Use the **ip access-list log-update** command to generate logging messages when the number of matches reaches a configurable threshold (rather than waiting for a 5-minute-interval). See the **ip access-list log-update** command for more information.

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing because of too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

If you enable Cisco Express Forwarding (CEF) and then create an access list that uses the **log** keyword, the packets that match the access list are not CEF-switched. They are fast-switched. Logging disables CEF.

Access List Filtering of IP Options

Access control lists can be used to filter packets with IP Options to prevent routers from being saturated with spurious packets containing IP Options. To see a complete table of all IP Options, including ones currently not in use, refer to the latest Internet Assigned Numbers Authority (IANA) information that is available from its URL: www.iana.org.

Cisco IOS software allows you to filter packets according to whether they contain one or more of the legitimate IP Options by entering either the IP Option value or the corresponding name for the *option-name* argument as shown in Table 31.

Table 31 IP Option Values and Names

IP Option Value or Name	Description
0 to 255	IP Options values.
add-ext	Match packets with Address Extension Option (147).
any-options	Match packets with any IP Option.
com-security	Match packets with Commercial Security Option (134).
dps	Match packets with Dynamic Packet State Option (151).
encode	Match packets with Encode Option (15).
eool	Match packets with End of Options (0).
ext-ip	Match packets with Extended IP Options (145).
ext-security	Match packets with Extended Security Option (133).
finn	Match packets with Experimental Flow Control Option (205).
imitd	Match packets with IMI Traffic Descriptor Option (144).
lsr	Match packets with Loose Source Route Option (131).
mtup	Match packets with MTU Probe Option (11).
mtur	Match packets with MTU Reply Option (12).
no-op	Match packets with No Operation Option (1).
nsapa	Match packets with NSAP Addresses Option (150).
psh	Matches the packets on the PSH bit.
record-route	Match packets with Router Record Route Option (7).
reflect	Creates reflexive access list entry.
rst	Matches the packets on the RST bit.
router-alert	Match packets with Router Alert Option (148).
sdb	Match packets with Selective Directed Broadcast Option (149).
security	Match packets with Base Security Option (130).
ssr	Match packets with Strict Source Routing Option (137).
stream-id	Match packets with Stream ID Option (136).
syn	Matches the packets on the SYN bit.
timestamp	Match packets with Time Stamp Option (68).

Filtering IP Packets Based on TCP Flags

The access list entries that make up an access list can be configured to detect and drop unauthorized TCP packets by allowing only the packets that have very specific groups of TCP flags set or not set. Users can select any desired combination of TCP flags with which to filter TCP packets. Users can configure access list entries in order to allow matching on a flag that is set and on a flag that is not set. Use the **+** and **-** keywords with a flag name to specify that a match is made based on whether a TCP header flag has been set. Use the **match-any** and **match-all** keywords to allow the packet if any or all, respectively, of the flags specified by the **+** or **-** keyword and *flag-name* argument have been set or not set.

Access List Processing of Fragments

The behavior of access list entries regarding the use or lack of use of the **fragments** keyword can be summarized as follows:

If the Access-List Entry Has...	Then...
...no **fragments** keyword (the default behavior), and assuming all of the access-list entry information matches,	For an access list entry that contains only Layer 3 information: • The entry is applied to nonfragmented packets, initial fragments, and noninitial fragments. For an access list entry that contains Layer 3 and Layer 4 information: • The entry is applied to nonfragmented packets and initial fragments. – If the entry is a **permit** statement, then the packet or fragment is permitted. – If the entry is a **deny** statement, then the packet or fragment is denied. • The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access list entry can be applied. If the Layer 3 portion of the access list entry matches, and – If the entry is a **permit** statement, then the noninitial fragment is permitted. – If the entry is a **deny** statement, then the next access list entry is processed. **Note** The **deny** statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.
...the **fragments** keyword, and assuming all of the access-list entry information matches,	The access list entry is applied only to noninitial fragments. The **fragments** keyword cannot be configured for an access list entry that contains any Layer 4 information.

Be aware that you should not add the **fragments** keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword. The packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the **fragments** keyword. Therefore, you may need two access list entries for every **deny** entry. The first **deny** entry of the pair will not include

the **fragments** keyword and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases in which there are multiple **deny** access list entries for the same host but with different Layer 4 ports, a single **deny** access list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets, and each counts individually as a packet in access list accounting and access list violation counts.

Note The **fragments** keyword cannot solve all cases that involve access lists and IP fragments.

Fragments and Policy Routing

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address** command and the access list has entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy-routed, even if the first fragment is not policy-routed.

By using the **fragments** keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made, and it is more likely that policy routing will occur as intended.

Creating an Access List Entry with Noncontiguous Ports

For Cisco IOS Release 12.3(7)T and later releases, you can specify noncontiguous ports on the same access control entry, which greatly reduces the number of access list entries required for the same source address, destination address, and protocol. If you maintain large numbers of access list entries, we recommend that you consolidate them when possible by using noncontiguous ports. You can specify up to ten port numbers following the **eq** and **neq** operators.

Examples

The following example sets conditions for a standard access list named Internetfilter:

```
ip access-list standard Internetfilter
 deny 192.168.34.0  0.0.0.255
 permit 172.16.0.0  0.0.255.255
 permit 10.0.0.0  0.255.255.255
! (Note: all other access implicitly denied.)
```

The following example denies HTTP traffic on Monday through Friday from 8:00 a.m. to 6:00 p.m.:

```
time-range no-http
 periodic weekdays 8:00 to 18:00
!
ip access-list extended strict
 deny tcp any any eq http time-range no-http
!
interface ethernet 0
 ip access-group strict in
```

The following example adds an entry with the sequence number 25 to extended IP access list 150:

```
ip access-list extended 150
 25 deny ip host 172.16.3.3 host 192.168.5.34
```

The following example removes the entry with the sequence number 25 from the extended access list example shown above:

```
 no 25
```

The following example sets a deny condition for an extended access list named filter2. The access list entry specifies that a packet cannot pass the named access list if it contains the Strict Source Routing IP Option, which is represented by the IP option value ssr.

```
ip access-list extended filter2
 deny ip any any option ssr
```

The following example sets a deny condition for an extended access list named kmdfilter1. The access list entry specifies that a packet cannot pass the named access list if the RST and FIN TCP flags have been set for that packet:

```
ip access-list extended kmdfilter1
 deny tcp any any match-any +rst +fin
```

The following example shows several **deny** statements that can be consolidated into one access list entry with noncontiguous ports. The **show access-lists** command is entered to display a group of access list entries for the access list named abc.

```
Router# show access-lists abc

Extended IP access list abc
 10 deny tcp any eq telnet any eq 450
 20 deny tcp any eq telnet any eq 679
 30 deny tcp any eq ftp any eq 450
 40 deny tcp any eq ftp any eq 679
```

Because the entries are all for the same **deny** statement and simply show different ports, they can be consolidated into one new access list entry. The following example shows the removal of the redundant access list entries and the creation of a new access list entry that consolidates the previously displayed group of access list entries:

```
ip access-list extended abc
 no 10
 no 20
 no 30
 no 40
 deny tcp any eq telnet ftp any eq 450 679
```

The following examples shows the creation of the consolidated access list entry:

```
Router# show access-lists abc

Extended IP access list abc
 10 deny tcp any eq telnet ftp any eq 450 679
```

The following access list filters IP packets containing Type of Service (ToS) level 3 with TTL values 10 and 20. It also filters IP packets with a TTL greater than 154 and applies that rule to noninitial fragments. It permits IP packets with a precedence level of flash and a TTL not equal to 1, and sends log messages about such packets to the console. All other packets are denied.

```
ip access-list extended canton
 deny ip any any tos 3 ttl eq 10 20
 deny ip any any ttl gt 154 fragments
 permit ip any any precedence flash ttl neq 1 log
```

Related Commands

Command	Description
absolute	Specifies an absolute time when a time range is in effect.
access-list (IP extended)	Defines an extended IP access list.

Command	Description
access-list (IP standard)	Defines a standard IP access list.
ip access-group	Controls access to an interface.
ip access-list	Defines an IP access list by name.
ip access-list log-update	Sets the threshold number of packets that cause a logging message.
ip access-list resequence	Applies sequence numbers to the access list entries in an access list.
ip options	Drops or ignores IP Options packets that are sent to the router.
logging console	Sends system logging (syslog) messages to all available TTY lines and limits messages based on severity.
match ip address	Distributes any routes that have a destination network number address that is permitted by a standard or extended access list, or performs policy routing on packets.
periodic	Specifies a recurring (weekly) time range for functions that support the time-range feature.
permit (IP)	Sets conditions under which a packet passes a named IP access list.
remark	Writes a helpful comment (remark) for an entry in a named IP access list.
show access-lists	Displays a group of access-list entries.
show ip access-list	Displays the contents of all current IP access lists.
time-range	Specifies when an access list or other feature is in effect.

deny (MAC ACL)

To set conditions for a MAC access list, use the **deny** command in MAC access-list extended configuration mode. To remove a condition from an access list, use the **no** form of this command.

deny {*src_mac_mask* | {**host name** *src_mac_name*} | **any**} {*dest_mac_mask* | {**host name** *dst_mac_name*} | **any**} [{*protocol_keyword* | {*ethertype_number ethertype_mask*}} [**vlan** *vlan_ID*] [**cos** *cos_value*]]

no deny {*src_mac_mask* | {**host name** *src_mac_name*} | **any**} {*dest_mac_mask* | {**host name** *dst_mac_name*} | **any**} [{*protocol_keyword* | {*ethertype_number ethertype_mask*}} [**vlan** *vlan_ID*] [**cos** *cos_value*]]

Syntax Description

src_mac_mask	Specifies the MAC address mask that identifies a selected block of source MAC addresses. A value of 1 represents a wildcard in that position.
host name *src_mac_name*	Specifies a source host that has been named using the **mac host name** command.
any	Specifies any source or any destination host as an abbreviation for the *src_mac_mask* or *dest_mac_mask* value of 1111.1111.1111, which declares all digits to be wildcards.
dest_mac_mask	Specifies the MAC address mask that identifies a selected block of destination MAC addresses.
host name *dst_mac_name*	Specifies a destination host that has been named using the **mac host name** command.
protocol_keyword	(Optional) Specifies a named protocol (for example, ARP).
ethertype_number	(Optional) The EtherType number specifies the protocol within the Ethernet packet.
ethertype_mask	(Optional) The EtherType mask allows a range of EtherTypes to be specified together. This is a hexadecimal number from 0 to FFFF. An EtherType mask of 0 requires an exact match of the EtherType.
vlan *vlan_ID*	(Optional) Specifies a VLAN.
cos *cos_value*	(Optional) Specifies the Layer 2 priority level for packets. The range is from 0 to 7.

Command Default

This command has no defaults.

Command Modes

MAC access-list extended configuration (config-ext-macl)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

Use this command following the **ip access-list** command to define the conditions under which a packet passes the access list.

- The **vlan** and **cos** keywords are not supported in MAC ACLs used for VACL filtering.
- The **vlan** keyword for VLAN-based QoS filtering in MAC ACLs can be globally enabled or disabled and is disabled by default.
- Enter MAC addresses as three 2-byte values in dotted hexadecimal format. For example, 0123.4567.89ab.
- Enter MAC address masks as three 2-byte values in dotted hexadecimal format. Use 1 bits as wildcards. For example, to match an address exactly, use 0000.0000.0000 (can be entered as 0.0.0).
- An entry without a protocol parameter matches any protocol.
- Enter an EtherType and an EtherType mask as hexadecimal values from 0 to FFFF.
- This list shows the EtherType values and their corresponding protocol keywords:
  - 0x0600—xns-idp—Xerox XNS IDP
  - 0x0BAD—vines-ip—Banyan VINES IP
  - 0x0baf—vines-echo—Banyan VINES Echo
  - 0x6000—etype-6000—DEC unassigned, experimental
  - 0x6001—mop-dump—DEC Maintenance Operation Protocol (MOP) Dump/Load Assistance
  - 0x6002—mop-console—DEC MOP Remote Console
  - 0x6003—decnet-iv—DEC DECnet Phase IV Route
  - 0x6004—lat—DEC Local Area Transport (LAT)
  - 0x6005—diagnostic—DEC DECnet Diagnostics
  - 0x6007—lavc-sca—DEC Local-Area VAX Cluster (LAVC), SCA
  - 0x6008—amber—DEC AMBER
  - 0x6009—mumps—DEC MUMPS
  - 0x0800—ip—Malformed, invalid, or deliberately corrupt IP frames
  - 0x8038—dec-spanning—DEC LANBridge Management
  - 0x8039—dsm—DEC DSM/DDP
  - 0x8040—netbios—DEC PATHWORKS DECnet NETBIOS Emulation
  - 0x8041—msdos—DEC Local Area System Transport
  - 0x8042—etype-8042—DEC unassigned
  - 0x809B—appletalk—Kinetics EtherTalk (AppleTalk over Ethernet)
  - 0x80F3—aarp—Kinetics AppleTalk Address Resolution Protocol (AARP)

Examples

This example shows how to create a MAC-Layer ACL named mac_layer that denies dec-phase-iv traffic with source address 0000.4700.0001 and destination address 0000.4700.0009, but allows all other traffic:

```
Router(config)# mac access-list extended mac_layer
Router(config-ext-macl)# deny 0000.4700.0001 0.0.0 0000.4700.0009 0.0.0 dec-phase-iv
Router(config-ext-macl)# permit any any
```

Related Commands

Command	Description
permit (MAC ACL)	Sets permit conditions for a named MAC access list.
mac access-list extended	Defines a MAC access list by name.
mac host	Assigns a name to a MAC address.
show mac access-group	Displays the contents of all current MAC access groups.

deny (WebVPN)

To set conditions in a named Secure Sockets Layer Virtual Private Network (SSL VPN) access list that will deny packets, use the **deny** command in webvpn acl configuration mode. To remove a deny condition from an access list, use the **no** form of this command.

deny [**url** [**any** | *url-string*]] [**ip** | **tcp** | **udp** | **http** | **https** | **cifs**] [**any** | *source-ip source-mask*] [**any** | *destination-ip destination-mask*] [**time-range** *time-range-name*] [**syslog**]

no deny url [**any** | *url-string*] [**ip** | **tcp** | **udp** | **http** | **https** | **cifs**] [**any** | *source-ip source-mask*] [**any** | *destination-ip destination-mask*] [**time-range** *time-range-name*] [**syslog**]

Syntax Description

url	(Optional) Filtering rules are applied to the URL. • Use the **any** keyword as an abbreviation for any URL.
url-string	(Optional) URL string defined as follows: **scheme://host[:port][/path]** • **scheme**—Can be HTTP, Secure HTTPS (HTTPS), or Common Internet File System (CIFS). This field is required in the URL string. • **host**—Can be a hostname or a host IP (host mask). The host can have one wildcard (*). • **port**—Can be any valid port number (1–65535). It is possible to have multiple port numbers separated by a comma (,). The port range is expressed using a dash (-). • **path**—Can be any valid path string. In the path string, the $user is translated to the current user name.
ip	(Optional) Denies only IP packets. When you enter the **ip** keyword, you must use the specific command syntax shown for the IP form of the deny command.
tcp	(Optional) Denies only TCP packets. When you enter the **tcp** keyword, you must use the specific command syntax shown for the TCP form of the deny command.
udp	(Optional) Denies only UDP packets. When you enter the **udp** keyword, you must use the specific command syntax shown for the UDP form of the deny command.
http	(Optional) Denies only HTTP packets. When you enter the **http** keyword, you must use the specific command syntax shown for the HTTP form of the deny command.
https	(Optional) Denies only HTTPS packets. When you enter the **https** keyword, you must use the specific command syntax shown for the HTTPS form of the deny command.
cifs	(Optional) Denies only CIFS packets. When you enter the **cifs** keyword, you must use the specific command syntax shown for the CIFS form of the deny command.
source-ip source-mask	(Optional) Number of the network or host from which the packet is being sent. There are three alternative ways to specify the source: • Use a 32-bit quantity in four-part dotted-decimal format. • Use the **any** keyword as an abbreviation for a source and source mask of 0.0.0.0 255.255.255.255. • Use **host** source as an abbreviation for a source and source-wildcard of source 0.0.0.0.

destination-ip destination-mask	(Optional) Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination: • Use a 32-bit quantity in four-part dotted-decimal format. • Use the **any** keyword as an abbreviation for a source and source mask of 0.0.0.0 255.255.255.255. • Use **host** source as an abbreviation for a source and source-wildcard of source 0.0.0.0.
time-range *time-range-name*	(Optional) Name of the time range that applies to this **deny** statement. The name of the time range and its restrictions are specified by the **time-range** and **absolute** or **periodic** commands, respectively.
syslog	(Optional) System logging messages are generated.

Command Default

There are no specific conditions under which a packet is denied passing the named access list.

Command Modes

Webvpn acl configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Use this command following the **acl** command to specify conditions under which a packet cannot pass the named access list.

The **time-range** keyword allows you to identify a time range by name. The **time-range**, **absolute**, and **periodic** commands specify when this deny statement is in effect.

Examples

The following example shows that all packets from the URL "https://10.168.2.228:34,80-90,100-/public" will be denied:

```
webvpn context context1
 acl acl1
  deny url "https://10.168.2.228:34,80-90,100-/public"
```

Related Commands

Command	Description
absolute	Specifies an absolute time for a time range.
periodic	Specifies a recurring (weekly) time range for functions that support the time-range feature.
permit (webvpn acl)	Sets conditions to allow a packet to pass a named SSL VPN access list.
time-range	Enables time-range configuration mode and defines time ranges for functions (such as extended access lists).

description (dot1x credentials)

To specify a description for an 802.1X profile, use the **description** command in dot1x credentials configuration mode. To remove the description, use the **no** form of this command.

description *text*

no description

Syntax Description

text	Text description. The description can be up to 80 characters.

Command Default

A description is not specified.

Command Modes

Dot1x credentials configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

Before using this command, the **dot1x credentials** command must have been configured.

An 802.1X credential structure is necessary when configuring a supplicant (client). This credentials structure may contain a username, password, and description.

Examples

The following example shows which credentials profile should be used when configuring a supplicant, and it provides a description of the credentials profile:

```
dot1x credentials basic-user
 username router
 password secret
 description This credentials profile should be used for most configured ports
```

The credentials structure can be applied to an interface, along with the **dot1x pae supplicant** command and keyword, to enable supplicant functionality on that interface.

```
interface fastethernet 0/1
 dot1x credentials basic-user
 dot1x pae supplicant
```

Related Commands

Command	Description
dot1x credentials	Specifies which 802.1X credentials profile to use.

description (identify zone)

To enter a description of a zone, use the **description** command in security zone configuration mode. To remove the description of the zone, use the **no** form of this command.

description *line-of-description*

no description *line-of-description*

Syntax Description

line-of-description	Description of the zone. You can enter up to 40 characters.

Command Default

None

Command Modes

Security zone configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

You can use this subcommand after entering the **zone security** or **zone-pair security** command.

Examples

The following example specifies that zone z1 is a testzone:

```
zone security z1
 description testzone
```

Related Commands

Command	Description
zone-pair security	Creates a zone-pair that is the type security.
zone security	Creates a zone.

description (identity policy)

To enter a description for an identity policy, use the **description** command in identity policy configuration mode. To remove the description, use the **no** form of this command.

description *line-of-description*

no description *line-of-description*

Syntax Description

line-of-description	Description of the identity policy.

Defaults

A description is not entered for the identity policy.

Command Modes

Identity policy configuration (config-identity-policy)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Examples

The following example shows that a default identity policy and its description ("policyname1") have been specified:

```
Router (config)# identity policy policyname1
Router (config-identity-policy)# description policyABC
```

Related Commands

Command	Description
description (identity profile)	Enters a description for an identity profile.

description (identity profile)

To enter a description for an identity profile, use the **description** command in identity profile configuration mode. To remove the description of the identity profile, use the **no** form of this command.

description *line-of-description*

no description *line-of-description*

Syntax Description

line-of-description	Description of the identity profile.

Defaults

A description is not entered for the identity profile.

Command Modes

Identity profile configuration (config-identity-prof)

Command History

Release	Modification
12.3(2)XA	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(8)T	This command was previously configured in dot1x configuration mode.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

The **identity profile** command and one of its keywords (**default**, **dot1x**, or **eapoudp**) must be entered in global configuration mode before the **description** command can be used.

Examples

The following example shows that a default identity profile and its description (“ourdefaultpolicy”) have been specified:

```
Router (config)# identity profile default
Router (config-identity-prof)# description ourdefaultpolicy
```

Related Commands

Command	Description
description (identity policy)	Enters a description for an identity policy.
identity profile	Creates an identity profile and enters identity profile configuration mode.

description (IKEv2 keyring)

To add the description of an Internet Key Exchange Version 2 (IKEv2) peer or profile, use the **description** command in the IKEv2 keyring peer configuration mode. To delete the description, use the **no** form of this command.

description *line-of-description*

no description *line-of-description*

Syntax Description

line-of-description	Description given to an IKE peer or profile.

Command Default

The peer or profile is not described.

Command Modes

IKEv2 keyring peer configuration (config-ikev2-keyring-peer)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to provide a descriptive line about the IKEv2 peer, peer group, or profile.

Examples

The following example shows that the description "connection from site A" has been added to an IKEv2 peer:

```
Router(config)# crypto ikev2 keyring keyr 1
Router(configikev2-keyring)# peer peer1
Router(config-ikev2-keyring-peer)# description connection from site A
```

Related Commands

Command	Description
address (ikev2 keyring)	Specifies the IPv4 address or the range of the peers in IKEv2 keyring.
crypto ikev2 keyring	Defines an IKEv2 keyring.
hostname (ikev2 keyring)	Specifies the hostname for the peer in the IKEv2 keyring.
identity (ikev2 keyring)	Identifies the peer with IKEv2 types of identity.

Command	Description
peer	Defines a peer or a peer group for the keyring.
pre-shared-key (ikev2 keyring)	Defines a preshared key for the IKEv2 peer.

description (isakmp peer)

To add the description of an Internet Key Exchange (IKE) peer, use the **description** command in ISAKMP peer configuration mode. To delete the description, use the **no** form of this command.

description *line-of-description*

no description *line-of-description*

Syntax Description

line-of-description	Description given to an IKE peer.

Defaults

No default behavior or values

Command Modes

ISAKMP peer configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.

Usage Guidelines

IKE peers that "sit" behind a Network Address Translation (NAT) device cannot be uniquely identified; therefore, they have to share the same peer description.

Examples

The following example shows that the description "connection from site A" has been added for an IKE peer:

```
Router# crypto isakmp peer address 10.2.2.9
Router (config-isakmp-peer)# description connection from site A
```

Related Commands

Command	Description
clear crypto session	Deletes crypto sessions (IPSec and IKE SAs).
show crypto isakmp peer	Displays peer descriptions.
show crypto session	Displays status information for active crypto sessions in a router.

destination host

To configure the fully qualified domain name (FQDN) of a Diameter peer, use the **destination host** command in diameter peer configuration submode. To disable the configured FQDN, use the **no** form of this command.

destination host *string*

no destination host *string*

Syntax Description

string	The FQDN of the Diameter peer.

Command Default

No FQDN is configured.

Command Modes

Diameter peer configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Examples

The following example shows how to configure the destination host:

```
Router(config-dia-peer)# destination host host1.example.com.
```

Related Commands

Command	Description
destination realm	Configures the destination realm of a Diameter peer.
diameter peer	Configures a Diameter peer and enters Diameter peer configuration submode.

destination realm

To configure the destination realm of a Diameter peer, use the **destination realm** command in diameter peer configuration submode. To disable the configured realm, use the **no** form of this command.

destination realm *string*

no destination realm *string*

Syntax Description

string	The destination realm (part of the domain @*realm*) in which a Diameter peer is located.

Command Default

No realm is configured.

Command Modes

Diameter peer configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

The realm might be added by the authentication, authorization, and accounting (AAA) client when sending a request to AAA. However, if the client does not add the attribute, then the value configured while in Diameter peer configuration submode is used when sending messages to the destination Diameter peer. If a value is not configured while in Diameter peer configuration submode, the value specified by the **diameter destination realm** global configuration command is used.

Examples

The following example shows how to configure the destination realm:

```
router (config-dia-peer)# destination realm example.com
```

Related Commands

Command	Description
diameter destination realm	Configures a global Diameter destination realm.
diameter peer	Configures a Diameter peer and enters Diameter peer configuration submode.

device (identity profile)

To statically authorize or reject individual devices, use the **device** command in identity profile configuration mode. To disable the authorization or rejection, use the **no** form of this command.

device {**authorize** {**ip address** *ip-address* **policy** *policy-name* | **mac-address** *mac-address* | **type** {**cisco** | **ip** | **phone**}} | **not-authorize**}

no device {**authorize** {**ip address** *ip-address* **policy** *policy-name* | **mac-address** *mac-address* | **type** {**cisco** | **ip** | **phone**}} | **not-authorize**}

Syntax Description

authorize	Configures an authorized device.
ip address	Specifies a device by its IP address.
ip-address	The IP address.
policy	Applies an associated policy with the device.
policy-name	Name of the policy.
mac-address	Specifies a device by its MAC address.
mac-address	The MAC address.
type	Specifies a device by its type.
cisco	Specifies a Cisco device.
ip	Specifies an IP device.
phone	Specifies a Cisco IP phone.
not-authorize	Configures an unauthorized device.

Defaults

A device is not statically authorized or rejected.

Command Modes

Identity profile configuration (config-identity-prof)

Command History

Release	Modification
12.3(2)XA	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(8)T	The **unauthorize** keyword was changed to **not authorize**. The *cisco-device* argument was deleted. The **ip address** keyword and *ip-address* argument were added. The **ip** and **phone** keywords were added.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

The **identity profile** command and **default**, **dot1x**, or **eapoudp** keywords must be entered in global configuration mode before the **device** command can be used.

Examples

The following configuration example defines an identity profile for Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) to statically authorize host 192.168.1.3 with "policyname1" as the associated identity policy:

```
Router(config)# identity profile eapoudp
Router(config-identity-prof)# device authorize ip-address 192.168.1.3 policy policyname1
```

Related Commands

Command	Description
identity profile eapoudp	Creates an identity profile.

dhcp (IKEv2)

To assign an IP address to the remote access client using a DHCP server, use the **dhcp** command in IKEv2 authorization policy configuration mode. To remove the assigned IP address, use the **no** form of this command.

dhcp {**giaddr** *ip-address* | **server** {*ip-address* | *hostname*} | **timeout** *seconds*}

no dhcp {**giaddr** | **server** | **timeout**}

Syntax Description

giaddr *ip-address*	Specifies the gateway IP address (giaddr).
server	Specifies addresses for the DHCP server.
ip-address	IP address of the DHCP server.
hostname	Hostname of the DHCP server. The hostname is resolved during configuration.
timeout *seconds*	Specifies the wait time in seconds before the next DHCP server in the list is tried.

Command Default

An IP address is not assigned by a DHCP server.

Command Modes

IKEv2 client group configuration (config-ikev2-author-policy)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

If this command is not configured, an IP address is assigned to a remote device using either a local pool that is configured on a router or a framed IP address attribute that is defined in RADIUS.

Note You can specify only one DHCP server.

Examples

The following example shows that the IP address of the DHCP server is 192.0.2.1 and that the time to wait until the next DHCP server on the list is tried is 6 seconds:

```
Router(config)# crypto ikev2 authorization policy home
Router(config-ikev2-client-config-group)# key abcd
Router(config-ikev2-client-config-group)# dhcp server 192.0.2.1
Router(config-ikev2-client-config-group)# dhcp timeout 6
```

Related Commands

Command	Description
crypto ikev2 authorization policy	Specifies an IKEv2 authorization policy group.

dhcp server (isakmp)

To assign an IP address or hostname using a DHCP server, use the **dhcp server** command in crypto ISAKMP group configuration mode. To remove the assigned IP address or hostname, use the **no** form of this command.

dhcp server {*ip-address* | *hostname*}

no dhcp server {*ip-address* | *hostname*}

Syntax Description

ip-address	Address of the DHCP server.
hostname	Hostname of the DHCP server.

Command Default

IP address is not assigned by a DHCP server.

Command Modes

Crypto ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

If this command is not configured, an IP address is assigned to a remote device using either a local pool that is configured on a router or a framed IP address attribute that is defined in RADIUS.

Note Up to five DHCP servers can be configured one at a time.

Note The DHCP proxy feature does not include functionality for the DHCP server to "push" the DNS, WINS server, or domain name to the remote client.

Examples

The following example shows that the IP address of the DHCP server is 10.2.3.4 and that the time to wait until the next DHCP server on the list is tried is 6 seconds:

```
Router (config)# crypto isakmp client configuration group home
 Router (config-isakmp-group)# key abcd
 Router (config-isakmp-group)# dhcp server 10.2.3.4
 Router (config-isakmp-group)# dhcp timeout 6
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

dhcp timeout

To set the wait time before the next DHCP server on the list is tried, use the **dhcp timeout** command in crypto ISAKMP group configuration mode. To remove the wait time that was set, use the **no** form of this command.

dhcp timeout *time*

no dhcp timeout *time*

Syntax Description

time	Response time in seconds. Value = 4 through 30.

Command Modes

Crypto ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.4(9)T	This command was introduced.

Examples

The following example shows that the IP address of the DHCP server is 10.2.3.4 and that the time to wait until the next DHCP server on the list is tried is 6 seconds:

```
Router (config)# crypto isakmp client configuration group home
 Router (config-isakmp-group)# dhcp server 10.2.3.4
 Router (config-isakmp-group)# key abcd
 Router (config-isakmp-group)# dhcp timeout 6
```

Related Commands

Command	Description
crypto isakmp client configuration group	Specifies to which group a policy profile will be defined.

dialer aaa

To allow a dialer to access the authentication, authorization, and accounting (AAA) server for dialing information, use the **dialer aaa** command in interface configuration mode. To disable this function, use the **no** form of this command.

dialer aaa [**password** *string* | **suffix** *string*]

no dialer aaa [**password** *string* | **suffix** *string*]

Syntax Description

password *string*	(Optional) Defines a nondefault password for authentication. The password string can be a maximum of 128 characters.
suffix *string*	(Optional) Defines a suffix for authentication. The suffix string can be a maximum of 64 characters.

Defaults

This feature is not enabled by default.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(3)T	This command was introduced.
12.1(5)T	The **password** and **suffix** keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is required for large scale dial-out and Layer 2 Tunneling Protocol (L2TP) dial-out functionality. With this command, you can specify a suffix, a password, or both. If you do not specify a password, the default password will be "cisco."

Note Only IP addresses can be specified as usernames for the **dialer aaa suffix** command.

Examples

This example shows a user sending out packets from interface Dialer1 with a destination IP address of 10.1.1.1. The username in the access-request message is "10.1.1.1@ciscoDoD" and the password is "cisco."

```
interface dialer1
 dialer aaa
 dialer aaa suffix @ciscoDoD password cisco
```

Related Commands

Command	Description
accept dialout	Accepts requests to tunnel L2TP dial-out calls and creates an accept-dialout VPDN subgroup.
dialer congestion-threshold	Specifies congestion threshold in connected links.
dialer vpdn	Enables a Dialer Profile or DDR dialer to use L2TP dial-out.

diameter origin host

To configure the fully qualified domain name (FQDN) of the host of a Diameter node, use the **diameter origin host** command in global configuration mode. To disable the configured FQDN, use the **no** form of this command.

diameter origin host *string*

no diameter origin host *string*

Syntax Description

string	Character string that describes the FQDN for a specific Diameter node.

Command Default

No realm is configured.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Because there is no host configured by default, it is mandatory to configure this information. The origin host information is sent in requests to a Diameter peer. Global Diameter protocol parameters are used if Diameter parameters have not been defined at a Diameter peer level.

Examples

The following example shows how to configure a Diameter origin host:

```
Router(config)# diameter origin host host1.example.com.
```

Related Commands

Command	Description
diameter origin realm	Configures origin realm information for a Diameter node.
diameter peer	Defines a Diameter peer and enters Diameter peer configuration mode.

diameter origin realm

To configure origin realm information for a Diameter node, use the **diameter origin realm** command in global configuration mode. To disable the configured realm information, use the **no** form of this command.

diameter origin realm *string*

no diameter origin realm *string*

Syntax Description

string	Character string that describes the realm information for a specific Diameter node.

Command Default

No realm is configured.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Because there is no realm configured by default, it is mandatory to configure this information. Origin realm information is sent in requests to a Diameter peer.

Examples

The following example shows how to configure a Diameter origin realm:

```
Router (config)# diameter origin realm example.com
```

Related Commands

Command	Description
diameter origin host	Configures the FQDN of the host of a Diameter node.
diameter peer	Defines a Diameter peer and enters Diameter peer configuration mode.

diameter peer

To configure a device as a Diameter Protocol peer and enter the Diameter peer configuration submode, use the **diameter peer** command in global configuration mode. To disable Diameter Protocol configuration for a peer, use the **no** form of this command.

diameter peer *name*

no diameter peer *name*

Syntax Description

name	Character string used to name the peer node to be configured for the Diameter Credit Control Application (DCCA).

Command Default

No Diameter peer is configured.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

This command enables the Diameter peer configuration submode. From the submode, you can configure other DCCA parameters. The configuration is applied when you exit the submode.

Examples

The following example shows how to configure a Diameter peer:

```
Router (config)# diameter peer dia_peer_1
```

Related Commands

Command	Description
address ipv4	Defines a route to the host of the Diameter peer using IPv4.
destination host	Configures the FQDN of a Diameter peer.
destination realm	Configures the destination realm in which a Diameter peer is located.
ip vrf forwarding	Associates a VRF with a Diameter peer.
security ipsec	Configures IPSec as the security protocol for the Diameter peer-to-peer connection.
show diameter peer	Displays the Diameter peer configuration.
source interface	Configures the interface to connect to the Diameter peer.
timer	Configures Diameter base protocol timers for peer-to-peer communication.
transport {tcp} port	Configures the transport protocol for connections to the Diameter peer.

diameter redundancy

To enable the Diameter node to be a Cisco IOS Redundancy Facility (RF) client and track session states, use the **diameter redundancy** command in global configuration mode. To disable this feature, use the **no** form of this command.

diameter redundancy

no diameter redundancy

Syntax Description

This command has no arguments or keywords.

Command Default

Diameter redundancy is not configured.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

When you configure Diameter redundancy on a device, that device will not initiate any TCP connection while it is a standby node. Upon transition to active status, the device initiates a TCP connection to the Diameter peer.

Note This command is required for service-aware Packet Data Protocol (PDP) session redundancy. For more information about service-aware PDP session redundancy, see the "GTP-Session Redundancy for Service-Aware PDPs Overview" section of the *Cisco GGSN Release 5.2 Configuration Guide*.

Examples

The following example shows how to configure Diameter redundancy:

```
Router (config)# diameter redundancy
```

Related Commands

Command	Description
diameter origin host	Configures the FQDN of the host of this Diameter node.
diameter origin realm	Configures the realm of origin in which this Diameter node is located.
diameter timer	Configures Diameter base protocol timers to use if none have been configured at the Diameter peer level.
diameter vendor support	Configures a Diameter node to advertise the vendor AVPs it supports in capability exchange messages with Diameter peers.

diameter timer

To set either the frequency of transport connection attempts or the interval for sending watchdog messages, use the **diameter timer** command in global configuration mode. To return to the default values, use the **no** form of this command.

diameter timer {**connection** | **transaction** | **watch-dog**} *value*

no diameter timer {**connection** | **transaction** | **watch-dog**} *value*

Syntax Description

connection	Maximum interval, in seconds, for the Gateway General Packet Radio Service (GPRS) Support Node (GGSN) to attempt reconnection to a Diameter peer after being disconnected due to a transport failure. The range is from 1 to 1000. The default is 30. A value of 0 configures the GGSN not to attempt reconnection.
transaction	Maximum interval, in seconds, the GGSN waits for a Diameter peer to respond before trying another peer. The range is from 1 to 1000. The default is 30.
watch-dog	Maximum interval, in seconds, the GGSN waits for a Diameter peer response to a watchdog packet. The range is from 1 to 1000. The default is 30. **Note** When the watchdog timer expires, a device watchdog request (DWR) is sent to the Diameter peer and the watchdog timer is reset. If a device watchdog answer (DWA) is not received before the next expiration of the watchdog timer, a transport failure to the Diameter peer has occurred.
value	The valid range, in seconds, from 1 to 1000. The default is 30.

Command Default

The default value for each timer is 30 seconds.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

When configuring timers, the value for the transaction timer should be larger than the transmission-timeout value, and, on the Serving GPRS Support Node (SGSN), the values configured for the number of GPRS Tunneling Protocol (GTP) N3 requests and T3 retransmissions must be larger than the sum of all possible server timers (RADIUS, Diameter Credit Control Application (DCCA), and Cisco Content Services Gateway (CSG)). Specifically, the SGSN N3*T3 must be greater than 2 x RADIUS timeout + *N* x DCCA timeout + CSG timeout where:

- The factor *2* is for both authentication and accounting.
- The value *N* is for the number of Diameter servers configured in the server group.

Examples

The following examples show how to configure the Diameter timers:

```
Router config# diameter timer connection 20

Router config# diameter timer watch-dog 25
```

Related Commands

Command	Description
aaa group server diameter	Defines a Diameter AAA server group.
diameter peer	Configures a Diameter peer and enters Diameter peer configuration submode.
timer	Configures the Diameter base protocol timers for a Diameter peer.

diameter vendor supported

To configure a Diameter node to advertise the vendor-specific attribute value pairs (AVPs) it recognizes, use the **diameter vendor supported** command in global configuration mode. To remove the supported vendor configuration, use the **no** form of this command.

diameter vendor supported {**Cisco** | **3gpp** | **Vodafone**}

no diameter vendor supported {**Cisco** | **3gpp** | **Vodafone**}

Syntax Description

Cisco	Configures the Diameter node to advertise support for the Cisco-specific AVPs.
3gpp	Configures the Diameter node to advertise support for the AVPs that support the Third-Generation Partnership Project (3GPP).
Vodafone	Configures the Diameter node to advertise support for the Vodafone-specific AVPs.

Command Default

No vendor identifier is configured.

Command Modes

Global configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Individual vendors can define AVPs specific to their implementation of the Diameter Credit Control Application (DCCA), or for individual applications. You can configure multiple instances of this command, as long as each instance has a different vendor identifier.

Examples

The following example shows how to configure DCCA to advertise support for a the Cisco-specific AVPs:

```
Router (config)# diameter vendor supported Cisco
```

Related Commands

Command	Description
diameter origin host	Configures the FQDN of the host of this Diameter node.
diameter origin realm	Configures the realm of origin in which this Diameter node is located.
diameter redundancy	Enables the Diameter node to be a Cisco IOS RF client and track session states.
diameter timer	Configures Diameter base protocol timers to use if none have been configured at the Diameter peer level.

disable open-media-channel

To prevent the creation of Real-time Transport Protocol (RTP) or RTP Control (RTCP) media channels when a Session Initiation Protocol (SIP) class map is used for SIP inspection, use the **disable open-media-channel** command in parameter-map type configuration mode. To enable the creation of RTP or RTCP media channels, use the **no** form of this command or remove this parameter map from the inspect action.

disable open-media-channel

no disable open-media-channel

Syntax Description

This command has no arguments or keywords.

Command Default

RTP and RTPC media channels are opened by the SIP inspection process.

Command Modes

Parameter-map type configuration (config-profile)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Cisco IOS Firewall Trust Relay Point (TRP) support enables Cisco IOS Firewall to process Simple Traversal of User Datagram Protocol (UDP) (STUN) messages. The STUN messages open ports (pinholes) for secondary channels (RTP and RTCP), which are necessary for implementation of TRPs in voice networks.

Cisco IOS Firewall supports partial SIP inspection that allows the SIP Application-level Gateway (ALG) to parse the SIP message in a packet to check for protocol conformance.

To configure partial SIP inspection in voice networks, you must use the **disable open-media-channel** command to configure SIP ALG so that it does not open pinholes for media information found in the SDP message.

When Cisco IOS TRP is used in voice network for firewall traversal, Partial SIP-ALG (enabled when this parameter map is attached to the inspect action) provides security for SIP control channel and STUN with Cisco Flow data (CFD) provides security for the RTP and RTCP channels. If Partial SIP-ALG is not used, the normal SIP-ALG will open RTP and RTCP channels by itself.

Examples

The following example shows how to create a parameter map that does not open a media channel when attached to a SIP class map:

```
Router(config)# parameter-map type protocol-info sip pmap-sip
Router(config-profile)# disable open-media-channel
```

Related Commands

Command	Description
parameter-map type protocol-info	Creates or modifies a protocol-specific parameter map and enters parameter-map type configuration mode.

disconnect ssh

To terminate a Secure Shell (SSH) connection on your router, use the **disconnect ssh** command in privileged EXEC mode.

disconnect ssh [**vty**] *session-id*

Syntax Description

vty	(Optional) Virtual terminal for remote console access.
session-id	The session-id is the number of connection displayed in the **show ip ssh** command output.

Defaults

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(5)S	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1 T.
12.2(17a)SX	This command was integrated into Cisco IOS Release 12.2(17a)SX.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

The **clear line vty** *n* command, where *n* is the connection number displayed in the **show ip ssh** command output, may be used instead of the **disconnect ssh** command.

When the EXEC connection ends, whether normally or abnormally, the SSH connection also ends.

Examples

The following example terminates SSH connection number 1:

```
disconnect ssh 1
```

Related Commands

Command	Description
clear line vty	Returns a terminal line to idle state using the privileged EXEC command.

dn

To associate the identity of a router with the distinguished name (DN) in the certificate of the router, use the **dn** command in crypto identity configuration mode. To remove this command from your configuration, use the **no** form of this command.

dn *name=string* [, *name=string*]

no dn *name=string* [, *name=string*]

Syntax Description

name=string	Identity used to restrict access to peers with specific certificates. Optionally, you can associate more than one identity.

Command Default

If this command is not enabled, the router can communicate with any encrypted interface that is not restricted on its IP address.

Command Modes

Crypto identity configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

Use the **dn** command to associate the identity of the router, which is defined in the **crypto identity** command, with the DN that the peer used to authenticate itself.

Note The *name* defined in the **crypto identity** command must match the *string* defined in the **dn** command. That is, the identity of the peer must be the same as the identity in the exchanged certificate.

This command allows you set restrictions in the router configuration that prevent those peers with specific certificates, especially certificates with particular DNs, from having access to selected encrypted interfaces.

An encrypting peer matches this list if it contains the attributes listed in any one line defined within the *name=string*.

Examples

The following example shows how to configure an IPsec crypto map that can be used only by peers that have been authenticated by the DN and if the certificate belongs to “green”:

```
crypto map map-to-green 10 ipsec-isakmp
 set peer 172.21.114.196
 set transform-set my-transformset
 match address 124
 identity to-green
!
crypto identity to-green
 dn ou=green
```

Related Commands

Command	Description
crypto identity	Configures the identity of the router with a given list of DNs in the certificate of the router.
fqdn	Associates the identity of the router with the hostname that the peer used to authenticate itself.

dn (IKEv2)

To enable and derive an IKEv2 name mangler from identity of type distinguished name (DN), use the **dn** command in IKEv2 name mangler configuration mode. To remove the name derived from DN, use the **no** form of this command.

dn {**common-name** | **country** | **domain** | **locality** | **organization** | **organization-unit** | **state**}

no dn

Syntax Description

common-name	Derives the name mangler from the common name portion in the DN.
country	Derives the name mangler from the country portion in the DN.
domain	Derives the name mangler from the domain portion in the DN.
locality	Derives the name mangler from the locality portion in the DN.
organization	Derives the name mangler from the organization portion in the DN.
organization-unit	Derives the name mangler from the organization-unit portion in the DN.
state	Derives the name mangler from the state portion in the DN.

Command Default

No default behavior or values.

Command Modes

IKEv2 name mangler configuration (config-ikev2-name-mangler)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to derive the name mangler from any field in the remote identity of type DN.

Examples

The following example shows how to derive a name for the name mangler from the country field of the DN:

```
Router(config)# crypto ikev2 name-mangler mangler2
Router(config-ikev2-name-mangler)# dn country
```

Related Commands

Command	Description
crypto ikev2 name mangler	Defines a name mangler.

dnis (AAA preauthentication)

To preauthenticate calls on the basis of the Dialed Number Identification Service (DNIS) number, use the **dnis** command in AAA preauthentication configuration mode. To remove the **dnis** command from your configuration, use the **no** form of this command.

dnis [**if-avail** | **required**] [**accept-stop**] [**password** *string*]

no dnis [**if-avail** | **required**] [**accept-stop**] [**password** *string*]

Syntax Description

if-avail	(Optional) Implies that if the switch provides the data, RADIUS must be reachable and must accept the string in order for preauthentication to pass. If the switch does not provide the data, preauthentication passes.
required	(Optional) Implies that the switch must provide the associated data, that RADIUS must be reachable, and that RADIUS must accept the string in order for preauthentication to pass. If these three conditions are not met, preauthentication fails.
accept-stop	(Optional) Prevents subsequent preauthentication elements from being tried once preauthentication has succeeded for a call element.
password *string*	(Optional) Password to use in the Access-Request packet. The default is cisco.

Defaults

The **if-avail** and **required** keywords are mutually exclusive. If the **if-avail** keyword is not configured, the preauthentication setting defaults to **required**.

The default password string is cisco.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines

You may configure more than one of the AAA preauthentication commands (**clid**, **ctype**, **dnis**) to set conditions for preauthentication. The sequence of the command configuration decides the sequence of the preauthentication conditions. For example, if you configure **dnis**, then **clid**, then **ctype**, then this is the order of the conditions considered in the preauthentication process.

In addition to using the preauthentication commands to configure preauthentication on the Cisco router, you must set up the preauthentication profiles on the RADIUS server.

Examples

The following example enables DNIS preauthentication using a RADIUS server and the password Ascend-DNIS:

```
aaa preauth
 group radius
 dnis password Ascend-DNIS
```

The following example specifies that incoming calls be preauthenticated on the basis of the DNIS number:

```
aaa preauth
 group radius
 dnis required
```

Related Commands

Command	Description
aaa preauth	Enters AAA preauthentication mode.
clid	Preauthenticates calls on the basis of the CLID number.
ctype	Preauthenticates calls on the basis of the call type.
dnis bypass (AAA preauthentication configuration)	Specifies a group of DNIS numbers that will be bypassed for preauthentication.
group (authentication)	Selects the security server to use for AAA preauthentication.
isdn guard-timer	Sets a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.

dnis (RADIUS)

To preauthenticate calls on the basis of the DNIS (Dialed Number Identification Service) number, use the **dnis** command in AAA preauthentication configuration mode. To remove the **dnis** command from your configuration, use the **no** form of this command.

dnis [**if-avail** | **required**] [**accept-stop**] [**password** *password*]

no dnis [**if-avail** | **required**] [**accept-stop**] [**password** *password*]

Syntax Description

if-avail	(Optional) Implies that if the switch provides the data, RADIUS must be reachable and must accept the string in order for preauthentication to pass. If the switch does not provide the data, preauthentication passes.
required	(Optional) Implies that the switch must provide the associated data, that RADIUS must be reachable, and that RADIUS must accept the string in order for preauthentication to pass. If these three conditions are not met, preauthentication fails.
accept-stop	(Optional) Prevents subsequent preauthentication elements such as **clid** or **ctype** from being tried once preauthentication has succeeded for a call element.
password *password*	(Optional) Defines the password for the preauthentication element.

Defaults

The **if-avail** and **required** keywords are mutually exclusive. If the **if-avail** keyword is not configured, the preauthentication setting defaults to **required**.

The default password string is cisco.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You may configure more than one of the authentication, authorization, and accounting (AAA) preauthentication commands (**clid**, **ctype**, **dnis**) to set conditions for preauthentication. The sequence of the command configuration decides the sequence of the preauthentication conditions. For example, if you configure **dnis**, then **clid**, then **ctype**, in this order, then this is the order of the conditions considered in the preauthentication process.

In addition to using the preauthentication commands to configure preauthentication on the Cisco router, you must set up the preauthentication profiles on the RADIUS server.

Examples

The following example specifies that incoming calls be preauthenticated on the basis of the DNIS number:

```
aaa preauth
 group radius
 dnis required
```

Related Commands

Command	Description
clid	Preauthenticates calls on the basis of the CLID number.
ctype	Preauthenticates calls on the basis of the call type.
dnis bypass (AAA preauthentication configuration)	Specifies a group of DNIS numbers that will be bypassed for preauthentication.
group (RADIUS)	Specifies the AAA RADIUS server group to use for preauthentication.

dnis bypass (AAA preauthentication configuration)

To specify a group of DNIS (Dialed Number Identification Service) numbers that will be bypassed for preauthentication, use the **dnis bypass** command in AAA preauthentication configuration mode. To remove the **dnis bypass** command from your configuration, use the **no** form of this command.

dnis bypass {*dnis-group-name*}

no dnis bypass {*dnis-group-name*}

Syntax Description

dnis-group-name	Name of the defined DNIS group.

Defaults

No DNIS numbers are bypassed for preauthentication.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Before using this command, you must first create a DNIS group with the **dialer dnis group** command.

Examples

The following example specifies that preauthentication be performed on all DNIS numbers except for two DNIS numbers (12345 and 12346), which have been defined in the DNIS group called hawaii:

```
aaa preauth
 group radius
 dnis required
 dnis bypass hawaii

dialer dnis group hawaii
 number 12345
 number 12346
```

Related Commands

Command	Description
dialer dnis group	Creates a DNIS group.
dnis (RADIUS)	Preauthenticates calls on the basis of the DNIS number.

dns

To specify the primary and secondary Domain Name Service (DNS) servers, use the **dns** command in ISAKMP group configuration mode or IKEv2 authorization policy configuration mode. To remove this command from your configuration, use the **no** form of this command.

dns *primary-server* [*secondary-server*]

no dns *primary-server* [*secondary-server*]

Syntax Description

primary-server	Name of the primary DNS server.
secondary-server	(Optional) Name of the secondary DNS server.

Defaults

A DNS server is not specified.

Command Modes

ISAKMP group configuration (config-isakmp-group)
IKEv2 authorization policy configuration (config-ikev2-author-policy)

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use the **dns** command to specify the primary and secondary DNS servers for the group.

You must enable the following commands before enabling the **dns** command:

- **crypto isakmp client configuration group**—Specifies the group policy information that has to be defined or changed.
- **crypto ikev2 authorization policy**—Specifies the local group policy authorization parameters.

Examples

The following example shows how to define a primary and secondary DNS server for the default group name:

```
crypto isakmp client configuration group default
 key cisco
 dns 10.2.2.2 10.3.2.3
 pool dog
 acl 199
```

Related Commands

Command	Description
acl	Configures split tunneling.
crypto ikev2 authorization policy	Specifies an IKEv2 authorization policy.
crypto isakmp client configuration group	Specifies the policy profile of the group that will be defined.
domain (isakmp-group)	Specifies the DNS domain to which a group belongs.

dnsix-dmdp retries

To set the retransmit count used by the Department of Defense Intelligence Information System Network Security for Information Exchange (DNSIX) Message Delivery Protocol (DMDP), use the **dnsix-dmdp retries** command in global configuration mode. To restore the default number of retries, use the **no** form of this command.

dnsix-dmdp retries *count*

no dnsix-dmdp retries *count*

Syntax Description

count	Number of times DMDP will retransmit a message. It can be an integer from 0 to 200. The default is 4 retries, or until acknowledged.

Defaults

Retransmits messages up to 4 times, or until acknowledged.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example sets the number of times DMDP will attempt to retransmit a message to 150:

```
dnsix-dmdp retries 150
```

Related Commands

Command	Description
dnsix-nat authorized-redirection	Specifies the address of a collection center that is authorized to change the primary and secondary addresses of the host to receive audit messages.
dnsix-nat primary	Specifies the IP address of the host to which DNSIX audit messages are sent.
dnsix-nat secondary	Specifies an alternate IP address for the host to which DNSIX audit messages are sent.
dnsix-nat source	Starts the audit-writing module and defines audit trail source address.
dnsix-nat transmit-count	Causes the audit-writing module to collect multiple audit messages in the buffer before sending the messages to a collection center.

dnsix-nat authorized-redirection

To specify the address of a collection center that is authorized to change the primary and secondary addresses of the host to receive audit messages, use the **dnsix-nat authorized-redirection** command in global configuration mode. To delete an address, use the **no** form of this command.

dnsix-nat authorized-redirection *ip-address*

no dnsix-nat authorized-redirection *ip-address*

Syntax Description

ip-address	IP address of the host from which redirection requests are permitted.

Defaults

An empty list of addresses.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use multiple **dnsix-nat authorized-redirection** commands to specify a set of hosts that are authorized to change the destination for audit messages. Redirection requests are checked against the configured list, and if the address is not authorized the request is rejected and an audit message is generated. If no address is specified, no redirection messages are accepted.

Examples

The following example specifies that the address of the collection center that is authorized to change the primary and secondary addresses is 192.168.1.1:

```
dnsix-nat authorization-redirection 192.168.1.1
```

dnsix-nat primary

To specify the IP address of the host to which Department of Defense Intelligence Information System Network Security for Information Exchange (DNSIX) audit messages are sent, use the **dnsix-nat primary** command in global configuration mode. To delete an entry, use the **no** form of this command.

dnsix-nat primary *ip-address*

no dnsix-nat primary *ip-address*

Syntax Description

ip-address	IP address for the primary collection center.

Defaults

Messages are not sent.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

An IP address must be configured before audit messages can be sent.

Examples

The following example configures an IP address as the address of the host to which DNSIX audit messages are sent:

```
dnsix-nat primary 172.16.1.1
```

dnsix-nat secondary

To specify an alternate IP address for the host to which Department of Defense Intelligence Information System Network Security for Information Exchange (DNSIX) audit messages are sent, use the **dnsix-nat secondary** command in global configuration mode. To delete an entry, use the **no** form of this command.

dnsix-nat secondary *ip-address*

no dnsix-nat secondary *ip-address*

Syntax Description

ip-address	IP address for the secondary collection center.

Defaults

No alternate IP address is known.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When the primary collection center is unreachable, audit messages are sent to the secondary collection center instead.

Examples

The following example configures an IP address as the address of an alternate host to which DNSIX audit messages are sent:

```
dnsix-nat secondary 192.168.1.1
```

dnsix-nat source

To start the audit-writing module and to define the audit trail source address, use the **dnsix-nat source** command in global configuration mode. To disable the Department of Defense Intelligence Information System Network Security for Information Exchange (DNSIX) audit trail writing module, use the **no** form of this command.

dnsix-nat source *ip-address*

no dnsix-nat source *ip-address*

Syntax Description

ip-address	Source IP address for DNSIX audit messages.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You must issue the **dnsix-nat source** command before any of the other **dnsix-nat** commands. The configured IP address is used as the source IP address for DMDP protocol packets sent to any of the collection centers.

Examples

The following example enables the audit trail writing module, and specifies that the source IP address for any generated audit messages should be the same as the primary IP address of Ethernet interface 0:

```
dnsix-nat source 192.168.2.5
interface ethernet 0
 ip address 192.168.2.5 255.255.255.0
```

dnsix-nat transmit-count

To have the audit writing module collect multiple audit messages in the buffer before sending the messages to a collection center, use the **dnsix-nat transmit-count** command in global configuration mode. To revert to the default audit message count, use the **no** form of this command.

dnsix-nat transmit-count *count*

no dnsix-nat transmit-count *count*

Syntax Description

count	Number of audit messages to buffer before transmitting to the server. It can be an integer from 1 to 200.

Defaults

One message is sent at a time.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

An audit message is sent as soon as the message is generated by the IP packet-processing code. The audit writing module can, instead, buffer up to several audit messages before transmitting to a collection center.

Examples

The following example configures the system to buffer five audit messages before transmitting them to a collection center:

```
dnsix-nat transmit-count 5
```

dns-timeout

To specify the Domain Name System (DNS) idle timeout (the length of time for which a DNS lookup session will continue to be managed while there is no activity), use the **dns-timeout** command in parameter-map type inspect configuration mode. To disable the timeout, use the **no** form of this command.

dns-timeout *seconds*

no dns-timeout *seconds*

Syntax Description

seconds	Length of time, in seconds, for which a DNS name lookup session will still be managed while there is no activity. The default is 5.

Command Default

The DNS idle timeout is disabled.

Command Modes

Parameter-map type inspect configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

You can use the **dns-timeout** subcommand when you are creating an inspect type parameter map. You can enter the **dns-timeout** subcommand after you enter the **parameter-map type inspect** command.

Use the **dns-timeout** command if you have DNS inspection configured and want to control the timeout of DNS sessions.

If DNS inspection is not configured, but you enter the **dns-timeout** command, the command does not take effect (that is, it is not applied to a DNS session).

For more detailed information about creating a parameter map, see the **parameter-map type inspect** command.

Examples

The following example specifies that if there is no activity, a DNS lookup session will continue to be managed for 25 seconds:

```
parameter-map type inspect insp-params
 dns-timeout 25
```

Related Commands

Command	Description
ip inspect dns-timeout	Specifies the DNS idle timeout (the length of time during which a DNS name lookup session will still be managed while there is no activity).
parameter-map type inspect	Configures an inspect parameter map for connecting thresholds, timeouts, and other parameters pertaining to the **inspect** action.

domain (AAA)

To configure username domain options for the RADIUS application, use the **domain** command in dynamic authorization local server configuration mode. To disable the username domain options configured, use the **no** form of this command.

domain {**delimiter** *character* | **stripping** [**right-to-left**]}

no domain {**delimiter** *character* | **stripping** [**right-to-left**]}

Syntax Description

delimiter *character*	Specifies the domain delimiter. One of the following options can be specified: **@**, **/**, **$**, **%**, ****, **#** or **-**
stripping	Compares the incoming username with the names oriented to the left of the @ domain delimiter.
right-to-left	Terminates the string at the first delimiter going from right to left.

Command Default

No username domain options are configured.

Command Modes

Dynamic authorization local server configuration (config-locsvr-da-radius)

Command History

Release	Modification
12.2(31)SB14	This command was introduced.
12.2(33)SRC5	This command was integrated into Cisco IOS Release 12.2(33)SRC5.
Cisco IOS XE Release 2.3	This command was modified. This command was implemented on ASR 1000 series routers.
15.1(2)T	This command was integrated into Cisco IOS Release 15.1(2)T. This command was also modified. The **right-to-left** keyword was added.

Usage Guidelines

If domain stripping is not configured, the full username provided in the authentication, authorization, and accounting (AAA) packet of disconnect (POD) messages is compared with the online subscribers. Configuring domain stripping allows you to send disconnect messages with only the username present before the @ domain delimiter. The network access server (NAS) compares and matches this username with any online subscriber with a potential domain.

For instance, when domain stripping is configured and you send a POD message with the username "test," a comparison between the POD message and online subscribers takes place, and subscribers with the username "test@cisco.com" or "test" match the specified username "test."

Examples

The following configuration example is used to match a username from right to left. If the username is user1@cisco.com@test.com, then the username to be matched by the POD message is user1@cisco.com.

```
Router# configure terminal
```

```
Router(config)# aaa server radius dynamic-author
Router(config-locsvr-da-radius)# domain stripping right-to-left
Router(config-locsvr-da-radius)# domain delimiter @
Router(config-locsvr-da-radius)# end
```

The following configuration example is used to match a username from left to right. If the username is user1@cisco.com@test.com, then the username to be matched by the POD message is user1.

```
Router# configure terminal
Router(config)# aaa server radius dynamic-author
Router(config-locsvr-da-radius)# domain stripping
Router(config-locsvr-da-radius)# domain delimiter @
Router(config-locsvr-da-radius)# end
```

Related Commands

Command	Description
aaa server radius dynamic-author	Configures a device as a AAA server to facilitate interaction with an external policy server.

domain (isakmp-group)

To specify the Domain Name Service (DNS) domain to which a group belongs, use the **domain** command in Internet Security Association Key Management Protocol (ISAKMP) group configuration mode. To remove this command from your configuration, use the **no** form of this command.

domain *name*

no domain *name*

Syntax Description

name	Name of the DNS domain.

Defaults

A DNS domain is not specified.

Command Modes

ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **domain** command to specify group domain membership.

You must enable the **crypto isakmp configuration group** command, which specifies group policy information that has to be defined or changed, before enabling the **domain** command.

Examples

The following example shows that members of the group “cisco” also belong to the domain “cisco.com”:

```
crypto isakmp client configuration group cisco
  key cisco
  dns 10.2.2.2 10.3.2.3
  pool dog
  acl 199
  domain cisco.com
```

Related Commands

Command	Description
acl	Configures split tunneling.
crypto isakmp client configuration group	Specifies the DNS domain to which a group belongs.
crypto isakmp keepalive	Specifies the primary and secondary DNS servers.

dot1x control-direction

Note Effective with Cisco IOS Release 12.2(33)SXI, the **dot1x control-direction** command is replaced by the **authentication control-direction** command. See the **authentication control-direction** command for more information.

To change an IEEE 802.1X controlled port to unidirectional or bidirectional, use the **dot1x control-direction** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

dot1x control-direction {**both** | **in**}

no dot1x control-direction

Syntax Description

both	Enables bidirectional control on the port.
in	Enables unidirectional control on the port.

Command Default

The port is set to bidirectional mode.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(25)SEC	This command was introduced.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Switches (ISRs) only.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SXI	This command was replaced by the **authentication control-direction** command.

Usage Guidelines

The IEEE 802.1x standard defines a client-server-based access control and authentication protocol that restricts unauthorized devices from connecting to a LAN through publicly accessible ports. 802.1x controls network access by creating two distinct virtual access points at each port. One access point is an uncontrolled port; the other is a controlled port. All traffic through the single port is available to both access points. 802.1x authenticates each user device that is connected to a switch port and assigns the port to a VLAN before making available any services that are offered by the switch or the LAN. Until the device is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL) traffic through the port to which the device is connected. After authentication is successful, normal traffic can pass through the port.

Unidirectional State

When you configure a port as unidirectional with the **dot1x control-direction in** interface configuration command, the port changes to the spanning-tree forwarding state.

When Unidirectional Controlled Port is enabled, the connected host is in the sleeping mode or power-down state. The host does not exchange traffic with other devices in the network. The host connected to the unidirectional port cannot send traffic to the network, the host can only receive traffic from other devices in the network.

Bidirectional State

When you configure a port as bidirectional with the **dot1x control-direction both** interface configuration command, the port is access-controlled in both directions. In this state, the switch port receives or sends only EAPOL packets; all other packets are dropped.

Using the **both** keyword or using the **no** form of this command changes the port to its bidirectional default setting.

Catalyst 6500 Series Switch

Setting the port as bidirectional enables 802.1X authentication with wake-on-LAN (WoL).

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time; that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows how to enable unidirectional control:

```
Switch(config-if)# dot1x control-direction in
```

The following examples show how to enable bidirectional control:

```
Switch(config-if)# dot1x control-direction both
```

or

```
Switch(config-if)# no dot1x control-direction
```

You can verify your settings by entering the **show dot1x all** privileged EXEC command. The **show dot1x all** command output is the same for all devices except for the port names and the state of the port. If a host is attached to the port but is not yet authenticated, a display similar to the following appears:

```
Supplicant MAC 0002.b39a.9275
AuthSM State = CONNECTING
BendSM State = IDLE
PortStatus = UNAUTHORIZED
```

If you enter the **dot1x control-direction in** command to enable unidirectional control, the following appears in the **show dot1x all** command output:

```
ControlDirection = In
```

If you enter the **dot1x control-direction in** command and the port cannot support this mode because of a configuration conflict, the following appears in the **show dot1x all** command output:

```
ControlDirection = In (Disabled due to port settings):
```

The following example shows how to reset the global 802.1X parameters:

```
Switch(config)# dot1x default
```

Catalyst 6500 Series Switch

The following example shows how to enable 802.1X authentication with WoL and set the port as bidirectional:

```
Switch(config)# interface gigabitethernet 5/1
Switch(config-if)# dot1x control-direction both
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)X

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
 dot1x control-direction in
```

Related Commands

Command	Description
show dot1x	Displays details for an identity profile.

dot1x credentials

To specify which 802.1X credential profile to use when configuring a supplicant (client) or to apply a credentials structure to an interface and to enter dot1x credentials configuration mode, use the **dot1x credentials** command in global configuration or interface configuration mode. To remove the credential profile, use the **no** form of this command.

dot1x credentials *name*

no dot1x credentials

Syntax Description

name	Name of the credentials profile.

Command Default

A credentials profile is not specified.

Command Modes

Global configuration
Interface configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

An 802.1X credential structure is necessary when configuring a supplicant. This credentials structure may contain a username, password, and description.

Examples

The following example shows which credentials profile should be used when configuring a supplicant:

```
dot1x credentials basic-user
 username router
 password secret
 description This credentials profile should be used for most configured ports
```

The credentials structure can be applied to an interface, along with the **dot1x pae supplicant** command and keyword, to enable supplicant functionality on that interface.

```
interface fastethernet 0/1
 dot1x credentials basic-user
 dot1x pae supplicant
```

Related Commands

Command	Description
anonymous-id (dot1x credential)	Specifies the anonymous identity that is associated with a credentials profile.
description (dot1x credential)	Specifies the description for an 802.1X credentials profile.

Command	Description
password (dot1x credential)	Specifies the password for an 802.1X credentials profile.
username (dot1x credential)	Specifies the username for an 802.1X credentials profile.

dot1x critical (global configuration)

To configure the IEEE 802.1X critical authentication parameters, use the **dot1x critical** command in global configuration mode.

dot1x critical {**eapol** | **recovery delay** *milliseconds*}

Syntax Description

eapol	Specifies that the switch sends an EAPOL-Success message when the switch successfully authenticates the critical port.
recovery delay *milliseconds*	Specifies the recovery delay period that the switch waits to reinitialize a critical port when an unavailable RADIUS server becomes available; valid values are from 1 to 10000, in milliseconds.

Command Default

The default settings are as follows:

- **eapol**—Disabled
- *milliseconds*—1000 milliseconds

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.
12.2(33)SXI	The **recovery delay** keyword was replaced by the **authentication critical recovery delay** command.

Examples

This example shows how to specify that the switch sends an EAPOL-Success message when the switch successfully authenticates the critical port:

```
Switch(config)# dot1x critical eapol
```

This example shows how to set the recovery delay period that the switch waits to reinitialize a critical port when an unavailable RADIUS server becomes available:

```
Switch(config)# dot1x critical recovery delay 1500
```

Related Commands

Command	Description
dot1x critical (interface configuration)	Enables 802.1X critical authentication on an interface.

dot1x critical (interface configuration)

To enable 802.1X critical authentication, and optionally, 802.1X critical authentication recovery and authentication, on an interface, use the **dot1x critical** command in interface configuration mode. To disable 802.1X critical authentication, and optionally, 802.1X critical authentication recovery and authentication, use the **no** form of this command.

dot1x critical [**recovery action reinitialize**]

no dot1x critical [**recovery action reinitialize**]

Syntax Description

recovery action reinitialize	(Optional) Enables 802.1X critical authentication recovery and specifies that the port is authenticated when an authentication server is available.

Command Default

The 802.1X critical authentication is enabled on an interface.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.

Examples

This example shows how to enable 802.1X critical authentication on an interface:

```
Router(config-if)# dot1x critical
```

This example shows how to enable 802.1X critical authentication recovery and authenticate the port when an authentication server is available:

```
Router(config-if)# dot1x critical recovery action reinitialize
```

This example shows how to disable 802.1X critical authentication on an interface:

```
Router(config-if)# no dot1x critical
```

Related Commands

Command	Description
dot1x critical (global configuration)	Configures the 802.1X critical authentication parameters.

dot1x default

To reset the global 802.1X authentication parameters to their default values as specified in the latest IEEE 802.1X standard, use the **dot1x default** command in global configuration or interface configuration mode.

dot1x default

Syntax Description

This command has no arguments or keywords.

Defaults

The default values are as follows:

- The per-interface 802.1X protocol enable state is disabled (force-authorized).
- The number of seconds between reauthentication attempts is 3600 seconds.
- The quiet period is 60 seconds.
- The retransmission time is 30 seconds.
- The maximum retransmission number is 2 times.
- The multiple host support is disabled.
- The client timeout period is 30 seconds.
- The authentication server timeout period is 30 seconds.

Command Modes

Global configuration (config)
Interface configuration (config-if)

Command History

Release	Modification
12.1(6)EA2	This command was introduced.
12.2(15)ZJ	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(14)SX	This command was implemented on the Supervisor Engine 720 in Cisco IOS Release 12.2(14)SX.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(17d)SXB	This command was implemented on the Supervisor Engine 2 in Cisco IOS Release 12.2(17d)SXB.
12.4(6)T	Interface configuration was added as a configuration mode for this command.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

The IEEE 802.1x standard defines a client-server-based access control and authentication protocol that restricts unauthorized devices from connecting to a LAN through publicly accessible ports. 802.1x controls network access by creating two distinct virtual access points at each port. One access point is an uncontrolled port; the other is a controlled port. All traffic through the single port is available to both access points. 802.1x authenticates each user device that is connected to a switch port and assigns the port to a VLAN before making available any services that are offered by the switch or the LAN. Until the device is authenticated, 802.1x access control allows only Extensible Authentication Protocol (EAP) over LAN (EAPOL) traffic through the port to which the device is connected. After authentication is successful, normal traffic can pass through the port.

Use the **show dot1x** command to verify your current 802.1X settings.

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time; that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows how to reset the global 802.1X parameters:

```
Router(config)# dot1x default
```

The following example show how to reset the global 802.1X parameters on FastEthernet interface 0:

```
Router(config)# interface FastEthernet0
Router(config-if)# dot1x default
```

Related Commands

Command	Description
dot1x critical (global configuration)	Configures the 802.1X critical authentication parameters.
dot1x critical (interface configuration)	Enables 802.1X critical authentication on an interface.
dot1x max-req	Sets the maximum number of times that the device sends an EAP request/identity frame to a client (assuming that a response is not received) before restarting the authentication process.
dot1x re-authentication (EtherSwitch)	Enables periodic reauthentication of the client for the Ethernet switch network module.
dot1x timeout (EtherSwitch)	Sets retry timeouts for the Ethernet switch network module.
show dot1x	Displays 802.1X information.
show dot1x (EtherSwitch)	Displays the 802.1X statistics, administrative status, and operational status for the device or for the specified interface.

dot1x guest-vlan

To specify an active VLAN as an IEEE 802.1x guest VLAN, use the **dot1x guest-vlan** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

dot1x guest-vlan *vlan-id*

no dot1x guest-vlan

Syntax Description

vlan-id	Specify an active VLAN as an IEEE 802.1x guest VLAN. The range is 1 to 4094.

Command Default

No guest VLAN is configured.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(14)EA1	This command was introduced.
12.2(25)SE	This command was modified to change the default guest VLAN behavior.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can configure a guest VLAN on a static-access port.

For each IEEE 802.1x port, you can configure a guest VLAN to provide limited services to clients (a device or workstation connected to the switch) not running IEEE 802.1x authentication. These users might be upgrading their systems for IEEE 802.1x authentication, and some hosts, such as Windows 98 systems, might not be IEEE 802.1x capable.

When you enable a guest VLAN on an IEEE 802.1x port, the software assigns clients to a guest VLAN when it does not receive a response to its Extensible Authentication Protocol over LAN (EAPOL) request/identity frame or when EAPOL packets are not sent by the client.

With Cisco IOS Release 12.4(11)T and later, the switch port maintains the EAPOL packet history. If another EAPOL packet is detected on the interface during the lifetime of the link, the guest VLAN feature is disabled. If the port is already in the guest VLAN state, the port returns to the unauthorized state, and authentication restarts. The EAPOL history is reset upon loss of link.

Any number of non-IEEE 802.1x-capable clients are allowed access when the switch port is moved to the guest VLAN. If an IEEE 802.1x-capable client joins the same port on which the guest VLAN is configured, the port is put into the unauthorized state in the RADIUS-configured or user-configured access VLAN, and authentication is restarted.

Guest VLANs are supported on IEEE 802.1x switch ports in single-host or multi-host mode.

You can configure any active VLAN except a Remote Switched Port Analyzer (RSPAN) VLAN or a voice VLAN as an IEEE 802.1x guest VLAN. The guest VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

After you configure a guest VLAN for an IEEE 802.1x port to which a DHCP client is connected, you might need to get a host IP address from a DHCP server. You can change the settings for restarting the IEEE 802.1x authentication process on the switch before the DHCP process on the client times out and tries to get a host IP address from the DHCP server. You should decrease the settings for the IEEE 802.1x authentication process using the **dot1x max-reauth-req** and **dot1x timeout tx-period** interface configuration commands. The amount of decrease depends on the connected IEEE 802.1x client type.

Examples

This example shows how to specify VLAN 5 as an IEEE 802.1x guest VLAN:

```
Switch(config-if)# dot1x guest-vlan 5
```

This example shows how to set 3 as the quiet time on the switch, to set 15 as the number of seconds that the switch waits for a response to an EAP-request/identity frame from the client before resending the request, and to enable VLAN 2 as an IEEE 802.1x guest VLAN when an IEEE 802.1x port is connected to a DHCP client:

```
Switch(config-if)# dot1x timeout max-reauth-req 3
Switch(config-if)# dot1x timeout tx-period 15
Switch(config-if)# dot1x guest-vlan 2
```

You can display the IEEE 802.1x administrative and operational status for the device or for the specified interface by entering the **show dot1x** [**interface** *interface-id*] privileged EXEC command.

Related Commands

Command	Description
dot1x max-reauth-req	Specifies the number of times that the switch retransmits an EAP-request/identity frame to the client before restarting the authentication process.
dot1x timeout	Sets authentication retry timeouts.
show dot1x	Displays details for an identity profile.

dot1x guest-vlan supplicant

To allow the 802.1x-capable supplicants to enter the guest VLAN, use the **dot1x guest-vlan supplicant** command in global configuration mode. To prevent the 802.1x-capable supplicants from entering the guest VLAN, use the **no** form of this command.

dot1x guest-vlan supplicant

no dot1x guest-vlan supplicant

Syntax Description

This command has no arguments or keywords.

Command Default

The 802.1x-capable supplicants are prevented from entering the guest VLAN.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.

Examples

This example shows how to allow the 802.1x-capable supplicants to enter the guest VLAN:

```
Router(config)# dot1x guest-vlan supplicant
```

This example shows how to prevent the 802.1x-capable supplicants from entering the guest VLAN:

```
Router(config)# no dot1x guest-vlan supplicant
```

Related Commands

Command	Description
dot1x critical (global configuration)	Configures the 802.1X critical authentication parameters.
dot1x critical (interface configuration)	Enables 802.1X critical authentication on an interface.

dot1x host-mode

Note Effective with Cisco IOS Release 12.2(33)SXI, the **dot1x host-mode** command is replaced by the **authentication host-mode** command. See the **authentication host-mode** command for more information.

To allow hosts on an IEEE 802.1X-authorized port, use the **dot1x host-mode** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

dot1x host-mode {**multi-auth** | **multi-host** | **single-host**}

no dot1x host-mode {**multi-auth** | **multi-host** | **single-host**}

Syntax Description

multi-auth	Specifies that all clients are authenticated individually on the port. The multi-auth mode is not supported on switch ports and is the default mode for switch ports.
multi-host	Ensures that the first client and all subsequent clients are allowed access to the port if the first client is successfully authenticated.
single-host	Ensures that only the first client is authenticated. All other clients are ignored and may cause a violation. The single-host mode is the default mode for switch ports.

Command Default

Hosts are not allowed on an 802.1X-authorized port.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(14)EA1	This command was introduced for switches. It replaced the **dot1x multiple-hosts** command.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Switches (ISRs) only.
12.2(33)SXI	This command was replaced by the **authentication host-mode** command.

Usage Guidelines

Before you use this command, use the **dot1x port-control auto** command to enables IEEE 802.1X port-based authentication, and cause the port to begin in the unauthorized state.

The **multi-auth** mode authenticates each new client separately.

In **multi-host** mode, only one of the attached hosts has to be successfully authorized for all hosts to be granted network access (the **multi-host** mode authenticates one client, but after the client is authenticated, traffic is allowed from all other MAC addresses.). If the port becomes unauthorized (reauthentication fails or an Extensible Authentication Protocol over LAN [EAPOL] logoff message is received), all attached clients are denied access to the network.

The **single-host** mode allows only one client per port; that is, one MAC address is authenticated, and all others are blocked.

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time; that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows how to enable IEEE 802.1X globally, to enable IEEE 802.1x on a port, and to enable multiple-hosts mode:

```
Switch(config)# dot1x system-auth-control
Switch(config)# interface gigabitethernet2/0/1
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x host-mode multi-host:
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x port-control	Enables 802.1X port-based authentication.
show dot1x	Displays details for an identity profile.

dot1x initialize

Note Effective with Cisco IOS Release 12.2(33)SXI, the **dot1x initialize** command is replaced by the **clear authentication session** command. See the **clear authentication session** command for more information.

To initialize 802.1X clients on all 802.1X-enabled interfaces, use the **dot1x initialize** command in privileged EXEC mode. This command does not have a **no** form.

dot1x initialize [**interface** *interface-name*]

Syntax Description

interface *interface-name*	(Optional) Specifies an interface to be initialized. If this keyword is not entered, all interfaces are initialized.

Defaults

State machines are not enabled.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(14)EA1	This command was introduced.
12.3(2)XA	This command was integrated into Cisco IOS Release 12.3(2)XA.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

Use this command to initialize the 802.1X state machines and to set up a fresh environment for authentication. After you enter this command, the port status becomes unauthorized.

Examples

The following example shows how to manually initialize a port:

```
Router# dot1x initialize interface gigabitethernet2/0/2
```

You can verify the unauthorized port status by entering the **show dot1x** [**interface** *interface-name*] command.

Related Commands

Command	Description
show dot1x	Displays details for an identity profile.

dot1x mac-auth-bypass

To enable a switch to authorize clients based on the client MAC address, use the **dot1x mac-auth-bypass** command in interface configuration mode. To disable MAC authentication bypass, use the **no** form of this command.

dot1x mac-auth-bypass [**eap**]

no dot1x mac-auth-bypass

Syntax Description

eap	(Optional) Configures the switch to use Extensible Authentication Protocol (EAP) for authorization.

Command Default

MAC authentication bypass is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.
15.1(4)M	This command was integrated into Cisco IOS Release 15.1(4)M.

Usage Guidelines

Note To use MAC authentication bypass on a routed port, ensure that MAC address learning is enabled on the port.

When the MAC authentication bypass feature is enabled on an 802.1X port, the switch uses the MAC address as the client identity. The authentication server has a database of client MAC addresses that are allowed network access. If authorization fails, the switch assigns the port to the guest VLAN if a VLAN is configured.

Examples

This example shows how to enable MAC authentication bypass:

```
Router(config)# interface fastethernet 5/1
Router(config-if)# dot1x mac-auth-bypass
```

This example shows how to configure the switch to use EAP for authorization:

```
Router(config)# interface fastethernet 5/1
Router(config-if)# dot1x mac-auth-bypass eap
```

This example shows how to disable MAC authentication bypass:

```
Router(config)# interface fastethernet 5/1
Router(config-if)# no dot1x mac-auth-bypass
```

Related Commands

Command	Description
dot1x critical (global configuration)	Configures the 802.1X critical authentication parameters.
dot1x critical (interface configuration)	Enables 802.1X critical authentication on an interface.

dot1x max-reauth-req

To set the maximum number of times the authenticator sends an Extensible Authentication Protocol (EAP) request/identity frame (assuming that no response is received) to the client , use the **dot1x max-reauth-req** command in interface configuration mode. To set the maximum number of times to the default setting of 2, use the **no** form of this command.

dot1x max-reauth-req *number*

no dot1x max-reauth-req

Syntax Description

number	Maximum number of times. The range is 1 through 10. The default is 2.

Command Default

The command default is 2.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SE	This command was introduced.
12.2(25)SEC	The *number* argument was added.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.

Usage Guidelines

You should change the default value of this command only to adjust for unusual circumstances, such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time, that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Verifying Settings

You can verify your settings by entering the **show dot1x** [**interface** *interface-id*] command.

Examples

The following example shows how to set 4 as the number of times that the authentication process is restarted before changing to the unauthorized state:

```
Router(config-if)# dot1x max-reauth-req 4
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x max-req	Sets the maximum number of times that a device can send an EAP request/identity frame to a client (assuming that a response is not received) before restarting the authentication process .
dot1x timeout tx-period	Sets the number of seconds that the switch waits for a response to an EAP request or identity frame from the client before resending the request.
show dot1x	Displays IEEE 802.1X status for the specified port.

dot1x max-req

To set the maximum number of times that a networking device or Ethernet switch network module can send an Extensible Authentication Protocol (EAP) request/identity frame to a client (assuming that a response is not received) before restarting the authentication process, use the **dot1x max-req** command in interface configuration or global configuration mode. To set the number of times to the default setting of 2, use the **no** form of this command.

dot1x max-req *retry-number*

no dot1x max-req

Syntax Description

retry-number	Maximum number of retries. The value is from 1 through 10. The default value is 2. The value is applicable to all EAP packets except for Request ID.

Defaults

The default number of retries is 2.

Command Modes

Interface configuration (config-if)
Global configuration (config)

Command History

Release	Modification
12.1(6)EA2	This command was introduced on the Cisco Ethernet switch network module.
12.2(14)SX	This command was implemented on the Supervisor Engine 720 in Cisco IOS Release 12.2(14)SX.
12.2(15)ZJ	This command was implemented on the Cisco Ethernet switch network module on the following platforms in Cisco IOS Release 12.2(15)ZJ: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series.
12.1(11)AX	This command was integrated into Cisco IOS Release 12.1(11)AX.
12.1(14)EA1	This command was integrated into Cisco IOS Release 12.1(14)EA1 and the configuration mode was changed to interface configuration mode except on the EtherSwitch network module.
12.3(2)XA	This command was integrated into Cisco IOS Release 12.3(2)XA and implemented on the following router platforms: Cisco 806, Cisco 831, Cisco 836, Cisco 837, Cisco 1701, Cisco 1710, Cisco 1721, Cisco 1751-V, and Cisco 1760.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T and implemented on the following router platforms: Cisco 1751, Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3640, Cisco 3640A, and Cisco 3660.
12.2(17d)SXB	This command was implemented on the Supervisor Engine 2 in Cisco IOS Release 12.2(17d)SXB.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.(33)SXH.

Usage Guidelines

The IEEE 802.1x standard defines a client-server-based access control and authentication protocol that restricts unauthorized devices from connecting to a LAN through publicly accessible ports. 802.1x controls network access by creating two distinct virtual access points at each port. One access point is an uncontrolled port; the other is a controlled port. All traffic through the single port is available to both access points. 802.1x authenticates each user device that is connected to a switch port and assigns the port to a VLAN before making available any services that are offered by the switch or the LAN. Until the device is authenticated, 802.1x access control allows only Extensible Authentication Protocol (EAP) over LAN (EAPOL) traffic through the port to which the device is connected. After authentication is successful, normal traffic can pass through the port.

Note You should change the default value of this command only to adjust for unusual circumstances, such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time, that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows that the maximum number of times that the networking device will send an EAP request or identity message to the client PC is 6:

```
Router(config) configure terminal
Router(config)# interface ethernet 0
Router(config-if)# dot1x max-req 6
```

The following example shows how to set the number of times that a switch sends an EAP request or identity frame to 5 before restarting the authentication process:

```
Router(config-if)# dot1x max-req 5
```

Related Commands

Command	Description
dot1x port-control	Enables manual control of the authorization state of a controlled port.
dot1x re-authentication	Globally enables periodic reauthentication of the client PCs on the 802.1X interface.
dot1x reauthentication (EtherSwitch)	Enables periodic reauthentication of the Ethernet switch network module client on the 802.1X interface.
dot1x timeout	Sets retry timeouts.
dot1x timeout (EtherSwitch)	Sets retry timeouts for the Ethernet switch network module.

Command	Description
show dot1x	Displays details for an identity profile.
show dot1x (EtherSwitch)	Displays the 802.1X statistics, administrative status, and operational status for the device or for the specified interface.

dot1x max-start

To set the maximum number of Extensible Authentication Protocol (EAP) start frames that a supplicant sends (assuming that no response is received) to the client before concluding that the other end is 802.1X unaware, use the **dot1x max-start** command in global configuration or interface configuration mode. To remove the maximum number-of-times setting, use the **no** form of this command.

dot1x max-start *number*

no dot1x max-start

Syntax Description

number	Maximum number of times that the router sends an EAP start frame. The value is from 1 to 65535. The default is 3.

Defaults

The default maximum number setting is 3.

Command Modes

Global configuration
Interface configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.
12.4(6)T	Global configuration mode was added for this command.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time, that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows that the maximum number of EAP over LAN- (EAPOL-) Start requests has been set to 5:

```
Router (config)# interface Ethernet1
Router (config-if)# dot1x pae supplicant
Router (config-if)# dot1x max-start 5
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x pae	Sets the PAE type during 802.1X authentication.
interface	Configures an interface type.

dot1x multi-hosts

To allow multiple hosts (clients) on an 802.1X-authorized port in interface configuration command mode, use the **dot1x multi-hosts** command. Use the **no** form of this command to disallow multiple hosts.

dot1x multi-hosts

no dot1x multi-hosts

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

Before entering this command, ensure that the **dot1x port-control** command is set to **auto** for the specified interface.

Examples

This example shows how to allow multiple hosts:

```
Router(config-if)# dot1x multi-hosts
Router(config-if)#
```

This example shows how to disallow multiple hosts:

```
Router(config-if)# no dot1x multi-hosts
Router(config-if)#
```

Related Commands

Command	Description
dot1x port-control	Sets the port control value.
show dot1x	Displays 802.1X information.

dot1x multiple-hosts

Note This command was replaced by the **dot1x host-mode** command effective with Cisco IOS Release 12.1(14)EA1 and Release 12.4(6)T.

To allow multiple hosts (clients) on an 802.1X-authorized switch port that has the **dot1x port-control** interface configuration command set to **auto**, use the **dot1x multiple-hosts** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

dot1x multiple-hosts

no dot1x multiple-hosts

Syntax Description

This command has no arguments or keywords.

Defaults

Multiple hosts are disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(6)EA2	This command was introduced.
12.2(15)ZJ	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.1(14)EA1	This command was replaced by the **dot1x host-mode** command in Cisco IOS Release 12.1(14)EA1.
12.4(6)T	This command was replaced by the **dot1x host-mode** command on the T-train.

Usage Guidelines

This command is supported only on switch ports.

This command enables you to attach multiple clients to a single 802.1X-enabled port. In this mode, only one of the attached hosts must be successfully authorized for all hosts to be granted network access. If the port becomes unauthorized (reauthentication fails or an Extensible Authentication Protocol over LAN [EAPOL]-logoff message is received), all attached clients are denied access to the network.

Use the **show dot1x** (EtherSwitch) privileged EXEC command with the **interface** keyword to verify your current 802.1X multiple host settings.

Examples

The following example shows how to enable 802.1X on Fast Ethernet interface 0/1 and to allow multiple hosts:

```
Router(config)# interface fastethernet0/1
Router(config-if)# dot1x port-control auto
Router(config-if)# dot1x multiple-hosts
```

Related Commands

Command	Description
dot1x default	Enables manual control of the authorization state of the port.
show dot1x (EtherSwitch)	Displays the 802.1X statistics, administrative status, and operational status for the device or for the specified interface.

dot1x pae

To set the Port Access Entity (PAE) type, use the **dot1x pae** command in interface configuration mode. To disable the PAE type that was set, use the **no** form of this command.

dot1x pae [**supplicant | authenticator | both**]

no dot1x pae [**supplicant | authenticator | both**]

Syntax Description

supplicant	(Optional) The interface acts only as a supplicant and will not respond to messages that are meant for an authenticator.
authenticator	(Optional) The interface acts only as an authenticator and will not respond to any messages meant for a supplicant.
both	(Optional) The interface behaves both as a supplicant and as an authenticator and thus will respond to all dot1x messages.

Defaults

PAE type is not set.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If the **dot1x system-auth-control** command has not been configured, the **supplicant** keyword will be the only keyword available for use with this command. (That is, if the **dot1x system-auth-control** command has not been configured, you cannot configure the interface as an authenticator.)

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time, that is, if it is configured on Layer2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows that the interface has been set to act as a supplicant:

```
Router (config)# interface Ethernet1
```

```
Router (config-if)# dot1x pae supplicant
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x system-auth-control	Enables 802.1X SystemAuthControl (port-based authentication).
interface	Configures an interface type.

dot1x port-control

Note Effective with Cisco IOS Release 12.2(33)SXI, the **dot1x port-control** command is replaced by the **authentication port-control** command. See the **authentication port-control** command for more information.

To enable manual control of the authorization state of a controlled port, use the **dot1x port-control** command in interface configuration mode. To disable the port-control value, use the **no** form of this command.

dot1x port-control {**auto** | **force-authorized** | **force-unauthorized**}

no dot1x port-control

Syntax Description

auto	Enables 802.1X port-based authentication and causes the port to begin in the unauthorized state, allowing only Extensible Authentication Protocol over LAN (EAPOL) frames to be sent and received through the port.
force-authorized	Disables 802.1X on the interface and causes the port to change to the authorized state without any authentication exchange required. The port transmits and receives normal traffic without 802.1X-based authentication of the client. The **force-authorized** keyword is the default.
force-unauthorized	Denies all access through this interface by forcing the port to change to the unauthorized state, ignoring all attempts by the client to authenticate.

Defaults

The default is force-authorized.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(6)EA2	This command was introduced for the Cisco Ethernet switch network module.
12.1(11)AX	This command was integrated into Cisco IOS Release 12.1(11)AX.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(15)ZJ	This command was implemented on the following platforms for the Cisco Ethernet switch network module: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series.
12.3(2)XA	This command was introduced on the following Cisco Switches: Cisco 806, Cisco 831, Cisco 836, Cisco 837, Cisco 1701, Cisco 1710, Cisco 1721, Cisco 1751-V, and Cisco 1760.

Release	Modification
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T. Switch support was added for the following platforms: Cisco 1751, Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3640, Cisco 3640A, and Cisco 3660.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was added for Cisco IOS Release 12.2(17d)SXB.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Switches (ISRs) only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was replaced by the **authentication port-control** command.

Usage Guidelines

For Ethernet Switch Network Modules

The following guidelines apply to Ethernet switch network modules:

- The 802.1X protocol is supported on Layer 2 static-access ports.
- You can use the **auto** keyword only if the port is not configured as one of these types:
  - Trunk port—If you try to enable 802.1X on a trunk port, an error message appears, and 802.1X is not enabled. If you try to change the mode of an 802.1X-enabled port to trunk, the port mode is not changed.
  - EtherChannel port—Before enabling 802.1X on the port, you must first remove it from the EtherChannel. If you try to enable 802.1X on an EtherChannel or on an active port in an EtherChannel, an error appears, and 802.1X is not enabled. If you enable 802.1X on a not-yet active port of an EtherChannel, the port does not join the EtherChannel.
  - Switch Port Analyzer (SPAN) destination port—You can enable 802.1X on a port that is a SPAN destination port; however, 802.1X is disabled until the port is removed as a SPAN destination. You can enable 802.1X on a SPAN source port.

To globally disable 802.1X on the device, you must disable it on each port. There is no global configuration command for this task.

For Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time; that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Verifying Settings

You can verify your settings by entering the **show dot1x** command and checking the Status column in the 802.1X Port Summary section of the display. An enabled status means that the port-control value is set to auto or to force-unauthorized.

Examples

The following example shows that the authentication status of the client PC will be determined by the authentication process:

```
Switch(config)# configure terminal
Switch(config)# interface ethernet 0
Switch(config-if)# dot1x port-control auto
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x max-req	Sets the maximum number of times that a switch or Ethernet switch network module can send an EAP request/identity frame to a client (assuming that a response is not received) before restarting the authentication process.
dot1x re-authentication	Globally enables periodic reauthentication of the client on the 802.1X interface.
dot1x reauthentication (EtherSwitch)	Enables periodic reauthentication of the client on the 802.1X interface.
dot1x timeout	Sets retry timeouts.
dot1x timeout (EtherSwitch)	Sets retry timeouts for the Ethernet switch network module.
show dot1x	Displays details for an identity profile.
show dot1x (EtherSwitch)	Displays the 802.1X statistics, administrative status, and operational status for the switch or for the specified interface.

dot1x re-authenticate (EtherSwitch)

To manually initiate a reauthentication of all 802.1X-enabled ports or the specified 802.1X-enabled port on a router with an Ethernet switch network module installed, use the **dot1x re-authenticate** command in privileged EXEC mode.

dot1x re-authenticate [**interface** *interface-type interface-number*]

Syntax Description

interface *interface-type interface-number*	(Optional) Specifies the slot and port number of the interface to reauthenticate.

Defaults

There is no default setting.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(6)EA2	This command was introduced.
12.2(15)ZJ	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.

Usage Guidelines

You can use this command to reauthenticate a client without waiting for the configured number of seconds between reauthentication attempts (reauthperiod) and automatic reauthentication.

Examples

The following example shows how to manually reauthenticate the device connected to Fast Ethernet interface 0/1:

```
Router# dot1x re-authenticate interface fastethernet 0/1
Starting reauthentication on FastEthernet0/1.
```

dot1x re-authenticate (privileged EXEC)

Note Effective with Cisco IOS Release 12.2(33)SXI, the **dot1x re-authenticate** command is replaced by the **clear authentication session** command. See the **clear authentication session** command for more information.

To manually initiate a reauthentication of the specified 802.1X-enabled ports, use the **dot1x re-authenticate** command in privileged EXEC mode.

dot1x re-authenticate [**interface** *interface-name interface-number*]

Syntax Description

interface *interface-name interface-number*	(Optional) Interface on which reauthentication is to be initiated.

Command Default

There is no default setting.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(11)AX	This command was introduced.
12.3(2)XA	This command was integrated into Cisco IOS Release12.3(2)XA.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.

Usage Guidelines

You can use this command to reauthenticate a client without having to wait for the configured number of seconds between reauthentication attempts (re-authperiod) and automatic reauthentication.

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time, that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows how to manually reauthenticate the device that is connected to a port:

```
Router# dot1x re-authenticate interface gigabitethernet2/0/1
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x reauthentication	Globally enables periodic reauthentication of the client PCs on the 802.1X interface.
dot1x timeout	Sets retry timeouts.

dot1x reauthentication

Note Effective with Cisco IOS Release 12.2(33)SXI, the **dot1x reauthentication** command is replaced by the **authentication periodic** command. See the **authentication periodic** command for more information.

To enable periodic reauthentication of the client PCs on the 802.1X interface, use the **dot1x reauthentication** command in interface configuration mode. To disable periodic reauthentication, use the **no** form of this command.

dot1x reauthentication

no dot1x reauthentication

Syntax Description

This command has no arguments or keywords.

Defaults

Periodic reauthentication is not set.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.3(2)XA	This command was integrated into Cisco IOS Release 12.3(2)XA.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.2(17d)SXB	This command was implemented on the Supervisor Engine 2 in Cisco IOS Release 12.2(17d)SXB.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Routers (ISRs) only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was replaced by the **authentication periodic** command.

Usage Guidelines

The reauthentication period can be set using the **dot1x timeout** command.

Cisco IOS Release 12.4(4)XC

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time; that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Examples

The following example shows that reauthentication has been enabled and the reauthentication period as been set for 1800 seconds:

```
Router(config)# configure terminal
Router(config)# interface ethernet 0
Router(config-if)# dot1x reauthentication
Router(config-if)# dot1x timeout reauth-period 1800
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)X

The following example shows Layer 3 802.1X support on a switched virtual interface using a Cisco 870 ISR:

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Cisco 7600 Series

The following example shows how to enable periodic reauthentication of the client:

```
Router(config-if)# dot1x reauthentication
Router(config-if)#
```

The following example shows how to disable periodic reauthentication of the client:

```
Router(config-if)# no dot1x reauthentication
Router(config-if)#
```

Related Commands

Command	Description
dot1x max-req	Sets the maximum number of times that a router can send an EAP request/identity frame to a client PC (assuming that a response is not received) before concluding that the client PC does not support 802.1X.
dot1x port-control	Sets an 802.1X port control value.
dot1x timeout	Sets retry timeouts.
show dot1x	Displays 802.1X information.

dot1x re-authentication (EtherSwitch)

To enable periodic reauthentication of the client for an Ethernet switch network module, use the **dot1x re-authentication** command in global configuration mode. To disable periodic reauthentication, use the **no** form of this command.

dot1x re-authentication

no dot1x re-authentication

Syntax Description

This command has no arguments or keywords.

Defaults

Periodic reauthentication is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(6)EA2	This command was introduced.
12.2(15)ZJ	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.

Usage Guidelines

You configure the amount of time between periodic reauthentication attempts by using the **dot1x timeout re-authperiod** global configuration command.

Examples

The following example shows how to disable periodic reauthentication of the client:

```
Router(config)# no dot1x re-authentication
```

The following example shows how to enable periodic reauthentication and set the number of seconds between reauthentication attempts to 4000 seconds:

```
Router(config)# dot1x re-authentication
Router(config)# dot1x timeout re-authperiod 4000
```

Related Commands

Command	Description
dot1x timeout (EtherSwitch)	Sets retry timeouts for the Ethernet switch network module.
show dot1x (EtherSwitch)	Displays the 802.1X statistics, administrative status, and operational status for the device or for the specified interface.

dot1x supplicant interface

To configure the dot1x supplicant for a given interface, use the **dot1x supplicant interface** command in privileged EXEC mode. To disable the configuration, use the **no** form of this command.

dot1x supplicant {**start** | **stop**} *profile-name* **interface** *type number*

Syntax Description

start	Starts the supplicant for a given interface.
stop	Stops the supplicant for a given interface.
profile-name	Profile name.
type number	Interface type and number.

Command Default

The dot1x supplicant interface is not configured.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows how to configure the dot1x supplicant for a Gigabit Ethernet interface:

```
Router# dot1x supplicant start n1 interface GigabitEthernet 0/0/1
```

Related Commands

Command	Description
dot1x default	Resets the global 802.1X authentication parameters to their default values as specified in the latest IEEE 802.1X standard.

dot1x system-auth-control

To globally enable 802.1X SystemAuthControl (port-based authentication), use the **dot1x system-auth-control** command in global configuration mode. To disable SystemAuthControl, use the **no** form of this command.

dot1x system-auth-control

no dot1x system-auth-control

Syntax Description

This command has no arguments or keywords.

Defaults

System authentication is disabled by default. If this command is disabled, all ports behave as if they are force authorized.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(2)XA	This command was introduced.
12.2(14)SX	This command was implemented on the Supervisor Engine 720.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

The IEEE 802.1x standard defines a client-server-based access control and authentication protocol that restricts unauthorized devices from connecting to a LAN through publicly accessible ports. 802.1x controls network access by creating two distinct virtual access points at each port. One access point is an uncontrolled port; the other is a controlled port. All traffic through the single port is available to both access points. 802.1x authenticates each user device that is connected to a switch port and assigns the port to a VLAN before making available any services that are offered by the switch or the LAN. Until the device is authenticated, 802.1x access control allows only Extensible Authentication Protocol (EAP) over LAN (EAPOL) traffic through the port to which the device is connected. After authentication is successful, normal traffic can pass through the port.

The **no** form of the command removes any 802.1X-related configurations.

Catalyst 6500 Series Switch and Cisco 7600 Series

You must enable Authentication, Authorization, and Accounting (AAA) and specify the authentication method list before enabling 802.1X. A method list describes the sequence and authentication methods to be queried to authenticate a user.

Examples

The following example shows how to enable SystemAuthControl:

```
Router(config)# dot1x system-auth-control
```

Related Commands

Command	Description
aaa authentication dot1x	Specifies one or more AAA methods for use on interfaces running IEEE 802.1X.
aaa new-model	Enables the AAA access-control model.
debug dot1x	Displays 802.1X debugging information.
description	Specifies a description for an 802.1X profile.
device	Statically authorizes or rejects individual devices.
dot1x initialize	Initializes 802.1X state machines on all 802.1X-enabled interfaces.
dot1x max-req	Sets the maximum number of times that a router or Ethernet switch network module can send an EAP request/identity frame to a client (assuming that a response is not received) before restarting the authentication process.
dot1x port-control	Enables manual control of the authorized state of a controlled port.
dot1x re-authenticate	Manually initiates a reauthentication of the specified 802.1X-enabled ports.
dot1x reauthentication	Globally enables periodic reauthentication of the client PCs on the 802.1X interface.
dot1x timeout	Sets retry timeouts.
identity profile	Creates an identity profile and enters identity profile configuration mode.
show dot1x	Displays details and statistics for an identity profile.
template	Specifies a virtual template from which commands may be cloned.

dot1x timeout

To configure the value for retry timeouts, use the **dot1x timeout** command in global configuration or interface configuration mode. To return to the default value for retry timeouts to, use the **no** form of this command.

All Platforms Except the Cisco 7600 Series Switch

dot1x timeout {**auth-period** *seconds* | **held-period** *seconds* | **quiet-period** *seconds* | **ratelimit-period** *seconds* | **reauth-period** {*seconds* | **server**} | **server-timeout** *seconds* | **start-period** *seconds* | **supp-timeout** *seconds* | **tx-period** *seconds*}

no dot1x timeout {**auth-period** *seconds* | **held-period** *seconds* | **quiet-period** *seconds* | **ratelimit-period** *seconds* | **reauth-period** {*seconds* | **server**} | **server-timeout** *seconds* | **start-period** *seconds* | **supp-timeout** *seconds* | **tx-period** *seconds*}

Cisco 7600 Series Switch

dot1x timeout {**reauth-period** *seconds* | **quiet-period** *seconds* | **tx-period** *seconds* | **supp-timeout** *seconds* | **server-timeout** *seconds*}

no dot1x timeout {**reauth-period** | **quiet-period** | **tx-period** | **supp-timeout** | **server-timeout**}

Syntax Description

auth-period *seconds*	Configures the time, in seconds, the supplicant (client) waits for a response from an authenticator (for packets other than Extensible Authentication Protocol over LAN [EAPOL]-Start) before timing out. • The range is from 1 to 65535. The default is 30.
held-period *seconds*	Configures the time, in seconds for which a supplicant will stay in the HELD state (that is, the length of time it will wait before trying to send the credentials again after a failed attempt). • The range is from 1 to 65535. The default is 60.
quiet-period *seconds*	Configures the time, in seconds, that the authenticator (server) remains quiet (in the HELD state) following a failed authentication exchange before trying to reauthenticate the client. • For all platforms except the Cisco 7600 series Switch, the range is from 1 to 65535. The default is 120. • For the Cisco 7600 series Switch, the range is from 0 to 65535. The default is 60.
ratelimit-period *seconds*	Throttles the EAP-START packets that are sent from misbehaving client PCs (for example, PCs that send EAP-START packets that result in the wasting of switch processing power). • The authenticator ignores EAPOL-Start packets from clients that have successfully authenticated for the rate-limit period duration. • The range is from 1 to 65535. By default, rate limiting is disabled.

reauth-period {*seconds* | **server**}	Configures the time, in seconds, after which an automatic reauthentication should be initiated. • The **server** keyword indicates that the reauthentication period value for the client should be obtained from the authentication, authorization, and accounting (AAA) server as the Session-Timeout (RADIUS Attribute 27) value. If the **server** keyword is used, the action upon reauthentication is also decided by the server and sent as the Termination-Action (RADIUS Attribute 29) value. The termination action could be either "terminate" or "reauthenticate." If the **server** keyword is not used, the termination action is always "reauthenticate." • For all platforms except the Cisco 7600 series switch, the range is from 1 to 65535. The default is 3600. • For the Cisco 7600 series switch, the range is from 1 to 4294967295. The default is 3600. See the "Usage Guidelines" section for additional information. **Note** Effective with Cisco IOS Release 12.2(33)SXI, this phrase is replaced by the **authentication timer reauthenticate** command. See the **authentication timer reauthenticate** command for more information.
server-timeout *seconds*	Configures the interval, in seconds, between two successive EAPOL-Start frames when they are being retransmitted. • For all platforms except the Cisco 7600 series switch, the range is from 1 to 65535. The default is 30. • For the Cisco 7600 series switch, the range is from 30 to 65535. The default is 30. If the server does not send a response to an 802.1X packet within the specified period, the packet is sent again.
start-period *seconds*	Configures the interval, in seconds, between two successive EAPOL-Start frames when they are being retransmitted. • The value is from 1 to 65535. The default is 30.
supp-timeout *seconds*	Sets the authenticator-to-supplicant retransmission time for all EAP messages other than EAP Request ID. • For all platforms except the Cisco 7600 series Switch, the range is from 1 to 65535. The default is 30. • For the Cisco 7600 series Switch, the range is from 30 to 65535. The default is 30.
tx-period *seconds*	Configures the number of seconds between retransmission of EAP request ID packets (assuming that no response is received) to the client. • For all platforms except the Cisco 7600 series switch, the range is from 1 to 65535. The default is 30. • For the Cisco 7600 series switch, the range is from 30 to 65535. The default is 30. • If an 802.1X packet is sent to the supplicant and the supplicant does not send a response after the retry period, the packet will be sent again.

Defaults

Periodic reauthentication and periodic rate-limiting are not done.

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.3(2)XA	This command was integrated into Cisco IOS Release 12.3(2)XA.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.2(18)SE	Ranges for the **server-timeout**, **supp-timeout**, and **tx-period** keywords were changed.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was added for Cisco IOS Release 12.2(17d)SXB.
12.3(11)T	The **auth-period**, **held-period**, and **start-period** keywords were added.
12.2(25)SEC	The range for the **tx-period** keyword was changed, and the **reauth-period** and **server-timeout** keywords were added.
12.1(11)AX	This command was introduced.
12.1(14)EA1	The **supp-timeout** and **server-timeout** keywords were added. The configuration mode for the command was changed to interface configuration mode.
12.4(6)T	The **supp-timeout** keyword was added, and this command was integrated into Cisco IOS Release 12.4(6)T.
12.4(4)XC	This command was integrated into Cisco IOS Release 12.4(4)XC for Cisco 870 Integrated Services Switches (ISRs) only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	The **reauth-period** keyword was replaced by the **authentication timer reauthenticate** command.

Usage Guidelines

For Cisco IOS Release 12.4(4)XC, on Cisco 870 ISRs only, this command can be configured on Layer 2 (for switch ports) and Layer 3 (for switched virtual interfaces). However, the command can function at only one layer at a time; that is, if it is configured on Layer 2, it cannot also be configured on Layer 3 and vice versa.

Cisco 7600 Switch

You must enable periodic reauthentication before you enter the **dot1x timeout reauth-period** command. Enter the **dot1x reauthentication** command to enable periodic reauthentication. The **dot1x timeout reauth-period** command affects the behavior of the system only if periodic reauthentication is enabled.

Examples

The following example shows that various 802.1X retransmission and timeout periods have been set:

```
Switch(config)# configure terminal
Switch(config)# interface ethernet 0
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x reauthentication
Switch(config-if)# dot1x timeout auth-period 2000
Switch(config-if)# dot1x timeout held-period 2400
Switch(config-if)# dot1x timeout reauth-period 1800
Switch(config-if)# dot1x timeout quiet-period 600
Switch(config-if)# dot1x timeout start-period 90
Switch(config-if)# dot1x timeout supp-timeout 300
Switch(config-if)# dot1x timeout tx-period 60
Switch(config-if)# dot1x timeout server-timeout 60
```

The following example shows how to return to the default reauthorization period:

```
Switch(config-if)# no dot1x timeout reauth-period
```

Cisco 7600 Switch

The following example shows how to set 802.1X retransmission and timeout periods on the Cisco 7600 Switch:

```
Switch(config-if)# dot1x timeout reauth-period 4000
Switch(config-if)# dot1x timeout tx-period 60
Switch(config-if)# dot1x timeout supp-timeout 25
Switch(config-if)# dot1x timeout server-timeout 25
```

802.1X Support on a Cisco 870 ISR for Cisco IOS Release 12.4(4)XC

The following example shows Layer 3 802.1X support on a switched virtual interface (using a Cisco 870 ISR):

```
interface FastEthernet0
 description  switchport connect to a client
!
interface FastEthernet1
 description  switchport connect to a client
!
interface FastEthernet2
 description  switchport connect to a client
!
interface FastEthernet3
 description  switchport connect to a client
!
interface FastEthernet4
 description  Connect to the public network
!
interface Vlan1
 description  Apply 802.1x functionality on SVI
 dot1x pae authenticator
 dot1x port-control auto
 dot1x reauthentication
```

Related Commands

Command	Description
dot1x max-req	Sets the maximum number of times that a switch or Ethernet switch module can send an EAP request/identity frame to a client (assuming that a response is not received) before restarting the authentication process.
dot1x port-control	Sets an 802.1X port control value.

Command	Description
dot1x re-authentication	Globally enables periodic reauthentication of the client PCs on the 802.1X interface.
show dot1x	Displays 802.1X information.

dot1x timeout (EtherSwitch)

To set the number of retry seconds between 802.1X authentication exchanges when an Ethernet switch network module is installed in the router, use the **dot1x timeout** command in global configuration mode. To return to the default setting, use the **no** form of this command.

dot1x timeout {**quiet-period** *seconds* | **re-authperiod** *seconds* | **tx-period** *seconds*}

no dot1x timeout {**quiet-period** *seconds* | **re-authperiod** *seconds* | **tx-period** *seconds*}

Syntax Description

quiet-period *seconds*	Specifies the time in seconds that the Ethernet switch network module remains in the quiet state following a failed authentication exchange with the client. The range is from 0 to 65535 seconds. The default is 60 seconds.
re-authperiod *seconds*	Specifies the number of seconds between reauthentication attempts. The range is from 1 to 4294967295. The default is 3660 seconds.
tx-period *seconds*	Time in seconds that the switch should wait for a response to an EAP-request/identity frame from the client before retransmitting the request. The range is from 1 to 65535 seconds. The default is 30 seconds.

Defaults

quiet-period: 60 seconds
re-authperiod: 3660 seconds
tx-period: 30 seconds

Command Modes

Global configuration

Command History

Release	Modification
12.1(6)EA2	This command was introduced.
12.2(15)ZJ	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.

Usage Guidelines

You should change the default values of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients or authentication servers.

quiet-period Keyword

During the quiet period, the Ethernet switch network module does not accept or initiate any authentication requests. If you want to provide a faster response time to the user, enter a smaller number than the default.

re-authperiod Keyword

The **re-authperiod** keyword affects the behavior of the the Ethernet switch network module only if you have enabled periodic reauthentication by using the **dot1x re-authentication** global configuration command.

Examples

The following example shows how to set the quiet time on the switch to 30 seconds:

```
Router(config)# dot1x timeout quiet-period 30
```

The following example shows how to enable periodic reauthentication and set the number of seconds between reauthentication attempts to 4000 seconds:

```
Router(config)# dot1x re-authentication
Router(config)# dot1x timeout re-authperiod 4000
```

The following example shows how to set 60 seconds as the amount of time that the switch waits for a response to an EAP-request/identity frame from the client before retransmitting the request:

```
Router(config)# dot1x timeout tx-period 60
```

Related Commands

Command	Description
dot1x max-req	Sets the maximum number of times that the device sends an EAP-request/identity frame before restarting the authentication process.
dot1x re-authentication (EtherSwitch)	Enables periodic reauthentication of the client for the Ethernet switch network module.
show dot1x (EtherSwitch)	Displays the 802.1X statistics, administrative status, and operational status for the device or for the specified interface.

dpd

To configure Dead Peer Detection (DPD), use the **dpd** command in IKEv2 profile configuration mode. To delete DPD, use the **no** form of this command.

dpd *interval retry-interval* {**on-demand** | **periodic**}

no dpd

Syntax Description

interval	Specifies the keepalive interval in seconds. The range is 10 to 3600.
retry-interval	Specifies the retry interval in seconds when there is no reply from the peer.
on-demand	Specifies the on-demand mode to send the keepalive only in the absence of any incoming data traffic, to check the liveness of the peer before sending any data.
periodic	Specifies the periodic mode to send keepalives regularly at a specified interval.

Command Default

DPD is disabled by default.

Command Modes

IKEv2 profile configuration (config-ikev2-profile)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to configure DPD globally for peers matching a profile. The DPD configuration in an Internet Key Exchange Version 2 (IKEv2) profile overrides the global DPD configuration.

Examples

The following example shows how to configure the periodic mode for DPD:

```
Router(config)# crypto ikev2 profile prf1
Router(config-ikev2-profile)# dpd 1000 250 periodic
```

Related Commands

Command	Description
crypto ikev2 dpd	Defines DPD globally for all peers.
crypto ikev2 profile	Defines IKEv2 profile.

drop (type access-control)

To configure a traffic class to discard packets belonging to a specific class, use the **drop** command in policy-map class configuration mode. To disable the packet discarding action in a traffic class, use the **no** form of this command.

drop [**all**]

no drop [**all**]

Syntax Description

all	(Optional) Discards the entire stream of packets belonging to the traffic class.

Defaults

The packet discarding action in a traffic class is disabled.

Command Modes

Policy-map class configuration (config-pmap-c)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Once the match criteria are applied to packets belonging to the specific traffic class using the **match class session** command in a class map, these packets can be discarded by configuring the **drop** command with the **all** keyword in a policy map. Packets match only on the packet session (flow) entry of the Flexible Packet Matching (FPM) access control list (ACL) pattern matching tool, and skip user-configured classification filters. When the **drop** command is specified with the **all** keyword, this command can only be associated with a class map that was created with the **class-map** command and **type access-control** keyword and used in a policy map that can be attached to one or more interfaces to specify a service policy that is created with the **policy-map** command and **type access-control** keyword.

Examples

The following example shows how to create and configure a traffic class called class1 for use in a policy map called **policy1**. The policy map (service policy) is attached to output serial interface 2/0. All packets that match access group 101 are placed in class1. Packets that belong to this class are discarded.

```
Router(config)# class-map class1
Router(config-cmap)# match access-group 101
Router(config-cmap)# exit
Router(config)# policy-map policy1
Router(config-pmap)# class class1
Router(config-pmap-c)# drop
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface serial2/0
Router(config-if)# service-policy output policy1
Router(config-if)# end
```

The following example shows how to configure a class map and policy map to specify the protocol stack class, the match criteria and action to take, and a combination of classes using session-based (flow-based) and nonsession-based actions. The **drop all** command is associated with the action to be taken on the policy.

```
Router(config)# class-map type access-control match-all my-HTTP
Router(config-cm)# match field tcp destport eq 8080
Router(config-cm)# match start tcp payload-start offset 20 size 10 regex "GET"

Router(config)# class-map type access-control match-all my-FTP
Router(config-cmap)# match field tcp destport eq 21

Router(config)# class-map type access-control match all class1
Router(config-cmap)# match class my-HTTP session
Router(config-cmap)# match start tcp payload-start offset 40 size 20 regex "abc.*def"

Router(config)# policy-map type access-control my_http_policy
Router(config-pmap)# class class1
Router(config-pmap-c)# drop all

Router(config)# interface gigabitEthernet 0/1
Router(config-if)# service-policy type access-control input my_http_policy
```

Related Commands

Command	Description
class	Specifies the name of a predefined traffic class, which was configured with the **class-map** command. The **class** command also classifies traffic to the traffic policy and enters policy-map class configuration mode.
class-map type access-control	Creates a class map to be used for matching packets to a specified class and enters class-map configuration mode for determining the exact pattern to look for in the protocol stack of interest.
log	Generates log messages for a predefined traffic class.
match class session	Configures match criteria for a class map used to identify a session (flow) containing packets of interest, which is then applied to all packets transmitted during the session.
policy-map type access-control	Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy, and enters policy-map configuration mode.
show class-map	Displays all class maps and their matching criteria.
show policy-map	Displays the configuration of all classes for a specified service policy map or all classes for all existing policy maps.
show policy-map interface	Displays the packet statistics of all classes that are configured for all service policies either on the specified interface or subinterface or on a specific PVC on the interface.

drop (zone-based policy)

To drop packets that are sent to the router, use the **drop** command in policy-map-class configuration mode.

drop [**log**]

Syntax Description

log	(Optional) Displays logging messages about dropped packets.

Command Default

Packets are not dropped.

Command Modes

Policy-map-class configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.
15.1(1)S	This command was introduced into Cisco IOS Release 15.1(1)S.

Usage Guidelines

You can use this command only after entering the **policy-map type inspect** and **class type inspect** commands.

Examples

The following example creates an inspect policy map named p1 and specifies that packets will be dropped on the traffic at c1:

```
policy-map type inspect p1
 class type inspect c1
  drop
```

The following example defines a policy map that will drop HTTP traffic:

```
access-list 101 permit ip 192.168.1 0.0.0.255 any
 class-map type inspect match-all c1
  match access-group 101
  match protocol http
policy-map type inspect p1
 class type inspect c1
 drop
```

Related Commands

Command	Description
class type inspect	Specifies the traffic (class) on which an action is to be performed.
policy-map type inspect	Creates Layer 3 and Layer 4 inspect type policy maps.

dtls port

To configure a desired port for the Datagram Transport Layer Security (DTLS) to listen, use the **dtls port** command in WebVPN gateway configuration mode. To disable the port, use the **no** form of this command.

dtls port *port-number*

no dtls port *port-number*

Syntax Description

port-number	DTLS port number. Range: 1025 to 65535. Default: 443.

Command Default

The default DTLS port is 443.

Command Modes

WebVPN gateway configuration (config-webvpn-gateway)

Command History

Release	Modification
15.1(2)T	This command was introduced.

Usage Guidelines

DTLS listens on port 443 by default. You can configure the desired DTLS port using the **dtls port** command.

Examples

The following example shows how to configure 1055 as the DTLS port for a WebVPN gateway "gateway1":

```
Router# configure terminal
Router(config)# webvpn gateway gateway1
Router(config-webvpn-gateway)# dtls port 1055
```

Related Commands

Command	Description
svc dtls	Enables DTLS support on the Cisco IOS SSL VPN.

dynamic

To define a named dynamic IP access list, use the **dynamic** command in access-list configuration mode. To remove the access lists, use the **no** form of this command.

dynamic *dynamic-name* [**timeout** *minutes*] {**deny** | **permit**} *protocol source source-wildcard destination destination-wildcard* [**precedence** *precedence*] [**tos** *tos*] [**log**] [**fragments**]

no dynamic *dynamic-name*

Internet Control Message Protocol (ICMP)

dynamic *dynamic-name* [**timeout** *minutes*] {**deny** | **permit**} **icmp** *source source-wildcard destination destination-wildcard* [*icmp-type* [*icmp-code*] | *icmp-message*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**fragments**]

Internet Group Management Protocol (IGMP)

dynamic *dynamic-name* [**timeout** *minutes*] {**deny** | **permit**} **igmp** *source source-wildcard destination destination-wildcard* [*igmp-type*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**fragments**]

Transmission Control Protocol (TCP)

dynamic *dynamic-name* [**timeout** *minutes*] {**deny** | **permit**} **tcp** *source source-wildcard* [*operator* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**established**] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**fragments**]

User Datagram Protocol (UDP)

dynamic *dynamic-name* [**timeout** *minutes*] {**deny** | **permit**} **udp** *source source-wildcard* [*operator* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**fragments**]

Syntax Description

dynamic-name	Identifies this access list as a dynamic access list. Refer to lock-and-key access documented in the "Configuring Lock-and-Key Security (Dynamic Access Lists)" chapter in the *Cisco IOS Security Configuration Guide*.
timeout *minutes*	(Optional) Specifies the absolute length of time (in minutes) that a temporary access-list entry can remain in a dynamic access list. The default is an infinite length of time and allows an entry to remain permanently. Refer to lock-and-key access documented in the "Configuring Lock-and-Key Security (Dynamic Access Lists)" chapter in the *Cisco IOS Security Configuration Guide*.
deny	Denies access if the conditions are matched.
permit	Permits access if the conditions are matched.
protocol	Name or number of an Internet protocol. It can be one of the keywords **eigrp**, **gre**, **icmp**, **igmp**, **ip**, **ipinip**, **nos**, **ospf**, **tcp**, or **udp**, or an integer in the range from 0 to 255 representing an Internet protocol number. To match any Internet protocol (including ICMP, TCP, and UDP), use the **ip** keyword. Some protocols allow further qualifiers described later.

source	Number of the network or host from which the packet is being sent. There are three alternative ways to specify the source: • Use a 32-bit quantity in four-part, dotted decimal format. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *source* as an abbreviation for a *source* and *source-wildcard* of *source* 0.0.0.0.
source-wildcard	Wildcard bits to be applied to source. There are three alternative ways to specify the source wildcard: • Use a 32-bit quantity in four-part, dotted decimal format. Place 1s in the bit positions you want to ignore. • Use the **any** keyword as an abbreviation for a *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *source* as an abbreviation for a *source* and *source-wildcard* of *source* 0.0.0.0.
destination	Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination: • Use a 32-bit quantity in four-part, dotted decimal format. • Use the **any** keyword as an abbreviation for the *destination* and *destination-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *destination* as an abbreviation for a *destination* and *destination-wildcard* of *destination* 0.0.0.0.
destination-wildcard	Wildcard bits to be applied to the destination. There are three alternative ways to specify the destination wildcard: • Use a 32-bit quantity in four-part, dotted-decimal format. Place 1s in the bit positions you want to ignore. • Use the **any** keyword as an abbreviation for a *destination* and *destination-wildcard* of 0.0.0.0 255.255.255.255. • Use **host** *destination* as an abbreviation for a *destination* and *destination-wildcard* of *destination* 0.0.0.0.
precedence *precedence*	(Optional) Packets can be filtered by precedence level, as specified by a number from 0 to 7, or by name as listed in the section “Usage Guidelines.”
tos *tos*	(Optional) Packets can be filtered by type of service (ToS) level, as specified by a number from 0 to 15, or by name as listed in the section “Usage Guidelines.”

log	(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the **logging console** command.) The message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval. The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.
fragments	(Optional) The access-list entry applies to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the **fragments** keyword, see the "Access List Processing of Fragments" and "Fragments and Policy Routing" sections in the "Usage Guidelines" section.
icmp-type	(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.
icmp-code	(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.
icmp-message	(Optional) ICMP packets can be filtered by an ICMP message type name or ICMP message type and code name. The possible names are found in the section "Usage Guidelines."
igmp-type	(Optional) IGMP packets can be filtered by IGMP message type or message name. A message type is a number from 0 to 15. IGMP message names are listed in the section "Usage Guidelines."
operator	(Optional) Compares source or destination ports. Possible operands include **lt** (less than), **gt** (greater than), **eq** (equal), **neq** (not equal), and **range** (inclusive range). If the operator is positioned after the *source* and *source-wildcard*, it must match the source port. If the operator is positioned after the *destination* and *destination-wildcard*, it must match the destination port. The **range** operator requires two port numbers. All other operators require one port number.
port	(Optional) The decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the section "Usage Guidelines" of the **access-list** (IP extended) command. TCP port names can only be used when filtering TCP. UDP port names can only be used when filtering UDP.
established	(Optional) For the TCP protocol only: Indicates an established connection. A match occurs if the TCP datagram has the ACK or RST bits set. The nonmatching case is that of the initial TCP datagram to form a connection.

Defaults

An extended access list defaults to a list that denies everything. An extended access list is terminated by an implicit deny statement.

Command Modes

Access-list configuration

Command History

Release	Modification
11.2	This command was introduced.
12.0(11)	The **fragments** keyword was added.
12.2(13)T	The **igrp** keyword was removed because the IGRP protocol is no longer available in Cisco IOS software.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can use named access lists to control the transmission of packets on an interface and restrict contents of routing updates. The Cisco IOS software stops checking the extended access list after a match occurs.

Fragmented IP packets, other than the initial fragment, are immediately accepted by any extended IP access list. Extended access lists used to control vty access or restrict the contents of routing updates must not match against the TCP source port, the ToS value, or the precedence of the packet.

Note Named IP access lists will not be recognized by any software release prior to Cisco IOS Release 11.2.

Note After an access list is created, any subsequent additions (possibly entered from the terminal) are placed at the end of the list. In other words, you cannot selectively add or remove access list command lines from a specific access list.

The following is a list of precedence names:

- **critical**
- **flash**
- **flash-override**
- **immediate**
- **internet**

Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the **fragments** keyword can be summarized as follows:

If the Access-List Entry has...	Then..
...no **fragments** keyword (the default behavior), and assuming all of the access-list entry information matches,	For an access-list entry containing only Layer 3 information: • The entry is applied to nonfragmented packets, initial fragments and noninitial fragments. For an access-list entry containing Layer 3 and Layer 4 information: • The entry is applied to nonfragmented packets and initial fragments. – If the entry is a **permit** statement, the packet or fragment is permitted. – If the entry is a **deny** statement, the packet or fragment is denied. • The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and – If the entry is a **permit** statement, the noninitial fragment is permitted. – If the entry is a **deny** statement, the next access-list entry is processed. **Note** The **deny** statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.
...the **fragments** keyword, and assuming all of the access-list entry information matches,	**Note** The access-list entry is applied only to noninitial fragments.The **fragments** keyword cannot be configured for an access-list entry that contains any Layer 4 information.

Be aware that you should not simply add the **fragments** keyword to every access-list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword, the packet is compared to the next access-list entry, and so on, until it is either permitted or denied by an access-list entry that does not contain the **fragments** keyword. Therefore, you may need two access-list entries for every **deny** entry. The first **deny** entry of the pair will not include the **fragments** keyword, and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases where there are multiple **deny** access-list entries for the same host but with different Layer 4 ports, a single **deny** access-list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

Note The **fragments** keyword cannot solve all cases involving access lists and IP fragments.

Fragments and Policy Routing

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address** command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the **fragments** keyword in access-list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

Examples

The following example defines a dynamic access list named abclist:

```
ip access-group abclist in
!
ip access-list extended abclist
 dynamic testlist timeout 5
 permit ip any any
 permit tcp any host 10.302.21.2 eq 23
```

Related Commands

Command	Description
clear access-template	Clears a temporary access-list entry from a dynamic access list manually.
distribute-list in (IP)	Filters networks received in updates.
distribute-list out (IP)	Suppresses networks from being advertised in updates.
ip access-group	Controls access to an interface.
ip access-list	Defines an IP access list by name.
logging console	Limits messages logged to the console based on severity.
show access-lists	Displays the contents of current IP and rate-limit access lists.
show ip access-list	Displays the contents of all current IP access lists.

eap

Note This command is removed effective with Cisco IOS Release 12.4(6)T.

To specify Extensible Authentication Protocol- (EAP-) specific parameters, use the **eap** command in identity profile configuration mode. To disable the parameters that were set, use the **no** form of this command.

eap {**username** *name* | **password** *password*}

no eap {**username** *name* | **password** *password*}

Syntax Description

username *name*	Username that will be sent to Request-Id packets.
password *password*	Password that should be used when replying to an Message Digest 5 (MD5) challenge.

Defaults

EAP parameters are not set.

Command Modes

Identity profile configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.
12.4(6)T	This command was removed.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command if your router is configured as a supplicant. This command provides the means for configuring the identity and the EAP MD5 password that will be used by 802.1X to authenticate.

Examples

The following example shows that the EAP username “user1” has been configured:

```
Router (config)# identity profile dot1x
Router (config-identity-prof)# eap username user1
```

Related Commands

Command	Description
identity profile	Creates an identity profile.

eap (IKEv2 profile)

To derive the name mangler from the remote identity of type Extensible Authentication Protocol (EAP), use the **eap** command in IKEv2 name mangler configuration mode. To remove the name derived from EAP, use the **no** form of this command.

eap {**all** | **dn** {**common-name** | **country** | **domain** | **locality** | **organization** | **organization-unit** | **state**} {**prefix** | **suffix** {**delimiter** {**.** | **@** | ****}}}

no eap

Syntax Description

all	Derives the name mangler from the entire EAP identity.
dn	Derives the name from identities of type DN in EAP.
common-name	Derives the name from the common name portion in the DN.
country	Derives the name from the country name specified in the DN.
domain	Derives the name from the domain name specified in the DN.
locality	Derives the name from the locality specified in the DN.
organization	Derives the name from the organization specified in the DN.
organization-unit	Derives the name from the organization-unit specified in the DN.
state	Derives the name from the state name specified in the DN.
prefix	Derives the name from the prefix in EAP.
suffix	Derives the name from the suffix in EAP.
delimiter {**.** | **@** | ****}	Refers to the specified delimiter in the prefix or suffix.

Command Default

No default behavior or values.

Command Modes

IKEv2 name mangler configuration (config-ikev2-name-mangler)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to derive the name mangler from any field in the remote identity of type EAP.

Examples

The following example shows how to derive a name for the name mangler from a specific delimiter in EAP prefix:

```
Router(config)# crypto ikev2 name-mangler mangler2
Router(config-ikev2-name-mangler)# eap prefix delimiter @
```

Related Commands

Command	Description
crypto ikev2 name mangler	Defines a name mangler.

eckeypair

To configure the trustpoint to use an Elliptic Curve (EC) key on which certificate requests are generated using ECDSA signatures, use the **eckeypair** command in ca-trustpoint configuration mode. To remove the encryption key, use the **no** form of this command.

eckeypair *label*

no eckeypair *label*

Syntax Description

label	Specifies the EC key label that is configured using the **crypto key generate rsa** or **crypto key generate ec keysize** command in global configuration mode. See the Configuring Internet Key Exchange for IPsec VPNs feature module for more information.

Command Default

The trustpoint is not configured with an EC key.

Command Modes

Ca-trustpoint configuration mode (ca-trustpoint)

Command History

Release	Modification
15.1(2)T	This command was introduced in Cisco IOS Release 15.1(2)T.

Usage Guidelines

If an ECDSA signed certificate is imported without a trustpoint configuration, then the label defaults to the FQDN value.

Examples

The following example configures the EC key label in a certificate enrollment in a PKI:

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# eckeypair Router_1_Key
```

Related Commands

Command	Description
crypto key generate ec keysize	Generates EC keys.
crypto key generate rsa	Generates RSA keys.
crypto pki trustpoint	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.

email (IKEv2 profile)

To derive the name mangler from the remote identity of type e-mail, use the **email** command in IKEv2 name mangler configuration mode. To remove the name derived from the e-mail, use the **no** form of this command.

email {**all** | **domain** | **username**}

no email

Syntax Description

all	Derives the name mangler from the entire FQDN.
domain	Derives the name mangler from the domain name in e-mail.
hostname	Derives the name mangler from the username in e-mail.

Command Default

No default behavior or values.

Command Modes

IKEv2 name mangler configuration (config-ikev2-name-mangler)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to derive the name mangler from any field in the remote identity of type e-mail.

Examples

The following example shows how to derive a name for the name mangler from the username in e-mail:

```
Router(config)# crypto ikev2 name-mangler mangler2
Router(config-ikev2-name-mangler)# email username
```

Related Commands

Command	Description
crypto ikev2 name mangler	Defines a name mangler.

enable

To change the privilege level for a CLI session or to use a CLI view for a CLI session, use the **enable** command in either user EXEC, privileged EXEC, or diagnostic mode.

enable [*privilege-level*] [**view** [*view-name*]]

Syntax Description

privilege-level	(Optional) Privilege level at which to log in.
view	(Optional) Enters into root view, which enables users to configure CLI views. **Note** This keyword is required if you want to configure a CLI view.
view-name	(Optional) Enters or exits a specified command-line interface (CLI) view. This keyword can be used to switch from one CLI view to another CLI view.

Defaults

Privilege-level 15 (privileged EXEC)

Command Modes

User EXEC (>)

Privileged EXEC (#)

Diagnostic Mode (diag)

Command History

Release	Modification
10.0	This command was introduced.
12.3(7)T	The **view** keyword and *view-name* argument were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRB	The **view** keyword and *view-name* argument were integrated into Cisco IOS Release 12.2(33)SRB.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SB	This command was integrated into Cisco IOS Release 12.2(22)SB.
Cisco IOS XE Release 2.1	This command became available on the ASR 1000 Series Routers, and became available in diagnostic mode for the first time.

Usage Guidelines

By default, using the **enable** command without the *privilege-level* argument in user EXEC mode causes the router to enter privileged EXEC mode (privilege-level 15).

Entering privileged EXEC mode enables the use of privileged commands. Because many of the privileged commands set operating parameters, privileged access should be password-protected to prevent unauthorized use. If the system administrator has set a password with the **enable password** global configuration command, you are prompted to enter the password before being allowed access to privileged EXEC mode. The password is case sensitive.

If an **enable** password has not been set, only enable mode can be accessed through the console connection.

Security levels can be set by an administrator using the **enable password** and **privilege level** commands. Up to 16 privilege levels can be specified, using the numbers 0 through 15. Using these privilege levels, the administrator can allow or deny access to specific commands. Privilege level 0 is associated with user EXEC mode, and privilege level 15 is associated with privileged EXEC mode.

For more information on defined privilege levels, see the *Cisco IOS Security Configuration Guide* and the *Cisco IOS Security Command Reference* publications.

If a level is not specified when entering the **enable** command, the user will enter the default mode of privileged EXEC (level 15).

Accessing a CLI View

CLI views restrict user access to specified CLI and configuration information. To configure and access CLI views, users must first enter into root view, which is accomplished via the **enable view** command (without the *view-name* argument). Thereafter, users are prompted for a password, which is the same password as the privilege level 15 password.

The *view-name* argument is used to switch from one view to another view.

To prevent dictionary attacks, a user is prompted for a password even if an incorrect view name is given. The user is denied access only after an incorrect view name and password are given.

Examples

In the following example, the user enters privileged EXEC mode (changes to privilege-level 15) by using the **enable** command without a privilege-level argument. The system prompts the user for a password before allowing access to the privileged EXEC mode. The password is not printed to the screen. The user then exits back to user EXEC mode using the **disable** command. Note that the prompt for user EXEC mode is the greater than symbol (>), and the prompt for privileged EXEC mode is the number sign (#).

```
Router> enable
Password: <letmein>
Router# disable
Router>
```

The following example shows which commands are available inside the CLI view “first” after the user has logged into this view:

```
Router# enable view first

Password:

00:28:23:%PARSER-6-VIEW_SWITCH:successfully set to view 'first'.
Router# ?
Exec commands:
  configure  Enter configuration mode
  enable     Turn on privileged commands
  exit       Exit from the EXEC
  show       Show running system information

Router# show ?

  ip       IP information
  parser   Display parser information
  version  System hardware and software status

Router# show ip ?

  access-lists            List IP access lists
```

```
  accounting              The active IP accounting database
  aliases                 IP alias table
  arp                     IP ARP table
  as-path-access-list     List AS path access lists
  bgp                     BGP information
  cache                   IP fast-switching route cache
  casa                    display casa information
  cef                     Cisco Express Forwarding
  community-list          List community-list
  dfp                     DFP information
  dhcp                    Show items in the DHCP database
  drp                     Director response protocol
  dvmrp                   DVMRP information
  eigrp                   IP-EIGRP show commands
  extcommunity-list       List extended-community list
  flow                    NetFlow switching
  helper-address          helper-address table
  http                    HTTP information
  igmp                    IGMP information
  irdp                    ICMP Router Discovery Protocol
.
.
```

The following example shows how to use the **enable view** command to switch from the root view to the CLI view “first”:

```
Router# enable view
Router#
01:08:16:%PARSER-6-VIEW_SWITCH:successfully set to view 'root'.
Router#
! Enable the show parser view command from the root view
Router# show parser view

Current view is 'root'
! Enable the show parser view command from the root view to display all views
Router# show parser view all

Views Present in System:
View Name:   first
View Name:   second
! Switch to the CLI view “first.”
Router# enable view first
Router#
01:08:09:%PARSER-6-VIEW_SWITCH:successfully set to view 'first'.
! Enable the show parser view command from the CLI view “first.”
Router# show parser view

Current view is 'first'
```

Related Commands

Command	Description
disable	Exits from privileged EXEC mode to user EXEC mode, or, if privilege levels are set, to the specified privilege level.
enable password	Sets a local password to control access to various privilege levels.
privilege level (global)	Sets a privilege level for a command.
privilege level (line)	Sets a privilege level for a command for a specific line.

enable password

To set a local password to control access to various privilege levels, use the **enable password** command in global configuration mode. To remove the password requirement, use the **no** form of this command.

enable password [**level** *level*] {*password* | [*encryption-type*] *encrypted-password*}

no enable password [**level** *level*]

Syntax Description

level *level*	(Optional) Level for which the password applies. You can specify up to 16 privilege levels, using numbers 0 through 15. Level 1 is normal EXEC-mode user privileges. If this argument is not specified in the command or the **no** form of the command, the privilege level defaults to 15 (traditional enable privileges).
password	Password users type to enter enable mode.
encryption-type	(Optional) Cisco-proprietary algorithm used to encrypt the password. Currently the only encryption type available is 5. If you specify *encryption-type*, the next argument you supply must be an encrypted password (a password already encrypted by a Cisco router).
encrypted-password	Encrypted password you enter, copied from another router configuration.

Defaults

No password is defined. The default is level 15.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Caution If neither the **enable password** command nor the **enable secret** command is configured, and if there is a line password configured for the console, the console line password will serve as the enable password for all VTY (Telnet and Secure Shell [SSH]) sessions.

Use this command with the **level** option to define a password for a specific privilege level. After you specify the level and the password, give the password to the users who need to access this level. Use the **privilege level** configuration command to specify commands accessible at various levels.

You will not ordinarily enter an encryption type. Typically you enter an encryption type only if you copy and paste into this command a password that has already been encrypted by a Cisco router.

Caution If you specify an encryption type and then enter a clear text password, you will not be able to reenter enable mode. You cannot recover a lost password that has been encrypted by any method.

If the **service password-encryption** command is set, the encrypted form of the password you create with the **enable password** command is displayed when a **more nvram:startup-config** command is entered.

You can enable or disable password encryption with the **service password-encryption** command.

An enable password is defined as follows:

- Must contain from 1 to 25 uppercase and lowercase alphanumeric characters.
- Must not have a number as the first character.
- Can have leading spaces, but they are ignored. However, intermediate and trailing spaces are recognized.
- Can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password *abc?123,* do the following:
  - Enter **abc**.
  - Type **Crtl-v**.
  - Enter **?123**.

  When the system prompts you to enter the enable password, you need not precede the question mark with the Ctrl-v; you can simply enter abc?123 at the password prompt.

Examples

The following example enables the password “pswd2” for privilege level 2:

```
enable password level 2 pswd2
```

The following example sets the encrypted password “1i5Rkls3LoyxzS8t9”, which has been copied from a router configuration file, for privilege level 2 using encryption type 7:

```
enable password level 2 5 $1$i5Rkls3LoyxzS8t9
```

Related Commands

Command	Description
disable	Exits privileged EXEC mode and returns to user EXEC mode.
enable	Enters privileged EXEC mode.
enable secret	Specifies an additional layer of security over the **enable password** command.
privilege	Configures a new privilege level for users and associate commands with that privilege level.
service password-encryption	Encrypts passwords.
show privilege	Displays your current level of privilege.

enable secret

To specify an additional layer of security over the **enable password** command, use the **enable secret** command in global configuration mode. To turn off the **enable secret** function, use the **no** form of this command.

enable secret [**level** *level*] {*password* **| 0 | 4 | 5** [*encryption-type*] *encrypted-password* **}**

no enable secret [**level** *level*] {*password* **| 0 | 4 | 5** [*encryption-type*] *encrypted-password* **}**

Syntax Description

level *level*	(Optional) Specifies the level for which the password applies. You can specify up to sixteen privilege levels, using the numerals 0 through 15. Level 1 is normal EXEC-mode user privileges. If the level argument is not specified in the command or in the **no** form of the command, the privilege level defaults to 15 (traditional enable privileges).
password	Password for users to enter enable mode. This password should be different from the password created with the **enable password** command.
0	Specifies an unencrypted clear-text password. The password is converted to a SHA256 secret and gets stored in the router.
4	Specifies an SHA256 encrypted secret string. The SHA256 secret string is copied from the router configuration.
5	Specifies a message digest alogrithm5 (MD5) encrypted secret.
encryption-type	(Optional) Cisco-proprietary algorithm used to encrypt the password. The encryption types available for this command are 4 and 5. If you specify a value for *encryption-type* argument, the next argument you supply must be an encrypted password (a password encrypted by a Cisco router).
encrypted-password	Encrypted password that is copied from another router configuration.

Command Default

No password is defined. The default level is 15.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)S	This command was integrated into Cisco IOS Release 15.0(1)S. Encryption types **0**, **4**, and **5** were added.

Usage Guidelines

Caution If neither the **enable password** command nor the **enable secret** command is configured, and if there is a line password configured for the console, the console line password will serve as the enable password for all vty (Telnet and Secure Shell [SSH]) sessions.

Use this command to provide an additional layer of security over the enable password. The **enable secret** command provides better security by storing the enable secret password using a non reversible cryptographic function. The added layer of security encryption provides is useful in environments where the password crosses the network or is stored on a TFTP server.

You will not ordinarily enter an encryption type. Typically you enter an encryption type only if you paste into this command an encrypted password that you copied from a router configuration file.

Caution If you specify an encryption type and then enter a clear-text password, you will not be able to reenter enable mode. You cannot recover a lost password that has been encrypted by any method.

If you use the same password for the **enable password** and **enable secret** commands, you receive an error message warning that this practice is not recommended, but the password will be accepted. By using the same password, however, you undermine the additional security the **enable secret** command provides.

Note After you set a password using the **enable secret** command, a password set using the **enable password** command works only if the **enable secret** is disabled or an older version of Cisco IOS software is being used, such as when running an older rxboot image. Additionally, you cannot recover a lost password that has been encrypted by any method.

If **service password-encryption** is set, the encrypted form of the password you create here is displayed when a **more nvram:startup-config** command is entered.

You can enable or disable password encryption with the **service password-encryption** command.

An enable password is defined as follows:

- Must contain from 1 to 25 uppercase and lowercase alphanumeric characters
- Must not have a number as the first character
- Can have leading spaces, but they are ignored. However, intermediate and trailing spaces are recognized.
- Can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password *abc?123,* do the following:
  - Enter **abc**.
  - Type **Crtl-v**.
  - Enter **?123**.

  When the system prompts you to enter the enable password, you need not precede the question mark with the Ctrl-v; you can simply enter **abc?123** at the password prompt.

Examples

The following example specifies the enable secret password of “password”:

```
enable secret password
```

After specifying an enable secret password, users must enter this password to gain access. Any passwords set through enable password will no longer work.

```
Password: password
```

The following example enables the encrypted password "1FaD0$Xyti5Rkls3LoyxzS8", which has been copied from a router configuration file, for privilege level 2 using encryption type 5:

```
enable password level 2 5 $1$FaD0$Xyti5Rkls3LoyxzS8
```

Related Commands

Command	Description
enable	Enters privileged EXEC mode.
enable password	Sets a local password to control access to various privilege levels.
service password-encryption	Encrypt passwords.

enabled (IPS)

To change the enabled status of a given signature or signature category, use the **enabled** command in signature-definition-status (config-sigdef-status) or IPS-category-action (config-ips-category-action) configuration mode. To return to the default action, use the **no** form of this command.

enabled {**true** | **false**}

no enabled

Syntax Description

true	Enables a specified signature or all signatures within a specified category.
false	Disables a specified signature or all signatures within a specified category.

Command Default

All commands are enabled.

Command Modes

Signature-definition-status configuration (config-sigdef-status)
IPS-category-action configuration (config-ips-category-action)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Use the **enabled** command to change the status of a signature or signature category to active (true) or inactive (false).

Examples

The following example shows how to change the status of signature 9000:0 to enabled:

```
Router(config)# ip ips signature-definition
Router(config-sig)# signature 9000 0
Router(config-sig-sig)# status
Router(config-sigdef-status)# enabled true
```

Related Commands

Command	Description
category	Specifies a signature category that is to be used for multiple signature actions or conditions.
signature	Specifies a signature for which the CLI user tunings will be changed.
status	Changes the enabled or retired status of a given signature or signature category.

encryption (IKE policy)

To specify the encryption algorithm within an Internet Key Exchange (IKE) policy, use the **encryption** command in Internet Security Association Key Management Protocol (ISAKMP) policy configuration mode. IKE policies define a set of parameters to be used during IKE negotiation. To reset the encryption algorithm to the default value, use the **no** form of this command.

encryption {**des** | **3des** | **aes** | **aes 192** | **aes 256**}

no encryption

Syntax Description

des	56-bit Data Encryption Standard (DES)-CBC as the encryption algorithm.
3des	168-bit DES (3DES) as the encryption algorithm.
aes	128-bit Advanced Encryption Standard (AES) as the encryption algorithm.
aes 192	192-bit AES as the encryption algorithm.
aes 256	256-bit AES as the encryption algorithm.

Command History

The 56-bit DES-CBC encryption algorithm

Command Modes

ISAKMP policy configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.0(2)T	The **3des** option was added.
12.2(13)T	The following keywords were added: **aes**, **aes 192**, and **aes 256**.
12.4(4)T	IPv6 support was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to specify the encryption algorithm to be used in an IKE policy.

If a user enters an IKE encryption method that the hardware does not support, a warning message will be displayed immediately after the **encryption** command is entered.

Examples

The following example configures an IKE policy with the 3DES encryption algorithm (all other parameters are set to the defaults):

```
crypto isakmp policy
 encryption 3des
 exit
```

The following example is a sample warning message that is displayed when a user enters an IKE encryption method that the hardware does not support:

```
encryption aes 256
WARNING:encryption hardware does not support the configured
    encryption method for ISAKMP policy 1
```

Related Commands

Command	Description
authentication (IKE policy)	Specifies the authentication method within an IKE policy.
crypto isakmp policy	Defines an IKE policy.
group (IKE policy)	Specifies the DH group identifier within an IKE policy.
hash (IKE policy)	Specifies the hash algorithm within an IKE policy.
lifetime (IKE policy)	Specifies the lifetime of an IKE SA.
show crypto isakmp policy	Displays the parameters for each IKE policy.

encryption (IKEv2 proposal)

To specify one or more encryption algorithms for an Internet Key Exchange Version 2 (IKEv2) proposal, use the **encryption** command in IKEv2 proposal configuration mode. To remove the encryption algorithm, use the **no** form of this command.

encryption {**3des**} {**aes-cbc-128**} {**aes-cbc-192**} {**aes-cbc-256**}

no encryption

Syntax Description

3des	Specifies 168-bit DES (3DES) as the encryption algorithm.
aes-cbc-128	Specifies 128-bit Advanced Encryption Standard-Cipher Block Chaining (AES-CBC) as the encryption algorithim.
aes-cbc-192	Specifies 192-bit AES-CBC as the encryption algorithim.
aes-cbc-256	Specifies 256-bit AES-CBC as the encryption algorithim.

Command Default

The encryption algorithm is not specified.

Command Modes

IKEv2 proposal configuration (config-ikev2-proposal)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify the encryption algorithm to be used in an IKEv2 proposal. The default encryption algorithm in the default proposal is 128-bit AES-CBC and 3 DES encryption algorithm.

Note You cannot selectively remove an encryption algorithm when multiple encryption algorithms are configured.

Examples

The following example configures an IKE proposal with the 3DES encryption algorithm:

```
Router(config)# crypto ikev2 proposal proposal1
Router(config-ikev2-proposal)# encryption 3des
```

Related Commands

Command	Description
crypto ikev2 proposal	Defines an IKEv2 proposal.
group (ikev2 proposal)	Specifies the DH group identifier in an IKEv2 proposal.

Command	Description
integrity (ikev2 proposal)	Specifies the integrity algorithm in an IKEv2 proposal.
show crypto ikev2 proposal	Displays the parameters for each IKEv2 proposal.

enforce-checksum

To enforce checksum verification for Flexible Packet Matching (FPM), use the **enforce-checksum** command in fpm package-info mode. To disable the checksum verification, use the **no** form of this command.

enforce-checksum

no enforce-checksum

Syntax Description

This command has no keywords and arguments.

Command Default

enforce checksum is enabled.

Command Modes

fpm package-info (config-fpm-pak-info)

Command History

Release	Modification
15.1(2)T	This command was introduced.

Usage Guidelines

The **enforce-checksum** command ensures that the FPM verifies the checksum of the package during load and that the package has not been tampered. This command is useful when you want to define your own filters inside the FPM packages by disabling enforce-checksum using **no enforce-checksum** command. However, it is recommended to keep the **enforce-checksum** enabled.

Examples

The following example shows how to enable the **enforce-checksum** command:

```
Router# configure terminal
Router(config)# fpm package-info
Router(config-fpm-pak-info)# enforce-checksum
```

engine (IPS)

To enter signature-definition-action-engine configuration mode, which allows you to change router actions for a specified signature, use the **engine** command in signature-definition-action configuration mode.

engine

Syntax Description

This command has no arguments or keywords.

Command Default

None

Command Modes

Signature-definition-action configuration (config-sigdef-action)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

If you wish to change router actions for a specific signature, you must issue the engine command to enter the appropriate configuration mode, which allows you to issue the **event-action** command and specify any supported action.

Examples

The following example shows how to configure signature 5726 to reset all TCP connections and produce an alert:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip ips signature-definition
Router(config-sigdef)# signature 5726 0
Router(config-sigdef-sig)# engine
Router(config-sigdef-sig-engine)# event-action reset-tcp-connection produce-alert
Router(config-sigdef-sig-engine)# exit
Router(config-sigdef-sig)# exit
Router(config-sigdef)#^ZDo you want to accept these changes? [confirm]
Router#
*Nov 9 21:50:55.847: %IPS-6-ENGINE_BUILDING: multi-string - 3 signatures - 12 of 11
engines
*Nov 9 21:50:55.859: %IPS-6-ENGINE_READY: multi-string - build time 12 ms - packets for
this engine will be scanned
*Nov 9 21:50:55.859: %SYS-5-CONFIG_I: Configured from console by cisco on console
```

Related Commands

Command	Description
event-action	Changes router actions for a signature or signature category.
signature	Specifies a signature for which the CLI user tunings will be changed.

enrollment

To specify the enrollment parameters of your certification authority (CA), use the **enrollment** command in ca-trustpoint configuration mode. To remove any of the configured parameters, use the **no** form of this command.

enrollment {**mode ra** | **retry count** *number* | **retry period** *minutes* | **url** *url*}

no enrollment {**mode ra** | **retry count** *number* | **retry period** *minutes* | **url** *url*}

Syntax Description

mode ra	Specifies registration authority (RA) mode as the mode supported by the CA.
retry count *number*	Specifies the number of times that a router will resend a certificate request when it does not receive a response from the previous request. The range is from 1 to 100. The default is 10.
retry period *minutes*	Specifies the wait period between certificate request retries. The range is from 1 to 60.
url *url*	Specifies the URL of the CA where your router should send certificate requests.

Defaults

RA mode is disabled.

After the router sends the first certificate request to the CA, it waits for 1 minute before sending a second request. After the second request, the interval between requests (the retry period) increases exponentially, with an additional 1 minute interval added at each increment.

The router sends a maximum of ten requests.

Your router does not know the CA URL until you specify it using **url** *url*.

Command Modes

CA-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(13)T	The **url** *url* option was enhanced to support TFTP enrollment.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.

Usage Guidelines

Use the **mode** keyword to specify the mode supported by the CA. This keyword is required if your CA system provides an RA.

Use the **retry period** *minutes* option to change the retry period from the default value. After requesting a certificate, the router waits to receive a certificate from the CA. If the router does not receive a certificate within a period of time (the retry period), the router will send another certificate request. The router will continue to send requests until it receives a valid certificate, until the CA returns an enrollment error, or until the configured number of retries is exceeded.

By default, the router sends a maximum of ten requests; you can change this parameter using the **retry count** *number* option. It stops sending requests when it receives a valid certificate, when the CA returns an enrollment error, or when the configured number of requests is reached.

Use the **url** *url* option to specify or change the URL of the CA. You can specify enrollment with Simple Certificate Enrollment Protocol (SCEP) using a HTTP URl or with TFTP using a TFTP URL.

If you are using (SCEP) for enrollment, *url* must be in the form http://CA_name, where CA_name is the CA's host Domain Name System (DNS) name or IP address. If you are using TFTP for enrollment, *url* must be in the form tftp://certserver/file_specification.

TFTP enrollment is used to send the enrollment request and retrieve the certificate of the CA and the certificate of the router. If the file_specification is included in the URL, the router will append an extension onto the file specification. When the **crypto ca authenticate** command is entered, the router will retrieve the certificate of the CA from the specified TFTP server. As appropriate, the router will append the extension ".ca" to the filename or the fully qualified domain name (FQDN). If the **url** *url* option does not include a file specification, the router's FQDN will be used.

Note The **crypto ca trustpoint** command replaces the **crypto ca identity** and **crypto ca trusted-root** commands and all related subcommands (all ca-identity and trusted-root configuration mode commands). If you enter a ca-identity or trusted-root subcommand, the configuration mode and command will be written back as ca-trustpoint.

Examples

The following example shows how to declare a CA named ka and how to specify registration authority mode. It also shows how to set a retry count of 8 and a retry period of 2 minutes:

```
Router(config)# crypto ca trustpoint ka
Router(ca-trustpoint)# enrollment mode ra
Router(ca-trustpoint)# enrollment retry count 8
Router(ca-trustpoint)# enrollment retry period 2
```

The following example shows how to declare a CA named ka and how to specify the URL of the CA as http://example:80:

```
Router(config)# crypto ca trustpoint ka
Router(ca-trustpoint)# enrollment url http://example:80
```

Related Commands

Command	Description
crypto ca authenticate	Authenticates the CA (by getting the CA's certificate).
crypto ca trustpoint	Declares the CA that your router should use.
enrollment command	Specifies the HTTP command that is sent to the CA for enrollment.
enrollment credential	Specifies an existing trustpoint from another vendor that is to be enrolled with the Cisco IOS certificate server.
enrollment http-proxy	Enables access to the CA by HTTP through the proxy server.
enrollment profile	Specifies that an enrollment profile can be used for certificate authentication and enrollment.
enrollment selfsigned	Specifies self-signed enrollment for a trustpoint.
enrollment terminal	Specifies manual cut-and-paste certificate enrollment.
enrollment url	Specifies the enrollment parameters of a CA.

enrollment command

To specify the HTTP command that is sent to the certification authority (CA) for enrollment, use the **enrollment command** command in ca-profile-enroll configuration mode.

enrollment command

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

After enabling this command, you can use the **parameter** command to specify enrollment parameters for your enrollment profile.

Examples

The following example shows how to configure the enrollment profile name “E” for certificate enrollment:

```
crypto ca trustpoint Entrust
  enrollment profile E
  serial

crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
crypto ca profile enrollment	Defines an enrollment profile.
parameter	Specifies parameters for an enrollment profile.

enrollment credential

To specify an existing trustpoint from another vendor that is to be enrolled with the Cisco IOS certificate server, use the **enrollment credential** command in ca-profile-enroll configuration mode.

enrollment credential *label*

Syntax Description

label	Name of the certification authority (CA) trustpoint of another vendor.

Defaults

No default behavior or values.

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

To configure a router that is already enrolled with a CA of another vendor that is to be enrolled with a Cisco IOS certificate server, you must configure a certificate enrollment profile (via the **crypto pki profile enrollment** command). Thereafter, you should issue the **enrollment credential** command, which specifies the trustpoint of another vendor that has to be enrolled with a Cisco IOS certificate server.

Examples

The following example shows how to configure a client router and a Cisco IOS certificate server to exchange enrollment requests via a certificate enrollment profile:

```
! Define the trustpoint "msca-root" that points to the non-Cisco IOS CA and enroll and
! authenticate the client with the non-Cisco IOS CA.
crypto pki trustpoint msca-root
 enrollment mode ra
 enrollment url http://msca-root:80/certsrv/mscep/mscep.dll
 ip-address FastEthernet2/0
 revocation-check crl
!
! Configure trustpoint "cs" for Cisco IOS CA.
crypto pki trustpoint cs
 enrollment profile cs1
 revocation-check crl
!
! Define enrollment profile "cs1," which points to Cisco IOS CA and mention (via the
! enrollment credential command) that "msca-root" is being initially enrolled with the
! Cisco IOS CA.
crypto pki profile enrollment cs1
 enrollment url  http://cs:80
 enrollment credential  msca-root!
```

```
! Configure the certificate server, and issue and the grant auto trustpoint command to
! instruct the certificate server to accept enrollment request only from clients who are
! already enrolled with trustpoint "msca-root."
crypto pki server cs
 database level minimum
 database url nvram:
 issuer-name CN=cs
 grant auto trustpoint msca-root
!
crypto pki trustpoint cs
 revocation-check crl
rsakeypair cs
!
crypto pki trustpoint msca-root
 enrollment mode ra
 enrollment url http://msca-root:80/certsrv/mscep/mscep.dll
 revocation-check crl
```

Related Commands

Command	Description
crypto pki profile enrollment	Defines an enrollment profile.

enrollment http-proxy

To access the certification authority (CA) by HTTP through the proxy server, use the **enrollment http-proxy** command in ca-trustpoint configuration mode.

enrollment http-proxy *host-name port-num*

Syntax Description

host-name	Defines the proxy server used to get the CA.
port-num	Specifies the port number used to access the CA.

Defaults

If this command is not enabled, the CA will not be accessed via HTTP.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.

Usage Guidelines

The **enrollment http-proxy** command must be used in conjunction with the **enrollment** command, which specifies the enrollment parameters for the CA.

Examples

The following example shows how to access the CA named “ka” by HTTP through the bomborra proxy server:

```
crypto ca trustpoint ka
 enrollment url http://kahului
 enrollment http-proxy bomborra 8080
 crl optional
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.
enrollment	Specifies the enrollment parameters of your CA.

enrollment mode ra

The **enrollment mode ra** command is replaced by the **enrollment command** command. See the **enrollment command** command for more information.

enrollment profile

To specify that an enrollment profile can be used for certificate authentication and enrollment, use the **enrollment profile** command in ca-trustpoint configuration mode. To delete an enrollment profile from your configuration, use the **no** form of this command.

enrollment profile *label*

no enrollment profile *label*

Syntax Description

label	Creates a name for the enrollment profile.

Defaults

Your router does not recognize any enrollment profiles until you declare one using this command.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

Before you can enable this command, you must enter the **crypto ca trustpoint** command.

The **enrollment profile** command enables your router to accept an enrollment profile, which can be configured via the **crypto ca profile enrollment** command. The enrollment profile, which consists of two templates, can be used to specify different URLs or methods for certificate authentication and enrollment.

Examples

The following example shows how to declare the enrollment profile named “E”:

```
crypto ca trustpoint Entrust
  enrollment profile E
  serial

crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
crypto ca profile enrollment	Defines an enrollment profile.
crypto ca trustpoint	Declares the CA that your router should use.

enrollment retry count

The **enrollment retry count** command is replaced by the **enrollment** command. See the **enrollment** command for more information.

enrollment retry period

The **enrollment retry period** command is replaced by the **enrollment** command. See the **enrollment** command for more information.

enrollment selfsigned

To specify self-signed enrollment for a trustpoint, use the **enrollment selfsigned** command in ca-trustpoint configuration mode. To delete self-signed enrollment from a trustpoint, use the **no** form of this command.

enrollment selfsigned

no enrollment selfsigned

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default behavior or values.

Command Modes

ca-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

Before you can use the **enrollment selfsigned** command, you must enable the **crypto pki trustpoint** command, which defines the trustpoint and enters ca-trustpoint configuration mode.

If you do not use this command, you should specify another enrollment method for the router by using an enrollment command such as **enrollment url** or **enrollment terminal**.

Examples

The following example shows a self-signed certificate being designated for a trustpoint named local:

```
crypto pki trustpoint local
 enrollment selfsigned
```

Related Commands

Command	Description
crypto pki trustpoint	Declares the CA that your router should use.

enrollment terminal (ca-profile-enroll)

To specify manual cut-and-paste certificate enrollment, use the **enrollment terminal** command in ca-profile-enroll configuration mode. To delete a current enrollment request, use the **no** form of this command.

enrollment terminal

no enrollment terminal

Syntax Description

This command has no arguments or keywords.

Defaults

A certificate enrollment request is not specified.

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

A user may manually cut-and-paste certificate authentication requests and certificates when a network connection between the router and certification authority (CA) is unavailable. After this command is enabled, the certificate request is printed on the console terminal so that it can be manually copied (cut) by the user.

Note Although most routers accept manual enrollment, the process can be tedious if a large number of routers have to be enrolled.

Examples

The following example shows how to configure the enrollment profile named "E" to perform certificate authentication via HTTP and manual certificate enrollment:

```
crypto ca profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment terminal
 parameter 1 value aaaa-bbbb-cccc
 parameter 2 value 5001
```

Related Commands

Command	Description
crypto ca profile enrollment	Defines an enrollment profile.

enrollment terminal (ca-trustpoint)

To specify manual cut-and-paste certificate enrollment, use the **enrollment terminal** command in ca-trustpoint configuration mode. To delete a current enrollment request, use the **no** form of this command.

enrollment terminal [**pem**]

no enrollment terminal [**pem**]

Syntax Description

pem	(Optional) Adds privacy-enhanced mail (PEM) boundaries to the certificate request.

Defaults

No default behavior or values

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.3(4)T	The **pem** keyword was added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

A user may want to manually cut-and-paste certificate requests and certificates when he or she does not have a network connection between the router and certification authority (CA). When this command is enabled, the router displays the certificate request on the console terminal, allowing the user to enter the issued certificate on the terminal.

The pem Keyword

Use the **pem** keyword to issue certificate requests (via the **crypto ca enroll** command) or receive issued certificates (via the **crypto ca import certificate** command) in PEM-formatted files through the console terminal. If the CA server does not support simple certificate enrollment protocol (SCEP), the certificate request can be presented to the CA server manually.

Note When generating certificate requests in PEM format, your router does not have to have the CA certificate, which is obtained via the **crypto ca authenticate** command.

Examples

The following example shows how to manually specify certificate enrollment via cut-and-paste. In this example, the CA trustpoint is "MS."

```
crypto ca trustpoint MS
 enrollment terminal
 crypto ca authenticate MS
!
crypto ca enroll MS
crypto ca import MS certificate
```

Related Commands

Command	Description
crypto ca authenticate	Authenticates the CA (by getting the certificate of the CA).
crypto ca enroll	Obtains the certificates of your router from the certification authority.
crypto ca import	Imports a certificate manually via TFTP or cut-and-paste at the terminal.
crypto ca trustpoint	Declares the CA that your router should use.

enrollment url (ca-identity)

The **enrollment url (ca-identity)** command is replaced by the **enrollment url (ca-trustpoint)** command. See the **enrollment url (ca-trustpoint)** command for more information.

enrollment url (ca-profile-enroll)

To specify the URL of the certification authority (CA) server to which to send enrollment requests, use the **enrollment url** command in ca-profile-enroll configuration mode. To delete the enrollment URL from your enrollment profile, use the **no** form of this command.

enrollment url *url*

no enrollment url *url*

Syntax Description

url	URL of the CA server to which your router should send certificate requests. If you are using Simple Certificate Enrollment Protocol (SCEP) for enrollment, the *url* argument must be in the form http://CA_name, where CA_name is the host Domain Name System (DNS) name or IP address of the CA. If you are using TFTP for enrollment, the *url* argument must be in the form tftp://certserver/file_specification. (If the URL does not include a file specification, the fully qualified domain name [FQDN] of the router will be used.)

Defaults

Your router does not recognize the CA URL until you specify it using this command.

Command Modes

Ca-profile-enroll configuration

Command History

Release	Modification
12.2(13)ZH	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

This command allows the user to specify a different URL or a different method for authenticating a certificate and enrolling a certificate; for example, manual authentication and TFTP enrollment.

Examples

The following example shows how to enable certificate enrollment via HTTP for the profile name “E”:

```
crypto pki trustpoint Entrust
  enrollment profile E
  serial

crypto pki profile enrollment E
 authentication url  http://entrust:81
 authentication command  GET /certs/cacert.der
 enrollment url  http://entrust:81/cda-cgi/clientcgi.exe
 enrollment command  POST reference_number=$P2&authcode=$P1
&retrievedAs=rawDER&action=getServerCert&pkcs10Request=$REQ
 parameter 1 value aaaa-bbbb-cccc
```

```
parameter 2 value 5001
```

Related Commands

Command	Description
crypto pki profile enrollment	Defines an enrollment profile.

enrollment url (ca-trustpoint)

To specify the enrollment parameters of a certification authority (CA), use the **enrollment url** command in ca-trustpoint configuration mode. To remove any of the configured parameters, use the **no** form of this command.

enrollment [**mode**] [**retry period** *minutes*] [**retry count** *number*] **url** *url* [**pem**]

no enrollment [**mode**] [**retry period** *minutes*] [**retry count** *number*] **url** *url* [**pem**]

Syntax Description

mode	(Optional) Specifies the registration authority (RA) mode, if your CA system provides an RA. By default, RA mode is disabled.
retry period *minutes*	(Optional) Specifies the period in which the router will wait before sending the CA another certificate request. The default is 1 minute between retries. (Specify from 1 to 60 minutes.)
retry count *number*	(Optional) Specifies the number of times a router will resend a certificate request when it does not receive a response from the previous request. The default is 10 retries. (Specify from 1 to 100 retries.)
url *url*	Specifies the URL of the file system where your router should send certificate requests. For enrollment method options, see Table 32.
pem	(Optional) Adds privacy-enhanced mail (PEM) boundaries to the certificate request.

Defaults

Your router does not know the CA URL until you specify it using the **url** *url* keyword and argument.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
11.3T	This command was introduced as the **enrollment url** (ca-identity) command.
12.2(8)T	This command replaced the **enrollment url** (ca-identity) command. The **mode**, **retry period** *minutes*, and **retry count** *number* keywords and arguments were added.
12.2(13)T	The **url** *url* option was enhanced to support TFTP enrollment.
12.3(4)T	The **pem** keyword was added, and the **url** *url* option was enhanced to support an additional enrollment method—the Cisco IOS File System (IFS).
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

Use the **mode** keyword to specify the mode supported by the CA. This keyword is required if your CA system provides an RA.

Use the **retry period** *minutes* option to change the retry period from the default of 1 minute between retries. After requesting a certificate, the router waits to receive a certificate from the CA. If the router does not receive a certificate within a specified period of time (the retry period), the router will send another certificate request. By default, the router will send a maximum of ten requests until it receives a valid certificate, until the CA returns an enrollment error, or until the configured number of retries (specified via the **retry count** *number* option) is exceeded.

Use the **pem** keyword to issue certificate requests (using the **crypto pki enroll** command) or receive issued certificates (using the **crypto pki import certificate** command) in PEM-formatted files.

Note When generating certificate requests in PEM format, your router does not have to have the CA certificate, which is obtained using the **crypto ca authenticate** command.

Use the **url** *url* option to specify or change the URL of the CA. Table 32 lists the available enrollment methods.

Table 32 Certificate Enrollment Methods

Enrollment Method	Description
bootflash	Enroll via bootflash: file system
cns	Enroll via Cisco Networking Services (CNS): file system
flash	Enroll via flash: file system
ftp	Enroll via FTP: file system
null	Enroll via null: file system
nvram	Enroll via NVRAM: file system
rcp	Enroll via remote copy protocol (rcp): file system
scp	Enroll via secure copy protocol (scp): file system
SCEP[1]	Enroll via Simple Certificate Enrollment Protocol (SCEP) (an HTTP URL)
system	Enroll via system: file system
TFTP[2]	Enroll via TFTP: file system

1. If you are using SCEP for enrollment, the URL must be in the form http://CA_name, where CA_name is the host Domain Name System (DNS) name or IP address of the CA.
2. If you are using TFTP for enrollment, the URL must be in the form tftp://certserver/file_specification. (The file_specification is optional. See the section "TFTP Certificate Enrollment" for additional information.)

TFTP Certificate Enrollment

TFTP enrollment is used to send the enrollment request and retrieve the certificate of the CA and the certificate of the router. If the file_specification is included in the URL, the router will append an extension onto the file specification. When the **crypto pki authenticate** command is entered, the router will retrieve the certificate of the CA from the specified TFTP server. As appropriate, the router will append the extension ".ca" to the filename or the fully qualified domain name (FQDN). (If the **url** *url* option does not include a file specification, the FQDN of the router will be used.)

Note The **crypto pki trustpoint** command replaces the **crypto ca identity** and **crypto ca trusted-root** commands and all related commands (all **ca-identity** and **trusted-root** configuration mode commands). If you enter a **ca-identity** or **trusted-root** command, the configuration mode and command will be written back as pki-trustpoint.

Examples

The following example shows how to declare a CA named "trustpoint" and specify the URL of the CA as "http://example:80":

```
crypto pki trustpoint trustpoint
 enrollment url http://example:80
```

Related Commands

Command	Description
crypto pki authenticate	Authenticates the CA (by getting the certificate of the CA).
crypto pki enroll	Obtains the certificate or certificates of your router from the CA.
crypto pki trustpoint	Declares the CA that your router should use.

eou allow

To allow additional Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) options, use the **eou allow** command in global configuration mode. To disable the options that have been set, use the **no** form of this command.

eou allow {**clientless** | **ip-station-id**}

no eou allow {**clientless** | **ip-station-id**}

Syntax Description

clientless	Allows authentication of clientless hosts (systems that do not run Cisco Trust Agent).
ip-station-id	Allows an IP address in the station-id field.

Defaults

No additional EAPoUDP options are allowed.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

The **eou allow** command used with the **clientless** keyword requires that a user group be configured on the Cisco Access Control Server (ACS) using the same username and password that are specified using the **eou clientless** command.

Examples

The following example shows that clientless hosts are allowed:

```
Router (config)# eou allow clientless
```

Related Commands

Command	Description
eou clientless	Sets user group credentials for clientless hosts.

eou clientless

To set user group credentials for clientless hosts, use the **eou clientless** command in global configuration mode. To remove the user group credentials, use the **no** form of this command.

eou clientless {**password** *password* | **username** *username*}

no eou clientless {**password | username**}

Syntax Description

password *password*	Sets a password.
username *username*	Sets a username.

Defaults

Username and password values are clientless.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

For this command to be effective, the **eou allow** command must also be enabled.

Examples

The following example shows that a clientless host with the username “user1” has been configured:

```
Router (config)# eou clientless username user1
```

The following example shows that a clientless host with the password “user123” has been configured:

```
Router (config)# eou clientless password user123
```

Related Commands

Command	Description
eou allow	Allows additional EAPoUDP options.

eou default

To set global Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) parameters to the default values, use the **eou default** command in global or interface configuration mode.

eou default

Syntax Description

This command has no arguments or keywords.

Defaults

The EAPoUDP parameters are set to their default values.

Command Modes

Global configuration (config)
Interface configuration (config-if)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

You can configure this command globally by using global configuration mode or for a specific interface by using interface configuration mode.

Using this command, you can reset existing values to their default values.

Examples

The following configuration example shows that EAPoUDP parameters have been set to their default values:

```
Router (config)# eou default
```

eou initialize

To manually initialize Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) state machines, use the **eou initialize** command in global configuration mode. This command does not have a **no** form.

eou initialize {**all** | **authentication** {**clientless** | **eap** | **static**} | **interface** *interface-name* | **ip** *ip-address* | **mac** *mac-address* | **posturetoken** *string*}

Syntax Description

all	Initiates reauthentication of all EAPoUDP clients. This keyword is the default.
authentication	Specifies the authentication type.
clientless	Clientless authentication type.
eap	EAP authentication type.
static	Static authentication type.
interface *interface-name*	Specifies a specific interface.
ip *ip-address*	Specifies a specific IP address.
mac *mac-address*	Specifies a specific MAC address.
posturetoken *string*	Specifies a specific posture token.

Command Default

None

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

If this command is used, existing EAPoUDP state machines will be reset.

Examples

The following example shows that all EAPoUDP state machines have been reauthenticated:

```
Router (config)# eou initialize all
```

Related Commands

Command	Description
eou revalidate	Revalidates an EAPoUDP association.

eou logging

To enable Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) system logging events, use the **eou logging** command in global configuration mode. To remove EAPoUDP logging, use the **no** form of this command.

eou logging

no eou logging

Syntax Description

This command has no arguments or keywords.

Defaults

Logging is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Examples

The following example shows that EAPoUDP logging has been enabled:

```
Router (config)# eou logging
```

The following is sample EAPoUDP logging output:

```
Apr  9 10:04:09.824: %EOU-6-SESSION: IP=10.0.0.1| HOST=DETECTED| Interface=FastEthernet0/0
*Apr  9 10:04:09.900: %EOU-6-CTA: IP=10.0.0.1| CiscoTrustAgent=DETECTED
*Apr  9 10:06:19.576: %EOU-6-POLICY: IP=10.0.0.1| TOKEN=Healthy
*Apr  9 10:06:19.576: %EOU-6-POLICY: IP=10.0.0.1| ACLNAME=#ACSACL#-IP-HealthyACL-40921e54
*Apr  9 10:06:19.576: %EOU-6-POSTURE: IP=10.0.0.1| HOST=AUTHORIZED|
Interface=FastEthernet0/0.420
*Apr  9 10:06:19.580: %EOU-6-AUTHTYPE: IP=10.0.0.1| AuthType=EAP
*Apr  9 10:06:04.424: %EOU-6-SESSION: IP=192.168.2.1| HOST=REMOVED|
Interface=FastEthernet0/0.420
```

eou max-retry

To set the number of maximum retry attempts for Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP), use the **eou max-retry** command in global or interface configuration mode. To remove the number of retries that were entered, use the **no** form of this command.

eou max-retry *number-of-retries*

no eou max-retry *number-of-retries*

Syntax Description

number-of-retries	Number of maximum retries that may be attempted. The value ranges from 1 through 10. The default is 3.

Defaults

The default number of retries is 3.

Command Modes

Global configuration (config)
Interface configuration (config-if)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4	The value range was changed from 1 through 3 to 1 through 10.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

You can configure this command globally by using global configuration mode or for a specific interface by using interface configuration mode.

Examples

The following example shows that the maximum number of retries for an EAPoUDP session has been set for 2:

```
Router (config)# eou max-retry 2
```

Related Commands

Command	Description
show eou	Displays information about EAPoUDP global values or EAPoUDP session cache entries.

eou port

To set the UDP port for Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP), use the **eou port** command in global configuration mode. This command has no **no** form.

eou port *port-number*

Syntax Description

port-number	Number of the port. The value ranges from 1 through 65535. The default value is 27186.

Defaults

The default *port-number* value is 27186.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Ensure that the port you set does not conflict with other UDP applications.

Examples

The following example shows that the port for an EAPoUDP session has been set to 200:

```
Router (config)# eou port 200
```

Related Commands

Command	Description
show eou	Displays information about EAPoUDP.

eou rate-limit

To set the number of simultaneous posture validations for Extensible Authentication Protocol over UDP (EAPoUDP), use the **eou rate-limit** command in global configuration mode. This command has no **no** form.

eou rate-limit *number-of-validations*

Syntax Description

number-of-validations	Number of clients that can be simultaneously validated. The value ranges from 1 through 200. The default value is 20.

Defaults

No default behaviors or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

If you set the rate limit to 0 (zero), rate limiting will be turned off.

If the rate limit is set to 100 and there are 101 clients, validation will not occur until one drops off.

To return to the default value, use the **eou default** command.

Examples

The following example shows that the number of posture validations has been set to 100:

```
Router (config)# eou rate-limit 100
```

Related Commands

Command	Description
eou default	Sets global EAPoUDP parameters to the default values.
show eou	Displays information about EAPoUDP.

eou revalidate

To revalidate an Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) association, use the **eou revalidate** command in privileged EXEC mode. To disable the revalidation, use the **no** form of this command.

eou revalidate {**all** | **authentication** {**clientless** | **eap** | **static**} | **interface** *interface-name* | **ip** *ip-address* | **mac** *mac-address* | **posturetoken** *string*}

no eou revalidate {**all** | **authentication** {**clientless** | **eap** | **static**} | **interface** *interface-name* | **ip** *ip-address* | **mac** *mac-address* | **posturetoken** *string*}

Syntax Description

all	Enables revalidation of all EAPoUDP clients. This keyword option is the default.
authentication	Specifies the authentication type.
clientless	Clientless authentication type.
eap	EAP authentication type.
static	Static authentication type.
interface *interface-name*	Name of the interface. (See Table 33 for the types of interface that may be shown.)
ip *ip-address*	IP address of the client.
mac *mac-address*	The 48-bit hardware address of the client.
posturetoken *string*	Name of the posture token.

Command Default

None

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

If you use this command, existing EAPoUDP sessions will be revalidated.

Table 33 lists the interface types that may be used with the **interface** keyword.

Table 33 Description of Interface Types

Interface Type	Description
Async	Asynchronous interface
BVI	Bridge-Group Virtual Interface

Table 33 Description of Interface Types (continued)

Interface Type	Description
CDMA-Ix	Code division multiple access Internet exchange (CDMA Ix) interface
CTunnel	Connectionless Network Protocol (CLNS) tunnel (Ctunnel) interface
Dialer	Dialer interface
Ethernet	IEEE 802.3 standard interface
Lex	Lex interface
Loopback	Loopback interface
MFR	Multilink Frame Relay bundle interface
Multilink	Multilink-group interface
Null	Null interface
Serial	Serial interface
Tunnel	Tunnel interface
Vif	Pragmatic General Multicast (PGM) Multicase Host interface
Virtual-PPP	Virtual PPP interface
Virtual-Template	Virtual template interface
Virtual-TokenRing	Virtual TokenRing interface

Examples

The following example shows that all EAPoUDP clients are to be revalidated:

```
Router# eou revalidate all
```

Related Commands

Command	Description
eou initialize	Manually initializes EAPoUDP state machines.

eou timeout

To set the Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) timeout values, use the **eou timeout** command in global or interface configuration mode. To remove the value that was set, use the **no** form of this command.

eou timeout {**aaa** *seconds* | **hold-period** *seconds* | **retransmit** *seconds* | **revalidation** *seconds* | **status query** *seconds*}

no timeout {**aaa** *seconds* | **hold-period** *seconds* | **retransmit** *seconds* | **revalidation** *seconds* | **status query** *seconds*}

Syntax Description

aaa *seconds*	Authentication, authorization, and accounting (AAA) timeout period, in seconds. The value range is from 1 through 60. Default=60.
hold-period *seconds*	Hold period following failed authentication, in seconds. The value range is from 60 through 86400. Default=180.
retransmit *seconds*	Retransmit period, in seconds. The value range is from 1 through 60. Default=3.
revalidation *seconds*	Revalidation period, in seconds. The value range is from 300 through 86400. Default=36000.
status query *seconds*	Status query period after revalidation, in seconds. The value range is from 30 through 1800. Default=300.

Defaults

No default behavior or values

Command Modes

Global configuration (config)
Interface configuration (config-if)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

You can configure this command globally by using global configuration mode or for a specific interface by using interface configuration mode.

Examples

The following example shows that the status query period after revalidation is set to 30:

```
Router (config)# eou timeout status query 30
```

Related Commands

Command	Description
show eou	Displays information about EAPoUDP global values.

error-msg

To display a specific error message when a user logs on to a Secure Sockets Layer Virtual Private Network (SSL VPN) gateway, use the **error-msg** command in webvpn acl configuration mode. To remove the error message, use the **no** form of this command.

error-msg *message-string*

no error-msg *message-string*

Syntax Description

message-string	Error message to be displayed.

Command Default

No special error message is displayed.

Command Modes

Webvpn acl configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

If the **error-url** command is configured, the user is redirected to the error URL for every request that is not allowed. If the **error-url** command is not configured, the user gets a standard, gateway-generated information page showing the message that was configured using the **error-msg** command.

Examples

This example shows that the following error message will be displayed when the user logs on to the SSL VPN gateway:

```
webvpn context context1
 acl acl1
  error-msg "If you have any questions, please contact <a
  href+mailto:employee1@example.com>Employee1</a>."
```

Related Commands

Command	Description
acl	Defines an ACL using a SSL VPN gateway at the Application Layer level and enters webvpn acl configuration mode.
error-url	Defines a URL as an ACL violation page using a SSL VPN gateway.
webvpn context	Configures a SSL VPN context and enters webvpn context configuration mode.

error-url

To define a URL as an access control list (ACL) violation page using a Secure Socket Layer Virtual Private Network (SSL VPN) gateway, use the **error-url** command in webvpn acl configuration mode. To remove the ACL violation page, use the **no** form of this command.

error-url *access-deny-page-url*

no error-url *access-deny-page-url*

Syntax Description

access-deny-page-url	URL to which a user is directed for an ACL violation.

Command Default

If this command is not configured, the gateway redirects the ACL violation page to a predefined URL.

Command Modes

Webvpn acl configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

If the **error-url** command is configured, the user is redirected to a predefined URL for every request that is not allowed. If the **error-url** command is not configured, the user gets a standard, gateway-generated error page.

Examples

The following example shows that the URL “http://www.example.com” has been defined as the ACL violation page:

```
webvpn context context1
 acl acl1
  error-url “http://www.example.com”
```

Related Commands

Command	Description
acl	Defines an ACL using a SSL VPN gateway at the Application Layer level.
error-msg	Displays a specific error message when a user logs on to a SSL VPN gateway.
webvpn context	Configures the SSL VPN context and enters webvpn context configuration mode.

evaluate

To nest a reflexive access list within an access list, use the **evaluate** command in access-list configuration mode. To remove a nested reflexive access list from the access list, use the **no** form of this command.

evaluate *name*

no evaluate *name*

Syntax Description

name	The name of the reflexive access list that you want evaluated for IP traffic entering your internal network. This is the name defined in the **permit** (reflexive) command.

Defaults

Reflexive access lists are not evaluated.

Command Modes

Access-list configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is used to achieve reflexive filtering, a form of session filtering.

Before this command will work, you must define the reflexive access list using the **permit** (reflexive) command.

This command nests a reflexive access list within an extended named IP access list.

If you are configuring reflexive access lists for an external interface, the extended named IP access list should be one which is applied to inbound traffic. If you are configuring reflexive access lists for an internal interface, the extended named IP access list should be one which is applied to outbound traffic. (In other words, use the access list opposite of the one used to define the reflexive access list.)

This command allows IP traffic entering your internal network to be evaluated against the reflexive access list. Use this command as an entry (condition statement) in the IP access list; the entry “points” to the reflexive access list to be evaluated.

As with all access list entries, the order of entries is important. Normally, when a packet is evaluated against entries in an access list, the entries are evaluated in sequential order, and when a match occurs, no more entries are evaluated. With a reflexive access list nested in an extended access list, the extended access list entries are evaluated sequentially up to the nested entry, then the reflexive access list entries are evaluated sequentially, and then the remaining entries in the extended access list are evaluated sequentially. As usual, after a packet matches *any* of these entries, no more entries will be evaluated.

Examples

The following example shows reflexive filtering at an external interface. This example defines an extended named IP access list *inboundfilters*, and applies it to inbound traffic at the interface. The access list definition permits all Border Gateway Protocol and Enhanced Interior Gateway Routing Protocol traffic, denies all Internet Control Message Protocol traffic, and causes all Transmission Control Protocol traffic to be evaluated against the reflexive access list *tcptraffic*.

If the reflexive access list *tcptraffic* has an entry that matches an inbound packet, the packet will be permitted into the network. *tcptraffic* only has entries that permit inbound traffic for existing TCP sessions.

```
interface Serial 1
 description Access to the Internet via this interface
 ip access-group inboundfilters in
!
ip access-list extended inboundfilters
 permit 190 any any
 permit eigrp any any
 deny icmp any any
 evaluate tcptraffic
```

Related Commands

Command	Description
ip access-list	Defines an IP access list by name.
ip reflexive-list timeout	Specifies the length of time that reflexive access list entries will continue to exist when no packets in the session are detected.
permit (reflexive)	Creates a reflexive access list and enables its temporary entries to be automatically generated.

event-action

To change router actions for a signature or signature category, use the **event-action** command in signature-definition-action-engine or IPS-category-action configuration mode. To revert to the default router action values, use the **no** form of this command.

event-action *action*

no event-action

Syntax Description

action	Router actions for a specified signature or signature category. The *action* argument can be any of the following options: • **deny-attacker-inline** • **deny-connection-inline** • **deny-packet-inline** • **produce-alert** • **reset-tcp-connection** **Note** Event actions for an individual signature must be entered on a single line. However, event actions associated with a category can be entered separately or on a single line.

Command Default

Default values for the signature or signature category will be used.

Command Modes

Signature-definition-action-engine configuration (config-sigdef-action-engine)
IPS-category-action configuration (config-ips-category-action)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Signature-Based Changes

After signature-based changes are complete, Cisco IOS Intrusion Prevention System (IPS) prompts the user to confirm whether or not the changes are acceptable. Confirming the changes instructs Cisco IOS IPS to compile the changes for the signature and modify memory structures to reflect the change. Also, Cisco IOS IPS will save the changes to the location specified via the **ip ips config location** command (for example, flash:ips5/*.xml).

You can issue the **show ip ips signatures** command to verify the event-action configuration. (The **show running-config** command does not show individual signature tuning information.)

Signature Category-Based Changes

After signature category-based changes are complete, the category tuning information is saved in the command-line interface (CLI) configuration.

Category configuration information is processed in the order that it is entered. Thus, it is recommended that the process of retiring all signatures occur before all other category tuning.

If a category is configured more than once, the parameters entered in the second configuration will be added to or will replace the previous configuration.

Examples

The following example shows how to configure signature 5726 to reset all TCP connections and produce an alert:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip ips signature-definition
Router(config-sigdef)# signature 5726 0
Router(config-sigdef-sig)# engine
Router(config-sigdef-sig-engine)# event-action reset-tcp-connection produce-alert
Router(config-sigdef-sig-engine)# exit
Router(config-sigdef-sig)# exit
Router(config-sigdef)#^ZDo you want to accept these changes? [confirm]
Router#
*Nov 9 21:50:55.847: %IPS-6-ENGINE_BUILDING: multi-string - 3 signatures - 12 of 11
engines
*Nov 9 21:50:55.859: %IPS-6-ENGINE_READY: multi-string - build time 12 ms - packets for
this engine will be scanned
*Nov 9 21:50:55.859: %SYS-5-CONFIG_I: Configured from console by cisco on console
```

The following example shows how to tune event-action parameters for the signature category "adware/spyware." All the tuning information will be applied to all signatures that belong to the adware/spyware signature category.

```
Router(config)# ip ips signature category
Router(config-ips-category)# category attack adware/spyware
Router(config-ips-category-action)# event-action produce-alert
Router(config-ips-category-action)# event-action deny-packet-inline
Router(config-ips-category-action)# event-action reset-tcp-connection
Router(config-ips-category-action)# retired false
Router(config-ips-category-action)# ^Z
Do you want to accept these changes:[confirmm]y
```

Related Commands

Command	Description
engine	Enters the signature-definition-action-engine configuration mode, which allows you to change router actions for a specified signature.
ip ips config location	Specifies the location in which the router will save signature information.
signature	Specifies a signature for which the CLI user tunings will be changed.
show ip ips	Displays IPS information such as configured sessions and signatures.

exclusive-domain

To add or remove a domain name to or from the exclusive domain list so that the Cisco IOS firewall does not have to send lookup requests to the vendor server, use the **exclusive-domain** command in URL parameter-map configuration mode. To disable this capability, use the **no** form of this command.

exclusive-domain {**deny** | **permit**} *domain-name*

no exclusive-domain {**deny** | **permit**} *domain-name*

Syntax Description

deny	Removes the specified domain name from the exclusive domain list. Blocks all traffic destined for the specified domain name.
permit	Adds the specified domain name to the exclusive domain list. Permits all traffic destined for the specified domain name.
domain-name	Domain name that is added or removed from the exclusive domain name list; for example, www.example.com.

Command Default

Disabled.

Command Modes

URL parameter-map configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

When you are creating or modifying a URL parameter map, you can enter the **exclusive-domain** subcommand after you enter the **parameter-map type urlfilter** command. For detailed information about creating a parameter map, see the **parameter-map type urlfilter** command.

The **exclusive-domain** command allows you to specify a list of domain names (exclusive domains) so that the Cisco IOS firewall does not create a lookup request for the traffic that is destined for one of the domains in the exclusive list. Thus, you can avoid sending lookup requests to the web server for traffic that is destined for a host that is completely allowed to all users. You can enter the complete domain name or a partial domain name.

Complete Domain Name

If you add a complete domain name, such as www.example.com, to the exclusive domain list, all traffic whose URLs are destined for this domain (such as www.example.com/news and www.example.com/index) is excluded from the URL filtering policies of the vendor server. On the basis of the configuration, the URLs are permitted or blocked (denied).

Partial Domain Name

If you add only a partial domain name to the exclusive domain list, such as example.com, all URLs whose domain names end with this partial domain name (such as www.example.com/products and www.example.com/eng) are excluded from the URL filtering policies of the vendor server. On the basis of the configuration, the URLs are permitted or blocked (denied).

Examples

The following example adds cisco.com to the exclusive domain list:

```
parameter-map type urlfilter u1
 exclusive-domain permit example.com
```

Related Commands

Command	Description
ip urlfilter exclusive-domain	Adds or removes a domain name to or from the exclusive domain list so that the Cisco IOS firewall does not have to send lookup requests to the vendor server.
parameter-map type urlfilter	Creates or modifies a parameter map for URL filtering parameters.

filter-hash

To specify the hash for verification and validation of decrypted contents, use the **filter-hash** command in FPM match encryption filter configuration mode.

filter-hash *hash-value*

Syntax Description

hash-value	Hash value obtained from the encrypted traffic classification definition file (eTCDF).

Command Default

No hash value is specified.

Command Modes

FPM match encryption filter configuration (c-map-match-enc-config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If you have access to an eTCDF or if you know valid values to configure encrypted Flexible Packet Matching (FPM) filters, you can configure the same eTCDF through the command-line interface instead of using the preferred method of loading the eTCDF on the router. You must create a class map of type access-control using the **class-map type** command, and use the **match encrypted** command to configure the match criteria for the class map on the basis of encrypted FPM filters and enter FPM match encryption filter configuration mode. You can then use the appropriate commands to specify the algorithm, cipher key, cipher value, filter hash, filter ID, and filter version. You can copy the values from the eTCDF by opening the eTCDF in any text editor.

Use the **filter-hash** command to specify the hash for verification and validation of decrypted contents.

Examples

The following example shows how to specify the hash value from the eTCDF file for verification and validation of decrypted contents:

```
Router(config)# class-map type access-control match-all c1
Router(config-cmap)# match encrypted
Router(c-map-match-enc-config)# filter-hash AABBCCDD11223344
Router(c-map-match-enc-config)#
```

Related Commands

Command	Description
class-map type	Creates a class map to be used for matching packets to a specified class.
match encrypted	Configures the match criteria for a class map on the basis of encrypted FPM filters and enters FPM match encryption filter configuration mode.

filter-id

To specify a filter-level ID for encrypted filters, use the **filter-id** command in FPM match encryption filter configuration mode.

filter-id *id-value*

Syntax Description

id-value	Filter-level ID value.

Command Default

No filter ID is specified.

Command Modes

FPM match encryption filter configuration (c-map-match-enc-config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If you have access to an encrypted traffic classification definition file (eTCDF) or if you know valid values to configure encrypted Flexible Packet Matching (FPM) filters, you can configure the same eTCDF through the command-line interface instead of using the preferred method of loading the eTCDF on the router. You must create a class map of type access-control using the **class-map type** command, and use the **match encrypted** command to configure the match criteria for the class map on the basis of encrypted FPM filters and enter FPM match encryption filter configuration mode. You can then use the appropriate commands to specify the algorithm, cipher key, cipher value, filter hash, filter ID, and filter version. You can copy the values from the eTCDF by opening the eTCDF in any text editor.

Use the **filter-id** command to specify a filter-level ID for encrypted filters.

Examples

The following example shows how to specify the filter ID value for an encrypted filter:

```
Router(config)# class-map type access-control match-all c1
Router(config-cmap)# match encrypted
Router(c-map-match-enc-config)# filter-id id2
Router(c-map-match-enc-config)#
```

Related Commands

Command	Description
class-map type	Creates a class map to be used for matching packets to a specified class.
match encrypted	Configures the match criteria for a class map on the basis of encrypted FPM filters and enters FPM match encryption filter configuration mode.

filter-version

To specify the filter-level version value for the encrypted filter, use the **filter-version** command in FPM match encryption filter configuration mode.

filter-version *version*

Syntax Description

version	Filter-level version value of the encrypted filter.

Command Default

No filter version is specified.

Command Modes

FPM match encryption filter configuration (c-map-match-enc-config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If you have access to an encrypted traffic classification definition file (eTCDF) or if you know valid values to configure encrypted Flexible Packet Matching (FPM) filters, you can configure the same eTCDF through the command-line interface instead of using the preferred method of loading the eTCDF on the router. You must create a class map of type access-control using the **class-map type** command, and use the **match encrypted** command to configure the match criteria for the class map on the basis of encrypted FPM filters and enter FPM match encryption filter configuration mode. You can then use the appropriate commands to specify the algorithm, cipher key, cipher value, filter hash, filter ID, and filter version. You can copy the values from the eTCDF by opening the eTCDF in any text editor.

Use the **filter-version** command to specify the filter-level version value for the encrypted filter.

Examples

The following example shows how to specify the filter version for the encrypted filter:

```
Router(config)# class-map type access-control match-all c1
Router(config-cmap)# match encrypted
Router(c-map-match-enc-config)# filter-version v1
Router(c-map-match-enc-config)#
```

Related Commands

Command	Description
class-map type	Creates a class map to be used for matching packets to a specified class.
match encrypted	Configures the match criteria for a class map on the basis of encrypted FPM filters and enters FPM match encryption filter configuration mode.

firewall

To specify secure virtual LAN (VLAN) groups and to attach them to firewall modules, use the **firewall** command in global configuration mode. To disable the configuration, use the **no** form of this command.

firewall {**autostate** | **module** *number* **vlan-group** *number* | **multiple-vlan-interfaces** | **vlan-group** *number vlan-range*}

no firewall {**autostate** | **module** *number* **vlan-group** *number* | **multiple-vlan-interfaces** | **vlan-group** *number vlan-range*}

Syntax Description

autostate	Enables auto state.
module	Specifies the module number to which a VLAN group is attached.
number	Module number. Valid values are from 1 to 6.
vlan-group	Specifies the secure group to which the VLANs are attached.
number	Group number. The range is from 1 to 65535.
multiple-vlan-interfaces	Enables multiple VLAN interfaces mode for firewall modules.
vlan-range	VLAN range. Valid values are from 2 to 1001 and 1006 to 4094.

Command Default

No secure VLAN groups are attached to firewall modules.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Examples

The following example shows how to configure a VLAN group:

```
Router(config)# firewall vlan-group 34 1-20
```

Related Commands

Command	Description
show firewall vlan-group	Displays secure VLANs attached to a secure group.

fpm package-group

To configure flexible packet matching (fpm) package support, use the **fpm package-group** command in global configuration mode. To disable fpm package support, use the **no** form of this command.

fpm package-group [*fpm-group-name*]

no fpm package-group [*fpm-group-name*]

Syntax Description

fpm-group-name	Specifies the fpm package group name.

Command Default

FPM groups are not configured by default.

Command Modes

Global configuration (config)#

Command History

Release	Modification
15.0(1)M	This command was introduced.

Examples

The following example enables **fpm package-group**:

```
Router(config)# fpm package-group fpm-group-76
```

Related Commands

Command	Description
fpm package-info	Enables fpm package transfer.

fpm package-info

To configure flexible packet matching (fpm) package transfer from an fpm server to a local server, use the **fpm package-info** command in global configuration mode. To disable fpm packet transfer, use the **no** form of this command.

fpm package-info

no fpm package-info

Syntax Description

This command has no keywords or arguments.

Command Default

The command is not configured by default.

Command Modes

Global configuration (config)#

Command History

Release	Modification
15.0(1)M	This command was introduced.

Examples

The following example enables fpm package transfer:

```
Router(config)# fpm package-info
```

Related Commands

Command	Description
fpm package-group	Configures fpm package group support.
show fpm package-group	Displays fpm package matching support configuration details.
show fpm package-info	Displays fpm package transfer configuration details.

fqdn (IKEv2 profile)

To derive the name mangler from the remote identity of type Fully Qualified Domain Name (FQDN), use the **fqdn** command in IKEv2 name mangler configuration mode. To remove the name derived from FQDN, use the **no** form of this command.

fqdn {**all** | **domain** | **hostname**}

no fqdn

Syntax Description

all	Derives the name mangler from the entire FQDN.
domain	Derives the name mangler from the domain name of FQDN.
hostname	Derives the name mangler from the hostname of FQDN.

Command Default

No default behavior or values.

Command Modes

IKEv2 name mangler configuration (config-ikev2-name-mangler)

Command History

Release	Modification
15.1(3)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to derive the name mangler from the remote identity of type FQDN.

Examples

The following example shows how to derive a name for the name mangler from the hostname of FQDN:

```
Router(config)# crypto ikev2 name-mangler mangler2
Router(config-ikev2-name-mangler)# fqdn hostname
```

Related Commands

Command	Description
crypto ikev2 name mangler	Defines a name mangler.

grant auto rollover

To enable automatic granting of certificate reenrollment requests for a Cisco IOS subordinate certificate authority (CA) server or registration authority (RA) mode CA, use the **grant auto rollover command** in certificate server configuration mode. To disable automatic granting of certificate reenrollment requests for a Cisco IOS subordinate or RA-mode CA server, use the **no** form of this command.

grant auto rollover {**ca-cert** | **ra-cert**}

no grant auto rollover {**ca-cert** | **ra-cert**}

Syntax Description

ca-cert	Specifies that auto renewal is enabled for the subordinate CA rollover certificate.
ra-cert	Specifies that auto renewal is enabled for the RA-mode CA rollover certificate.

Command Default

Automatic granting of certificate reenrollment requests for a Cisco IOS subordinate CA server or RA-mode CA reenrollment requests is not enabled. Reenrollment requests will have to be granted manually.

Command Modes

Certificate server configuration (cs-server).

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

The first time a CA is enabled, a certificate request is sent to its superior CA. This initial request must be granted manually. The **grant auto rollover** command allows subsequent renewal certificate grant requests to be automatically processed by the CA for either a subordinate CA certificate (by designating the **ca-cert** keyword) or an RA-mode CA (by designating the **ra-cert** keyword), thereby eliminating the need for operator intervention.

Examples

The following example shows how the user can enable automatic granting of certificate reenrollment requests for a Cisco IOS subordinate CA server:

```
Router(cs-server)# grant auto rollover ca-cert
```

Related Commands

Command	Description
auto-rollover	Enables the automated CA certificate rollover functionality.
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.

grant auto trustpoint

To specify the certification authority (CA) trustpoint of another vendor from which the Cisco IOS certificate server will automatically grant certificate enrollment requests, use the **grant auto trustpoint** command in certificate server configuration mode.

grant auto trustpoint *label*

Syntax Description

label	Name of the non-Cisco IOS CA trustpoint.

Defaults

No default behavior or values.

Command Modes

Certificate server configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

After the network administrator for the server configures and authenticates a trustpoint for the CA of another vendor, the **grant auto trustpoint** command is issued to reference the newly created trustpoint and enroll the router with a Cisco IOS CA.

Note The newly created trustpoint can only be used one time (which occurs when the router is enrolled with the Cisco IOS CA). After the initial enrollment is successfully completed, the credential information will be deleted from the enrollment profile.

The Cisco IOS certificate server will automatically grant only the requests from clients who were already enrolled with the CA of another vendor. All other requests must be manually granted—unless the server is set to be in auto grant mode (via the **grant automatic** command).

Caution The **grant automatic** command can be used for testing and building simple networks and should be disabled before the network is accessible by the Internet. However, it is recommended that you do not issue this command if your network is generally accessible.

Examples

The following example shows how to configure a client router and a Cisco IOS certificate server to exchange enrollment requests via a certificate enrollment profile:

```
! Define the trustpoint "msca-root" that points to the non-Cisco IOS CA and enroll and
! authenticate the client with the non-Cisco IOS CA.
```

```
crypto pki trustpoint msca-root
 enrollment mode ra
 enrollment url http://msca-root:80/certsrv/mscep/mscep.dll
 ip-address FastEthernet2/0
 revocation-check crl
!
! Configure trustpoint "cs" for Cisco IOS CA.
crypto pki trustpoint cs
 enrollment profile cs1
 revocation-check crl
!
! Define enrollment profile "cs1," which points to Cisco IOS CA and mention (via the
! enrollment credential command) that "msca-root" is being initially enrolled with the
! Cisco IOS CA.
crypto pki profile enrollment cs1
 enrollment url  http://cs:80
 enrollment credential  msca-root!

! Configure the certificate server, and issue the grant auto trustpoint command to
! instruct the certificate server to accept enrollment request only from clients who are
! already enrolled with trustpoint "msca-root."
crypto pki server cs
 database level minimum
 database url nvram:
 issuer-name CN=cs
 grant auto trustpoint msca-root
!
crypto pki trustpoint cs
 revocation-check crl
rsakeypair cs
!
crypto pki trustpoint msca-root
 enrollment mode ra
 enrollment url http://msca-root:80/certsrv/mscep/mscep.dll
 revocation-check crl
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.

grant none

To specify all certificate requests to be rejected, use the **grant none** command in certificate server configuration mode. To disable automatic rejection of certificate enrollment, use the **no** form of this command.

grant none

no grant none

Syntax Description

This command has no arguments or keywords.

Defaults

Certificate enrollment is manual; that is, authorization is required.

Command Modes

Certificate server configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples

The following example shows how to automatically reject all certificate enrollment requests for the certificate server "myserver":

```
Router#(config) ip http server
Router#(config) crypto pki server myserver
Router#(cs-server) database level minimum
Router#(cs-server)# grant none
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.
grant automatic	Specifies automatic certificate enrollment.

grant ra-auto

To specify that all enrollment requests from a Registration Authority (RA) be granted automatically, use the **grant ra-auto** command in certificate server configuration mode. To disable automatic certificate enrollment, use the **no** form of this command.

grant ra-auto

no grant ra-auto

Syntax Description

This command has no arguments or keywords.

Defaults

Certificate enrollment is manual; that is, authorization is required.

Command Modes

Certificate server configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

When grant ra-auto mode is configured on the issuing certificate server, ensure that the RA mode certificate server is running in manual grant mode so that enrollment requests are authorized individually by the RA.

Note For the **grant ra-auto** command to work, you have to include "cn=ioscs RA" or "ou=ioscs RA" in the subject name of the RA certificate.

Examples

The following output shows that the issuing certificate server is configured to issue a certificate automatically if the request comes from an RA:

```
Router (config)# crypto pki server myserver
Router-ca (cs-server)# grant ra-auto
% This will cause all certificate requests that are already authorized by known RAs to be
automatically granted.

Are you sure you want to do this? [yes/no]:yes
```

Related Commands

Command	Description
crypto pki server	Enables a Cisco IOS certificate server and enters certificate server configuration mode.

group(firewall)

To enter redundancy application group configuration mode, use the **group** command in redundancy application configuration mode. To remove the group configuration, use the **no** form of this command.

group *id*

no group *id*

Syntax Description

id	Redundancy group ID. Valid values are 1 and 2.

Command Default

No group is configured.

Command Modes

Redundancy application configuration (config-red-app)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced.

Examples

The following example shows how to configure a redundancy group with group ID 1:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# application redundancy
Router(config-red-app)# group 1
Router(config-red-app-grp)#
```

Related Commands

Command	Description
application redundancy	Enters redundancy application configuration mode.

group (authentication)

To specify the authentication, authorization, and accounting (AAA) TACACS+ server group to use for preauthentication, use the **group** command in AAA preauthentication configuration mode. To remove the **group** command from your configuration, use the **no** form of this command.

group {**tacacs+** *server-group*}

no group {**tacacs+** *server-group*}

Syntax Description

tacacs+	Uses a TACACS+ server for authentication.
server-group	Name of the server group to use for authentication.

Defaults

No method list is configured.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You must configure the **group** command before you configure any other AAA preauthentication command (**clid**, **ctype**, **dnis**, or **dnis bypass**).

Examples

The following example enables Dialed Number Identification Service (DNIS) preauthentication using the abc123 server group and the password aaa-DNIS:

```
aaa preauth
 group abc123
 dnis password aaa-DNIS
```

Related Commands

Command	Description
aaa preauth	Enters AAA preauthentication mode.
dnis (authentication)	Enables AAA preauthentication using DNIS.

group (IKE policy)

To specify one or more Diffie-Hellman (DH) group identifier(s) for use in an Internet Key Exchange (IKE) policy, which defines a set of parameters to be used during IKE negotiation, use the **group** command in Internet Security Association Key Management Protocol (ISAKMP) policy configuration mode. To reset the DH group identifier to the default value, use the **no** form of this command.

group {**1** | **2** | **5** | **14** | **15** | **16** | **19** | **20** | **24**}

no group

Syntax Description

1	Specifies the 768-bit DH group.
2	Specifies the 1024-bit DH group.
5	Specifies the 1536-bit DH group.
14	Specifies the 2048-bit DH group.
15	Specifies the 3072-bit DH group.
16	Specifies the 4096-bit DH group.
19	Specifies the 256-bit elliptic curve DH (ECDH) group.
20	Specifies the 384-bit ECDH group.
24	Specifies the 2048-bit DH/DSA group.

Command Default

DH group 1

Command Modes

ISAKMP policy configuration (config-isakmp)

Command History

Release	Modification
11.3 T	This command was introduced.
12.1(1.3)T	Support was added for DH group 5.
12.4(4)T	Support for IPv6 was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.2	Support was added for DH groups 14, 15, and 16 on the Cisco ASR 1000 series routers.
15.1(2)T	This command was modified. The **14**, **15**, **16**, **19**, and **20** keywords were added.

Usage Guidelines

The group chosen must be strong enough (have enough bits) to protect the IPsec keys during negotiation. A generally accepted guideline recommends the use of a 2048-bit group after 2013 (until 2030). Either group 14 or group 24 can be selected to meet this guideline. Even if a longer-lived security method is needed, the use of Elliptic Curve Cryptography is recommended, but group 15 and group 16 can also be considered.

The ISAKMP group and the IPsec perfect forward secrecy (PFS) group should be the same if PFS is used. If PFS is not used, a group is not configured in the IPsec crypto map.

Examples

The following example shows how to configure an IKE policy with the 1024-bit DH group (all other parameters are set to the defaults):

```
Router(config)# crypto isakmp policy 15
Router(config-isakmp) group 2
Router(config-isakmp) exit
```

Related Commands

Command	Description
authentication (IKE policy)	Specifies the authentication method within an IKE policy.
crypto isakmp policy	Defines an IKE policy.
encryption (IKE policy)	Specifies the encryption algorithm within an IKE policy.
hash (IKE policy)	Specifies the hash algorithm within an IKE policy.
lifetime (IKE policy)	Specifies the lifetime of an IKE SA.
show crypto isakmp policy	Displays the parameters for each IKE policy.

group (IKEv2 proposal)

To specify one or more Diffie-Hellman (DH) group identifier(s) for use in an Internet Key Exchange Version 2 (IKEv2) proposal, use the **group** command in IKEv2 proposal configuration mode. To reset the DH group identifier to the default value, use the **no** form of this command.

group {**1** | **2** | **5** | **14** | **15** | **16** | **19** | **20** | **24**}

no group

Syntax Description

1	Specifies the 768-bit DH group.
2	Specifies the 1024-bit DH group.
5	Specifies the 1536-bit DH group.
14	Specifies the 2048-bit DH group
15	Specifies the 3072-bit DH group.
16	Specifies the 4096-bit DH group.
19	Specifies the 256-bit elliptic curve DH (ECDH) group.
20	Specifies the 384-bit ECDH group.
24	Specifies the 2048-bit DH/DSA group.

Command Default

DH group 2 and 5 in the IKEv2 proposal.

Command Modes

IKEv2 proposal configuration (config-ikev2-proposal)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(2)T	This command was modified. The **14**, **15**, **16**, **19**, and **20** keywords were added.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

The group chosen must be strong enough (have enough bits) to protect the IPsec keys during negotiation. A generally accepted guideline recommends the use of a 2048-bit group after 2013 (until 2030). Either group 14 or group 24 can be selected to meet this guideline. Even if a longer-lived security method is needed, the use of Elliptic Curve Cryptography is recommended, but group 15 and group 16 can also be considered.

Examples

The following example shows how to configure an IKEv2 proposal with the 1024-bit DH group:

```
Router(config)# crypto ikev2 proposal proposal1
Router(config-ikev2-proposal)# group 2
```

```
Router(config-ikev2-proposal)# exit
```

Related Commands

Command	Description
crypto ikev2 proposal	Defines an IKEv2 proposal.
encryption (ikev2 proposal)	Specifies the encryption algorithm in an IKEv2 proposal.
integrity (ikev2 proposal)	Specifies the integrity algorithm in an IKEv2 proposal.
show crypto ikev2 proposal	Displays the algorithms configured in each IKEv2 proposal.

group (local RADIUS server)

To enter user group configuration mode and to configure shared settings for a user group, use the **group** command in local RADIUS server configuration mode. To remove the group configuration from the local RADIUS server, use the **no** form of this command.

group *group-name*

no group *group-name*

Syntax Description

group-name	Name of user group.

Defaults

No default behavior or values

Command Modes

Local RADIUS server configuration

Command History

Release	Modification
12.2(11)JA	This command was introduced on Cisco Aironet Access Point 1100 and Cisco Aironet Access Point 1200.
12.3(11)T	This command was implemented on the following platforms: Cisco 2600XM, Cisco 2691, Cisco 2811, Cisco 2821, Cisco 2851, Cisco 3700, and Cisco 3800 series routers.

Examples

The following example shows that shared settings are being configured for group “team1”:

```
group team1
```

Related Commands

Command	Description
block count	Configures the parameters for locking out members of a group to help protect against unauthorized attacks.
clear radius local-server	Clears the statistics display or unblocks a user.
debug radius local-server	Displays the debug information for the local server.
nas	Adds an access point or router to the list of devices that use the local authentication server.
radius-server host	Specifies the remote RADIUS server host.
radius-server local	Enables the access point or router to be a local authentication server and enters into configuration mode for the authenticator.
reauthentication time	Specifies the time (in seconds) after which access points or wireless-aware routers must reauthenticate the members of a group.

Command	Description
show radius local-server statistics	Displays statistics for a local network access server.
ssid	Specifies up to 20 SSIDs to be used by a user group.
user	Authorizes a user to authenticate using the local authentication server.
vlan	Specifies a VLAN to be used by members of a user group.

group (RADIUS)

To specify the authentication, authorization, and accounting (AAA) RADIUS server group to use for preauthentication, use the **group** command in AAA preauthentication configuration mode. To remove the **group** command from your configuration, use the **no** form of this command.

group *server-group*

no group *server-group*

Syntax Description

server-group	Specifies a AAA RADIUS server group.

Defaults

No default behavior or values.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines

You must configure a RADIUS server group with the **aaa group server radius** command in global configuration mode before using the **group** command in AAA preauthentication configuration mode.

You must configure the **group** command before you configure any other AAA preauthentication command (**clid**, **ctype**, **dnis**, or **dnis bypass**).

Examples

The following example shows the creation of a RADIUS server group called “maestro” and then specifies that DNIS preauthentication be performed using this server group:

```
aaa group server radius maestro
 server 10.1.1.1
 server 10.2.2.2
 server 10.3.3.3

aaa preauth
 group maestro
 dnis required
```

Related Commands

Command	Description
aaa group server radius	Groups different RADIUS server hosts into distinct lists and distinct methods.
clid	Preauthenticates calls on the basis of the CLID number.
ctype	Preauthenticates calls on the basis of the call type.

Command	Description
dnis (RADIUS)	Preauthenticates calls on the basis of the DNIS number.
dnis bypass (AAA preauthentication configuration)	Specifies a group of DNIS numbers that will be bypassed for preauthentication.

group-lock

The **group-lock** command attribute is used to check if a user attempting to connect to a group belongs to this group. This attribute is used in conjunction with the extended authentication (Xauth) username. The user name must include the group to which it belongs. The group is then matched against the VPN group name (ID_KEY_ID) that is passed during the Internet Key Exchange (IKE). If the groups do not match, then the client connection is terminated.

To allow the extended authentication (Xauth) username to be entered when preshared key authentication is used with IKE, use the **group-lock** command in Internet Security Association Key Management Protocol (ISAKMP) group configuration mode. To remove the group lock, use the **no** form of this command.

Note Preshared keys are supported only. Certificates are not supported.

group-lock

no group-lock

Syntax Description

This command has no arguments or keywords.

Defaults

Group lock is not configured.

Command Modes

ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

The Group-Lock attribute can be used if preshared key authentication is used with IKE. When the user enables the **group-lock** command attribute, one of the following extended Xauth usernames can be entered:

name/group

name\group

name@group

name%group

where the \ / @ % are the delimiters. The group that is specified after the delimiter is then compared against the group identifier that is sent during IKE aggressive mode. The groups must match or the connection is rejected.

Caution Do not use the Group-Lock attribute if you are using RSA signature authentication mechanisms such as certificates. Use the User-VPN-Group attribute instead.

The Group-Lock attribute is configured on a Cisco IOS router or in the RADIUS profile. This attribute has local (gateway) significance only and is not passed to the client.

Note If local authentication is used, then the Group-Lock attribute is the only option.

The username in the local or RADIUS database must be of the following format:

username[/,\,%,@]group.

Examples

The following example shows how Group-Lock attribute is configured in the CLI using the **group-lock** command:

Note You must enable the **crypto isakmp client configuration group** command, which specifies group policy information that has to be defined or changed, before enabling the **group-lock** command.

```
crypto isakmp client configuration group cisco
  group-lock
```

The following example shows how an attribute-value (AV) pair for the User-VPN-Group attribute is added in the RADIUS configuration:

Note If RADIUS is used for user authentication, then use the User-VPN-Group attribute instead of the Group-Lock attribute.

```
ipsec:group-lock=1
```

Related Commands

Command	Description
acl	Configures split tunneling.
crypto isakmp client configuration group	Specifies the DNS domain to which a group belongs.

hash (ca-trustpoint)

To specify the cryptographic hash function the Cisco IOS client will use for self-signed certificates, use the **hash** command in ca-trustpoint configuration mode. To return to the default cryptographic hash function, use the **no** form of this command.

hash {**md5** | **sha1** | **sha256** | **sha384** | **sha512**}

no hash

Syntax Description

md5	Specifies that Message-Digest algorithm 5 (MD5), the default hash function, will be used.
sha1	Specifies that Secure Hash Algorithm (SHA-1) hash function will be used.
sha256	Specifies that the SHA-256 hash function will be used.
sha384	Specifies that the SHA-384 hash function will be used.
sha512	Specifies that the SHA-512 hash function will be used.

Command Default

By default, for self-signed certificates, the Cisco IOS client uses the MD5 cryptographic hash function.

Command Modes

Ca-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.4(15)T	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

The **hash** command in ca-trustpoint configuration mode sets the hash function for the signature that the Cisco IOS client will use to sign its self-signed certificates. This hash setting does not specify what kind of signature the certificate authority (CA) will use when it issues a certificate to this client.

Examples

The following example configures the trustpoint “MyTP” and sets the cryptographic hash function to SHA-384:

```
crypto pki trustpoint MyTP
   enrollment url http://MyTP
   ip-address FastEthernet0/0
   revocation-check none
   hash sha384
```

Related Commands

Command	Description
hash (cs-server)	Specifies the cryptographic hash function the Cisco IOS certificate server will use to sign certificates issued by the CA.

hash (cs-server)

To specify the cryptographic hash function the Cisco IOS certificate server will use to sign certificates issued by the certificate authority (CA), use the **hash** command in cs-server configuration mode. To return to the default cryptographic hash function, use the no form of this command.

hash {**md5** | **sha1** | **sha256** | **sha384** | **sha512**}

no hash

Syntax Description

md5	Specifies that the Message-Digest algorithm 5 (MD5), the default hash function, will be used.
sha1	Specifies that the Secure Hash Algorithm (SHA-1) hash function will be used.
sha256	Specifies that the SHA-256 hash function will be used.
sha384	Specifies that the SHA-384 hash function will be used.
sha512	Specifies that the SHA-512 hash function will be used.

Command Default

By default, to sign certificates issued by CA, the Cisco IOS client uses the MD5 cryptographic hash function.

Command Modes

Cs-server configuration (cs-server)

Command History

Release	Modification
12.4(14)XK	This command was introduced.
Cisco IOS XE Release 2.4	This command was implemented on the Cisco ASR 1000 series routers.

Usage Guidelines

The **hash** command in cs-server configuration mode sets the hash function for the signature that the Cisco IOS CA will use to sign all of the certificates issued by the server. If the CA is a root CA, it will use the hash function in its own, self-signed certificate.

Examples

The following example configures a certificate server, MyCS, and sets the cryptographic hash function to SHA-512 for the certificate server:

```
crypto pki server MyCS
database level complete
issuer-name CN=company,L=city,C=country
grant auto
hash sha512
lifetime crl 168
```

The following is sample output from the **show crypto ca certificates** command. This output shows that the CA has been configured and that the hash function SHA-512 has been specified.

```
CA Certificate
Status: Available
Certificate Serial Number: 01
Certificate Usage: Signature
Issuer:
cn=company
l=city
c=country
Subject:
cn=company
l=city
c=country
Validity Date:
start date: 01:32:35 GMT Aug 3 2006
end date: 01:32:35 GMT Aug 2 2009
Associated Trustpoints: MyTP
Certificate Subject:
Name: MyCS.cisco.com
IP Address: 192.168.10.2
Status: Pending Key
Usage: General Purpose
Certificate Request Fingerprint SHA1: 05080A60 82DE9395 B35607C2 38F3A0C3 50609EF8
Associated Trustpoint: MyTP
```

Related Commands

Command	Description
hash (ca-trustpoint)	Specifies the cryptographic hash function the Cisco IOS client will use for self-signed certificates.

hash (IKE policy)

To specify the hash algorithm within an Internet Key Exchange policy, use the **hash** command in Internet Security Association Key Management Protocol (ISAKMP) policy configuration mode. IKE policies define a set of parameters to be used during IKE negotiation. To reset the hash algorithm to the default secure hash algorithm (SHA)-1 hash algorithm, use the **no** form of this command.

hash {**sha** | **sha256** | **sha384** | **md5**}

no hash

Syntax Description

sha	Specifies SHA-1 (HMAC variant) as the hash algorithm.
sha256	Specifies SHA-2 family 256-bit (HMAC variant) as the hash algorithm.
sha384	Specifies SHA-2 family 384-bit (HMAC variant) as the hash algorithm.
md5	Specifies MD5 (HMAC variant) as the hash algorithm.

Defaults

The SHA-1 hash algorithm

Command Modes

ISAKMP policy configuration

Command History

Release	Modification
11.3 T	This command was introduced.
12.4(4)T	IPv6 support was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.1	This command was introduced on Cisco ASR 1000 Series Routers.
15.1(2)T	This command was modified. The **sha256** and **sha384** keywords were added.

Usage Guidelines

Use this command to specify the hash algorithm to be used in an IKE policy.

Examples

The following example configures an IKE policy with the MD5 hash algorithm (all other parameters are set to the defaults):

```
crypto isakmp policy 15
 hash md5
 exit
```

Related Commands

Command	Description
authentication (IKE policy)	Specifies the authentication method within an IKE policy.
crypto isakmp policy	Defines an IKE policy.
encryption (IKE policy)	Specifies the encryption algorithm within an IKE policy.
group (IKE policy)	Specifies the Diffie-Hellman group identifier within an IKE policy.
lifetime (IKE policy)	Specifies the lifetime of an IKE SA.
show crypto isakmp policy	Displays the parameters for each IKE policy.

heading

To configure the heading that is displayed above URLs listed on the portal page of a SSL VPN, use the **heading** command in webvpn URL list configuration mode. To remove the heading, use the **no** form of this command.

heading *text-string*

no heading

Syntax Description

text-string	The URL list heading entered as a text string. The heading must be in quotation marks if it contains spaces.

Command Default

A heading is not configured.

Command Modes

Webvpn URL list configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Examples

The following example configures a heading for a URL list:

```
Router(config)# webvpn context context1
Router(config-webvpn-context)# url-list ACCESS
Router(config-webvpn-url)# heading "Quick Links"
Router(config-webvpn-url)#
```

Related Commands

Command	Description
url-list	Enters webvpn URL list configuration mode to configure the list of URLs to which a user has access on the portal page of a SSL VPN.

hide-url-bar

To prevent the URL bar from being displayed on the SSL VPN portal page, use the **hide-url-bar** command in webvpn group policy configuration mode. To display the URL bar on the portal page, use the **no** form of this command.

hide-url-bar

no hide-url-bar

Syntax Description

This command has no arguments or keywords.

Command Default

The URL bar is displayed on the SSL VPN portal page.

Command Modes

Webvpn group policy configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

The configuration of this command applies only to clientless mode access.

Examples

The following example hides the URL bar on the SSL VPN portal page:

```
Router(config)# webvpn context context1
Router(config-webvpn-context)# policy group ONE
Router(config-webvpn-group)# hide-url-bar
Router(config-webvpn-group)#
```

Related Commands

Command	Description
policy group	Enters webvpn group policy configuration mode to configure a policy group.
webvpn context	Enters webvpn context configuration mode to configure the SSL VPN context.

host (webvpn url rewrite)

To select the name of the host site to be mangled on a Secure Socket Layer virtual private network (SSL VPN) gateway, use the **host** command in webvpn url rewrite configuration mode. To deselect a site, use the **no** form of this command.

host *host-name*

no host *host-name*

Syntax Description

host-name	Hostname of the site to be mangled.

Command Default

A host site is not selected.

Command Modes

Webvpn url rewrite (config-webvpn-url-rewrite)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Examples

The following example shows that the site www.examplecompany.com is to be mangled:

```
Router (config)# webvpn context
Router (config-webvpn-context)# url rewrite
Router (config-webvpn-url-rewrite)# host www.examplecompany.com
```

Related Commands

Command	Description
ip (webvpn url rewrite)	Configures the IP address of the site to be mangled on an SSL VPN gateway.
unmatched-action (webvpn url rewrite)	Defines the action when the user request does not match the IP address or host site configuration.

hostname (IKEv2 keyring)

To specify the hostname for the peer in the Internet Key Exchange Version 2 (IKEv2) keyring, use the **hostname** command IKEv2 keyring peer configuration mode. To remove the hostname, use the **no** form of this command.

hostname *name*

no hostname

Syntax Description

name	Name for the peer.

Command Default

The hostname is not specified.

Command Modes

IKEv2 keyring peer configuration (config-ikev2-keyring-peer)

Command History

Release	Modification
15.1(1)T	This command was introduced.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

When configuring the IKEv2 keyring, use this command to identify the peer using hostname, which is:

- Independent of the IKEv2 identity.
- Available on an IKEv2 initiator only.
- Provided by IPsec to IKEv2 as part of a security association setup request to identify the peer.
- Used to identify the peer only with crypto maps and not with tunnel protection.

Examples

The following example shows how to configure the hostname for a peer when configuring an IKEv2 keyring:

```
Router(config)# crypto ikev2 keyring keyring-1
Router(config-ikev2-keyring)# peer peer1
Router(config-ikev2-keyring-peer)# description peer1
Router(config-ikev2-keyring-peer)# hostname peer1.example.com
```

Related Commands

Command	Description
address (ikev2 keyring)	Specifies the IPv4 address or the range of the peers in IKEv2 key.
crypto ikev2 keyring	Defines an IKEv2 keyring.

Command	Description
description (ikev2 keyring)	Describes an IKEv2 peer or a peer group for the IKEv2 keyring.
identity (ikev2 keyring)	Identifies the peer with IKEv2 types of identity.
peer	Defines a peer or a peer group for the keyring.
pre-shared-key (ikev2 keyring)	Defines a preshared key for the IKEv2 peer.

hostname (WebVPN)

To configure the hostname for a SSL VPN gateway, use the **hostname** command in webvpn gateway configuration mode. To remove the hostname from the SSL VPN gateway configuration, use the **no** form of this command.

hostname *name*

no hostname

Syntax Description

name	Specifies the hostname.

Command Default

The hostname is not configured.

Command Modes

Webvpn gateway configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

A hostname is configured for use in the URL and cookie-mangling process. In configurations where traffic is balanced among multiple SSL VPN gateways, the hostname configured with this command maps to the gateway IP address configured on the load-balancing device(s).

Examples

The following example configures a hostname for a SSL VPN gateway:

```
Router(config)# webvpn gateway GW_1
Router(config-webvpn-gateway)# hostname VPN_Server
```

Related Commands

Command	Description
webvpn gateway	Defines a SSL VPN gateway and enters webvpn gateway configuration mode.

http proxy-server

To direct Secure Socket Layer virtual private network (SSL VPN) user requests through a backend HTTP proxy server, use the **http proxy-server** command in webvpn policy group configuration mode. To redirect user requests to internal servers, use the **no** form of this command.

http proxy-server {*dns-name* | *ip-address*} **port** *port-number*

no http proxy-server

Syntax Description

dns-name	Domain Name System (DNS) to be directed to the HTTP proxy server.
ip-address	IP address to be directed to the HTTP proxy server.
port *port-number*	Port number of the backend HTTP proxy server.

Command Default

User requests are routed directly to internal servers.

Command Modes

Webvpn policy group configuration (config-webvpn-group)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Examples

The following example shows that requests from IP address 10.1.1.1 are to be routed to the proxy server (port number 2034):

```
Router (config)# webvpn context e1
Router (config-webvpn-context)# policy group g1
Router (config-webvpn-group)# http proxy-server 10.1.1.1 port 2034
Router (config-webvpn-group)# exit
Router (config-webvpn-context)# default-group-policy g1
```

http-redirect

To configure HTTP traffic to be carried over secure HTTP (HTTPS), use the **http-redirect** command in webvpn gateway configuration mode. To remove the HTTPS configuration from the SSL VPN gateway, use the **no** form of this command.

http-redirect [**port** *number*]

no http-redirect

Syntax Description

port *number*	(Optional) Specifies a port number. The value for this argument is a number from 1 to 65535.

Command Default

The following default value is used if this command is configured without entering the **port** keyword:

port *number* : 80

Command Modes

Webvpn gateway configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

When this command is enabled, the HTTP port is opened and the SSL VPN gateway listens for HTTP connections. HTTP connections are redirected to use HTTPS. Entering the **port** keyword and *number* argument configures the gateway to listen for HTTP traffic on the specified port. Entering the **no** form, disables HTTP traffic redirection. HTTP traffic is handled by the HTTP server if one is running.

Examples

The following example, starting in global configuration mode, redirects HTTP traffic (on TCP port 80) over to HTTPS (on TCP port 443):

```
Router(config)# webvpn gateway SSL_GATEWAY
Router(config-webvpn-gateway)# http-redirect
```

Related Commands

Command	Description
webvpn gateway	Defines a SSL VPN gateway and enters webvpn gateway configuration mode.

hw-module slot subslot only

Note This command is deleted effective with Cisco IOS Release 12.2SXI.

To change the mode of the Cisco 7600 SSC-400 card to allocate full buffers to the specified subslot, use the **hw-module slot subslot only** command in global configuration mode. If this command is not used, the total amount of buffers available is divided between the two subslots on the Cisco 7600 SSC-400.

Note This command automatically generates a reset on the Cisco 7600 SSC-400. See Usage Guidelines below for details.

hw-module slot *slot* **subslot** *subslot* **only**

Syntax Description

slot	Chassis slot number where the Cisco 7600 SSC-400 is located. Refer to the appropriate hardware manual for slot information. For SIPs and SSCs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on the SSC where the IPSec VPN SPA is installed.

Defaults

No default behavior or values.

Command Modes

Global configuration mode

Command History

Release	Modification
12.2(18)SXF2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2SXI	This command was deleted.

Usage Guidelines

Follow these guidelines and restrictions when configuring a Cisco 7600 SSC-400 and IPSec VPN SPAs using the **hw-module slot subslot only** command:

- This command is useful when supporting IP multicast over GRE on the IPSec VPN SPA.
- When this command is executed, it automatically takes a reset action on the Cisco 7600 SSC-400 and issues the following prompt to the console:

```
Module n will be reset? Confirm [n]:
```

The prompt will default to “N” (no). You must type “Y” (yes) to activate the reset action.

- When in this mode, if you manually plug in a second SPA, or if you attempt to reset the SPA (by entering a **no hw-module subslot shutdown** command, for example), a message is displayed on the router console which refers you to the customer documentation.

Examples

The following example allocates full buffers to the SPA that is installed in subslot 0 of the SIP located in slot 1 of the router and takes a reset action of the Cisco 7600 SSC-400.

```
Router(config)# hw-module slot 4 subslot 1 only
Module 4 will be reset? Confirm [no]: y
```

Note that the prompt will default to “N” (no). You must type “Y” (yes) to activate the reset action.

Related Commands

Command	Description
ip multicast-routing	Enables IP multicast routing.
ip pim	Enables Protocol Independent Multicast (PIM) on an interface.

icmp idle-timeout

To configure the timeout for Internet Control Message Protocol (ICMP) sessions, use the **icmp idle-timeout** command in parameter-map type inspect configuration mode. To disable the timeout, use the **no** form of this command.

icmp idle-timeout *seconds*

no icmp idle-timeout *seconds*

Syntax Description

seconds	ICMP timeout, in seconds. The default is 10.

Command Default

The ICMP timeout is disabled.

Command Modes

Parameter-map type inspect configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

When you are configuring an inspect type parameter map, you can enter the **icmp idle-timeout** subcommand after you enter the **parameter-map type inspect** command. For more detailed information about creating a parameter map, see the **parameter-map type inspect** command.

Examples

The following example specifies that the ICMP session will timeout in 90 seconds:

```
parameter-map type inspect insp-params
 icmp idle-timeout 90
```

Related Commands

Command	Description
parameter-map type inspect	Configures an inspect parameter map for connecting thresholds, timeouts, and other parameters pertaining to the **inspect** action.

ida-client server url

To specify the IDA-server url that the IOS IDA client communicates with to download files from the Cisco.com server, use the **ida-client server url** command in global configuration mode. To revert back to the default value, use the **no** form of this command.

ida-client server url *url*

no ida-client server url *url*

Syntax Description

url	Specifies the IDA-server url. You must enter the following URL: https://www.cisco.com/cgi-bin/front.x/ida/locator/locator.pl

Command Default

The default IDA-server URL is: https://www.cisco.com/cgi-bin/ida/locator/locator.pl

Note Do not use the default URL in your configuration.

Command Modes

Global configuration

Command History

Release	Modification
15.0(1)M	This command was introduced.
15.1(1)T	This command was modified to include a default IDA-server URL.

Usage Guidelines

Enter the following URL for the **ida-client server url** command to specify the IDA-server URL:

```
Router(config)# ida-client server url
https://www.cisco.com/cgi-bin/front.x/ida/locator/locator.pl
```

Related Commands

Command	Description
ips signature update cisco	Initiates a one-time download of an IPS signatures from Cisco.com.
upgrade automatic abortversion	Cancels the scheduled reloading of the router with a new Cisco IOS software image.
upgrade automatic getversion	Downloads a Cisco IOS software image directly from www.cisco.com or from a non-Cisco server.
upgrade automatic runversion	Reloads the router with a new Cisco IOS software image.

identity local

To specify the local Internet Key Exchange Version 2 (IKEv2) identity type, use the **identity local** command in IKEv2 profile configuration mode. To remove the identity, use the **no** form of this command.

identity local {**address** {*ipv4-address* | *ipv6-address*} | **dn** | **fqdn** *fqdn-string* | **email** *e-mail-string* | **key-id** *opaque-string*}

no identity local

Syntax Description

address {*ipv4-address* | *ipv6-address*}	Uses the IPv4 or IPv6 address as the local identity.
dn	Uses the distinguished name as the local identity.
fqdn *fqdn-string*	Uses the Fully Qualified Domain Name (FQDN) as the local identity.
email *email-string*	Uses the e-mail ID as the local identity.
key-id *opaque-string*	Uses the proprietary type opaque string as the local identity.

Command Default

If the local authentication method is a preshared key, the default local identity is the IP address (IPv4 or IPv6). If the local authentication method is an RSA signature, the default local identity is Distinguished Name.

Command Modes

IKEv2 profile configuration (config-ikev2-profile)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(4)M	This command was modified. Support was added for IPv6 addresses.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify the local IKEv2 identity type as an IPv4 address or IPv6 address, a DN, an FQDN, an e-mail ID, or a key ID. The local IKEv2 identity is used by the local IKEv2 peer to identify itself to the remote IKEv2 peers in the AUTH exchange using the IDi field.

Note You can configure one local IKEv2 identity type for a profile.

Examples

The following example shows how to specify an IPv4 address as the local IKEv2 identity:

```
Router(config)# crypto ikev2 profile profile1
Router(config-ikev2-profile)# identity local address 10.0.0.1
```

The following example shows how to specify an IPv6 address as the local IKEv2 identity:

```
Router(config)# crypto ikev2 profile profile1
Router(config-ikev2-profile)# identity local address 2001:DB8:0::1
```

Related Commands

Command	Description
crypto ikev2 profile	Defines an IKEv2 profile.

identity (IKEv2 keyring)

To identify a peer with Internet Key Exchange Version 2 (IKEv2) types of identity, use the **identity** command in IKEv2 keyring peer configuration mode. To remove the identity, use the **no** form of this command.

identity{**address** {*ipv4-address* | *ipv6-address*} | **fqdn** *name* | **email** *e-mail-id* | **key-id** *key-id*}

no identity

Syntax Description

address {*ipv4-address* | *ipv6-address*}	Uses the IPv4 or IPv6 address to identify the peer.
fqdn *name*	Uses the Fully Qualified Domain Name (FQDN) to identify the peer.
email *e-mail-id*	Uses the e-mail ID to identify the peer.
key-id *key-id*	Uses the proprietory types to identify the peer.

Command Default

Identity types are not specified to a peer.

Command Modes

IKEv2 keyring peer configuration (config-ikev2-keyring-peer)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(4)M	This command was modified. Support was added for IPv6 addresses.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to identify the peer using IKEv2 types of identity such as an IPv4 or IPv6 address, an FQDN, an email, or a key ID. Key lookup using IKEv2 identity is available only on the responder because the peer ID is not available on the initiator at the time of starting the IKEv2 session and the initiator looks up keys during session startup.

Examples

The following example shows how to associate an FQDN to the peer:

```
Router(config)# crypto ikev2 keyring keyring-4
Router(config-keyring)# peer abc
Router(config-keyring-peer)# description abc domain
Router(config-keyring-peer)# identity fqdn example.com
```

Related Commands

Command	Description
address (ikev2 keyring)	Specifies the IPv4 or IPv6 address or the range of the peers in IKEv2 keyring.
crypto ikev2 keyring	Defines an IKEv2 keyring.
description (ikev2 keying)	Describes an IKEv2 peer or a peer group for the IKEv2 keyring.
hostname (ikev2 keyring)	Specifies the hostname for the peer in the IKEv2 keyring.
peer	Defines a peer or a peer group for the keyring.
pre-shared-key (ikev2 keyring)	Defines a preshared key for the IKEv2 peer.

identity (IKEv2 profile)

To specify how the local or remote router identifies itself to the peer and communicates with the peer in the Rivest, Shamir and Adleman (RSA) authentication exchange, use the **identity** command in IKEv2 profile configuration mode. To delete a match, use the **no** form of this command.

identity [**local** {**dn** [**trustpoint** *trustpoint-name* [**serial** *certificate-serial*]] | **address** *ip-address* | **fqdn** *string* | **email** *string*} | **remote** {**dn** [**ou=**..., **o=**...] | **address** *ip-address* | **fqdn** *string* | **email** *string*}]

no identity [**local** {**dn** [**trustpoint** *trustpoint-name* [**serial** *certificate-serial*]] | **address** *ip-address* | **fqdn** *string* | **email** *string*} | **remote** {**dn** [**ou=**..., **o=**...] | **address** *ip-address* | **fqdn** *string* | **email** *string*}]

Syntax Description

local	Specifies the local router.
dn	Specifies the distinguished name (DN) of the local or remote router.
trustpoint *trustpoint-name*	(Optional) Specifies the PKI trustpoint name to use with the RSA signature authentication method on the local router.
serial *certificate-serial*	(Optional) Specifies the serial number of the trustpoint certificate on the local router.
address *ip-address*	Specifies the IP address of the remote or local router.
fqdn *fqdn-name*	Specifies the Fully Qualified Domain Name (FQDN) of the remote or local router.
email *e-mail ID*	Specifies the email ID of the remote or local router.
ou=..., **o=**...	(Optional) Specifies the organizational Unit (OU) field of the subject name in the trustpoint certificate.

Command Default

An identity profile is not specified for a local or remote router regarding the RSA authentication exchange.

Command Modes

IKEv2 profile configuration (crypto-ikev2-profile)#

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(2)T	This command was modified. The **local**, **dn**, **trustpoint**, **serial**, and **ou=** keywords were added to this command.

Usage Guidelines

Use the **identity** command to identify the local or remote router by its DN, trustpoint, IP address, FQDN, or email address.

Examples

The following example shows how an IKEv2 profile is matched on the remote identity. The following profile caters to peers that identify using **fqdn example.com** and authenticate with **rsa-signature** using **trustpoint-remote**. The local node authenticates with **pre-share** using **keyring-1**.

```
Router(config)# crypto ikev2 profile profile2
Router(config-ikev2-profile)# match identity remote fqdn example.com
Router(config-ikev2-profile)# identity local email router2@example.com
Router(config-ikev2-profile)# authentication local pre-share
Router(config-ikev2-profile)# authentication remote rsa-sig
Router(config-ikev2-profile)# keyring keyring-1
Router(config-ikev2-profile)# pki trustpoint trustpoint-remote verify
Router(config-ikev2-profile)# lifetime 300
Router(config-ikev2-profile)# dpd 5 10 on-demand
Router(config-ikev2-profile)# virtual-template 1
```

Related Commands

Command	Description
crypto ikev2 profile	Defines an IKEv2 profile.
match (IKEv2 profile)	Matches a profile on front-door VPN routing and forwarding (FVRF) or local parameters such as IP address or peer identity or peer certificate.
authentication (IKEv2 profile)	Specifies the local and remote authentication methods in an Internet Key Exchange Version 2 (IKEv2) profile.
keyring (IKEv2 profile)	Specifies a locally defined or accounting, authentication and authorization (AAA) based keyring.
pki trustpoint	Specifies the router to use the PKI trustpoints in the RSA signature authentication.

identity address ipv4

To identify a Group Domain of Interpretation (GDOI) group address, use the **identity address ipv4** command in GDOI group configuration mode. To remove the group address, use the **no** form of this command.

identity address ipv4 {*address*}

no identity address ipv4 {*address*}

Syntax Description

address	IP address of the group.

Command Default

A group address is not identified.

Command Modes

GDOI group configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

This command or the **identity number** command is required for a GDOI configuration.

Examples

The following example shows that the identity address is 10.2.2.2:

```
identity address ipv4 10.2.2.2
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group.
identity number	Identifies a GDOI group number.

identity number

To identify a Group Domain of Interpretation (GDOI) group number, use the **identity number** command in GDOI group configuration mode. To remove the group number, use the **no** form of this command.

identity number {*number*}

no identity number {*number*}

Syntax Description

number	Number of the group.

Command Default

A GDOI group number is not identified.

Command Modes

GDOI group configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

This command or the **identity address ipv4** command is required for a GDOI configuration.

Examples

The following example shows the group number is 3333:

```
identity number 3333
```

Related Commands

Command	Description
crypto gdoi group	Identifies a GDOI group and enters GDOI group configuration mode.
identity address ipv4	Identifies a GDOI group address.

identity policy

To create an identity policy and to enter identity policy configuration mode, use the **identity policy** command in global configuration mode. To remove the policy, use the **no** form of this command.

identity policy *policy-name* [**access-group** *group-name* | **description** *line-of-description* | **redirect** *url* | **template** [**virtual-template** *interface-number*]]

no identity policy *policy-name* [**access-group** *name* | **description** *line-of-description* | **redirect** *url* | **template** [**virtual-template** *interface-number*]]

Syntax Description

policy-name	Name of the policy.
access-group *group-name*	(Optional) Access list to be applied.
description *line-of-description*	(Optional) Description of the policy.
redirect *url*	(Optional) Redirects clients to a particular URL.
template	(Optional) Virtual template interface from which commands may be cloned.
virtual-template *interface-number*	(Optional) Virtual template number. The values range from 1 through 200.

Defaults

An identity policy is not created.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

An identity policy has to be associated with an identity profile.

Examples

The following example shows that an access policy named “policyname2” is being created. The access-group attribute is set to “allow-access.” The redirect URL is set to “http://remediate-url.com.” This access policy will be associated with a statically authorized device in the identity profile.

```
Router (config)# identity policy policyname2
Router (config-identity-policy)# access-group allow-access
Router (config-identity-policy)# redirect url http://remediate-url.com
```

Related Commands

Command	Description
identity profile	Creates an identity profile.

identity profile

To create an identity profile and to enter identity profile configuration mode, use the **identity profile** command in global configuration mode. To disable an identity profile, use the **no** form of this command.

identity profile {**default** | **dot1x** | **eapoudp** | **auth-proxy**}

no identity profile {**default** | **dot1x** | **eapoudp** | **auth-proxy**}

Syntax Description

default	Service type is default.
dot1x	Service type for 802.1X.
eapoudp	Service type for Extensible Authentication Protocol over UDP (EAPoUDP).
auth-proxy	Service type for authentication proxy.

Command Default

An identity profile is not created.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(2)XA	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(8)T	The **eapoudp** keyword was added.
12.4(6)T	The **dot1x** keyword was removed.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **identity profile** command and **default** keyword allow you to configure static MAC addresses of a client computer that does not support 802.1X and to authorize or unauthorize them statically. After you have issued the **identity profile** command and **default** keyword and the router is in identity profile configuration mode, you can specify the configuration of a template that can be used to create the virtual access interface to which unauthenticated supplicants (client computers) will be mapped.

The **identity profile** command and the **dot1x** keyword are used by the supplicant and authenticator. Using the **dot1x** keyword, you can set the username, password, or other identity-related information for an 802.1X authentication.

Using the **identity profile** command and the **eapoudp** keyword, you can statically authenticate or unauthenticate a device either on the basis of the device IP address or MAC address or on the type, and the corresponding network access policy can be specified using the **identity policy** command.

Examples

The following example shows that an identity profile and its description have been specified:

```
Router (config)# identity profile default
Router (config-identity-prof)# description description_entered_here
```

The following example shows that an EAPoUDP identity profile has been created:

```
Router (config)# identity policy eapoudp
```

Related Commands

Command	Description
debug dot1x	Displays 802.1X debugging information.
description	Specifies a description for an 802.1X profile.
device	Statically authorizes or rejects individual devices.
dot1x initialize	Initializes 802.1X state machines on all 802.1X-enabled interfaces.
dot1x max-req	Sets the maximum number of times that a router can send an EAP request/identity frame to a client PC.
dot1x max-start	Sets the maximum number of times the authenticator sends an EAP request/identity frame (assuming that no response is received) to the client.
dot1x pae	Sets the PAE type during 802.1X authentication.
dot1x port-control	Enables manual control of the authorization state of a controlled port.
dot1x re-authenticate	Manually initiates a reauthtication of the specified 802.1X-enabled ports.
dot1x re-authentication	Globally enables periodic reauthentication of the client PCs on the 802.1X interface.
dot1x system-auth-control	Enables 802.1X SystemAuthControl (port-based authentication).
dot1x timeout	Sets retry timeouts.
identity policy	Creates an identity policy.
show dot1x	Displays details for an identity profile.
template (identity profile)	Specifies a virtual template from which commands may be cloned.

identity profile eapoudp

To create an identity profile and to enter Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) profile configuration mode, use the **identity profile eapoudp** command in global configuration mode. To remove the policy, use the **no** form of this command.

identity profile eapoudp

no identity profile eapoudp

Syntax Description

This command has no arguments or keywords.

Defaults

No EAPoUDP identity profile exists.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Using this command, you can statically authenticate or unauthenticate a device either on the basis of the device IP address or MAC address or on the type, and the corresponding network access policy can be specified using the **identity policy** command.

Examples

The following example shows that an EAPoUDP identity profile has been created:

```
Router (config)# identity profile eapoudp
```

Related Commands

Command	Description
identity policy	Creates an identity policy.

idle-timeout (WebVPN)

Note Effective with Cisco IOS Release 12.4(6)T, the **idle-timeout (WebVPN)** command is not available in Cisco IOS software.

To set the default idle timeout for a Secure Sockets Layer Virtual Private Network (SSLVPN) if no idle timeout has been defined or if the idle timeout is zero (0), use the **idle-timeout** command in Web VPN configuration mode. To revert to the default value, use the **no** form of this command.

idle-timeout [**never** | *seconds*]

no idle-timeout [**never** | *seconds*]

Syntax Description

never	(Optional) The idle timeout function is disabled.
seconds	(Optional) Idle timeout in seconds. The values are from 180 seconds (3 minutes) to 86400 seconds (24 hours).

Defaults

If command is not configured, the default idle timeout is 1800 seconds (30 minutes).

Command Modes

Web VPN configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(6)T	This command was removed.

Usage Guidelines

Configuring this command prevents stale sessions.

Examples

The following example shows that the idle timeout has been set for 1200 seconds:

```
Router (config)# webvpn
Router (config-webvpn)# idle-timeout 1200
```

The following example shows that the idle timeout function is disabled:

```
Router (config)# webvpn
Router (config-webvpn)# idle-timeout never
```

Related Commands

Command	Description
webvpn	Enters Web VPN configuration mode.

if-state nhrp

To enable the Next Hop Resolution Protocol (NHRP) to control the state of the tunnel interface, use the **if-state nhrp** command in interface configuration mode. To disable NHRP control of the tunnel interface state, use the **no** form of this command.

if-state nhrp

no if-state nhrp

Syntax Description

This command has no arguments or keywords.

Command Default

NHRP tunnel interface state control is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

If the system detects that one or more of the Next Hop Servers (NHSs) configured on the interface is up, then the tunnel interface state is also declared as ‘up’. If all NHSs configured on the interface are down, then the tunnel interface state is also declared as ‘down’.

The system does not consider NHSs configured with ‘no-reply’ when determining the interface state.

Examples

The following example shows how to enable NHRP control of the tunnel interface state:

```
Router(config)# interface tunnel 1
Router(config-if)# if-state nhrp
```

Related Commands

Command	Description
show ip interface	Displays the usability status of interfaces configured for IP.
show ip nhrp nhs	Displays NHRP NHS information.

import

To import a user-defined URL list into a webvpn context, use the **import** command in the webvpn URL list configuration mode. To disable the URL list, use the **no** form of this command.

import *device*:*file*

no import *device*:*file*

Syntax Description

device:*file*	• *device*:*file*—Storage device on the system and the file name. The file name should include the directory location.

Command Default

A user-defined URL list is not imported.

Command Modes

Webvpn URL list configuration (config-webvpn-url)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

If this command is used under the **url-list** command, the **url-text** command is not allowed. The **import** command and the **url-list** commands are mutually exclusive when used for a particular URL list. (If you use them together, you will receive this message: "Please remove the imported url-list.")

Also, if a URL list is configured using the **url-text** command, the **import** command is not allowed. (If you use them together, you will receive this message: "Please remove all the URLs before importing a file.")

Examples

The following example shows that the URL list file "test-url.xml" is being imported from flash:

```
Router (config)# webvpn context
 Router (config-webvpn-context)# url-list test
 Router (config-webvpn-url)# import flash:est-url.xml
```

Related Commands

Command	Description
webvpn create template	Creates templates for multilanguage support for messages in an SSL VPN.

include-local-lan

To configure the Include-Local-LAN attribute to allow a nonsplit-tunneling connection to access the local subnetwork at the same time as the client, use the **include-local-lan** command in Internet Security Association Key Management Protocol (ISAKMP) group configuration mode. To disable the attribute that allows the nonsplit-tunneling connection, use the **no** form of this command.

include-local-lan

no include-local-lan

Syntax Description

This command has no arguments or keywords.

Defaults

A nonsplit-tunneling connection is not able to access the local subnet at the same time as the client.

Command Modes

ISAKMP group configuration (config-isakmp-group)

Command History

Release	Modification
12.3(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

If split tunneling is not in use (that is, the SPLIT_INCLUDE attribute was not negotiated), you lose not only Internet access, but also access to resources on the local subnetworks. The Include-Local-LAN attribute allows the server to push the attribute to the client, which allows for a nonsplit-tunneling connection to access the local subnetwork at the same time as the client (that is, the connection is to the subnetwork to which the client is directly attached).

The Include-Local-LAN attribute is configured on a Cisco IOS router or in the RADIUS profile.

To configure the Include-Local-LAN attribute, use the **include-local-lan** command.

An example of an attribute-value (AV) pair for the Include-Local-LAN attribute is as follows:

```
ipsec:include-local-lan=1
```

You must enable the **crypto isakmp client configuration group** command, which specifies group policy information that has to be defined or changed, before enabling the **include-local-lan** command.

Note

- The Include-Local-LAN attribute can be applied only by a RADIUS user.
- The attribute can be applied on a per-user basis after the user has been authenticated.
- The attribute can override any similar group attributes.

- User-based attributes are available only if RADIUS is used as the database.

Examples

The following example shows that the Include-Local-LAN has been configured:

```
crypto isakmp client configuration group cisco
 include-local-lan
```

Syntax Description

Command	Description
acl	Configures split tunneling.
crypto isakmp client configuration group	Specifies the DNS domain to which a group belongs.

incoming

To configure filtering for incoming IP traffic, use the **incoming** command in router IP traffic export (RITE) configuration mode. To disable filtering for incoming traffic, use the **no** form of this command.

incoming {**access-list** {*standard* | *extended* | *named*} | **sample one-in-every** *packet-number*}

no incoming {**access-list** {*standard* | *extended* | *named*} | **sample one-in-every** *packet-number*}

Syntax Description

access-list {*standard* | *extended* | *named*}	An existing numbered (standard or extended) or named access control list (ACL). **Note** The filter is applied only to exported traffic, not normal router traffic.
sample one-in-every *packet-number*	Exports only one packet out of every specified number of packets. Valid range for the *packet-number* argument is 2 to 2147483647 packets. By default, all traffic is exported.

Defaults

If this command is not enabled, all incoming IP traffic will be filtered via sampling.

Command Modes

RITE configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.2(25)S	This command was integrated into Cisco IOS Release 12.2(25)S.

Usage Guidelines

When configuring a network device for exporting IP traffic, you can issue the **incoming** command to filter unwanted traffic via the following methods:

- ACLs, which accept or deny an IP packet for export
- Sampling, which allows you to export one in every few packets in which you are interested. Use this option when it is not necessary to export all incoming traffic. Also, sampling is useful when a monitored ingress interface can send traffic faster than the egress interface can transmit it.

Examples

The following example shows how to configure the profile "corp1," which will send captured IP traffic to host "00a.8aab.90a0" at the interface "FastEthernet 0/1." This profile is also configured to export one in every 50 packets and to allow incoming traffic only from the ACL "ham_ACL."

```
Router(config)# ip traffic-export profile corp1
Router(config-rite)# interface FastEthernet 0/1
Router(config-rite)# bidirectional
Router(config-rite)# mac-address 00a.8aab.90a0
Router(config-rite)# outgoing sample one-in-every 50
Router(config-rite)# incoming access-list ham_acl
Router(config-rite)# exit
Router(config)# interface FastEthernet 0/0
```

```
Router(config-if)# ip traffic-export apply corp1
```

Related Commands

Command	Description
ip traffic-export profile	Creates or edits an IP traffic export profile and enables the profile on an ingress interface.
outgoing	Configures filtering for outgoing export traffic.

initiate mode

To configure the Phase 1 mode of an Internet Key Exchange (IKE), use the **initiate mode** command in ISAKMP profile configuration mode. To remove the mode that was configured, use the **no** form of this command.

initiate mode aggressive

no initiate mode aggressive

Syntax Description

aggressive	Aggressive mode is initiated.

Defaults

IKE initiates main mode.

Command Modes

ISAKMP profile configuration (config-isa-prof)

Command History

Release	Modification
12.2(15)T	This command was introduced.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

Use this command if you want to initiate an IKE aggressive mode exchange instead of a main mode exchange.

Examples

The following example shows that aggressive mode has been configured:

```
crypto isakmp profile vpnprofile
 initiate mode aggressive
```

inservice (WebVPN)

To enable a SSL VPN gateway or context process, use the **inservice** command in webvpn gateway configuration or webvpn context configuration mode. To disable a SSL VPN gateway or context process without removing the configuration from the router configuration file, use the **no** form of this command.

inservice

no inservice

Syntax Description

This command has no arguments or keywords.

Command Default

A SSL VPN gateway or context process is not enabled.

Command Modes

Webvpn gateway configuration
Webvpn context configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

The enable form of this command initializes required system data structures, initializes TCP sockets, and performs other start-up tasks related to the SSL VPN gateway or context process. The gateway and context processes must both be “inservice” to enable SSL VPN.

Examples

The following example enables the SSL VPN gateway process named SSL_GATEWAY:

```
Router(config)# webvpn gateway SSL_GATEWAY
Router(config-webvpn-gateway)# inservice
```

The following example configures and activates the SSL VPN context configuration:

```
Router(config)# webvpn context context1
Router(config-webvpn-context)# inservice
```

Related Commands

Command	Description
webvpn context	Enters webvpn configuration mode to configure the SSL VPN context.
webvpn gateway	Defines a SSL VPN gateway and enters webvpn gateway configuration mode.

inspect

To enable Cisco IOS stateful packet inspection, use the **inspect** command in policy-map-class configuration mode. To disable stateful packet inspection, use the **no** form of this command.

inspect [*parameter-map-name*]

no inspect [*parameter-map-name*]

Syntax Description

parameter-map-name	(Optional) Name of a previously configured inspect parameter-map. If you do not specify a parameter map name, the software uses the default values for all the parameters.

Command Default

None

Command Modes

Policy-map-class configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

You can use this subcommand after entering the **policy-map type inspect**, **class type inspect**, and **parameter-map type** inspect commands.

To enable Cisco IOS stateful packet inspection, enter the name of an inspect parameter-map that was previously configured by using the **parameter-map type inspect** command.

This command lets you specify the attributes that will be used for the inspection.

Examples

The following example specifies inspection parameters for alert and audit-trail, and requests the **inspect** action with the specified parameters:

```
parameter-map type inspect insp-params
 alert on
 audit-trail on

policy-map type inspect mypolicy
 class type inspect inspect-traffic
  inspect inspect-params
```

Related Commands

Command	Description
class type inspect	Specifies the traffic (class) on which an action is to be performed.
parameter-map type inspect	Configures an inspect type parameter map for connecting thresholds, timeouts, and other parameters pertaining to the **inspect** action.
policy-map type inspect	Creates a Layer 3 or Layer 4 inspect type policy map.

integrity

To specify one or more integrity algorithms for an Internet Key Exchange Version 2 (IKEv2) proposal, use the **integrity** command in IKEv2 proposal configuration mode. To remove the configuration of the hash algorithm, use the **no** form of this command.

integrity {**sha1**} {**sha256**} {**sha384**} {**sha512**} {**md5**}

no integrity

Syntax Description

sha1	Specifies Secure Hash Algorithm (SHA-1 - HMAC variant) as the hash algorithm.
sha256	Specifies SHA-2 family 256-bit (HMAC variant) as the hash algorithm.
sha384	Specifies SHA-2 family 384-bit (HMAC variant) as the hash algorithm.
sha512	Specifies SHA-2 family 512-bit (HMAC variant) as the hash algorithm.
md5	Specifies Message-Digest algorithm 5 (MD5 - HMAC variant) as the hash algorithm.

Command Default

The default integrity algorithm is used.

Command Modes

IKEv2 proposal configuration (config-ikev2-proposal)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(2)T	This command was modified. The **sha256** and **sha384** keywords were added.
Cisco IOS XE Release 3.3S	This command was integrated into Cisco IOS XE Release 3.3S.

Usage Guidelines

Use this command to specify the integrity algorithm to be used in an IKEv2 proposal. The default integrity algorithms in the default proposal are SHA-1 and MD5.

Note You cannot selectively remove an integrity algorithm when multiple integrity algorithms are configured.

Suite-B adds support for the SHA-2 family (HMAC variant) hash algorithm used to authenticate packet data and verify the integrity verification mechanisms for the IKEv2 proposal configuration. HMAC is a variant that provides an additional level of hashing.

Examples

The following example configures an IKEv2 proposal with the MD5 integrity algorithm:

```
Router(config)# crypto ikev2 proposal proposal1
Router(config-ikev2-proposal)# integrity md5
```

Related Commands

Command	Description
crypto ikev2 proposal	Defines an IKEv2 proposal.
encryption (ikev2 proposal)	Specifies the encryption algorithm in an IKEv2 proposal.
group (ikev2 proposal)	Specifies the Diffie-Hellman group identifier in an IKEv2 proposal.
show crypto ikev2 proposal	Displays the parameters for each IKEv2 proposal.

interface (RITE)

To specify the outgoing interface for exporting traffic, use the **interface** command in router IP traffic export (RITE) configuration mode. To disable an interface, use the **no** form of this command.

interface *interface-name*

no interface *interface-name*

Syntax Description

interface-name	Name of interface in which IP packets are exported.

Defaults

If this command is not enabled, the exported IP traffic profile does not recognize an interface in which to send captured IP traffic.

Command Modes

RITE configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.2(25)S	This command was integrated into Cisco IOS Release 12.2(25)S.

Usage Guidelines

After you configure an IP traffic export profile via the **ip traffic-export profile** global configuration command, you should issue the **interface** command; otherwise, the profile will be unable to export the captured IP packets. If you do not specify the **interface** command, you will receive a warning, which states that the profile is incomplete, when you attempt to apply the profile to an interface via the **ip traffic-export apply profile** interface configuration command.

Note Currently, only Ethernet and Fast Ethernet interfaces are supported.

Examples

The following example shows how to configure the profile “corp1,” which will send captured IP traffic to host “00a.8aab.90a0” at the interface “FastEthernet 0/1.” This profile is also configured to export one in every 50 packets and to allow incoming traffic only from the access control list ACL “ham_ACL.”

```
Router(config)# ip traffic-export profile corp1
Router(config-rite)# interface FastEthernet 0/1
Router(config-rite)# bidirectional
Router(config-rite)# mac-address 00a.8aab.90a0
Router(config-rite)# outgoing sample one-in-every 50
Router(config-rite)# incoming access-list ham_acl
Router(config-rite)# exit
Router(config)# interface FastEthernet 0/0
Router(config-if)# ip traffic-export apply corp1
```

Related Commands

Command	Description
ip traffic-export apply profile	Applies an IP traffic export profile to a specific interface.
ip traffic-export profile	Creates or edits an IP traffic export profile and enables the profile on an ingress interface.

interface (VASI)

To configure a Virtual Routing and Forwarding (VRF)-Aware Software Infrastructure (VASI) virtual interface, use the **interface** command in global configuration mode. To remove a VASI configuration, use the **no** form of this command.

interface {**vasileft** | **vasiright**} *number*

no interface {**vasileft** | **vasiright**} *number*

Syntax Description

vasileft	Configures the vasileft interface.
vasiright	Configures the vasiright interface.
number	Identifier of the VASI interface. The range is from 1 to 1000.

Command Default

VASI interface is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 2.6	This command was introduced.
Cisco IOS XE Release 3.1S	This command was modified. The *number* argument was modified to accept 500 VASI interfaces.
Cisco IOS XE Release 3.3S	This command was modified. The *number* argument was modified to accept 1000 VASI interfaces.

Usage Guidelines

The vasileft and vasiright interfaces must be configured before the VASI interface becomes active. The two halves of the interface pair must be configured separately. If only one half of the interface is configured and not the other half, then the VASI interface does not become active.

Examples

The following example shows how to configure vasileft and vasiright interfaces:

```
Router(config)# interface vasileft 200
router(config-if)# vrf forwarding table1
Router(config-if)# ip address 192.168.0.1 255.255.255.0
Router(config-if)# exit

Router(config)# interface vasiright 200
router(config-if)# vrf forwarding table2
Router(config-if)# ip address 192.168.1.1 255.255.255.0
Router(config-if)# exit
```

Related Commands

Command	Description
debug adjacency (VASI)	Displays debugging information for VASI adjacency.
debug interface (VASI)	Displays debugging information for VASI interface descriptor block.
debug vasi	Displays VASI debugging information.
show vasi pair	Displays the status of a VASI pair.

interface virtual-template

To create a virtual template interface that can be configured and applied dynamically in creating virtual access interfaces, use the **interface virtual-template** command in global configuration mode. To remove a virtual template interface, use the **no** form of this command.

interface virtual-template *number*

no interface virtual-template *number*

Syntax Description

number	Number used to identify the virtual template interface. Up to 200 virtual template interfaces can be configured. On the Cisco 10000 series router, up to 4095 virtual template interfaces can be configured.

Command Default

No virtual template interface is defined.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.2F	This command was introduced.
12.2(4)T	This command was enhanced to increase the maximum number of virtual template interfaces from 25 to 200.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SB	This command's default configuration was modified for SNMP and implemented on the Cisco 10000 series router for the PRE3 and PRE4.

Usage Guidelines

A virtual template interface is used to provide the configuration for dynamically created virtual access interfaces. It is created by users and can be saved in NVRAM.

After the virtual template interface is created, it can be configured in the same way as a serial interface.

Virtual template interfaces can be created and applied by various applications such as virtual profiles, virtual private dialup networks (VPDNs), PPP over ATM, protocol translation, and Multichassis Multilink PPP (MMP).

Cisco 10000 Series Router

You can configure up to 4095 total virtual template interfaces on the Cisco 10000 series router.

To ensure proper scaling and to minimize CPU utilization, we recommend the following virtual template interface settings:

- A keepalive timer of 30 seconds or greater using the **keepalive** command. The default is 10 seconds.

- Do not enable the Cisco Discovery Protocol (CDP). CDP is disabled by default. Use the **no cdp enable** command to disable CDP, if necessary.
- Disable link-status event messaging using the **no logging event link-status** command.
- To prevent the virtual-access subinterfaces from being registered with the SNMP functionality of the router and using memory, do not use the router's SNMP management tools to monitor PPP sessions. Use the **no virtual-template snmp** command to disable the SNMP management tools.

When a virtual template interface is applied dynamically to an incoming user session, a virtual access interface (VAI) is created.

If you configure a virtual template interface with interface-specific commands, the Cisco 10000 series router does not achieve the highest possible scaling. To verify that the router does not have interface-specific commands within the virtual template interface configuration, use the **test virtual-template** <*number*> **subinterface** command.

In Cisco IOS Release 12.2(33)SB, the default configuration for the **virtual-template snmp** command was changed to **no virtual-template snmp**. This prevents large numbers of entries into the MIB ifTable, thereby avoiding CPU Hog messages as SNMP uses the interfaces MIB and other related MIBs. If you configure the **no virtual-template snmp** command, the router no longer accepts the **snmp trap link-status** command under a virtual-template interface. Instead, the router displays a configuration error message such as the following:

```
Router(config)# interface virtual-template 1
Router(config-if)# snmp trap link-status
%Unable set link-status enable/disable for interface
```

If your configuration already has the **snmp trap link-status** command configured under a virtual-template interface and you upgrade to Cisco IOS Release 12.2(33)SB, the configuration error occurs when the router reloads even though the virtual template interface is already registered in the interfaces MIB.

Examples

Cisco 10000 Series Router

The following example creates a virtual template interface called Virtual-Template1:

```
Router(config)# interface Virtual-Template1
Router(config-if)# ip unnumbered Loopback1
Router(config-if)# keepalive 60
Router(config-if)# no peer default ip address
Router(config-if)# ppp authentication pap
Router(config-if)# ppp authorization vpn1
Router(config-if)# ppp accounting vpn1
Router(config-if)# no logging event link-status
Router(config-if)# no virtual-template snmp
```

Virtual Template with PPP Authentication Example

The following example creates and configures virtual template interface 1:

```
interface virtual-template 1 type ethernet
 ip unnumbered ethernet 0
 ppp multilink
 ppp authentication chap
```

IPsec Virtual Template Example

The following example shows how to configure a virtual template for an IPsec virtual tunnel interface.

```
interface virtual-template1 type tunnel
 ip unnumbered Loopback1
```

```
tunnel mode ipsec ipv4
tunnel protection ipsec profile virtualtunnelinterface
```

Related Commands

Command	Description
cdp enable	Enables Cisco Discovery Protocol (CDP) on an interface.
clear interface virtual-access	Tears down the live sessions and frees the memory for other client uses.
keepalive	Enables keepalive packets and to specify the number of times that the Cisco IOS software tries to send keepalive packets without a response before bringing down the interface.
show interface virtual-access	Displays the configuration of the active VAI that was created using a virtual template interface.
tunnel protection	Associates a tunnel interface with an IPsec profile.
virtual interface	Sets the zone name for the connected AppleTalk network.
virtual-profile	Enables virtual profiles.
virtual template	Specifies the destination for a tunnel interface.

ip (webvpn url rewrite)

To configure the IP address of the site to be mangled on a Secure Socket Layer virtual private network (SSL VPN) gateway, use the **ip** command in webvpn url rewrite configuration mode. To deselect the IP address, use the **no** form of this command.

ip *ip-address*

no ip *ip-address*

Syntax Description

ip-address	IP address of the site to be mangled.

Command Default

A site is not selected for mangling.

Command Modes

Webvpn url rewrite (config-webvpn-url-rewrite)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Examples

The following example shows that the IP address 10.1.0.0 255.255.0.0 has been selected for mangling:

```
Router (config)# webvpn context
Router (config-webvpn-context)# url rewrite
Router (config-webvpn-url-rewrite)# ip 10.1.0.0 255.255.0.0
```

Related Commands

Command	Description
host (webvpn url rewrite)	Selects the host name of the site to be mangled on an SSL VPN gateway.
unmatched-action (webvpn url rewrite)	Defines the action when the user request does not match the IP address or host site configuration.

ip access-group

To apply an IP access list or object group access control list (OGACL) to an interface or a service policy map, use the **ip access-group** command in the appropriate configuration mode. To remove an IP access list or OGACL, use the **no** form of this command.

ip access-group {*access-list-name* | *access-list-number*} {**in** | **out**}

no ip access-group {*access-list-number* | *access-list-name*} {**in** | **out**}

Syntax Description

access-list-name	Name of the existing IP access list or OGACL as specified by an **ip access-list** command.
access-list-number	Number of the existing access list. This is a decimal number from 1 to 199 or from 1300 to 2699.
in	Filters on inbound packets.
out	Filters on outbound packets.

Defaults

An access list is not applied.

Command Modes

Interface configuration (config-if)
Service policy-map configuration (config-service-policymap)

Command History

Release	Modification
10.0	This command was introduced.
11.2	The *access-list-name* argument was added.
12.2(28)SB	This command was made available in service policy-map configuration mode.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.4(20)T	The *access-list-name* keyword was modified to accept the name of an OGACL.

Usage Guidelines

If the specified access list does not exist, all packets are passed (no warning message is issued).

Applying Access Lists to Interfaces

Access lists or OGACLs are applied on either outbound or inbound interfaces. For standard inbound access lists, after an interface receives a packet, the Cisco IOS software checks the source address of the packet against the access list. For extended access lists or OGACLs, the networking device also checks the destination access list or OGACL. If the access list or OGACL permits the address, the software continues to process the packet. If the access list or OGACL rejects the address, the software discards the packet and returns an Internet Control Management Protocol (ICMP) host unreachable message.

For standard outbound access lists, after a device receives and routes a packet to a controlled interface, the software checks the source address of the packet against the access list. For extended access lists or OGACLs, the networking device also checks the destination access list or OGACL. If the access list or OGACL permits the address, the software sends the packet. If the access list or OGACL rejects the address, the software discards the packet and returns an ICMP host unreachable message.

When you enable outbound access lists or OGACLs, you automatically disable autonomous switching for that interface. When you enable inbound access lists or OGACLs on any CBus or CxBus interface, you automatically disable autonomous switching for all interfaces (with one exception—a Storage Services Enabler (SSE) configured with simple access lists can still switch packets, on output only).

Applying Access Lists or OGACLs to Service Policy Maps

You can use the **ip access-group** command to configure Intelligent Services Gateway (ISG) per-subscriber firewalls. Per-subscriber firewalls are Cisco IOS IP access lists or OGACLs that are used to prevent subscribers, services, and pass-through traffic from accessing specific IP addresses and ports.

ACLs and OGACLs can be configured in user profiles or service profiles on an authentication, authorization, and accounting (AAA) server or in service policy maps on an ISG. OGACLS or numbered or named IP access lists can be configured on the ISG, or the ACL or OGACL statements can be included in the profile configuration.

When an ACL or OGACL is added to a service, all subscribers of that service are prevented from accessing the specified IP address, subnet mask, and port combinations through the service.

Examples

The following example applies list 101 on packets outbound from Ethernet interface 0:

```
Router> enable
Router# configure terminal
Router(config)# interface ethernet 0
Router(config-if)# ip access-group 101 out
```

Related Commands

Command	Description
deny	Sets conditions in a named IP access list or OGACL that will deny packets.
ip access-list	Defines an IP access list or OGACL by name or number.
object-group network	Defines network object groups for use in OGACLs.
object-group service	Defines service object groups for use in OGACLs.
permit	Sets conditions in a named IP access list or OGACL that will permit packets.
show ip access-list	Displays the contents of IP access lists or OGACLs.
show object-group	Displays information about object groups that are configured.

ip access-list

To define an IP access list or object-group access control list (ACL) by name or number or to enable filtering for packets with IP helper-address destinations, use the **ip access-list** command in global configuration mode. To remove the IP access list or object-group ACL or to disable filtering for packets with IP helper-address destinations, use the **no** form of this command.

ip access-list {{**standard** | **extended**} {*access-list-name* | *access-list-number*} | **helper egress check**}

no ip access-list {{**standard** | **extended**} {*access-list-name* | *access-list-number*} | **helper egress check**}

Syntax Description

standard	Specifies a standard IP access list.
extended	Specifies an extended IP access list. Required for object-group ACLs.
access-list-name	Name of the IP access list or object-group ACL. Names cannot contain a space or quotation mark, and must begin with an alphabetic character to prevent ambiguity with numbered access lists.
access-list-number	Number of the access list. • A standard IP access list is in the ranges 1–99 or 1300–1999. • An extended IP access list is in the ranges 100–199 or 2000–2699.
helper egress check	Enables permit or deny matching capability for an outbound access list that is applied to an interface, for traffic that is relayed via the IP helper feature to a destination server address.

Command Default

No IP access list or object-group ACL is defined, and outbound ACLs do not match and filter IP helper relayed traffic.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.4(20)T	This command was modified. Object-group ACLs are now accepted when the **deny** and **permit** commands are used in standard IP access-list configuration mode or extended IP access-list configuration mode.
Cisco IOS XE Release 3.2S	This command was implemented on Cisco ASR 1000 series routers.
15.0(1)M	This command was modified. The **helper**, **egress**, and **check** keywords were added.

Usage Guidelines

Use this command to configure a named or numbered IP access list or an object-group ACL. This command places the router in access-list configuration mode, where you must define the denied or permitted access conditions by using the **deny** and **permit** commands.

Specifying the **standard** or **extended** keyword with the **ip access-list** command determines the prompt that appears when you enter access-list configuration mode. You must use the **extended** keyword when defining object-group ACLs.

You can create object groups and IP access lists or object-group ACLs independently, which means that you can use object-group names that do not yet exist.

Named access lists are not compatible with Cisco IOS software releases prior to Release 11.2.

Use the **ip access-group** command to apply the access list to an interface.

The **ip access-list helper egress check** command enables outbound ACL matching for permit or deny capability on packets with IP helper-address destinations. When you use an outbound extended ACL with this command, you can permit or deny IP helper relayed traffic based on source or destination User Datagram Protocol (UDP) ports. The **ip access-list helper egress check** command is disabled by default; outbound ACLs will not match and filter IP helper relayed traffic.

Examples

The following example defines a standard access list named Internetfilter:

```
Router> enable
Router# configure terminal
Router(config)# ip access-list standard Internetfilter
Router(config-std-nacl)# permit 192.168.255.0 0.0.0.255
Router(config-std-nacl)# permit 10.88.0.0 0.0.255.255
Router(config-std-nacl)# permit 10.0.0.0 0.255.255.255
```

The following example shows how to create an object-group ACL that permits packets from the users in my_network_object_group if the protocol ports match the ports specified in my_service_object_group:

```
Router> enable
Router# configure terminal
Router(config)# ip access-list extended my_ogacl_policy
Router(config-ext-nacl)# permit tcp object-group my_network_object_group portgroup
my_service_object_group any
Router(config-ext-nacl)# deny tcp any any
```

The following example shows how to enable outbound ACL filtering on packets with helper-address destinations:

```
Router> enable
Router# configure terminal
Router(config)# ip access-list helper egress check
```

Related Commands

Command	Description
deny	Sets conditions in a named IP access list or in an object-group ACL that will deny packets.
ip access-group	Applies an ACL or an object-group ACL to an interface or a service policy map.
object-group network	Defines network object groups for use in object-group ACLs.
object-group service	Defines service object groups for use in object-group ACLs.
permit	Sets conditions in a named IP access list or in an object-group ACL that will permit packets.
show ip access-list	Displays the contents of IP access lists or object-group ACLs.
show object-group	Displays information about object groups that are configured.

ip access-list hardware permit fragments

To permit all noninitial fragments in the hardware, use the **ip access-list hardware permit fragments** command in global configuration mode. To return to the default settings, use the **no** form of this command.

ip access-list hardware permit fragments

no ip access-list hardware permit fragments

Syntax Description

This command has no arguments or keywords.

Defaults

All fragments from flows that are received from an ACE with Layer 4 ports and permit action are permitted. All other fragments are dropped in the hardware. This action also applies to flows that are handled in the software regardless of this command setting.

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(18)SXF5	This command was changed to affect all ACLs currently applied to interfaces and not just newly-applied ACLs. See the “Usage Guidelines” section for more information.

Usage Guidelines

Flow fragments that match ACEs with Layer 4 ports and permit results are permitted in the hardware, and all other fragments are dropped. An entry is added in the TCAM for each ACE with Layer 4 ports and permit action. This action could cause large ACLs to not fit in the TCAM. If this is the case, use the **ip access-list hardware permit fragments** command to permit all noninitial fragments in the hardware.

Note Configurations that you modify after you entered the **ip access-list hardware permit fragments** command will permit all noninitial fragments in the hardware. Hardware configurations that you modified before you entered the **ip access-list hardware permit fragments** command will not be changed.

Note Hardware configurations that you modify after you entered the **no ip access-list hardware permit fragments** command will return to the default settings. Hardware configurations that you modified before you entered the **no ip access-list hardware permit fragments** command do not change.

The initial flow fragments that match the ACEs with Layer 4 ports and permit results are permitted in the hardware. All other initial fragments are dropped in the hardware.

Catalyst 6500 Series Switches

The following restrictions apply to Cisco IOS releases before Cisco IOS Release 12.2(18)SX5:

Note Configurations that you modify after you entered the **ip access-list hardware permit fragments** command will permit all noninitial fragments in the hardware. Hardware configurations that you modified before you entered the **ip access-list hardware permit fragments** command will not be changed.

Note Hardware configurations that you modify after you entered the **no ip access-list hardware permit fragments** command will return to the default settings. Hardware configurations that you modified before you entered the **no ip access-list hardware permit fragments** command do not change.

In Cisco IOS releases after Cisco IOS Release 12.2(18)SX5, this command affects all ACLs currently applied to interfaces and not just newly-applied ACLs.

Examples

This example shows how to permit all noninitial fragments in the hardware:

```
Router(config)# ip access-list hardware permit fragments
```

This example shows how to return to the default settings:

```
Router(config)# no ip access-list hardware permit fragments
```

Related Commands

Command	Description
show ip interface	Displays the usability status of interfaces that are configured for IP.

ip access-list logging interval

To configure the logging interval for access list entries, use the **ip access-list logging interval** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ip access-list logging interval *interval*

no ip access-list logging interval

Syntax Description

interval	Access list logging interval, in milliseconds. The range is from 0 to 2147483647.

Command Default

Access list logging intervals are not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows how to set the access list logging interval to 100 milliseconds:

```
Router# configure terminal
Router(config)# ip access-list logging interval 100
```

Related Commands

Command	Description
ip access-list logging hash-generation	Enables hash-value generation for ACE syslog entries.

ip access-list log-update

To set the threshold number of packets that generate a log message if they match an access list, use the **ip access-list log-update** command in global configuration mode. To remove the threshold, use the **no** form of this command.

ip access-list log-update threshold *number-of-matches*

no ip access-list log-update

Syntax Description

number-of-matches	Threshold number of packets necessary to match an access list before a log message is generated. The range is 0 to 2147483647. There is no default number of matches.

Defaults

Log messages are sent at the first matching packet and at 5-minute intervals after that.

Command Modes

Global configuration

Command History

Release	Modification
12.0(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Log messages are generated if you have specified the **log** keyword in the **access-list (IP standard)**, **access-list (IP extended)**, **deny (IP)**, **dynamic**, or **permit** command.

Log messages provide information about the packets that are permitted or denied by an access list. By default, log messages appear at the console. (The level of messages logged to the console is controlled by the **logging console** command.) The log message includes the access list number, whether the packet was permitted or denied, and other information.

By default, the log messages are sent at the first matching packet and after that, identical messages are accumulated for 5-minute intervals, with a single message being sent with the number of packets permitted and denied during that interval. However, you can use the **ip access-list log-update** command to set the number of packets that, when match an access list (and are permitted or denied), cause the system to generate a log message. You might want to do this to receive log messages more frequently than at 5-minute intervals.

Caution If you set the *number-of-matches* argument to 1, a log message is sent right away, rather than caching it; every packet that matches an access list causes a log message. A setting of 1 is not recommended because the volume of log messages could overwhelm the system.

Even if you use the **ip access-list log-update** command, the 5-minute timer remains in effect, so the cache is emptied at the end of 5 minutes, regardless of the count of messages in the cache. Regardless of when the log message is sent, the cache is flushed and the count reset to 0 for that message the same way it is when a threshold is not specified.

If the syslog server is not directly connected to a LAN that the router shares, any intermediate router might drop the log messages because they are UDP (unreliable) messages.

Examples

The following example enables logging whenever the 1000th packet matches an access list entry:

```
ip access-list log-update threshold 1000
```

Related Commands

Command	Description
access-list (IP extended)	Defines an extended IP access list.
access-list (IP standard)	Defines a standard IP access list.
deny (IP)	Sets conditions under which a packet is denied by a named IP access list.
dynamic	Defines a named dynamic IP access list.
logging console	Limits messages logged to the console, based on severity.
permit	Sets conditions under which a packet passes a named IP access list.

ip access-list resequence

To apply sequence numbers to the access list entries in an access list, use the **ip access-list resequence** command in global configuration mode.

ip access-list resequence *access-list-name starting-sequence-number increment*

Syntax Description

access-list-name	Name of the access list. Names cannot contain a space or quotation mark.
starting-sequence-number	Access list entries will be resequenced using this initial value. The default value is 10. The range of possible sequence numbers is 1 through 2147483647.
increment	The number by which the sequence numbers change. The default value is 10. For example, if the increment value is 5 and the beginning sequence number is 20, the subsequent sequence numbers are 25, 30, 35, 40, and so on.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)S	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command allows the **permit** and **deny** entries of a specified access list to be resequenced with an initial sequence number value determined by the *starting-sequence-number* argument, and continuing in increments determined by the *increment* argument. If the highest sequence number exceeds the maximum possible sequence number, then no sequencing occurs.

For backward compatibility with previous releases, if entries with no sequence numbers are applied, the first entry is assigned a sequence number of 10, and successive entries are incremented by 10. The maximum sequence number is 2147483647. If the generated sequence number exceeds this maximum number, the following message is displayed:

```
Exceeded maximum sequence number.
```

If the user enters an entry without a sequence number, it is assigned a sequence number that is 10 greater than the last sequence number in that access list and is placed at the end of the list.

If the user enters an entry that matches an already existing entry (except for the sequence number), then no changes are made.

If the user enters a sequence number that is already present, the following error message is generated:

```
Duplicate sequence number.
```

If a new access list is entered from global configuration mode, then sequence numbers for that access list are generated automatically.

Distributed support is provided so that the sequence numbers of entries in the Route Processor (RP) and line card (LC) are in synchronization at all times.

Sequence numbers are not saved in NVRAM. That is, the sequence numbers themselves are not saved. In the event that the system is reloaded, the configured sequence numbers revert to the default sequence starting number and increment.

This command works with named standard and extended IP access lists. Because the name of an access list can be designated as a number, numbers are acceptable as names as long as they are entered in named access list configuration mode.

Examples

The following example resequences an access list named kmd1. The starting sequence number is 100, and the increment value is 5:

```
ip access-list resequence kmd1 100 5
```

Related Commands

Command	Description
deny (IP)	Sets conditions under which a packet does not pass a named IP access list.
permit (IP)	Sets conditions under which a packet passes a named IP access list.

ip access-list logging hash-generation

To enable hash-value generation for access control entry (ACE) syslog entries, use the **ip access-list logging hash-generation** command in global configuration mode. To disable hash value generation, use the **no** form of this command.

ip access-list logging hash-generation

no ip access-list logging hash-generation

Syntax Description

This command has no arguments or keywords.

Command Default

Hash value generation is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

Cisco IOS routers generate syslog entries for log-enabled ACEs. The system appends a tag (either a user-defined cookie or a router-generated MD5 hash value) to ACE syslog entries. This tag uniquely identifies the ACE, within an access control list (ACL), that generated the syslog entry.

Use this command to generate an MD5 hash value for all the log enabled ACEs in the system that do not have a user-defined cookie. The system attaches the router-generated hash value to the corresponding ACE. The hash value is stored locally in the router's NVRAM and persists through router reloads.

Examples

The following example shows how to enable hash value generation on the router, for IP access list syslog entries:

```
Router(config)# ip access-list logging hash-generation
Router(config)#
*Aug 7 01:10:12.077: %IPACL-HASHGEN: ACL: 101 seq no : 20 Hash code is 0x75F079
```

Related Commands

Command	Description
access-list (IP extended)	Defines an extended IP access list.
access-list (IP standard)	Defines a standard IP access list.
debug ip access-list hash-generation	Displays debugging information about ACL hash generation.
show ip access-list	Displays the contents of all current access lists.

ip-address (ca-trustpoint)

To specify a dotted IP address or an interface that will be included as "unstructuredAddress" in the certificate request, use the **ip-address** command in ca-trustpoint configuration mode. To restore the default behavior, use the **no** form of this command.

ip-address {*ip-address* | *interface* | **none**]

no ip-address

Syntax Description

ip-address	Specifies a dotted IP address that will be included as "unstructuredAddress" in the certificate request.
interface	Specifies an interface, from which the router can get an IP address, that will be included as "unstructuredAddress" in the certificate request.
none	Specifies that an IP address is not to be included in the certificate request.

Defaults

An IP address is not configured. You will be prompted for the IP address during certificate enrollment.

Command Modes

Ca-trustpoint configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.

Usage Guidelines

Before you can issue this command, you must enable the **crypto ca | pki trustpoint** command, which declares the certification authority (CA) that your router should use and enters ca-trustpoint configuration mode. The **ip-address** command is a subcommand that allows you to specify a certificate enrollment parameter.

Use the **ip-address** command to include the IP address of the specified interface in the certificate request or to specify that an IP address should not be included in the certificate request.

If this command is enabled, you will not be prompted for an IP address during certificate enrollment.

Examples

The following example shows how to include the IP address of the Ethernet-0 interface in the certificate request for the trustpoint "frog":

```
crypto ca trustpoint frog
 enrollment url http://frog.phoobin.com/
 subject-name OU=Spiral Dept., O=tiedye.com
 ip-address ethernet-0
```

The following example shows that an IP address is not to be included in the certificate request:

```
crypto ca trustpoint root
 enrollment url http://10.3.0.7:80
 fqdn none
```

```
ip-address none
subject-name CN=subject1, OU=PKI, O=Cisco Systems, C=US
```

Related Commands

Command	Description
crypto ca trustpoint	Declares the CA that your router should use.

ip address dhcp

To acquire an IP address on an interface from the DHCP, use the **ip address dhcp** command in interface configuration mode. To remove any address that was acquired, use the **no** form of this command.

ip address dhcp [**client-id** *interface-type number*] [**hostname** *hostname*]

no ip address dhcp [**client-id** *interface-type number*] [**hostname** *hostname*]

Syntax Description

client-id	(Optional) Specifies the client identifier. By default, the client identifier is an ASCII value. The **client-id** *interface-type number* option sets the client identifier to the hexadecimal MAC address of the named interface.
interface-type	(Optional) Interface type. For more information, use the question mark (?) online help function.
number	(Optional) Interface or subinterface number. For more information about the numbering syntax for your networking device, use the question mark (?) online help function.
hostname	(Optional) Specifies the hostname.
hostname	(Optional) Name of the host to be placed in the DHCP option 12 field. This name need not be the same as the hostname entered in global configuration mode.

Defaults

The hostname is the globally configured hostname of the router.
The client identifier is an ASCII value.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.1(2)T	This command was introduced.
12.1(3)T	This command was modified. The **client-id** keyword and *interface-type number* argument were added.
12.2(3)	This command was modified. The **hostname** keyword and *hostname* argument were added. The behavior of the **client-id** *interface-type number* option changed. See the “Usage Guidelines” section for details.
12.2(8)T	This command was modified. The command was expanded for use on PPP over ATM (PPPoA) interfaces and certain ATM interfaces.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(3)T	This command was modified. Support was provided on the tunnel interface.

Usage Guidelines

Note Prior to Cisco IOS Release 12.2(8)T, the **ip address dhcp** command could be used only on Ethernet interfaces.

The **ip address dhcp** command allows any interface to dynamically learn its IP address by using the DHCP protocol. It is especially useful on Ethernet interfaces that dynamically connect to an Internet service provider (ISP). Once assigned a dynamic address, the interface can be used with the Port Address Translation (PAT) of Cisco IOS Network Address Translation (NAT) to provide Internet access to a privately addressed network attached to the router.

The **ip address dhcp** command also works with ATM point-to-point interfaces and will accept any encapsulation type. However, for ATM multipoint interfaces you must specify Inverse ARP via the **protocol ip inarp** interface configuration command and use only the aa15snap encapsulation type.

Some ISPs require that the DHCPDISCOVER message have a specific hostname and client identifier that is the MAC address of the interface. The most typical usage of the **ip address dhcp client-id** *interface-type number* **hostname** *hostname* command is when *interface-type* is the Ethernet interface where the command is configured and *interface-type number* is the hostname provided by the ISP.

A client identifier (DHCP option 61) can be a hexadecimal or an ASCII value. By default, the client identifier is an ASCII value. The **client-id** *interface-type number* option overrides the default and forces the use of the hexadecimal MAC address of the named interface.

Note Between Cisco IOS Releases 12.1(3)T and 12.2(3), the **client-id** optional keyword allows the change of the fixed ASCII value for the client identifier. After Release 12.2(3), the optional **client-id** keyword forces the use of the hexadecimal MAC address of the named interface as the client identifier.

If a Cisco router is configured to obtain its IP address from a DHCP server, it sends a DHCPDISCOVER message to provide information about itself to the DHCP server on the network.

If you use the **ip address dhcp** command with or without any of the optional keywords, the DHCP option 12 field (hostname option) is included in the DISCOVER message. By default, the hostname specified in option 12 will be the globally configured hostname of the router. However, you can use the **ip address dhcp hostname** *hostname* command to place a different name in the DHCP option 12 field than the globally configured hostname of the router.

The **no ip address dhcp** command removes any IP address that was acquired, thus sending a DHCPRELEASE message.

You might need to experiment with different configurations to determine the one required by your DHCP server. Table 34 shows the possible configuration methods and the information placed in the DISCOVER message for each method.

Table 34 Configuration Method and Resulting Contents of the DISCOVER Message

Configuration Method	Contents of DISCOVER Messages
ip address dhcp	The DISCOVER message contains "cisco- *mac-address* -Eth1" in the client ID field. The *mac-address* is the MAC address of the Ethernet 1 interface and contains the default hostname of the router in the option 12 field.
ip address dhcp hostname *hostname*	The DISCOVER message contains "cisco- *mac-address* -Eth1" in the client ID field. The *mac-address* is the MAC address of the Ethernet 1 interface, and contains *hostname* in the option 12 field.
ip address dhcp client-id ethernet 1	The DISCOVER message contains the MAC address of the Ethernet 1 interface in the client ID field and contains the default hostname of the router in the option 12 field.
ip address dhcp client-id ethernet 1 hostname *hostname*	The DISCOVER message contains the MAC address of the Ethernet 1 interface in the client ID field and contains *hostname* in the option 12 field.

Examples

In the examples that follow, the command **ip address dhcp** is entered for Ethernet interface 1. The DISCOVER message sent by a router configured as shown in the following example would contain "cisco- *mac-address* -Eth1" in the client-ID field, and the value abc in the option 12 field.

```
hostname abc
!
interface Ethernet 1
 ip address dhcp
```

The DISCOVER message sent by a router configured as shown in the following example would contain "cisco- mac-address -Eth1" in the client-ID field, and the value def in the option 12 field.

```
hostname abc
!
interface Ethernet 1
 ip address dhcp hostname def
```

The DISCOVER message sent by a router configured as shown in the following example would contain the MAC address of Ethernet interface 1 in the client-id field, and the value abc in the option 12 field.

```
hostname abc
!
interface Ethernet 1
 ip address dhcp client-id Ethernet 1
```

The DISCOVER message sent by a router configured as shown in the following example would contain the MAC address of Ethernet interface 1 in the client-id field, and the value def in the option 12 field.

```
hostname abc
!
interface Ethernet 1
 ip address dhcp client-id Ethernet 1 hostname def
```

Related Commands

Command	Description
ip dhcp pool	Configures a DHCP address pool on a Cisco IOS DHCP server and enters DHCP pool configuration mode.

ip address (WebVPN)

To configure a proxy IP address on a Secure Socket Layer virtual private network (SSL VPN) gateway, use the **ip address** command in webvpn gateway configuration mode. To remove the proxy IP address from the SSL VPN gateway, use the **no** form of this command.

ip address *ip-address* [**port** *port-number*] [**standby** *name*]

no ip address

Syntax Description

ip-address	IPv4 address.
port *port-number*	(Optional) Specifies the port number for proxy traffic. A number from 1 to 65535 can be entered for this argument. The default port number 443 is used if this command is configured without entering the **port** keyword.
standby *name*	• (Optional) Indicates that the IP address is a virtual address configured on one of the router interfaces using Hot StandbyRouting Protocol (HSRP). • *name*—Must be the same as the HSRP group name that was configured on the router interface. **Note** Note that the *name* argument is not an optional parameter when the **standby** keyword is used.

Command Default

A proxy IP address is not configured.

Command Modes

Webvpn gateway configuration (config-webvpn-gateway)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(20)T	The **standby** keyword and *name* arguments were added.

Usage Guidelines

The **ip address** command is used to configure a proxy IP address for an SSL VPN gateway. The IP address is the termination point for all SSL VPN client connections. This IP address can be any routable IP address assigned to a valid interface.

Examples

The following example configures 192.168.1.1 as a proxy address on an SSL VPN gateway. Proxy traffic is directed over port 443.

```
Router(config)# webvpn gateway SSL_GATEWAY
Router(config-webvpn-gateway)# ip address 192.168.1.1 port 443
```

The following example shows that Router 1 and Router 2 are configured for HSRP on Gateway Webvpn:

Router 1 Configuration

```
Router# configure terminal
Router config)# interface g0/1
Router (config-if)# standby 0 ip 10.1.1.1
Router (config-if)# standby 0 name SSLVPN
Router (config-if)# exit
Router (config)# webvpn gateway Webvpn
Router (config-webvpn-gateway)# ip address 10.1.1.1 port 443 standby SSLVPN
```

Router 2 Configuration

```
Router# configure terminal
Router (config)# interface g0/0
Router (config-if)# standby 0 ip 10.1.1.1
Router (config-if)# standby 0 name SSLVPN2
Router (config-if)# exit
Router (config)# webvpn gateway Webvpn
Router (config-webvpn-gateway)# ip address 10.1.1.1 port 443 standby SSLVPN2
```

Related Commands

Command	Description
standby name	Configures the name of the standby group.
webvpn gateway	Defines an SSL VPN gateway and enters webvpn gateway configuration mode.

ip admission

To create a Layer 3 network admission control rule to be applied to the interface, or to create a policy that can be applied on an interface when the authentication, authorization and accounting (AAA) server is unreachable, use the **ip admission** command in interface configuration mode. To create a global policy that can be applied on a network access device, use the **ip admission** command with the optional keywords and argument in global configuration mode. To remove the admission control rule, use the **no** form of this command.

ip admission *admission-name* [**event timeout aaa policy identity** *identity-policy-name*]

no ip admission *admission-name* [**event timeout aaa policy identity** *identity-policy-name*]

Syntax Description

admission-name	Authentication or admission rule name.
event timeout aaa policy identity	Specifies an authentication policy to be applied when the AAA server is unreachable.
identity-policy-name	Authentication or admission rule name to be applied when the AAA server is unreachable.

Command Default

A network admission control rule is not applied to the interface.

Command Modes

Interface configuration (config-if)
Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(11)T	This command was modified to include the **event timeout aaa policy identity** keywords and the *identity-policy-name* argument.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

The admission rule defines how you apply admission control.

The optional keywords and argument define the network admission policy to be applied to a network access device or an interface when no AAA server is reachable. The command can be used to associate a default identity policy with Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP) sessions.

Examples

The following example shows how to apply a network admission control rule named “nacrule1” to the interface:

```
Router (config-if)# ip admission nacrule1
```

The following example shows how to apply an identity policy named “example” to the device when the AAA server is unreachable:

```
Router (config)# ip admission nacrule1 event timeout aaa policy identity example
```

Related Commands

Command	Description
interface	Defines an interface.

ip admission consent banner

To display a banner on the authentication proxy consent webpage, use the **ip admission consent banner** command in global configuration mode. To disable a display of the banner, use the **no** form of this command.

ip admission consent banner {**file** *file-name* | **text** *banner-text*}

no ip admission consent banner

Syntax Description

file *file-name*	Specifies a file that is to be shown as the consent webpage.
text *banner-text*	Specifies a text string to replace the default banner, which is the name of the router. The text string should be written in the following format: "C *banner-text* C," where "C" is a delimiting character.

Command Default

A banner is not displayed on the authentication proxy consent webpage.

Command Modes

Global configuration

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

The **ip admission consent banner** command allows users to configure one of two possible scenarios:

- The **ip admission consent banner** command with a filename is enabled.

  In this scenario, the administrator supplies the location and name of the file that is to be used for the consent webpage.

- The **ip admission consent banner** command with the banner text is enabled.

  In this scenario, the administrator can supply multiline text that will be converted to HTML by the auth-proxy parser code. Thus, only the multiline text is displayed on the authentication proxy login page.

Note If the **ip admission consent banner** command is not enabled, nothing will be displayed to the user on a consent login page except a text box to enter the username and a text box to enter the password.

Note When HTTP authentication proxy is configured together with the Consent feature, any HTTP authentication proxy-related configurations or policies will override the Consent Page-related configurations or policies. For example, if the **ip admission name** *admission-name* **consent** command is configured, the **ip admission consent banner** command is ignored, and only the banner that is configured by the **ip admission auth-proxy-banner** command is shown.

Examples

The following example shows how to display the file “consent_page.html” located in flash:

```
ip admission consent-banner file flash:consent_page.html
```

The following example shows how to specify the custom banner “Consent-Page-Banner-Text” to be displayed in the authentication proxy consent webpage:

```
ip admission consent-banner text ^C Consent-Page-Banner-Text ^C
```

Related Commands

Command	Description
ip auth-proxy auth-proxy-banner	Displays a banner, such as the router name, in the authentication proxy login page.

ip admission name

To create an IP network admission control rule, use the **ip admission name** command in global configuration mode. To remove the network admission control rule, use the **no** form of this command.

ip admission name *admission-name* [**eapoudp** [**bypass**] | **proxy** {**ftp** | **http** | **telnet**} | **service-policy type tag** {*service-policy-name*}] [**list** {*acl* | *acl-name*}] [**event**] [**timeout aaa**] [**policy identity** {*identity-policy-name*}]

no ip admission name *admission-name* [**eapoudp** [**bypass**] | **proxy** {**ftp** | **http** | **telnet**} | **service-policy type tag** {*service-policy-name*}] [**list** {*acl* | *acl-name*}] [**event**] [**timeout aaa**] [**policy identity** {*identity-policy-name*}]

Syntax for Authentication Proxy Consent Webpage

ip admission name *admission-name* **consent** [[**absolute-timer** *minutes*] [**event**] [**inactivity-time** *minutes*] [**list** {*acl* | *acl-name*}] [**parameter-map** *consent-parameter-map-name*]]

no ip admission name *admission-name* **consent** [[**absolute-timer** *minutes*] [**event**] [**inactivity-time** *minutes*] [**list** {*acl* | *acl-name*}] [**parameter-map** *consent-parameter-map-name*]]

Syntax Description

admission-name	Name of network admission control rule.
eapoudp	(Optional) Specifies IP network admission control using Extensible Authentication Protocol over UDP (EAPoUDP).
bypass	(Optional) Admission rule bypasses EAPoUDP communication.
proxy	(Optional) Specifies authentication proxy.
ftp	Specifies that FTP is to be used to trigger the authentication proxy.
http	Specifies that HTTP is to be used to trigger authentication proxy.
telnet	Specified that Telnet is to be used to trigger authentication proxy.
service-policy type tag	(Optional) A control plane service policy is to be configured.
service-policy-name	Control plane tag service policy that is configured using the **policy-map type control tag** {*policy name*} command, keyword, and argument. This policy map is used to apply the actions on the host when a tag is received.
list	(Optional) Associates the named rule with an access control list (ACL).
acl	Applies a standard, extended list to a named admission control rule. The value ranges from 1 through 199.
acl-name	Applies a named access list to a named admission control rule.
event	(Optional) Identifies the condition that triggered the application of the policy.
timeout aaa	(Optional) Specifies that the AAA server is unreachable.
policy identity	Configures the application of an identity policy to be used while the AAA server is unreachable.
identity-policy-name	Specifies the identity policy to apply.

consent	Associates an authentication proxy consent webpage with the IP admission rule specified via the *admission-name* argument.
absolute-timer *minutes*	(Optional) Elapsed time, in minutes, before the external server times out.
inactivity-time *minutes*	(Optional) Elapsed time, in minutes, before the external file server is deemed unreachable.
parameter-map	(Optional) A parameter map policy is to be associated with consent profile.
consent-parameter-map-name	Specifies the consent profile parameters to apply.

Command Default

An IP network admission control rule is not created.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(6)T	The **bypass** and **service-policy type tag** keywords and *service-policy-name* argument were added.
12.4(11)T	The **event**, **timeout aaa**, and **policy identity** keywords and the *identity-policy-name* argument were added.
12.4(15)T	The following keywords and arguments were added: **consent**, **absolute-timer,** *minutes*, **inactivity-time**, *minutes,* **parameter-map**, and *consent-parameter-map-name*.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The admission rule defines how you apply admission control.

You can associate the named rule with an ACL, providing control over which hosts use the admission control feature. If no standard access list is defined, the named admission rule intercepts IP traffic from all hosts whose connection-initiating packets are received at the configured interface.

The **bypass** keyword allows an administrator the choice of not having to use the EAPoUDP-based posture validation for the hosts that are trying to connect on the port. The bypass can be used if an administrator knows that the hosts that are connected on the port do not have the Cisco Trust Agent client installed.

The **service-policy type tag** {*service-policy-name*} keywords and argument allow you to associate the service policy of the type tag with the IP admission rule. On the network access device (NAD), a set of policies can be associated with an arbitrary tag string, and if the AAA server sends the same tag in response to the posture validation or authentication response, the policies that are associated with the tag can be applied on the host. The **service policy** keyword is an optional keyword, and if the service policy is not associated with the IP admission name, the policies that are received from the AAA server are applied on the host.

The **list** keyword option allows you to apply a standard, extended (1 through 199) or named access list to a named admission control rule. IP connections that are initiated by hosts in the access list are intercepted by the admission control feature.

The **event** keyword option allows you to specify the condition that triggered application of an identity policy.

The **timeout aaa** keyword option specifies that the AAA server is unreachable, and this condition is triggering the application of an identity policy.

The **policy identity** keyword and the *identity-policy-name* argument allow you to configure application of an identity policy and specify the policy type to be applied while the AAA server is unreachable.

The **consent** keyword and the **parameter-map** *consent-parameter-map-name* keyword and argument allow you to associate the authentication proxy consent feature with an IP admission rule. The consent feature enables customers to display a consent webpage to an end user, providing access to wireless services only after the end user accepts the agreement.

Examples

"Tag and Template" Feature Examples

The following example shows that an IP admission control rule is named "greentree" and that it is associated with ACL "101." Any IP traffic that is destined to a previously configured network (using the **access-list** command) will be subjected to antivirus state validation using EAPoUDP.

```
Router (config)# ip admission name greentree eapoudp list 101
```

The following example shows that EAPoUDP bypass has been configured:

```
Router (config)# ip admission name greentree eapoudp bypass list 101
```

In the following service policy example, tags named "healthy" and "non_healthy" can be received from an AAA server, the policy map is defined on the NAD, and the tag policy type is associated with the IP admission name "greentree."

Class Map Definition for the "healthy class" Type Tag

```
Router (config)# class-map type tag healthy_class
Router(config-cmap)# match tag healthy
Router(config-cmap)# end
```

Class Map Definition for the "non_healthy_class" Type Tag

```
Router (config)# class-map type tag non_healthy_class
Router (config-cmap)# match tag non_healthy
Router (config-cmap)# end
```

Policy Map Definition

```
! The following line will be associated with the IP admission name.
Router (config)# policy-map type control tag global_class
! The following line refers to the healthy class map that was defined above.
Router (config-pmap)# class healthy_class
Router (config-pmap-c)# identity policy healthy_policy
Router(config-pmap-c)# exit
The following line refers to the non_healthy class that was defined above.
Router (config-pmap)# class non_healthy_class
Router(config-pmap-c)# identity policy non_healthy_policy
Router (config-pmap-c)# end
```

Identity Policy Definition

```
Router (config)# identity policy healthy_policy
```

```
! The following line is the IP access list for healthy users.
Router (config-identity-policy)# access-group healthy
Router (config-identity-policy)# end
Router (config)# identity policy non_healthy_policy
Router (config-identity-policy)# access-group non_healthy
Router (config-identity-policy)# end
```

Defining Access Lists

```
Router (config)# ip access-list extended healthy_class
! The following line can be anything, but as an example, traffic is being allowed.
Router (config-ext-nacl)# permit ip any any
Router (config-ext-nac)# end
Router (config)# ip access-list extended non_healthy_class
! The following line is only an example. In practical cases, you could prevent a user from
accessing specific networks.
Router (config-ext-nacl)# deny ip any any
Router (config-ext-nac)# end
```

Associating the Policy Map with the IP Admission Name

```
Router (config)# ip admission name greentree service-policy type tag global_class
! In the next line, the admission name can be associated with the interface.
Router (config)# interface fastethernet 1/0
Router (config-if)# ip admission greentree
```

In the above configuration, if the AAA server sends a tag named "healthy" or "non_healthy" for any host, the policies that are associated with the appropriate identity policy will be applied on the host.

NAC—Auth Fail Open Feature Examples

The following example shows how to define an IP admission control rule named “samplerule” and attach it to a specific interface:

```
Router (config)# ip admission name samplerule eapoudp list 101 event timeout aaa policy
identity aaa_fail_policy
Router (config)# interface fastethernet 1/1
Router (config-if)# ip admission samplerule
Router (config-if)# end
```

In the above configuration, if the specified interface is not already authorized when the AAA server becomes unreachable, it will operate under the specified policy until revalidation is possible.

Authentication Proxy Consent Webpage Example

The following example shows how to configure an IP admission consent rule and associate the consent rule with the definitions of the parameter map “consent_parameter_map”:

```
ip admission name consent-rule consent inactivity-time 204 absolute-timer 304
parameter-map consent_parameter_map list 103
ip admission consent-banner file flash:consent_page.html
ip admission consent-banner text ^C Consen-Page-Banner-Text ^C
ip admission max-login-attempts 5
ip admission init-state-timer 15
ip admission auth-proxy-audit
ip admission inactivity-timer 205
ip admission absolute-timer 305
ip admission ratelimit 100
ip http server
ip http secure-server
!
interface FastEthernet 0/0
 description ### CLIENT-N/W ###
 ip address 192.168.100.170 255.255.255.0
```

```
 ip access-group 102 in
 ip admission consent-rule
 no shut
 exit
!
interface FastEthernet 0/1
 description ### AAA-DHCP-AUDIT-SERVER-N/W ###
 ip address 192.168.104.170 255.255.255.0
 no shut
 exit
!
line con 0
 exec-timeout 0 0
 login authentication noAAA
 exit
!
line vty 0 15
 exec-timeout 0 0
 login authentication noAAA
 exit
!
```

Related Commands

Command	Description
ip address	Sets a primary or secondary IP address for an interface.
ip admission event timeout aaa policy identity	Defines a policy to be applied when the AAA server is unreachable.

ip admission proxy http

To specify the display of custom authentication proxy web pages during web-based authentication, use the **ip admission proxy http** command in global configuration mode. To specify the use of the default web page, use the **no** form of this command.

ip admission proxy http {{**login** | **success** | **failure** | **login expired**} **page file** *device*:*file-name*} | {**success redirect** *url*}}

no ip admission proxy http {{**login** | **success** | **failure** | **login expired**} **page file** *device*:*file-name*} | {**success redirect** *url*}}

Syntax Description

login	Specifies a locally stored web page to be displayed during login.
success	Specifies a locally stored web page to be displayed when the login is successful.
failure	Specifies a locally stored web page to be displayed when the login has failed.
login expired	Specifies a locally stored web page to be displayed when the login has expired.
device	Specifies a disk or flash memory in the switch memory file system where the custom HTML file is stored.
file-name	Specifies the name of the custom HTML file to be used in place of the default HTML file for the specified condition.
success redirect *url*	Specifies an external web page to be displayed when the login is successful.

Command Default

The internal default authentication proxy web pages are displayed during web-based authentication.

Command Modes

Global configuration

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

When configuring the use of customized authentication proxy web pages, consider the following guidelines:

- To enable the custom web pages feature, you must specify all four custom HTML files. If fewer than four files are specified, the internal default HTML pages will be used.
- The four custom HTML files must be present on the disk or flash of the switch. The maximum size of each HTML file is 8 KB.
- Any images on the custom pages must be located on an accessible HTTP server. An intercept ACL must be configured within the admission rule to allow access to the HTTP server.
- Any external link from a custom page will require configuration of an intercept ACL within the admission rule.

- Any name resolution required for external links or images will require configuration of an intercept ACL within the admission rule to access a valid DNS server.
- If the custom web pages feature is enabled, a configured auth-proxy-banner will not be used.
- If the custom web pages feature is enabled, the redirection URL for successful login feature will not be available.
- Because the custom login page is a public web form, consider the following guidelines for this page:
  - The login form must accept user input for the username and password and must POST the data as uname and pwd.
  - The custom login page should follow best practices for a web form, such as page timeout, hidden password, and prevention of redundant submissions.
- When configuring a redirection URL for successful login, consider the following guidelines:
  - If the custom authentication proxy web pages feature is enabled, the redirection URL feature is disabled and will not be available in the CLI. You can perform redirection in the custom login success page.
  - If the redirection URL feature is enabled, a configured auth-proxy-banner will not be used.

Examples

The following example shows how to configure custom authentication proxy web pages:

```
Router(config)# ip admission proxy http login page file disk1:login.htm
Router(config)# ip admission proxy http success page file disk1:success.htm
Router(config)# ip admission proxy http fail page file disk1:fail.htm
Router(config)# ip admission proxy http login expired page file disk1:expired.htm
```

The following example shows how to verify the configuration of custom authentication proxy web pages:

```
Router# show ip admission configuration

Authentication proxy webpage
 Login page         : disk1:login.htm
 Success page       : disk1:success.htm
 Fail Page          : disk1:fail.htm
 Login expired Page : disk1:expired.htm

Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Session ratelimit is 100
Authentication Proxy Watch-list is disabled
Authentication Proxy Auditing is disabled
Max Login attempts per user is 5
```

The following example shows how to configure a redirection URL for successful login:

```
Router(config)# ip admission proxy http success redirect www.example.com
```

The following example shows how to verify the redirection URL for successful login:

```
Router# show ip admission configuration

Authentication Proxy Banner not configured
Customizable Authentication Proxy webpage not configured
HTTP Authentication success redirect to URL: http://www.example.com
Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Watch-list is disabled
```

```
Authentication Proxy Max HTTP process is 7
Authentication Proxy Auditing is disabled
Max Login attempts per user is 5
```

Related Commands

Command	Description
ip http server **ip https server**	Enables the HTTP server within the switch.
show ip admission configuration	Displays the configuration of web-based authentication ip admission.

ip audit

To apply an audit specification created with the **ip audit** command to a specific interface and for a specific direction, use the **ip audit** command in interface configuration mode. To disable auditing of the interface for the specified direction, use the **no** version of this command.

ip audit *audit-name* {**in** | **out**}

no ip audit *audit-name* {**in** | **out**}

Syntax Description

audit-name	Name of an audit specification.
in	Inbound traffic.
out	Outbound traffic.

Defaults

No audit specifications are applied to an interface or direction.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **ip audit** interface configuration command to apply an audit specification created with the **ip audit** command to a specific interface and for a specific direction.

Examples

In the following example, the audit specification MARCUS is applied to an interface and direction:

```
interface e0
 ip audit MARCUS in
```

In the following example, the audit specification MARCUS is removed from the interface on which it was previously added:

```
interface e0
 no ip audit MARCUS in
```

ip audit attack

To specify the default actions for attack signatures, use the **ip audit attack** command in global configuration mode. To set the default action for attack signatures, use the **no** form of this command.

ip audit attack {**action** [**alarm**] [**drop**] [**reset**]}

no ip audit attack

Syntax Description

action	Specifies an action for the attack signature to take in response to a match.
alarm	(Optional) Sends an alarm to the console, NetRanger Director, or to a syslog server. Used with the **action** keyword.
drop	(Optional) Drops the packet. Used with the **action** keyword.
reset	(Optional) Resets the TCP session. Used with the **action** keyword.

Defaults

The default action is **alarm**.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **ip audit attack** global configuration command to specify the default actions for attack signatures.

Examples

In the following example, the default action for attack signatures is set to all three actions:

```
ip audit attack action alarm drop reset
```

ip audit info

To specify the default actions for info signatures, use the **ip audit info** command in global configuration mode. To set the default action for info signatures, use the **no** form of this command.

ip audit info {**action** [**alarm**] [**drop**] [**reset**]}

no ip audit info

Syntax Description

action	Sets an action for the info signature to take in response to a match.
alarm	(Optional) Sends an alarm to the console, NetRanger Director, or to a syslog server. Used with the **action** keyword.
drop	(Optional) Drops the packet. Used with the **action** keyword.
reset	(Optional) Resets the TCP session. Used with the **action** keyword.

Defaults

The default action is **alarm**.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **ip audit info** global configuration command to specify the default actions for info signatures.

Examples

In the following example, the default action for info signatures is set to all three actions:

```
ip audit info action alarm drop reset
```

ip audit name

To create audit rules for info and attack signature types, use the **ip audit name** command in global configuration mode. To delete an audit rule, use the **no** form of this command.

ip audit name *audit-name* {**info** | **attack**} [**list** *standard-acl*] [**action** [**alarm**] [**drop**] [**reset**]]

no ip audit name *audit-name* {**info** | **attack**}

Syntax Description

audit-name	Name for an audit specification.
info	Specifies that the audit rule is for info signatures.
attack	Specifies that the audit rule is for attack signatures.
list	(Optional) Specifies an ACL to attach to the audit rule.
standard-acl	(Optional) Integer representing an access control list. Use with the **list** keyword.
action	(Optional) Specifies an action or actions to take in response to a match.
alarm	(Optional) Sends an alarm to the console, NetRanger Director, or to a syslog server. Use with the **action** keyword.
drop	(Optional) Drops the packet. Use with the **action** keyword.
reset	(Optional) Resets the TCP session. Use with the **action** keyword.

Defaults

If an action is not specified, the default action is **alarm**.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Any signatures disabled with the **ip audit signature** command do not become a part of the audit rule created with the **ip audit name** command.

Examples

In the following example, an audit rule called INFO.2 is created, and configured with all three actions:

```
ip audit name INFO.2 info action alarm drop reset
```

In the following example, an info signature is disabled and an audit rule called INFO.3 is created:

```
ip audit signature 1000 disable
```

```
ip audit name INFO.3 info action alarm drop reset
```

In the following example, an audit rule called ATTACK.2 is created with an attached ACL 91, and the ACL is created:

```
ip audit name ATTACK.2 list 91
access-list 91 deny 10.1.0.0 0.0.255.255
access-list 91 permit any
```

ip audit notify

To specify the method of event notification, use the **ip audit notify** command in global configuration mode. To disable event notifications, use the **no** form of this command.

ip audit notify {**nr-director** | **log**}

no ip audit notify {**nr-director** | **log**}

Syntax Description

nr-director	Send messages in NetRanger format to the NetRanger Director or Sensor.
log	Send messages in syslog format.

Defaults

The default is to send messages in syslog format.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If messages are sent to the NetRanger Director, then you must also configure the NetRanger Director's Post Office transport parameters using the **ip audit po remote** command.

Examples

In the following example, event notifications are specified to be sent in NetRanger format:

```
ip audit notify nr-director
```

Related Commands

Command	Description
ip audit po local	Specifies the local Post Office parameters used when sending event notifications to the NetRanger Director.
ip audit po remote	Specifies one or more sets of Post Office parameters for NetRanger Directors receiving event notifications from the router.

ip audit po local

To specify the local Post Office parameters used when sending event notifications to the NetRanger Director, use the **ip audit po local** command in global configuration mode. To set the local Post Office parameters to their default settings, use the **no** form of this command.

ip audit po local hostid *id-number* **orgid** *id-number*

no ip audit po local [**hostid** *id-number* **orgid** *id-number*]

Syntax Description

hostid	Specifies a NetRanger host ID.
id-number	Unique integer in the range 1 to 65535 used in NetRanger communications to identify the local host. The default host ID is 1.
orgid	Specifies a NetRanger organization ID.
id-number	Unique integer in the range 1 to 65535 used in NetRanger communications to identify the group to which the local host belongs. The default organization ID is 1.

Defaults

The default organization ID is 1. The default host ID is 1.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **ip audit po local** global configuration command to specify the local Post Office parameters used when sending event notifications to the NetRanger Director.

Examples

In the following example, the local host is assigned a host ID of 10 and an organization ID of 500:

```
ip audit po local hostid 10 orgid 500
```

ip audit po max-events

To specify the maximum number of event notifications that are placed in the router's event queue, use the **ip audit po max-events** command in global configuration mode. To set the number of recipients to the default setting, use the **no** version of this command.

ip audit po max-events *number-of-events*

no ip audit po max-events

Syntax Description

number-of-events	Integer in the range from 1 to 65535 that designates the maximum number of events allowable in the event queue. The default is 100 events.

Defaults

The default number of events is 100.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Raising the number of events past 100 may cause memory and performance impacts because each event in the event queue requires 32 KB of memory.

Examples

In the following example, the number of events in the event queue is set to 250:

```
ip audit po max-events 250
```

ip audit po protected

To specify whether an address is on a protected network, use the **ip audit po protected** command in global configuration mode. To remove network addresses from the protected network list, use the **no** form of this command.

ip audit po protected *ip-addr* [**to** *ip-addr*]

no ip audit po protected [*ip-addr*]

Syntax Description

ip-addr	IP address of a network host.
to *ip-addr*	(Optional) Specifies a range of IP addresses.

Defaults

If no addresses are defined as protected, then all addresses are considered outside the protected network.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can enter a single address at a time or a range of addresses at a time. You can also make as many entries to the protected networks list as you want. When an attack is detected, the corresponding event contains a flag that denotes whether the source or destination of the packet belongs to a protected network or not.

If you specify an IP address for removal, that address is removed from the list. If you do not specify an address, then all IP addresses are removed from the list.

Examples

In the following example, a range of addresses is added to the protected network list:

```
ip audit po protected 10.1.1.0 to 10.1.1.255
```

In the following example, three individual addresses are added to the protected network list:

```
ip audit po protected 10.4.1.1
ip audit po protected 10.4.1.8
ip audit po protected 10.4.1.25
```

In the following example, an address is removed from the protected network list:

```
no ip audit po protected 10.4.1.1
```

ip audit po remote

To specify one or more set of Post Office parameters for NetRanger Directors receiving event notifications from the router, use the **ip audit po remote** global configuration command. To remove a NetRanger Director's Post Office parameters as defined by host ID, organization ID, and IP address, use the **no** form of this command.

ip audit po remote hostid *host-id* **orgid** *org-id* **rmtaddress** *ip-address* **localaddress** *ip-address* [**port** *port-number*] [**preference** *preference-number*] [**timeout** *seconds*] [**application** {**director** | **logger**}]

no ip audit po remote hostid *host-id* **orgid** *org-id* **rmtaddress** *ip-address*

Syntax Description

host-id	Unique integer in the range from 1 to 65535 used in NetRanger communications to identify the local host. Use with the **hostid** keyword.
hostid	Specifies a NetRanger host ID.
org-id	Unique integer in the range from 1 to 65535 used in NetRanger communications to identify the group in which the local host belongs. Use with the **orgid** keyword.
orgid	Specifies a NetRanger organization ID.
rmtaddress	Specifies the IP address of the NetRanger Director.
localaddress	Specifies the IP address of the Cisco IOS Firewall IDS router.
ip-address	IP address of the NetRanger Director or Cisco IOS Firewall IDS router's interface. Use with the **rmtaddress** and **localaddress** keywords.
port-number	(Optional) Integer representing the UDP port on which the NetRanger Director is listening for event notifications. Use with the **port** keyword.
port	(Optional) Specifies a User Datagram Protocol port through which to send messages.
preference	(Optional) Specifies a route preference for communication.
preference-number	(Optional) Integer representing the relative priority of a route to a NetRanger Director, if more than one route exists. Use with the **preference** keyword.
seconds	(Optional) Integer representing the heartbeat timeout value for Post Office communications. Use with the **timeout** keyword.
timeout	(Optional) Specifies a timeout value for Post Office communications.
application	(Optional) Specifies the type of application that is receiving the Cisco IOS Firewall IDS messages.
director	(Optional) Specifies that the receiving application is the NetRanger Director interface.
logger	(Optional) Specifies that the receiving application is a NetRanger Sensor.

Defaults

The default organization ID is 1.

The default host ID is 1.

The default UDP port number is 45000.

The default preference is 1.

The default heartbeat timeout is 5 seconds.

The default application is **director**.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

A router can report to more than one NetRanger Director. In this case, use the **ip audit po remote** command to add each NetRanger Director to which the router sends notifications.

More than one route can be established to the same NetRanger Director. In this case, you must give each route a preference number that establishes the relative priority of routes. The router always attempts to use the lowest numbered route, switching automatically to the next higher number when a route fails, and then switching back when the route begins functioning again.

A router can also report to a NetRanger Sensor. In this case, use the **ip audit po remote** command and specify **logger** as the application.

Examples

In the following example, two communication routes for the same dual-homed NetRanger Director are defined:

```
ip audit po remote hostid 30 orgid 500 rmtaddress 10.1.99.100 localaddress 10.1.99.1
preference 1
ip audit po remote hostid 30 orgid 500 rmtaddress 10.1.4.30 localaddress 10.1.4.1
preference 2
```

The router uses the first entry to establish communication with the NetRanger Director defined with host ID 30 and organization ID 500. If this route fails, then the router will switch to the secondary communications route. As soon as the first route begins functioning again, the router switches back to the primary route and closes the secondary route.

In the following example, a different Director is assigned a longer heartbeat timeout value because of network congestion, and is designated as a logger application:

```
ip audit po remote hostid 70 orgid 500 rmtaddress 10.1.8.1 localaddress 10.1.8.100 timeout
10 application director
```

ip audit signature

To attach a policy to a signature, use the **ip audit signature** command in global configuration mode. To remove the policy, use the **no** form of this command. If the policy disabled a signature, then the **no** form of this command reenables the signature. If the policy attached an access list to the signature, the **no** form of this command removes the access list.

ip audit signature *signature-id* {**disable** | **list** *acl-list*}

no ip audit signature *signature-id*

Syntax Description

signature-id	Unique integer specifying a signature as defined in the NetRanger Network Security Database.
disable	Disables the ACL associated with the signature.
list	Specifies an ACL to associate with the signature.
acl-list	Unique integer specifying a configured ACL on the router. Use with the **list** keyword.

Defaults

No policy is attached to a signature.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command allow you to set two policies: disable the audit of a signature or qualify the audit of a signature with an access list.

If you are attaching an access control list to a signature, then you also need to create an audit rule with the **ip audit name** command and apply it to an interface with the **ip audit** command.

Examples

In the following example, a signature is disabled, another signature has ACL 99 attached to it, and ACL 99 is defined:

```
ip audit signature 6150 disable
ip audit signature 1000 list 99

access-list 99 deny 10.1.10.0 0.0.0.255
access-list 99 permit any
```

ip audit smtp

To specify the number of recipients in a mail message over which a spam attack is suspected, use the **ip audit smtp** command in global configuration mode. To set the number of recipients to the default setting, use the **no** form of this command.

ip audit smtp spam *number-of-recipients*

no ip audit smtp spam

Syntax Description

spam	Specifies a threshold beyond which the Cisco IOS Firewall IDS alarms on spam e-mail.
number-of-recipients	Integer in the range of 1 to 65535 that designates the maximum number of recipients in a mail message before a spam attack is suspected. Use with the **spam** keyword. The default is 250 recipients.

Defaults

The default number of recipients is 250.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **ip audit smtp** global configuration command to specify the number of recipients in a mail message over which a spam attack is suspected.

Examples

In the following example, the number of recipients is set to 300:

```
ip audit smtp spam 300
```

ip auth-proxy (global configuration)

To set the the authentication proxy idle timeout or maximum number of idle connections, use the **ip auth-proxy** command in global configuration mode. To return the idle timeout or maximum number of idle connections to their default values, use the **no** form of this command.

ip auth-proxy {**absolute-timer** *min* | **inactivity-timer** *min* | **init-state-timer** *min*| **max-nodata-conns** *number*}

no ip auth-proxy [**absolute-timer**] [**inactivity-timer**] [**init-state-timer**] [**max-nodata-conns**]

Syntax Description

absolute-timer *min*	Length of time in minutes that an ingress IP authentication proxy session can remain active. After this timer expires, each session must go through the entire process of establishing its connection as if it was a new request. The range is 0 to 35,791. The default is 0.
inactivity-timer *min*	Length of time in minutes that an active ingress session can be present with no activity or data from the end client. If this timer expires without activity or data, the session is cleared. The range is 1 to 2,147,483,647. The default is 60. **Note** This keyword and argument pair replaces the **auth-cache-time** *min* keyword and argument pair.
init-state-timer *min*	Length of time in minutes that an ingress authentication proxy session can stay in the INIT state. An ingress session is first registered in the INIT state until the user enters their username and password credentials. If the timer expires before the credentials are entered, the session is removed. The range is 1 to 15. The default is 2.
max-nodata-conns *number*	Maximum number of idle (“no data”) TCP connections that can exist globally for the IP authentication feature. The range is 1 to 1,000. The default is 3.

Command Default

The absolute timer is enabled indefinitely. The inactivity timer, and the INIT state timer are enabled. The limit on the number of global idle TCP connections is enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(1)	The **inactivity-timer** and **absolute-timer** keywords were added.
12.4(6)T	The **init-state-timer** keyword was added
12.2(33)SRA	This command was integrated into Cisco IOS release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You use the **ip auth-proxy** command to set the global idle timeout value for the authentication proxy. The idle timeout value is the length of time an authentication cache entry, along with its associated dynamic user access control list, is cleared after a period of inactivity.

You use the **absolute-timer** keyword to configure the length of time during which the authentication proxy on the enabled interface is active. After the absolute timer expires, the authentication proxy is disabled regardless of any activity. You can override the global absolute timeout value with the local (per protocol) value, which you can enable by using the **ip auth-proxy name** command. The absolute timer is turned off by default, and the authentication proxy is enabled indefinitely.

You must set the value of the **inactivity-timer** keyword to a higher value than the idle timeout of any Context-Based Access Control (CBAC) protocols. Otherwise, when the authentication proxy removes the user profile (and its associated dynamic user ACLs), there might be idle connections monitored by CBAC. Removing these user-specific ACLs could cause those idle connections to hang. If the CBAC idle timeout value is shorter, CBAC resets these connections when the CBAC idle timeout expires, which is before the authentication proxy removes the user profile.

You use the **init-state-timer** keyword to configure the amount of time that the authentication proxy is allowed to clear connections that are in the INIT state. Authentication attempts can remain in the INIT state when the router is loaded heavily and the authentication is not completed in two minutes. This problem is more likely if HTTPS is used for authenticating users. The default value of two minutes is usually sufficient to handle most cases, but if not, you should use the **init-state-timer** keyword to increase this value.

You use the **max-nodata-conns** keyword to limit the number of idle TCP connections (TCP sessions that are active but do not transmit data for a long period of time). There is no timer associated with this number.

Examples

The following example sets the inactivity timer to 30 minutes:

```
Router> enable
Router# configure terminal
Router(config)# ip auth-proxy inactivity-timer 30
```

The following example sets the INIT state timer to 15 minutes:

```
Router> enable
Router# configure terminal
Router(config)# ip auth-proxy init-state-timer 15
```

Related Commands

Command	Description
ip auth-proxy name	Creates an authentication proxy rule.
show ip auth-proxy configuration	Displays the authentication proxy entries or the running authentication proxy configuration.

ip auth-proxy (interface configuration)

To apply an authentication proxy rule at a firewall interface, use the **ip auth-proxy** command in interface configuration mode. To remove the authentication proxy rules, use the **no** form of this command.

ip auth-proxy *auth-proxy-name*

no ip auth-proxy *auth-proxy-name*

Syntax Description

auth-proxy-name	Specifies the name of the authentication proxy rule to apply to the interface configuration. The authentication proxy rule is established with the **ip auth-proxy name** command.

Defaults

No default behavior or values.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **ip auth-proxy** command to enable the named authentication proxy rule at the firewall interface. Traffic passing through the interface from hosts with an IP address matching the standard access list and protocol type (HTTP) is intercepted for authentication if no corresponding authentication cache entry exists. If no access list is defined, the authentication proxy intercepts traffic from all hosts whose connection initiating packets are received at the configured interface.

Use the **no** form of this command with a rule name to disable the authentication proxy for a given rule on a specific interface. If a rule is not specified, the **no** form of this command disables the authentication proxy on the interface.

Examples

The following example configures interface Ethernet0 with the HQ_users rule:

```
interface e0
 ip address 172.21.127.210 255.255.255.0
 ip access-group 111 in
 ip auth-proxy HQ_users
 ip nat inside
```

Related Commands

Command	Description
ip auth-proxy name	Creates an authentication proxy rule.

ip auth-proxy auth-proxy-banner

To display a banner, such as the router name, in the authentication proxy login page, use the **ip auth-proxy auth-proxy-banner** command in global configuration mode. To disable display of the banner, use the **no** form of this command.

ip auth-proxy auth-proxy-banner {**ftp** | **http** | **telnet**} [*banner-text*]

no ip auth-proxy auth-proxy-banner {**ftp** | **http** | **telnet**}

Syntax Description

ftp	Specifies the FTP protocol.
http	Specifies the HTTP protocol.
telnet	Specifies the Telnet protocol.
banner-text	(Optional) Specifies a text string to replace the default banner, which is the name of the router. The text string should be written in the following format: "C banner-text C," where "C" is a delimiting character.

Defaults

This command is not enabled, and a banner is not displayed on the authentication proxy login page.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(1)	The following keywords were added: **ftp**, **http**, and **telnet**.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **ip auth-proxy auth-proxy-banner** command allows users to configure one of two possible scenarios:

- The **ip auth-proxy auth-proxy-banner** command is enabled.

  In this scenario, the administrator has not supplied any text. Thus, a default banner that states the following: "Cisco Systems, <router's hostname> Authentication" will be displayed in the authentication proxy login page. This scenario is most commonly used.

- The **ip auth-proxy auth-proxy-banner** command with the *banner-text* argument is enabled.

  In this scenario, the administrator can supply multiline text that will be converted to HTML by the auth-proxy parser code. Thus, *only* the multiline text will displayed in the authentication proxy login page. You will *not* see the default banner, "Cisco Systems, <router's hostname> Authentication."

Note If the **ip auth-proxy auth-proxy-banner** command is not enabled, there will not be any banner configuration. Thus, nothing will be displayed to the user on authentication proxy login page except a text box to enter the username and a text box to enter the password.

Examples

The following example causes the router name to be displayed in the authentication proxy login page:

```
ip auth-proxy auth-proxy-banner ftp
```

The following example shows how to specify the custom banner “whozat” to be displayed in the authentication proxy login page:

```
ip auth-proxy auth-proxy-banner telnet CwhozatC
```

Related Commands

Command	Description
ip auth-proxy name	Creates an authentication proxy rule.

ip auth-proxy max-login-attempts

To limit the number of login attempts at a firewall interface in the interface configuration command mode, use the **ip auth-proxy max-login-attempts** command. Use the **no** form of this command to return to the default settings.

ip auth-proxy max-login-attempts *number*

no ip auth-proxy max-login-attempts

Syntax Description

number	Maximum number of login attempts. The range is 1 to 2147483647. The default value depends on the authentication mechanism: • FTP: 5 • HTTP: 30 • Telnet: 3

Defaults

Enabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

This command is supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2 only.

This command is supported on the firewall interfaces only.

The maximum login attempt functionality is independent of the watch-list feature. (You create a watch list with the **ip access-list hardware permit fragments** command.) If you do not configure a watch list, the existing authentication proxy behavior occurs, but it displays the new number for retries. If you configure a watch list, when the maximum is reached, the session is blocked and the IP address is put in the watch list.

Examples

This example shows how to set a limit to the number of login attempts at a firewall interface:

```
Router(config-if)# ip auth-proxy max-login-attempts 4
Router(config-if)#
```

Related Commands

Command	Description
clear ip auth-proxy watch-list	Deletes a single watch-list entry or all watch-list entries.
ip auth-proxy watch-list	Enables and configures an authentication proxy watch list.
show ip auth-proxy watch-list	Displays the information about the authentication proxy watch list.

ip auth-proxy name

To create an authentication proxy rule, use the **ip auth-proxy name** command in global configuration mode. To remove the authentication proxy rules, use the **no** form of this command.

Cisco IOS 12.4(6)T and Later Releases

ip auth-proxy name *auth-proxy-name* {**ftp** | **http** | **telnet**} [**event timeout aaa policy identity** *id-policy-name*] [**absolute-timer** *timeout*] [**auth-cache-time** *timeout*] [**inactivity-time** *timeout*] [**list** {*list-num* [**service-policy type tag** *policy-name*] | *std-list-num* | *list-name*}] [**service-policy type tag** *service-policy-name*]

no ip auth-proxy name *auth-proxy-name* {**ftp** | **http** | **telnet**}

Cisco IOS Release 12.2(33)SRA, 12.2SX, and Later Releases

ip auth-proxy name *auth-proxy-name* {**ftp** | **http** | **telnet**} [**event timeout aaa policy identity** *id-policy-name*] [**absolute-timer** *timeout*] [**auth-cache-time** *timeout*] [**inactivity-time** *timeout*] [**list** {*list-num* | *std-list-num* | *list-name*}]

no ip auth-proxy name *auth-proxy-name* {**ftp** | **http** | **telnet**}

Syntax Description

auth-proxy-name	A name of up to 16 alphanumeric characters to be associated with an authentication proxy rule.
ftp	Specifies FTP to trigger the authentication proxy.
http	Specifies HTTP to trigger the authentication proxy.
telnet	Specifies Telnet to trigger the authentication proxy.
event timeout aaa policy identity *id-policy-name*	(Optional) Specifies the event to be associated with the policy, timeout of the based event, AAA fail policy to be applied, Identity fail policy to be applied, and Identity policy name.
absolute-timer *timeout*	(Optional) Specifies a window in which the authentication proxy on the enabled interface is active. Enter a value in the range 0 to 35791 minutes. The default value is 0 minutes.
auth-cache-time *timeout*	(Optional) Alias of inactivity timeout in minutes. Enter a value in the range 1 to 35791 minutes.
inactivity-time *min*	(Optional) Overrides the global authentication proxy cache timer for a specific authentication proxy name, offering more control over timeout values. Enter a value in the range 1 to 35791 minutes. The default value is equal to the value set with the **ip auth-proxy** command. **Note** This option deprecates the **auth-cache-time** *timeout* option.
list {*list-num* | *std-list-num* | *list-name*}	(Optional) Specifies a standard (1 to 99), extended (1 to 199), or named IP access list to use with the authentication proxy. With this option, the authentication proxy is applied only to those hosts in the access list. If no list is specified, all connections initiating HTTP, FTP, or Telnet traffic arriving at the interface are subject to authentication.

service-policy type tag	(Optional) A control plane service policy is to be configured.
service-policy-name	(Optional) Control plane tag service policy that is configured using the **policy-map type control tag** *policy-map-name* command. This policy map is used to apply the actions on the host when a tag is received.

Command Default

The default value is equal to the value set with the **ip auth-proxy auth-cache-time** command.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2	Support for named and extend access lists was introduced.
12.3(1)	The following keywords were introduced: • **ftp** • **telnet** • **inactivity-time** *timeout* • **absolute-timer** *timeout*
12.4(6)T	The **service-policy type tag** keywords and *service-policy-name* argument were added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **event**, **timeout**, **aaa**, **policy**, **identity** keywords and the *id-policy-name* argument were added.

Usage Guidelines

This command creates a named authentication proxy rule, and it allows you to associate that rule with an access control list (ACL), providing control over which hosts use the authentication proxy. The rule is applied to an interface on a router using the **ip auth-proxy** command.

Use the **inactivity-time** *timeout* option to override the global the authentication proxy cache timer. This option provides control over timeout values for specific authentication proxy rules. The authentication proxy cache timer monitors the length of time (in minutes) that an authentication cache entry, along with its associated dynamic user access control list, is managed after a period of inactivity. When that period of inactivity (idle time) expires, the authentication entry and the associated dynamic access lists are deleted.

Use the **list** option to associate a set of specific IP addresses or a named ACL with the **ip auth-proxy name** command.

Use the **no** form of this command with a rule name to remove the authentication proxy rules. If no rule is specified, the **no** form of this command removes all the authentication rules on the router, and disables the proxy at all interfaces.

Note You must use the **aaa authorization auth-proxy** command with the **ip auth-proxy name** command. Together these commands set up the authorization policy to be retrieved by the firewall. Refer to the **aaa authorization auth-proxy** command for more information.

Examples

The following example shows how to create the HQ_users authentication proxy rule. Because an access list is not specified in the rule, all connection-initiating HTTP traffic is subjected to authentication.

```
ip auth-proxy name HQ_users http
```

The following example shows how to create the Mfg_users authentication proxy rule and apply it to hosts specified in ACL 10:

```
access-list 10 192.168.7.0 0.0.0.255
ip auth-proxy name Mfg_users http list 10
```

The following example shows how to set the timeout value for Mfg_users to 30 minutes:

```
access-list 15 any
ip auth-proxy name Mfg_users http inactivity-timer 30 list 15
```

The following example shows how to disable the Mfg_users rule:

```
no ip auth-proxy name Mfg_users
```

The following example shows how to disable the authentication proxy at all interfaces and remove all the rules from the router configuration:

```
no ip auth-proxy xyz ftp
```

Related Commands

Command	Description
aaa authorization	Sets parameters that restrict network access to a user.
ip auth-proxy (global)	Sets the authentication proxy idle timeout value (that is, the length of time an authentication cache entry, along with its associated dynamic user ACL, is managed after a period of inactivity).
ip auth-proxy (interface)	Applies an authentication proxy rule at a firewall interface.
show ip auth-proxy configuration	Displays the authentication proxy entries or the running authentication proxy configuration.

ip auth-proxy watch-list

To enable and configure an authentication proxy watch list in the interface configuration command mode, use the **ip auth-proxy watch-list** command. To disable the watch-list functionality, remove an IP address from the watch list. Or, to return to the default setting, use the **no** form of this command.

ip auth-proxy watch-list {**add-item** *ip-addr* | **enable** | **expiry-time** *minutes*}

no ip auth-proxy watch-list [**add-item** *ip-addr* | **expiry-time**]

Syntax Description

add-item *ip-addr*	Adds an IP address to the watch list.
enable	Enables a watch list.
expiry-time *minutes*	Specifies the duration of time that an entry is in the watch list; see the "Usage Guidelines" section for valid values.

Defaults

The defaults are as follows:

- *minutes* is **30** minutes.
- The watch-list functionality is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

This command is supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2 only.

The valid values for minutes are from 0 to the largest 32-bit positive number (0x7FFFFFFF or 2147483647 in decimal). Setting the *minutes* to 0 (zero) places the entries in the list permanently.

This command is supported on the firewall interfaces only.

Use the **no** form of this command to do the following:

- **no ip auth-proxy watch-list**—Disables the watch-list functionality.
- **no ip auth-proxy watch-list add-item** *ip-addr*—Removes the IP address from the watch list.
- **no ip auth-proxy watch-list expiry-time**—Returns to the default setting.

A watch list consists of IP addresses that have opened TCP connections to port 80 and have not sent any data. No new connections are accepted from this type of IP address (to port 80) and the packet is dropped.

An entry remains in the watch list for the time that is specified by **expiry-time** *minutes*.

When you disable a watch list, no new entries are put into the watch list, but the sessions are put in SERVICE_DENIED state. The timer deletes sessions after 2 minutes.

Examples

This example shows how to enable an authentication proxy watch list:

```
Router(config-if)# ip auth-proxy watch-list enable
Router(config-if)#
```

This example shows how to disable an authentication proxy watch list:

```
Router(config-if)# no ip auth-proxy watch-list
Router(config-if)#
```

This example shows how to add an IP address to a watch list:

```
Router(config-if)# ip auth-proxy watch-list add-item 10.0.0.2
Router(config-if)#
```

This example shows how to set the duration of time that an entry is in a watch list:

```
Router(config-if)# ip auth-proxy watch-list expiry-time 29
Router(config-if)#
```

Related Commands

Command	Description
clear ip auth-proxy watch-list	Deletes a single watch-list entry or all watch-list entries.
ip auth-proxy max-login-attempts	Limits the number of login attempts at a firewall interface.
show ip auth-proxy watch-list	Displays the information about the authentication proxy watch list.

ip dhcp client broadcast-flag (interface)

To configure a DHCP client to set or clear the broadcast flag, use the **ip dhcp client broadcast-flag** command in interface configuration mode. To disable the configuration, use the **no** form of this command.

ip dhcp client broadcast-flag {**clear** | **set**}

no ip dhcp client broadcast-flag

Syntax Description

clear	Clears the broadcast flag.
set	Sets the broadcast flag.

Command Default

The broadcast flag is set.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

For a DHCP server to work on a Dynamic Multipoint VPN (DMVPN) network, the DHCP client available on the spoke must unicast the DHCP messages from the server to the client. By default, the DHCP client on the spoke broadcasts the DHCP messages. The broadcast flag is set during broadcast. Hence, the DHCP client on the spoke must have an option to clear the DHCP broadcast flag. You can use the **ip dhcp client broadcast-flag** command to configure the DHCP client to set or clear the broadcast flag.

Examples

The following example shows how to configure a DHCP client to clear the broadcast flag:

```
Router(config)# tunnel 1
Router(config-if)# ip dhcp client broadcast-flag clear
```

Related Commands

Command	Description
ip address dhcp	Acquires an IP address on an interface from the DHCP.
ip dhcp support tunnel unicast	Configures a spoke-to-hub tunnel to unicast the DHCP replies over the DMVPN network.

ip dhcp support tunnel unicast

To configure a spoke-to-hub tunnel to unicast DHCP replies over a Dynamic Multipoint VPN (DMVPN) network, use the **ip dhcp support tunnel unicast** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ip dhcp support tunnel unicast

no ip dhcp support tunnel unicast

Syntax Description

This command has no arguments or keywords.

Command Default

A spoke-to-hub tunnel broadcasts the replies over the DMVPN network.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

By default, the DHCP replies are broadcast from the DMVPN hub to the spoke. The DHCP relay agent must unicast the DHCP messages for a DHCP server to be functional in the DMVPN environment. Hence for the DHCP to be functional in DMVPN environment, you must configure the DHCP relay agent to unicast the DHCP messages.

Use the **ip dhcp support tunnel unicast** command to configure the DHCP relay agent to unicast the DHCP protocol messages from the server (hub) to the client (spoke). The relay agent uses the nonbroadcast multiaccess (NBMA) address to create temporary routes in Next Hop Resolution Protocol (NHRP) to help unicast the DHCPOFFER and DHCPACK messages to the spoke.

Examples

The following example shows how to configure a spoke-to-hub tunnel to unicast the replies over a DMVPN network:

```
Router(config)# ip dhcp support tunnel unicast
```

Related Commands

Command	Description
ip address dhcp	Configures an IP address on an interface acquired through DHCP.
ip dhcp client broadcast-flag	Configures the DHCP client to set or clear the broadcast flag.

ip-extension

To specify that IP extensions are included in a certificate request either for enrollment or generation of a certificate authority (CA) certificate for the Cisco IOS CA, use the **ip-extension** command in ca-trustpoint configuration mode. To remove a previously specified IP extension, use the **no** form of this command.

ip-extension [**multicast** | **unicast**] {**inherit** [**ipv4** | **ipv6**] | **prefix** *ipaddress* | **range** *min-ipaddress max-ipaddress*}

no ip-extension [**multicast** | **unicast**] {**inherit** [**ipv4** | **ipv6**] | **prefix** *ipaddress* | **range** *min-ipaddress max-ipaddress*}

Syntax Description

multicast	(Optional) Specifies that only multicast traffic, a subsequent address family identifier (SAFI), will be included in certificate requests.  **Note** If neither multicast nor unicast traffic is specified, both will be included in a certificate request.
unicast	(Optional) Specifies that only unicast traffic, a SAFI, will be included in certificate requests.  **Note** If neither multicast nor unicast traffic is specified, both will be included in a certificate request.
inherit	Specifies that IP addresses will be inherited from an issuer certificate. The issuer's certificate is first checked to find a certificate containing the address range or prefix. If no match is found, the certificate from the next issuer in the chain is checked, and so forth, up the certificate chain, recursively, until a match is located.
ipv4	(Optional) Specifies that only IPv4 addresses are inherited.  **Note** If neither an **ipv4** nor an **ipv6** address is specified, both address families are inherited.
ipv6	(Optional) Specifies that only IPv6 addresses are inherited.  **Note** If neither an **ipv4** nor an **ipv6** address is specified, both address families are inherited.

prefix *ipaddress*	Specifies the IP address prefix or a single IP address for either an IPv4 or IPv6 address. The IP address formats are: • A.B.C.D IPv4 address • A.B.C.D/nn IPv4 prefix • X:X:X:X::X IPv6 address • X:X:X:X::X/<0-128> IPv6 prefix
range	Specifies that there is a range of IP addresses.
min-ipaddress	The beginning IP address in the IP address range, in either IPv4 or IPv6 address format. The IP address formats are: • A.B.C.D Beginning IPv4 address in the range • X:X:X:X::X Beginning IPv6 address in the range
max-ipaddress	The ending IP address in the IP address range, in either IPv4 or IPv6 address format. The IP address formats are: • A.B.C.D Ending IPv4 address in the range • X:X:X:X::X Ending IPv6 address in the range

Command Default

No IP extensions will be included in a certificate request.

Command Modes

Ca-trustpoint configuration (ca-trustpoint)

Command History

Release	Modification
12.4(22)T	This command was introduced.
12.4(24)T	Support for IPv6 Secure Neighbor Discovery (SeND) was added.

Usage Guidelines

The **ip-extension** command may be used to specify IP extensions for a public key infrastructure (PKI) server or client and may be issued one or more times, including multiple issuances with the **inherit**, **prefix**, and **range** keywords. For the inherit option, if the address family is not specified, both IPv4 and IPv6 addresses will be inherited. When the IPv4 or IPv6 address family is not specified for prefix or range, the address family will be determined from the address format.

Note It is recommended that you validate each **ip-extension** command line against your existing IP-extension configuration according to RFC 3779, verifying that IP address ranges do not overlap. The issue's certificate may not be available to validate the issuer's certificate for subsets of addresses.

Examples

The following example shows how to specify that multiple IP extensions are included in the server certificate request:

```
Router(ca-trustpoint)# ip-extension multicast prefix 10.64.0.0/11

! Only multicast traffic with the IPv4 prefix 10.64.0.0/11 will be included in certificate
requests.

Router(ca-trustpoint)# ip-extension prefix 2001:100:1::/48

! Multicast and unicast traffic with the IPv6 prefix 2001:100:1::/48 will be included in
certificate requests.

Router(ca-trustpoint)# ip-extension inherit

! Multicast and unicast traffic with IPv4 and IPv6 addresses will be inherited from the
issuer's certificate.

Router(ca-trustpoint)# ip-extension inherit ipv6

! Multicast and unicast traffic with IPv6 addresses only will be inherited from the
issuer's certificate.

Router(ca-trustpoint)# ip-extension unicast range 209.165.200.225 143.255.55.255

! Unicast traffic within the specified IPv4 address range will be included in the
certificate request.

Router(ca-trustpoint)# ip-extension range 2001:1:1::1 2001:1:2:ffff:ffff:ffff:ffff:ffff

! Multicast and unicast traffic within the specified IPv6 address range will be included
in the certificate request.
```

The following is sample output from the **show crypto pki certificates verbose** command. The output displays X.509 certificate IP address extension information where the IPv4 multicast prefix has been set to 10.64.0.0/11, and the IPv4 unicast range has been set to 209.165.201.1 209.165.201.30.

show crypto pki trustpoints	Displays information about trustpoints that are configured on the router.

ip http ezvpn

To enable the Cisco Easy VPN remote web server interface, use the **ip http ezvpn** command in global configuration mode. To disable the Cisco Easy VPN remote web server interface, use the **no** form of this command.

Cisco uBR905 and Cisco BR925 cable access routers

ip http ezvpn

no ip http ezvpn

Syntax Description

This command has no arguments or keywords.

Defaults

The Cisco Easy VPN Remote web server interface is disabled by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(8)YJ	This command was introduced for the Cisco uBR905 and Cisco uBR925 cable access routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS 12.2SX family of releases. Support in a specific 12.2SX release is dependent on your feature set, platform, and platform hardware.

Usage Guidelines

This command enables the Cisco Easy VPN Remote web server, an onboard web server that allows users to connect an IPSec Easy VPN tunnel and to provide the required authentication information. The Cisco Easy VPN Remote web server allows the user to perform these functions without having to use the Cisco command-line interface (CLI).

Before using this command, you must first enable the Cisco web server that is onboard the cable access router by entering the **ip http server** command. Then use the **ip http ezvpn** command to enable the Cisco Easy VPN remote web server. You can then access the web server by entering the IP address for the Ethernet interface of the router in your web browser.

Note The Cisco Easy VPN Remote web interface does not work with the cable monitor web interface in Cisco IOS Release 12.2(8)YJ. To access the cable monitor web interface, you must first disable the Cisco Easy VPN remote web interface with the **no ip http ezvpn** command, and then enable the cable monitor with the **ip http cable-monitor** command.

Examples

The following example shows how to enable the Cisco Easy VPN remote web server interface:

```
Router# configure terminal
Router(config)# ip http server
Router(config)# ip http ezvpn
Router(config)# exit
Router# copy running-config startup-config
```

Related Commands

Command	Description
ip http cable-monitor	Enables and disables the Cable Monitor Web Server feature.
ip http port	Configures the TCP port number for the HTTP web server of the router.
ip http server	Enables and disables the HTTP web server of the router.

ip inspect

To apply a set of inspection rules to an interface, use the ip inspect command in interface configuration mode. There are two different modes for this command, configuration mode and interface configuration mode. To remove the set of rules from the interface, use the **no** form of this command.

Global Configuation Mode

ip inspect *inspection-name* {**in** | **out**} [**redundancy** | **stateful** *hsrp-group-name*} | **update seconds** *seconds*]

no ip inspect *inspection-name* {**in** | **out**} [**redundancy** | **stateful** *hsrp-group-name*} | **update seconds** *seconds*]

Interface Configuration Mode

ip inspect *inspection-name* {**in** | **out}** [**redundancy** | **stateful** *hsrp-group-name*]

no ip inspect *inspection-name* {**in** | **out}** [**redundancy** | **stateful** *hsrp-group-name*]

Syntax Description

Interface Configuration Mode	
inspection-name	Identifies which set of inspection rules to apply.
in	Applies the inspection rules to inbound interface.
out	Applies the inspection rules to outbound interface.
redunancy	Enables reduncany.
stateful	Enables stateful redundancy.
hsrp-group-name	The hsrp-group name that is used to configure box-to-box HA
Global Configuration Mode	
redundancy	Redundancy settings for firewall sessions
update	Update settings for firewall HA sessions
seconds *seconds*	The time interval between consecutive updates from 10 to 60 seconds. The default is 10 seconds.

Command Default

If no set of inspection rules is applied to an interface, no traffic will be inspected by CBAC. If **redundancy stateful <hsrp-grp-name>** is not used, there will be no stateful firewall high-availability.

Command Modes

Interface configuration mode(conf-if)

Command History

Release	Modification
11.2	This command was introduced.
12.4(6)T	Added support for **redunancy**, **update**, **seconds**, and **stateful** keywords.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to apply a set of inspection rules to an interface.

Typically, if the interface connects to the external network, you apply the inspection rules to outbound traffic; alternately, if the interface connects to the internal network, you apply the inspection rules to inbound traffic.

In the Interface Configuration mode, use **ip inspect<name> in/out redundancy stateful <hsrp-group>** command. Use the redundancy stateful <hsrp-grp> option to turn on stateful high availability for all session that come up on this inspect rule. The incoming IP traffic is the return traffic of an existing session. It not necessary to have redundancy stateful HSRP group name if you do not require IOS Firewall High availability.

In the Global Configuration mode, use **ip inspect redundancy update seconds <10-60>**. Use the redundancy update seconds option to configure the time interval between the synchronization of the active and standby firewall HA sessions.

Examples

The following example applies a set of inspection rules named MY-INSPECT_RULE to serial0 interface's outbound traffic. This causes the inbound IP traffic to be permitted only if the traffic is part of an existing session, and to be denied if the traffic is not part of an existing session.

```
interface serial0
ip inspect MY-INSPECT_RULE out redundancy stateful B2B-HA-HSRP-GRP
```

Related Commands

Command	Description
ip inspect name	Defines a set of inspection rules.

ip inspect alert-off

To disable Context-based Access Control (CBAC) alert messages, which are displayed on the console, use the **ip inspect alert-off** command in global configuration mode. To enable CBAC alert messages, use the **no** form of this command.

ip inspect alert-off [**vrf** *vrf-name*]

no ip inspect alert-off [**vrf** *vrf-name*]

Syntax Description

vrf *vrf-name*	(Optional) Disables CBAC alert messages only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

Alert messages are displayed.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example disables CBAC alert messages:

```
ip inspect alert-off
```

ip inspect audit trail

To turn on Context-based Access Control (CBAC) audit trail messages, which will be displayed on the console after each CBAC session closes, use the **ip inspect audit trail** command in global configuration mode. To turn off CBAC audit trail messages, use the **no** form of this command.

ip inspect audit trail [**vrf** *vrf-name*]

no ip inspect audit trail [**vrf** *vrf-name*]

Syntax Description

vrf *vrf-name*	(Optional) Turns on CBAC audit trail messages only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

Audit trail messages are not displayed.

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to turn on CBAC audit trail messages.

Examples

The following example turns on CBAC audit trail messages:

```
ip inspect audit trail
```

Afterward, audit trail messages such as the following are displayed. These messages are examples of audit trail messages. To determine which protocol was inspected, see the port number of the responder. The port number follows the IP address of the responder.

```
%FW-6-SESS_AUDIT_TRAIL: tcp session initiator (192.168.1.13:33192) sent 22 bytes --
responder (192.168.129.11:25) sent 208 bytes
%FW-6-SESS_AUDIT_TRAIL: ftp session initiator 192.168.1.13:33194) sent 336 bytes --
responder (192.168.129.11:21) sent 325 bytes
```

The following example disables CBAC alert messages for VRF interface vrf1:

```
ip inspect audit-trail vrf vrf1
```

Following are examples of audit trail messages:

```
00:10:15: %FW-6-SESS_AUDIT_TRAIL: VRF-vrf1:Stop udp session: initiator
(192.168.14.1:40801) sent 54 bytes -- responder (192.168.114.1:7) sent 54 bytes
00:10:47: %FW-6-SESS_AUDIT_TRAIL: VRF-vrf1:Stop ftp-data session: initiator
(192.168.114.1:20) sent 80000 bytes -- responder (192.168.14.1:38766) sent 0 bytes
00:10:47: %FW-6-SESS_AUDIT_TRAIL: VRF-vrf1:Stop ftp session: initiator
(192.168.14.1:38765) sent 80 bytes -- responder (192.168.114.1:21) sent 265 bytes
00:10:57: %FW-6-SESS_AUDIT_TRAIL: VRF-vrf1:Stop rcmd session: initiator (192.168.14.1:531)
sent 31 bytes -- responder (192.168.114.1:514) sent 12 bytes
00:10:57: %FW-6-SESS_AUDIT_TRAIL: VRF-vrf1:Stop rcmd-data session: initiator
(192.168.114.1:594) sent 0 bytes -- responder (192.168.14.1:530) sent 0 bytes
```

ip inspect dns-timeout

To specify the Domain Name System (DNS) idle timeout (the length of time during which a DNS name lookup session will still be managed while there is no activity), use the **ip inspect dns-timeout** command in global configuration mode. To reset the timeout to the default of 5 seconds, use the **no** form of this command.

ip inspect dns-timeout *seconds* [**vrf** *vrf-name*]

no ip inspect dns-timeout *seconds* [**vrf** *vrf-name*]

Syntax Description

seconds	Specifies the length of time in seconds, for which a DNS name lookup session will still be managed while there is no activity. The default is 5 seconds.
vrf *vrf-name*	(Optional) Specifies the DNS idle timeout only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

5 seconds

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When the software detects a valid User Datagram Protocol (UDP) packet for a new DNS name lookup session, if Context-based Access Control (CBAC) inspection is configured for UDP, the software establishes state information for the new DNS session.

If the software detects no packets for the DNS session for a time period defined by the DNS idle timeout, the software will not continue to manage state information for the session.

The DNS idle timeout applies to all DNS name lookup sessions inspected by CBAC.

The DNS idle timeout value overrides the global UDP timeout. The DNS idle timeout value also enters aggressive mode and overrides any timeouts specified for specific interfaces when you define a set of inspection rules with the **ip inspect name** command.

Examples

The following example sets the DNS idle timeout to 30 seconds:

```
ip inspect dns-timeout 30
```

The following example sets the DNS idle timeout back to the default (5 seconds):

```
no ip inspect dns-timeout
```

ip inspect hashtable

To change the size of the session hash table, use the **ip inspect hashtable** command in global configuration mode. To restore the size of the session hash table to the default, use the **no** form of this command.

ip inspect hashtable *number*

no ip inspect hashtable *number*

Syntax Description

number	Size of the hash table in terms of buckets. Possible values for the hash table are 1024, 2048, 4096, and 8192; the default value is 1024.

Defaults

1024 buckets

Command Modes

Global configuration

Command History

Release	Modification
12.2(8)T	This command was introduced.

Usage Guidelines

Use the **ip inspect hashtable** command to increase the size of the hash table when the number of concurrent sessions increases or to reduce the search time for the session. Collisions in a hash table result in poor hash function distribution because many entries are hashed into the same bucket for certain patterns of addresses. Even if a hash function distribution evenly dispenses the input across all of the buckets, a small hash table size will not scale well if there are a large number of sessions. As the number of sessions increase, the collisions increase, which increases the length of the linked lists, thereby, deteriorating the throughput performance.

Note You should increase the hash table size when the total number of sessions running through the context-based access control (CBAC) router is approximately twice the current hash size; decrease the hash table size when the total number of sessions is reduced to approximately half the current hash size. Essentially, try to maintain a 1:1 ratio between the number of sessions and the size of the hash table.

Examples

The following example shows how to change the size of the session hash table to 2048 buckets:

```
ip inspect hashtable 2048
```

ip inspect L2-transparent dhcp-passthrough

To allow a transparent firewall to forward Dynamic Host Control Protocol (DHCP) pass-through traffic, use the **ip inspect L2-transparent dhcp-passthrough** command in global configuration mode. To return to the default functionality, use the **no** form of this command.

ip inspect L2-transparent dhcp-passthrough

no ip inspect L2-transparent dhcp-passthrough

Syntax Description

This command has no arguments or keywords.

Defaults

This command is not enabled; thus, DHCP packets are forwarded or denied according to the configured access control list (ACL).

Command Modes

Global configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

A transparent firewall allows a Cisco IOS Firewall (a Layer 3 device) to operate as a Layer 2 firewall in bridging mode. Thus, the firewall can exist "transparently" to a network, no longer requiring users to reconfigure their statically defined network devices.

The **ip inspect L2-transparent dhcp-passthrough** command overrides the ACL for DHCP packets; that is, DHCP packets are forwarded even if the ACL is configured to deny all IP packets. Thus, this command can be used to enable a transparent firewall to forward DHCP packets across the bridge without inspection so clients on one side of the bridge can get an IP address from a DHCP server on the opposite side of the bridge.

Examples

Allowing DHCP Pass-Through Traffic

In this example, the static IP address of the client is removed, and the address is acquired via DHCP using the **ip address dhcp** command on the interface that is connected to the transparent firewall.

```
Router# show debug

ARP:
  ARP packet debugging is on
L2 Inspection:
  INSPECT L2 firewall debugging is on
  INSPECT L2 firewall DHCP debugging is on
Router#
Router#
! Configure DHCP passthrough
Router(config)# ip insp L2-transparent dhcp-passthrough
```

```
! The DHCP discover broadcast packet arrives from the client. Since this packet is a
! broadcast (255.255.255.255), it arrives in the flood path
*Mar  1 00:35:01.299:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1

*Mar  1 00:35:01.299:L2FW:src 0.0.0.0 dst 255.255.255.255
! The DHCP pass through flag is checked and the packet is allowed
*Mar  1 00:35:01.299:L2FW:DHCP packet seen. Pass-through flag allows the packet
! The packet is a broadcast packet and therefore not sent to CBAC
*Mar  1 00:35:01.299:L2FW*:Packet is broadcast or multicast.PASS
! The DHCP server 97.0.0.23 responds to the client's request
*Mar  1 00:35:01.303:L2FW:insp_l2_flood:input is Ethernet1 output is Ethernet0
*Mar  1 00:35:01.303:L2FW*:Src 172.16.0.23 dst 255.255.255.255 protocol udp
*Mar  1 00:35:01.307:L2FW:udp ports src 67 dst 68
*Mar  1 00:35:01.307:L2FW:src 172.16.0.23 dst 255.255.255.255
*Mar  1 00:35:01.307:L2FW:DHCP packet seen. Pass-through flag allows the packet
*Mar  1 00:35:01.307:L2FW*:Packet is broadcast or multicast.PASS
*Mar  1 00:35:01.311:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1
*Mar  1 00:35:01.311:L2FW*:Src 0.0.0.0 dst 255.255.255.255 protocol udp
*Mar  1 00:35:01.311:L2FW:udp ports src 68 dst 67
*Mar  1 00:35:01.311:L2FW:src 0.0.0.0 dst 255.255.255.255
*Mar  1 00:35:01.315:L2FW:DHCP packet seen. Pass-through flag allows the packet
*Mar  1 00:35:01.315:L2FW*:Packet is broadcast or multicast.PASS
*Mar  1 00:35:01.315:L2FW:insp_l2_flood:input is Ethernet1 output is Ethernet0
*Mar  1 00:35:01.323:L2FW*:Src 172.16.0.23 dst 255.255.255.255 protocol udp
*Mar  1 00:35:01.323:L2FW:udp ports src 67 dst 68
*Mar  1 00:35:01.323:L2FW:src 172.16.0.23 dst 255.255.255.255
*Mar  1 00:35:01.323:L2FW:DHCP packet seen. Pass-through flag allows the packet
*Mar  1 00:35:01.323:L2FW*:Packet is broadcast or multicast.PASS
! The client has an IP address (172.16.0.5) and has issued a G-ARP to let everyone know
it's address
*Mar  1 00:35:01.327:IP ARP:rcvd rep src 172.16.0.5 0008.a3b6.b603, dst 172.16.0.5 BVI1
Router#
```

Denying DHCP Pass-Through Traffic

In this example, DHCP pass-through traffic is not allowed (via the **no ip inspect L2-transparent dhcp-passthrough** command). The client is denied when it attempts to acquire a DHCP address from the server.

```
! Deny DHCP pass-through traffic
Router(config)# no ip inspect L2-transparent dhcp-passthrough

! The DHCP discover broadcast packet arrives from the client
*Mar  1 00:36:40.003:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1
*Mar  1 00:36:40.003:L2FW*:Src 0.0.0.0 dst 255.255.255.255 protocol udp
*Mar  1 00:36:40.003:L2FW:udp ports src 68 dst 67
*Mar  1 00:36:40.007:L2FW:src 0.0.0.0 dst 255.255.255.255
! The pass-through flag is checked
*Mar  1 00:36:40.007:L2FW:DHCP packet seen. Pass-through flag denies the packet
! The packet is dropped because the flag does not allow DHCP passthrough traffic. Thus,
! the client cannot acquire an address, and it times out
*Mar  1 00:36:40.007:L2FW:FLOOD Dropping the packet after ACL check.
```

Related Commands

Command	Description
debug ip inspect L2-transparent	Enables debugging messages for transparent firewall events.
show ip inspect	Displays Cisco IOS Firewall configuration and session information.

ip inspect log drop-pkt

To log all packets dropped by the firewall, use the **ip inspect log drop-pkt** command in global configuration mode. To return to the default state, use the **no** form of this command.

ip inspect log drop-pkt

no ip inspect log drop-pkt

Syntax Description

This command has no arguments or keywords.

Command Default

Packets dropped by the firewall are not logged.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(7)T1	This command was introduced.
12.3(8)T	This command was integrated into Release 12.3(8)T.

Usage Guidelines

To see the packets that are dropped by the firewall, the **ip inspect log drop-pkt** command must be enabled.

Examples

The following example shows how to enable the logging of packets dropped by the firewall:

```
Router> enable
Router# configure terminal
Router(config)# ip inspect log drop-pkt
```

The following example shows a possible message that can be displayed when packets are dropped:

```
*Sep 9 19:56:28.699: %FW-6-DROP_PKT: Dropping tcp pkt 17.2.2.1:0 => 19.2.2.1:0 with ip
ident 229 due to Invalid Header length

*Sep 9 20:30:47.839: %FW-6-DROP_TCP_PKT: Dropping tcp pkt 17.2.2.1:42829 => 19.2.2.1:80
due to SYN pkt with illegal flags -- ip ident 23915 tcpflags 40962 seq.no 3928613134 ack 0

*Sep 10 00:30:24.931: %FW-6-DROP_TCP_PKT: Dropping tcp pkt 17.2.2.1:45771 =>

19.2.2.1:80 due to SYN with data or with PSH/URG flags -- ip ident 55001 tcpflags 40962
seq.no 2232798685 ack 0

*Aug 29 21:57:16.895: %FW-6-DROP_PKT: Dropping tcp pkt 17.2.2.1:51613 => 19.2.2.1:80 due
to Out-Of-Order Segment
```

Table 35 describes messages that occur when packets are dropped.

Table 35 ip inspect log drop-pkt Messages

Field	Description
Invalid Header length	The datagram is so small that it could not contain the layer 4 TCP, Universal Computer Protocol (UCP), or Internet Control Message Protocol (ICMP) header.
Police rate limiting	Rate limiting is enabled, and the packet in question has exceeded the rate limit.
Session limiting	Session limiting is on, and the session count exceeds the configured session threshold.
Bidirectional traffic disabled	Session is unidirectional and the firewall is seeing packets in the other direction and dropping the session.
SYN with data or with PSH/URG flags	TCP SYN packet is seen with data.
Segment matching no TCP connection	Non-initial TCP segment is received without a valid session.
Invalid Segment	There is an invalid TCP segment.
Invalid Seq#	The packet contains an invalid TCP sequence number.
Invalid Ack (or no Ack)	The packet contains an invalid TCP acknowledgement number.
Invalid Flags	Flags in a TCP segment are invalid.
Invalid Checksum	There is an invalid TCP checksum.
SYN inside current window	A synchronization packet is seen within the window of an already established TCP connection.
RST inside current window	A reset (RST) packet is observed within the window of an already established TCP connection.
Out-Of-Order Segment	The packets in a segment are out of order.
Retransmitted Segment with Invalid Flags	A retransmitted packet was already acknowledged by the receiver.
Stray Segment	A TCP segment is received that should not have been received through the TCP state machine such as a TCP SYN packet being received in the listen state.
Internal Error	The TCP state machine that is maintained by the firewall encounters an internal error.
Invalid Window scale option	The responder on one side of a firewall proposes an illegal window scale option. The window scale option is illegal in this case because the initiating side did not propose the option first.
Invalid TCP options	The options in the TCP header are not TCP protocol compliant.

Related Commands

Command	Description
ip inspect tcp block-non-session	Blocks packets that do not belong to the existing firewall TCP sessions in the inbound and outbound directions.
ip inspect tcp finwait-time	Defines how long a TCP session will still be managed after the firewall detects a FIN-exchange.
ip inspect tcp idle-time	Specifies the TCP idle timeout (the length of time a TCP session will still be managed while there is no activity).
ip inspect tcp max-incomplete host	Specifies threshold and blocking time values for TCP host-specific DoS detection and prevention.
ip inspect tcp reassembly	Sets parameters that define how Cisco IOS Firewall application inspection and Cisco IOS IPS will handle out-of-order TCP packets.
ip inspect tcp synwait-time	Defines how long the software will wait for a TCP session to reach the established state before dropping the session.
ip inspect udp idle-time	Specifies the UDP idle timeout (the length of time for which a UDP session will still be managed while there is no activity).

ip inspect max-incomplete high

To define the number of existing half-open sessions that will cause the software to start deleting half-open sessions, use the **ip inspect max-incomplete high** command in global configuration mode. To reset the threshold to the default of 500 half-open sessions, use the **no** form of this command.

ip inspect max-incomplete high *number* [**vrf** *vrf-name*]

no ip inspect max-incomplete high

Syntax Description

number	Specifies the number of existing half-open sessions that will cause the software to start deleting half-open sessions. The default is 500 half-open sessions.
vrf *vrf-name*	(Optional) Defines the number of existing half-open sessions only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

500 half-open sessions

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

An unusually high number of half-open sessions (either absolute or measured as the arrival rate) could indicate that a denial-of-service attack is occurring. For TCP, “half-open” means that the session has not reached the established state. For User Datagram Protocol (UDP), “half-open” means that the firewall has detected traffic from one direction only.

Context-based Access Control (CBAC) measures both the total number of existing half-open sessions and the rate of session establishment attempts. Both TCP and UDP half-open sessions are counted in the total number and rate measurements. Measurements are made once a minute.

When the number of existing half-open sessions rises above a threshold (the **max-incomplete high** number), the software will delete half-open sessions as required to accommodate new connection requests. The software will continue to delete half-open requests as necessary, until the number of existing half-open sessions drops below another threshold (the **max-incomplete low** number).

The global value specified for this threshold applies to all TCP and UDP connections inspected by CBAC.

Examples

The following example causes the software to start deleting half-open sessions when the number of existing half-open sessions rises above 900, and to stop deleting half-open sessions when the number drops below 800:

```
ip inspect max-incomplete high 900
ip inspect max-incomplete low 800
```

The following example shows an ALERT_ON message generated for the **ip inspect max-incomplete high** command:

```
ip inspect max-incomplete high 20 vrf vrf1
show log / include ALERT_ON
00:59:00:%FW-4-ALERT_ON: VRF-vrf1:getting aggressive, count (21/20) current 1-min rate: 21
```

Related Commands

Command	Description
ip inspect max-incomplete low	Defines the number of existing half-open sessions that will cause the software to stop deleting half-open sessions.
ip inspect one-minute high	Defines the rate of new unestablished sessions that will cause the software to start deleting half-open sessions.
ip inspect one-minute low	Defines the rate of new unestablished TCP sessions that will cause the software to stop deleting half-open sessions.
ip inspect tcp max-incomplete host	Specifies the threshold and blocking time values for TCP host-specific DoS detection and prevention.

ip inspect max-incomplete low

To define the number of existing half-open sessions that will cause the software to stop deleting half-open sessions, use the **ip inspect max-incomplete low** command in global configuration mode. To reset the threshold to the default of 400 half-open sessions, use the **no** form of this command.

ip inspect max-incomplete low *number* [**vrf** *vrf-name*]

no ip inspect max-incomplete low

Syntax Description

number	Specifies the number of existing half-open sessions that will cause the software to stop deleting half-open sessions. The default is 400 half-open sessions.
vrf *vrf-name*	(Optional) Defines the number of existing half-open sessions only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

400 half-open sessions

Command Modes

no ip inspect name *inspection-name* [**parameter max-sessions** *number*] **fragment** [**max** *number* **timeout** *seconds*]

Application Firewall Provisioning Syntax

ip inspect name *inspection-name* [**parameter max-sessions** *number*] **appfw** *policy-name*

no ip inspect name *inspection-name* [**parameter max-sessions** *number*] **appfw** *policy-name*

User-Defined Application Syntax

ip inspect name *inspection-name user-10* [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*}

no ip inspect name *inspection-name user-10* [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*}

Session Limiting Syntax

no ip inspect name *inspection-name* [**parameter max-sessions** *number*]

Syntax Description

inspection-name	Name the set of inspection rules. If you want to add a protocol to an existing set of rules, use the same *inspection-name* as the existing set of rules. **Note** The *inspection-name* cannot exceed 16 characters; otherwise, the name will be truncated to the 16-character limit.
parameter max-sessions *number*	(Optional) Limits the number of established firewall sessions that a firewall rule creates. By default, there is no limit to the number of firewall sessions.
protocol	A protocol keyword listed in Table 36 or Table 37.
alert {**on** | **off**}	(Optional) For each inspected protocol, the generation of alert messages can be set be **on** or **off**. If no option is selected, alerts are generated on the basis of the setting of the **ip inspect alert-off** command.
audit-trail {**on** | **off**}	(Optional) For each inspected protocol, **audit trail** can be set **on** or **off**. If no option is selected, an audit trail message is generated depending on the configuration of the **ip inspect audit-trail** command.
timeout *seconds*	(Optional) To override the global TCP or UDP, or Internet Control Message Protocol (ICMP) idle timeouts for the specified protocol, specify the number of seconds for a different idle timeout. This timeout overrides the global TCP, UDP, or ICMP timeouts but will not override the global Domain Name System (DNS) timeout.
http	Specifies the HTTP protocol for Java applet blocking.
java-list *access-list*	(Optional) Specifies the numbered standard access list to use to determine “friendly” sites. This keyword is available only for the HTTP protocol, for Java applet blocking. Java blocking works only with numbered standard access lists.
urlfilter	(Optional) Associates URL filtering with HTTP inspection.
smtp | **esmtp**	Specifies the protocol being used to inspect the traffic.
max-data *number*	(Optional) Specifies the maximum amount of data, in bytes, that can be transferred in a single Simple Mail Transport Protocol (SMTP) session. After the maximum value is exceeded, the firewall logs an alert message and closes the session. The default value is 20MB.
rpc program-number *number*	Specifies the program number to permit. This keyword is available only for the remote-procedure call (RPC) protocol.

wait-time *minutes*	(Optional) Specifies the number of minutes to keep a small gap in the firewall to allow subsequent connections from the same source address and to the same destination address and port. The default wait-time is zero minutes. This keyword is available only for the RPC protocol.
imap	Specifies that the Internet Message Access Protocol (IMAP) is being used.
reset	(Optional) Resets the TCP connection if the client enters a nonprotocol command before authentication is complete.
secure-login	(Optional) Causes a user at a nonsecure location to use encryption for authentication.
pop3	Specifies that the Post Office Protocol, Version 3 (POP3) is being used.
fragment	Specifies fragment inspection for the named rule.
max *number*	(Optional) Specifies the maximum number of unassembled packets for which state information (structures) is allocated by Cisco IOS software. Unassembled packets are packets that arrive at the router interface before the initial packet for a session. The acceptable range is 50 through 10000. The default is 256 state entries. • Memory is allocated for the state structures, and setting this value to a larger number may cause memory resources to be exhausted.
timeout *seconds* (fragmentation)	(Optional) Configures the number of seconds that a packet state structure remains active. When the timeout value expires, the router drops the unassembled packet, freeing that structure for use by another packet. The default timeout value is 1 second. • If this number is set to a value greater that 1 second, it is automatically adjusted by the Cisco IOS software when the number of free state structures goes below certain thresholds: when the number of free states is fewer than 32, the timeout is divided by 2. When the number of free states is fewer than 16, the timeout is set to 1 second.
appfw	Specifies application firewall provisioning.
policy-name	Application firewall policy name. **Note** This name must match the name specified via the **appfw policy-name** command.

Command Default No inspection rules are defined.

Command Modes Global configuration (config)

Command History

Release	Modification
11.2P	This command was introduced.
12.0(5)T	This command was modified. Support was added for configurable alert and audit trail, IP fragmentation checking, and NetShow protocol.
12.2(11)YU	This command was modified. Support was added for ICMP and Session Initiation Protocol (SIP) protocols. The **urlfilter** keyword was added to the HTTP inspection syntax.
12.2(15)T	This command was modified. Support was added for ICMP, SIP, and the **urlfilter** keyword was added.
12.3(1)	This command was modified. Skinny protocol support was added.
12.3(7)T	This command was modified. Extended Simple Mail Transfer Protocol (ESMTP) protocol support was added.
12.3(14)T	This command was modified. The **appfw** keyword and the *policy-name* argument were added to support application firewall provisioning. The **parameter max-sessions**, **reset**, **router-traffic,** and **secure-login**, and keywords were added. Support for a larger list of protocols including user-defined applications was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(1)T	This command was modified. Support for the CU-SeeMe protocol and the **cuseeme** keyword was removed.

Usage Guidelines

To define a set of inspection rules, enter the **ip inspect name** command for each protocol that you want the Cisco IOS firewall to inspect, using the same *inspection-name*. Give each set of inspection rules a unique *inspection-name*, which should not exceed the 16-character length limit. Define either one or two sets of rules per interface—you can define one set to examine both inbound and outbound traffic, or you can define two sets: one for outbound traffic and one for inbound traffic. The **no ip inspect-name** *protocol* removes the inspection rule for the specified protocol.

no ip inspect name command removes the entire set of inspection rules.

To define a single set of inspection rules, configure inspection for all the desired application-layer protocols, and for ICMP, TCP, and UDP, or as desired. This combination of TCP, UDP, and application-layer protocols join together to form a single set of inspection rules with a unique name. (There are no application-layer protocols associated with ICMP.)

To remove the inspection rule for a protocol, use the **no** form of this command with the specified inspection name and protocol; To remove the entire set of inspection rules, use the **no** form of this command only; that is, do not list any inspection names or protocols.

In general, when inspection is configured for a protocol, return traffic entering the internal network will be permitted only if the packets are part of a valid, existing session for which state information is being maintained.

Table 36 Protocol Keywords—Transport-Layer and Network-Layer Protocols

Protocol	Keyword
ICMP	**icmp**
TCP	**tcp**
UDP	**udp**

Note The TCP, UDP, and H.323 protocols support the **router-traffic** keyword, which enables inspection of traffic destined to or originated from a router. The command format is as follows:

ip inspect name *inspection-nam*e {**tcp** | **udp** | **H323**} [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**router-traffic**][**timeout** *seconds*]

TCP and UDP Inspection

You can configure TCP and UDP inspection to permit TCP and UDP packets to enter the internal network through the firewall, even if the application-layer protocol is not configured to be inspected. However, TCP and UDP inspection do not recognize application-specific commands, and therefore might not permit all return packets for an application, particularly if the return packets have a different port number from the previous exiting packet.

Any application-layer protocol that is inspected will take precedence over the TCP or UDP packet inspection. For example, if inspection is configured for FTP, all control channel information will be recorded in the state table, and all FTP traffic will be permitted back through the firewall if the control channel information is valid for the state of the FTP session. The fact that TCP inspection is configured is irrelevant.

With TCP and UDP inspection, packets entering the network must exactly match an existing session. The entering packets must have the same source or destination addresses and source or destination port numbers as the exiting packet (but reversed). Otherwise, the entering packets will be blocked at the interface.

Granular protocol inspection allows you to specify TCP or UDP ports by using the port-to-application mapping (PAM) table. This eliminates having to inspect all applications running under TCP or UDP and the need for multiple ACLs to filter the traffic.

Using the PAM table, you can pick an existing application or define a new one for inspection, thereby simplifying Access Control List (ACL) configuration.

ICMP Inspection

ICMP inspection sessions are done on the basis of the source address of the inside host that originates the ICMP packet. Dynamic ACLs are created for return ICMP packets of the allowed types (echo-reply,destination unreachable, time-exceeded, and timestamp reply) for each session. No port numbers associated with an ICMP session, and the permitted IP address of the return packet is a wild-card in the ACL. The wildcard address is because the IP address of the return packet cannot be known in advance for time-exceeded and destination-unreachable replies. These replies can come from intermediate devices rather than the intended destination.

Application-Layer Protocol Inspection

In general, if you configure inspection for an application-layer protocol, packets for that protocol should be permitted to exit the firewall (by configuring the correct ACL), and packets for that protocol will be allowed back in through the firewall only if they belong to a valid existing session. Each protocol packet is inspected to maintain information about the session state.

Java, H.323, RPC, SIP, and SMTP inspection have additional information, described in the next five sections. Table 37 lists the supported application-layer protocols.

Table 37 Protocol Keywords—Application-Layer Protocols

Protocol	Keyword
Application Firewall	**appfw**
CU-SeeMe	**cuseeme**
ESMTP	**smtp**
FTP	**ftp**
IMAP	**imap**
Java	**http**
H.323	**h323**
Microsoft NetShow	**netshow**
POP3	**pop3**
RealAudio	**realaudio**
RPC	**rpc**
SIP	**sip**
Simple Mail Transfer Protocol (SMTP)	**smtp**
Skinny Client Control Protocol (SCCP)	**skinny**
StreamWorks	**streamworks**
Structured Query Language*Net (SQL*Net)	**sqlnet**
TFTP	**tftp**
UNIX R commands (rlogin, rexec, rsh)	**rcmd**
VDOLive	**vdolive**
WORD	**user-defined application name**; **use prefix -user** **Note** All applications that appear under the **show ip port-map** command are supported.

Java Inspection

Java inspection enables Java applet filtering at the firewall. Java applet filtering distinguishes between trusted and untrusted applets by relying on a list of external sites that you designate as “friendly.” If an applet is from a friendly site, the firewall allows the applet through. If the applet is not from a friendly site, the applet will be blocked. Alternately, you could permit applets from all sites except sites specifically designated as “hostile.”

Note Before you configure Java inspection, you must configure a numbered standard access list that defines "friendly" and "hostile" external sites. You configure this numbered standard access list to permit traffic from friendly sites, and to deny traffic from hostile sites. If you do not configure a numbered standard access list, but use a "placeholder" access list in the **ip inspect name** *inspection-name* **http** command, all Java applets will be blocked.

Note Java blocking forces a strict order on TCP packets. To properly verify that Java applets are not in the response, a firewall will drop any TCP packet that is out of order. Because the network—not the firewall—determines how packets are routed, the firewall cannot control the order of the packets; the firewall can only drop and retransmit all TCP packets that are not in order.

Caution Context-Based Access Control (CBAC) does not detect or block encapsulated Java applets. Therefore, Java applets that are wrapped or encapsulated, such as applets in .zip or .jar format, are *not* blocked at the firewall. CBAC also does not detect or block applets loaded via FTP, gopher, or HTTP on a nonstandard port.

H.323 Inspection

If you want CBAC inspection to work with NetMeeting 2.0 traffic (an H.323 application-layer protocol), you must also configure inspection for TCP, as described in the chapter "Configuring Context-Based Access Control" in the *Cisco IOS Security Configuration Guide*. This requirement exists because NetMeeting 2.0 uses an additional TCP channel not defined in the H.323 specification.

RPC Inspection

RPC inspection allows the specification of various program numbers. You can define multiple program numbers by creating multiple entries for RPC inspection, each with a different program number. If a program number is specified, all traffic for that program number will be permitted. If a program number is not specified, all traffic for that program number will be blocked. For example, if you created an RPC entry with the NFS program number, all NFS traffic will be allowed through the firewall.

SIP Inspection

You can configure SIP inspection to permit media sessions associated with SIP-signaled calls to traverse the firewall. Because SIP is frequently used to signal both incoming and outgoing calls, it is often necessary to configure SIP inspection in both directions on a firewall (both from the protected internal network and from the external network). Because inspection of traffic from the external network is not done with most protocols, it may be necessary to create an additional inspection rule to cause only SIP inspection to be performed on traffic coming from the external network.

SMTP Inspection

SMTP inspection causes SMTP commands to be inspected for illegal commands. Packets with illegal commands are modified to a "xxxx" pattern and forwarded to the server. This process causes the server to send a negative reply, forcing the client to issue a valid command. An illegal SMTP command is any command except the following:

- DATA
- HELO
- HELP

- MAIL
- NOOP
- QUIT
- RCPT
- RSET
- SAML
- SEND
- SOML
- VRFY

ESMTP Inspection

Like SMTP, ESMTP inspection also causes the commands to be inspected for illegal commands. Packets with illegal commands are modified to a "xxxx" pattern and forwarded to the server. This process causes the server to send a negative reply, forcing the client to issue a valid command. An illegal ESMTP command is any command except the following:

- AUTH
- DATA
- EHLO
- ETRN
- HELO
- HELP
- MAIL
- NOOP
- QUIT
- RCPT
- RSET
- SAML
- SEND
- SOML
- VRFY

In addition to inspecting commands, the ESMTP firewall also inspects the following extensions via deeper command inspection:

- Message Size Declaration (SIZE)
- Remote Queue Processing Declaration (ETRN)
- Binary MIME (BINARYMIME)
- Command Pipelining
- Authentication
- Delivery Status Notification (DSN)

- Enhanced Status Code (ENHANCEDSTATUSCODE)
- 8bit-MIMEtransport (8BITMIME)

Note SMTP and ESMTP cannot exist simultaneously. An attempt to configure both protocols will result in an error message.

Use of the urlfilter Keyword

If you specify the **urlfilter** keyword, the Cisco IOS Firewall will interact with a URL filtering software to control web traffic for a given host or user on the basis of a specified security policy.

Note Enabling HTTP inspection with or without any option triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the **java-list** *access-list* option. Configuring URL filtering without enabling the **java-list** *access-list* option will severely impact performance.

Use of the timeout Keyword

If you specify a timeout for any of the transport-layer or application-layer protocols, the timeout will override the global idle timeout for the interface to which the set of inspection rules is applied.

If the protocol is TCP or a TCP application-layer protocol, the timeout will override the global TCP idle timeout. If the protocol is UDP or a UDP application-layer protocol, the timeout will override the global UDP idle timeout.

If you do not specify a timeout for a protocol, the timeout value applied to a new session of that protocol will be taken from the corresponding TCP or UDP global timeout value valid at the time of session creation.

The default ICMP timeout is deliberately short (10 seconds) due to the security hole that is opened by allowing ICMP packets with a wild-card source address back into the inside network. The timeout will occur 10 seconds after the last outgoing packet from the originating host. For example, if you send a set of 10 ping packets spaced one second apart, the timeout will expire in 20 seconds or 10 seconds after the last outgoing packet. However, the timeout is not extended for return packets. If a return packet is not seen within the timeout window, the gap will be closed and the return packet will not be allowed in. Although the default timeout can be made longer if desired, it is recommended that this value be kept relatively short.

IP Fragmentation Inspection

CBAC inspection rules can help protect hosts against certain denial-of-service attacks involving fragmented IP packets. Even though the firewall keeps an attacker from making actual connections to a given host, the attacker may still be able to disrupt services provided by that host. This is done by sending many noninitial IP fragments or by sending complete fragmented packets through a router with an ACL that filters the first fragment of a fragmented packet. These fragments can tie up resources on the target host as it tries to reassemble the incomplete packets.

Using fragmentation inspection, the firewall maintains an *interfragment state* (structure) for IP traffic. Noninitial fragments are discarded unless the corresponding initial fragment was permitted to pass through the firewall. Noninitial fragments received before the corresponding initial fragments are discarded.

Note Fragmentation inspection can have undesirable effects in certain cases, because it can result in the firewall discarding any packet whose fragments arrive out of order. There are many circumstances that can cause out-of-order delivery of legitimate fragments. Apply fragmentation inspection in situations where legitimate fragments, which are likely to arrive out of order, might have a severe performance impact.

Because routers running Cisco IOS software are used in a very large variety of networks, and because the CBAC feature is often used to isolate parts of internal networks from one another, the fragmentation inspection feature is not enabled by default. Fragmentation detection must be explicitly enabled for an inspection rule using the **ip inspect name** command. Unfragmented traffic is never discarded because it lacks a fragment state. Even when the system is under heavy attack with fragmented packets, legitimate fragmented traffic, if any, will still get some fraction of the firewall's fragment state resources, and legitimate, unfragmented traffic can flow through the firewall unimpeded.

Application Firewall Provisioning

Application firewall provisioning allows you to configure your Cisco IOS Firewall to detect and prohibit a specific protocol type of traffic.

Most firewalls provide packet filtering capabilities that simply permit or deny traffic without inspecting the data stream; the Cisco IOS application firewall can detect whether a packet is in compliance with a given HTTP protocol. If the packet is determined to be unauthorized, it will be dropped, the connection will be reset, and a syslog message will be generated, as appropriate.

User-Defined Applications

You can define your own applications and enter them into the PAM table using the **ip port-map** command. Then you set up your inspection rules by inserting your user-defined application as a value for the *protocol* argument in the **ip inspect name** command.

Session Limiting

Users can limit the number of established firewall sessions that a firewall rule creates by setting the "max-sessions" threshold. A session counter is maintained for each firewall interface. When a session count exceeds the specified threshold, an alert FW-4-SESSION_THRESHOLD_EXCEEDED message is logged to the syslog server and no new sessions can be created.

Examples

The following example causes the software to inspect TCP sessions and UDP sessions, and to specifically allow CU-SeeMe, FTP, and RPC traffic back through the firewall for existing sessions only. For UDP traffic, audit-trail is on. For FTP traffic, the idle timeout is set to override the global TCP idle timeout. For RPC traffic, program numbers 100003, 100005, and 100021 are permitted.

```
ip inspect name myrules tcp
ip inspect name myrules udp audit-trail on
ip inspect name myrules cuseeme
ip inspect name myrules ftp timeout 120
ip inspect name myrules rpc program-number 100003
ip inspect name myrules rpc program-number 100005
ip inspect name myrules rpc program-number 100021
```

The following example adds fragment checking to software inspection of TCP and UDP sessions for the rule named "myrules." In this example, the firewall software will allocate 100 state structures, and the timeout value for dropping unassembled packets is set to 4 seconds. If 100 initial fragments for 100 different packets are sent through the router, all of the state structures will be used up. The initial

fragment for packet 101 will be dropped. Additionally, if the number of free state structures (structures available for use by unassembled packets) drops below the threshold values, 32 or 16, the timeout value is automatically reduced to 2 or 1, respectively. Changing the timeout value frees up packet state structures more quickly.

```
ip inspect name myrules tcp
ip inspect name myrules udp audit-trail on
ip inspect name myrules cuseeme
ip inspect name myrules ftp timeout 120
ip inspect name myrules rpc program-number 100003
ip inspect name myrules rpc program-number 100005
ip inspect name myrules rpc program-number 100021
ip inspect name myrules fragment max 100 timeout 4
```

The following firewall and SIP example shows how to allow outside-initiated calls and internal calls. For outside-initiated calls, an ACL needs to be accessed to allow for the traffic from the initial signaling packet from outside. Subsequent signaling and media channels will be allowed by the inspection module.

```
ip inspect name voip sip
interface FastEthernet0/0
 ip inspect voip in
!
!
interface FastEthernet0/1
 ip inspect voip in
 ip access-group 100 in
!
!
access-list 100 permit udp host <gw ip> any eq 5060
access-list 100 permit udp host <proxy ip> any eq 5060
access-list deny ip any any
```

The following example shows two configured inspections named fw_only and fw_urlf; URL filtering will work only on the traffic that is inspected by fw_urlf. Note that the **java-list** *access-list* option has been enabled, which disables java scanning.

```
ip inspect name fw_only http java-list 51 timeout 30
interface e0
 ip inspect fw_only in
!
ip inspect name fw_urlf  http java-list 51 urlfilter timeout 30
interface e1
 ip inspect fw_urlf in
```

The following example shows how to define the HTTP application firewall policy mypolicy. This policy includes all supported HTTP policy rules. This example also includes sample output from the **show appfw configuration** and **show ip inspect config** commands, which allow you to verify the configured setting for the application policy.

```
! Define the HTTP policy.
appfw policy-name mypolicy
 application http
  strict-http action allow alarm
  content-length maximum 1 action allow alarm
  content-type-verification match-req-rsp action allow alarm
  max-header-length request 1 response 1 action allow alarm
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc default action allow alarm
  request-method extension default action allow alarm
  transfer-encoding type default action allow alarm
!
!
```

```
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
 ip inspect firewall in
!
!
! Issue the show appfw configuration command and the show ip inspect config command after
the inspection rule "mypolicy" is applied to all incoming HTTP traffic on the
FastEthernet0/0 interface.
!
Router# show appfw configuration

Application Firewall Rule configuration
  Application Policy name mypolicy
    Application http
      strict-http action allow alarm
      content-length minimum 0 maximum 1 action allow alarm

Related Commands

Command	Description
ip inspect	Applies a set of inspection rules to an interface.
ip inspect alert-off	Disables CBAC alert messages.
ip inspect audit trail	Turns on CBAC audit trail messages, which will be displayed on the console after each CBAC session close.

ip inspect one-minute high

To define the rate of new unestablished sessions that will cause the software to start deleting half-open sessions, use the **ip inspect one-minute high** command in global configuration mode. To reset the threshold to the default of 500 half-open sessions, use the **no** form of this command.

i**p inspect one-minute high** *number* [**vrf** *vrf-name*]

no ip inspect one-minute high

Syntax Description

number	Specifies the rate of new unestablished TCP sessions that will cause the software to start deleting half-open sessions. The default is 500 half-open sessions.
vrf *vrf-name*	(Optional) Defines the information only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

500 half-open sessions

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

An unusually high number of half-open sessions (either absolute or measured as the arrival rate) could indicate that a denial-of-service attack is occurring. For TCP, “half-open” means that the session has not reached the established state. For User Datagram Protocol (UDP), “half-open” means that the firewall has detected traffic from one direction only.

Context-based Access Control (CBAC) measures both the total number of existing half-open sessions and the rate of session establishment attempts. Both TCP and UDP half-open sessions are included in the total number and rate measurements. Measurements are made once a minute.

When the rate of new connection attempts rises above a threshold (the **one-minute high** number), the software will delete half-open sessions as required to accommodate new connection attempts. The software will continue to delete half-open sessions as necessary, until the rate of new connection attempts drops below another threshold (the **one-minute low** number). The rate thresholds are measured as the number of new session connection attempts detected in the last one-minute sample period. (The rate is calculated as an exponentially decayed rate.)

The global value specified for this threshold applies to all TCP and UDP connections inspected by CBAC.

Examples

The following example causes the software to start deleting half-open sessions when more than 1000 session establishment attempts have been detected in the last minute, and to stop deleting half-open sessions when fewer than 950 session establishment attempts have been detected in the last minute:

```
ip inspect one-minute high 1000
ip inspect one-minute low 950
```

Related Commands

Command	Description
ip inspect one-minute low	Defines the rate of new unestablished TCP sessions that will cause the software to stop deleting half-open sessions.
ip inspect max-incomplete high	Defines the number of existing half-open sessions that will cause the software to start deleting half-open sessions.
ip inspect max-incomplete low	Defines the number of existing half-open sessions that will cause the software to stop deleting half-open sessions.
ip inspect tcp max-incomplete host	Specifies the threshold and blocking time values for TCP host-specific DoS detection and prevention.

ip inspect one-minute low

To define the rate of new unestablished TCP sessions that will cause the software to stop deleting half-open sessions, use the **ip inspect one-minute low** command in global configuration mode. To reset the threshold to the default of 400 half-open sessions, use the **no** form of this command.

ip inspect one-minute low *number* [**vrf** *vrf-name*]

no ip inspect one-minute low

Syntax Description

number	Specifies the rate of new unestablished TCP sessions that will cause the software to stop deleting half-open sessions. The default is 400 half-open sessions.
vrf *vrf-name*	(Optional) Defines the information only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

400 half-open sessions

Command Modes

Usage Guidelines

An unusually high number of half-open sessions (either absolute or measured as the arrival rate) could indicate that a denial-of-service attack is occurring. For TCP, “half-open” means that the session has not reached the established state. For User Datagram Protocol (UDP), “half-open” means that the firewall has detected traffic from one direction only.

Context-based Access Control (CBAC) measures both the total number of existing half-open sessions and the rate of session establishment attempts. Both TCP and UDP half-open sessions are included in the total number and rate measurements. Measurements are made once a minute.

When the rate of new connection attempts rises above a threshold (the **one-minute high** number), the software will delete half-open sessions as required to accommodate new connection attempts. The software will continue to delete half-open sessions as necessary, until the rate of new connection attempts drops below another threshold (the **one-minute low** number). The rate thresholds are measured as the number of new session connection attempts detected in the last one-minute sample period. (The rate is calculated as an exponentially decayed rate.)

The global value specified for this threshold applies to all TCP and UDP connections inspected by CBAC.

Examples

The following example causes the software to start deleting half-open sessions when more than 1000 session establishment attempts have been detected in the last minute, and to stop deleting half-open sessions when fewer than 950 session establishment attempts have been detected in the last minute:

```
ip inspect one-minute high 1000
ip inspect one-minute low 950
```

Related Commands

Command	Description
ip inspect max-incomplete high	Defines the number of existing half-open sessions that will cause the software to start deleting half-open sessions.
ip inspect max-incomplete low	Defines the number of existing half-open sessions that will cause the software to stop deleting half-open sessions.
ip inspect one-minute high	Defines the rate of new unestablished sessions that will cause the software to start deleting half-open sessions.
ip inspect tcp max-incomplete host	Specifies the threshold and blocking time values for TCP host-specific DoS detection and prevention.

ip inspect tcp block-non-session

To block packets that do not belong to the existing firewall TCP sessions in the inbound and outbound directions, use the **ip inspect tcp block-non-session** command in global configuration mode. To return to the default state, use the **no** form of this command.

ip inspect tcp block-non-session [**vrf** *vrf-name*]

no inspect tcp block-non-session [**vrf** *vrf-name*]

Syntax Description

vrf	(Optional) Declares a specific VPN routing/forwarding instance (VRF).
vrf-name	(Optional) Name of the VRF.

Command Default

TCP packets that do not belong to an existing TCP session on the firewall are allowed through the firewall.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(6)	This command was introduced.
12.3(7)T	This command was integrated into Release 12.3(6)T.
12.3(7)XI	This command was integrated into the Release 12.3(7)XI.
12.3(14)T	The **vrf** keyword and *vrf-name* argument were added.

Usage Guidelines

This command will deny TCP packets that do not belong to an existing TCP session the firewall knows about. To be applicable, the following conditions must be met:

- The TCP packets should traverse interfaces where a firewall rule is applicable.
- The TCP packets should be non-connection initiating (that is, packets without the SYN bit set in them). For connection initiating packets, the existing rules of session creation would apply.

Examples

The following example shows how to configure the firewall to block any externally initiated TCP sessions:

```
Router> enable
Router# config terminal
Router(config)# ip inspect tcp block-non-session
```

Related Commands

Command	Description
ip inspect log drop-pkt	Logs all packets dropped by the firewall.
ip inspect tcp finwait-time	Defines how long a TCP session will still be managed after the firewall detects a FIN-exchange.
ip inspect tcp idle-time	Specifies the TCP idle timeout (the length of time a TCP session will still be managed while there is no activity).
ip inspect tcp max-incomplete host	Specifies threshold and blocking time values for TCP host-specific (DoS) detection and prevention.
ip inspect tcp reassembly	Sets parameters that define how Cisco IOS Firewall application inspection and Cisco IOS IPS will handle out-of-order TCP packets.
ip inspect tcp synwait-time	Defines how long the software will wait for a TCP session to reach the established state before dropping the session.
ip inspect udp idle-time	Specifies the UDP idle timeout (the length of time for which a UDP session will still be managed while there is no activity).

ip inspect tcp finwait-time

To define how long a TCP session will still be managed after the firewall detects a FIN-exchange, use the **ip inspect tcp finwait-time** command in global configuration mode. To reset the timeout to the default of 5 seconds, use the **no** form of this command.

ip inspect tcp finwait-time *seconds* [**vrf** *vrf-name*]

no ip inspect tcp finwait-time

Syntax Description

seconds	Specifies how long a TCP session will be managed after the firewall detects a FIN-exchange. The default is 5 seconds.
vrf *vrf-name*	(Optional) Defines the information only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

5 seconds

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When the software detects a valid TCP packet that is the first in a session, and if Context-based Access Control (CBAC) inspection is configured for the protocol of the packet, the software establishes state information for the new session.

Use this command to define how long TCP session state information will be maintained after the firewall detects a FIN-exchange for the session. The FIN-exchange occurs when the TCP session is ready to close.

The global value specified for this timeout applies to all TCP sessions inspected by CBAC.

The timeout set with this command is referred to as the “finwait” timeout.

Note If the -n option is used with rsh, and the commands being executed do not produce output before the “finwait” timeout, the session will be dropped and no further output will be seen.

Examples

The following example changes the finwait timeout to 10 seconds:

```
ip inspect tcp finwait-time 10
```

The following example changes the finwait timeout back to the default (5 seconds):

```
no ip inspect tcp finwait-time
```

ip inspect tcp idle-time

To specify the TCP idle timeout (the length of time a TCP session will still be managed while there is no activity), use the **ip inspect tcp idle-time** command in global configuration mode. To reset the timeout to the default of 3600 seconds (1 hour), use the **no** form of this command.

ip inspect tcp idle-time *seconds* [**vrf** *vrf-name*]

no ip inspect tcp idle-time

Syntax Description

seconds	Specifies the length of time, in seconds, for which a TCP session will still be managed while there is no activity. The default is 3600 seconds (1 hour).
vrf *vrf-name*	(Optional) Specifies the TCP idle timer only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

3600 seconds (1 hour)

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When the software detects a valid TCP packet that is the first in a session, and if Context-based Access Control (CBAC) inspection is configured for the packet's protocol, the software establishes state information for the new session.

If the software detects no packets for the session for a time period defined by the TCP idle timeout, the software will not continue to manage state information for the session.

The global value specified for this timeout applies to all TCP sessions inspected by CBAC. This global value can be overridden for specific interfaces when you define a set of inspection rules with the **ip inspect name** (global configuration) command.

Note This command does not affect any of the currently defined inspection rules that have explicitly defined timeouts. Sessions created based on these rules still inherit the explicitly defined timeout value. If you change the TCP idle timeout with this command, the new timeout will apply to any new inspection rules you define or to any existing inspection rules that do not have an explicitly defined timeout. That is, new sessions based on these rules (having no explicitly defined timeout) will inherit the global timeout value.

Examples

The following example sets the global TCP idle timeout to 1800 seconds (30 minutes):

```
ip inspect tcp idle-time 1800
```

The following example sets the global TCP idle timeout back to the default of 3600 seconds (one hour):

```
no ip inspect tcp idle-time
```

ip inspect tcp max-incomplete host

To specify threshold and blocking time values for TCP host-specific denial-of-service (DoS) detection and prevention, use the **ip inspect tcp max-incomplete host** command in global configuration mode. To reset the threshold and blocking time to the default values, use the **no** form of this command.

ip inspect tcp max-incomplete host *number* **block-time** *minutes* [**vrf** *vrf-name*]

no ip inspect tcp max-incomplete host

Syntax Description

number	Specifies how many half-open TCP sessions with the same host destination address can exist at a time, before the software starts deleting half-open sessions to the host. Use a number from 1 to 250. The default is 50 half-open sessions.
block-time	Specifies blocking of connection initiation to a host.
minutes	Specifies how long the software will continue to delete new connection requests to the host. The default is 0 minutes.
vrf *vrf-name*	(Optional) Specifies the information only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

50 half-open sessions and 0 minutes

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

An unusually high number of half-open sessions with the same destination host address could indicate that a denial-of-service attack is being launched against the host. For TCP, “half-open” means that the session has not reached the established state.

Whenever the number of half-open sessions with the same destination host address rises above a threshold (the **max-incomplete host** number), the software will delete half-open sessions according to one of the following methods:

- If the **block-time** *minutes* timeout is 0 (the default):

  The software will delete the oldest existing half-open session for the host for every new connection request to the host. This ensures that the number of half-open sessions to a given host will never exceed the threshold.

- If the **block-time** *minutes* timeout is greater than 0:

  The software will delete all existing half-open sessions for the host, and then block all new connection requests to the host. The software will continue to block all new connection requests until the **block-time** expires.

The software also sends syslog messages whenever the **max-incomplete host** number is exceeded and when blocking of connection initiations to a host starts or ends.

The global values specified for the threshold and blocking time apply to all TCP connections inspected by Context-based Access Control (CBAC).

Examples

The following example changes the max-incomplete host number to 40 half-open sessions, and changes the block-time timeout to 2 minutes:

```
ip inspect tcp max-incomplete host 40 block-time 2
```

The following example resets the defaults (50 half-open sessions and 0 minutes):

```
no ip inspect tcp max-incomplete host
```

Related Commands

Command	Description
ip inspect max-incomplete high	Defines the number of existing half-open sessions that will cause the software to start deleting half-open sessions.
ip inspect max-incomplete low	Defines the number of existing half-open sessions that will cause the software to stop deleting half-open sessions.
ip inspect one-minute high	Defines the rate of new unestablished sessions that will cause the software to start deleting half-open sessions.
ip inspect one-minute low	Defines the rate of new unestablished TCP sessions that will cause the software to stop deleting half-open sessions.

ip inspect tcp reassembly

To set parameters that define how Cisco IOS Firewall application inspection and Cisco IOS Intrusion Prevention System (IPS) will handle out-of-order TCP packets, use the **ip inspect tcp reassembly** command in global configuration mode. To disable at least one defined parameter, use the **no** form of this command.

ip inspect tcp reassembly {**alarm** {**on** | **off**} | **memory limit** *size-in-kb* | **queue length** *number-of-packets* | **timeout** *seconds*} [**vrf** *vrf-name*]

no ip inspect tcp reassembly {**alarm** | **queue length** | **timeout** | **memory limit**} [**vrf** *vrf-name*]

Syntax Description

alarm {**on** | **off**}	Specifies the alert message configuration. If enabled, a syslog message is generated when an out-of-order packet is dropped. Default value: **on**
memory	Specifies the memory use allowed by the TCP reassembly module.
limit *size-in-kb*	Specifies the limit of out of order queue size.
queue	Specifies the out of order queue parameters.
length *number-of-packets*	Maximum number of out-of-order packets that can be held per queue (buffer). (There are two queues per session.) Available value range: 0 to 1024. Default value: 16. **Note** If the queue length is set to 0, all out-of-order packets are dropped; that is, TCP out-of-order packet buffering and reassembly is disabled.
timeout *seconds*	Number of seconds the TCP reassembly module will hold out-of-order segments that are waiting for the first segment missing in the sequence. After the timeout timer has expired, a retry timer is started. The value for the retry timer is four times the configured timeout value.
vrf *vrf-name*	Specifies the VPN routing and forwarding (VRF) parameter and name.

Command Default

Queue length: 16

Memory Limit: 1024 kilobytes

Alarm: on

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(11)T	This command was introduced.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

The queue length Value

The value specified for the queue length is applicable for two queues per session: one queue is for the initiator traffic and the other queue is for the responder traffic. For example, the default queue size is 16. Thus, up to 16 packets can be held per queue, so 16 packets per queue results in a maximum of 32 packets per session.

When the maximum queue length value is reached, the packet being switched is dropped unless it is the packet that will be processed by a firewall or IPS. If the packet is dropped, a syslog message, which explains why the packet was dropped, will be generated. (To generate syslog messages, you must have the alarm option set to "on.")

The timeout Value

When a timer expires for the first time, the packets in the queue are not deleted. However, after the retry timer expires, the session is deleted, a syslog message is generated, and all unprocessed, out-of-order packets still in the queue are deleted.

The memory limit Value

When the limit for TCP reassembly memory is reached, packets from the reassembly queue of the current session are released so incoming packets can be accepted. Packets from the end of the queue are released to ensure that they are farthest away from the hole that is to be filled. However, if the queue is empty and the maximum memory has been reached, the incoming packet is dropped.

The alarm Value

If an alarm value is not configured, the value is set to "on," unless the **ip inspect alarm** command is enabled and set to off; thus, syslog messages related to TCP connections will not be generated. However, if the alarm value for this command is set to "on" and the **ip inspect alarm** command is set to "off," the value of the **ip inspect alarm** command is ignored and syslog messages are generated.

The alarm value is independent of and in addition to the syslog messages that can be enabled for a Cisco IOS Firewall or Cisco IOS IPS.

Examples

The following example shows how to instruct Cisco IOS IPS how to handle out-of-order packets for TCP connections:

```
Router(config)# ip inspect tcp reassembly queue length 18
Router(config)# ip inspect tcp reassembly memory limit 200
```

Related Commands

Command	Description
ip inspect tcp block-non-session	Blocks packets that do not belong to the existing firewall TCP sessions in the inbound and outbound directions.

ip inspect tcp synwait-time

To define how long the software will wait for a TCP session to reach the established state before dropping the session, use the **ip inspect tcp synwait-time** command in global configuration mode. To reset the timeout to the default of 30 seconds, use the **no** form of this command.

ip inspect tcp synwait-time *seconds* [**vrf** *vrf-name*]

no ip inspect tcp synwait-time

Syntax Description

seconds	Specifies how long, in seconds, the software will wait for a TCP session to reach the established state before dropping the session. The default is 30 seconds.
vrf *vrf-name*	(Optional) Defines the information only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

30 seconds

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to define how long Cisco IOS software will wait for a TCP session to reach the established state before dropping the session. The session is considered to have reached the established state after the first synchronize sequence number (SYN) bit of the session is detected.

The global value specified for this timeout applies to all TCP sessions inspected by Context-based Access Control (CBAC).

Examples

The following example changes the synwait timeout to 20 seconds:

```
ip inspect tcp synwait-time 20
```

The following example changes the synwait timeout back to the default (30 seconds):

```
no ip inspect tcp synwait-time
```

ip inspect tcp window-scale-enforcement loose

To configure Cisco IOS software to disable the window scale option check for a TCP packet that has an invalid window scale option under the Context-Based Access Control (CBAC) firewall, use the **ip inspect tcp window-scale-enforcement loose** command in global configuration mode. To return to the command default, use the **no** form of this command.

ip inspect tcp window-scale-enforcement loose

no ip inspect tcp window-scale-enforcement loose

Command Default

The strict window scale option check is enabled in the firewall by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

The window scale extension expands the definition of the TCP window to 32 bits and then uses a scale factor to carry this 32-bit value in the 16-bit Window field of the TCP header. Cisco IOS software enforces strict checking of the TCP window scale option. See section 2 of RFC1323, "TCP Window Scale Option," for more information on this function.

There are occasions when a server may be using a non-RFC compliant TCP/IP protocol stack. In this case, the initiator does not offer the window scale option, but the responder has the option enabled with a window scale factor that is not zero.

Cisco IOS administrators who experience issues with a noncompliant server may not have control over the client to which they need to connect. Disabling the Cisco IOS firewall to connect to the noncompliant server is not desirable and may fail if each endpoint cannot agree on the window scaling factor to use for its respective receive window.

The **ip inspect tcp window-scale-enforcement loose** command is used in global configuration mode to allow noncompliant window scale negotiation and works without the firewall being disabled to access the noncompliant servers. This command works under the CBAC firewall, which intelligently filters TCP and UDP packets based on application-layer protocol session information. CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. CBAC is configured using an inspect rule only on interfaces. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions. Traffic entering or leaving the configured interface is inspected based on the direction that the inspect rule was applied.

Examples

The following example configures the IOS to disable the window scale option check in the CBAC firewall for a TCP packet that has an invalid window scale option:

```
Router# config
Router(config)# ip inspect tcp window-scale-enforcement loose
```

Related Commands

Command	Description
ip inspect tcp synwait-time	Configures the length of time the software waits for a TCP session to reach the established state before dropping the session.

ip inspect udp idle-time

To specify the User Datagram Protocol (UDP) idle timeout (the length of time for which a UDP "session" will still be managed while there is no activity), use the **ip inspect udp idle-time** command in global configuration mode. To reset the timeout to the default of 30 seconds, use the **no** form of this command.

ip inspect udp idle-time *seconds* [**vrf** *vrf-name*]

no ip inspect udp idle-time

Syntax Description

seconds	Specifies the length of time a UDP "session" will still be managed while there is no activity. The default is 30 seconds.
vrf *vrf-name*	(Optional) Specifies the UDP idle timeout only for the specified Virtual Routing and Forwarding (VRF) interface.

Defaults

30 seconds

Command Modes

Global configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.3(14)T	The **vrf** *vrf-name* keyword/argument pair was added.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When the software detects a valid UDP packet, if Context-based Access Control (CBAC) inspection is configured for the packet's protocol, the software establishes state information for a new UDP "session." Because UDP is a connectionless service, there are no actual sessions, so the software approximates sessions by examining the information in the packet and determining if the packet is similar to other UDP packets (for example, it has similar source or destination addresses) and if the packet was detected soon after another similar UDP packet.

If the software detects no UDP packets for the UDP session for the a period of time defined by the UDP idle timeout, the software will not continue to manage state information for the session.

The global value specified for this timeout applies to all UDP sessions inspected by CBAC. This global value can be overridden for specific interfaces when you define a set of inspection rules with the **ip inspect name** command.

Note This command does not affect any of the currently defined inspection rules that have explicitly defined timeouts. Sessions created based on these rules still inherit the explicitly defined timeout value. If you change the UDP idle timeout with this command, the new timeout will apply to any new inspection rules you define or to any existing inspection rules that do not have an explicitly defined timeout. That is, new sessions based on these rules (having no explicitly defined timeout) will inherit the global timeout value.

Examples

The following example sets the global UDP idle timeout to 120 seconds (2 minutes):

```
ip inspect udp idle-time 120
```

The following example sets the global UDP idle timeout back to the default of 30 seconds:

```
no ip inspect udp idle-time
```

integrity

To specify one or more integrity algorithms for an Internet Key Exchange Version 2 (IKEv2) proposal, use the **integrity** command in IKEv2 proposal configuration mode. To remove the configuration of the hash algorithm, use the **no** form of this command.

integrity {**sha1** | **sha256** | **sha384** | **md5**}

no integrity

Syntax Description

sha1	Specifies Secure Hash Algorithm (SHA-1 - HMAC variant) as the hash algorithm.
sha256	Specifies SHA-2 family 256-bit (HMAC variant) as the hash algorithm.
sha384	Specifies SHA-2 family 384-bit (HMAC variant) as the hash algorithm.
md5	Specifies Message-Digest algorithm 5 (MD5 - HMAC variant) as the hash algorithm.

Command Default

The default integrity algorithm is used.

Command Modes

IKEv2 proposal configuration (config-ikev2-proposal)

Command History

Release	Modification
15.1(1)T	This command was introduced.
15.1(2)T	This command was modified. The **sha256** and **sha384** keywords were added.

Usage Guidelines

Use this command to specify the integrity algorithm to be used in an IKEv2 proposal. The default integrity algorithms in the default proposal are SHA-1 and MD5.

Note You cannot selectively remove an integrity algorithm when multiple integrity algorithms are configured.

Suite-B adds support for the SHA-2 family (HMAC variant) hash algorithm used to authenticate packet data and verify the integrity verification mechanisms for the IKEv2 proposal configuration. HMAC is a variant that provides an additional level of hashing.

Examples

The following example configures an IKEv2 proposal with the MD5 integrity algorithm:

```
Router(config)# crypto ikev2 proposal proposal1
Router(config-ikev2-proposal)# integrity md5
```

Related Commands

Command	Description
crypto ikev2 proposal	Defines an IKEv2 proposal.
encryption (ikev2 proposal)	Specifies the encryption algorithm in an IKEv2 proposal.
group (ikev2 proposal)	Specifies the Diffie-Hellman group identifier in an IKEv2 proposal.
show crypto ikev2 proposal	Displays the parameters for each IKEv2 proposal.

ip interface

To configure a virtual gateway IP interface on a Secure Socket Layer Virtual Private Network (SSL VPN) gateway, use the **ip interface** command in webvpn gateway configuration mode. To disable the configuration, use the **no** form of this command.

ip interface *type number* [**port** {**443** | *port-number*}]

no ip interface

Syntax Description

type	Interface type. For more information, use the question mark (?) online help function.
number	Interface or subinterface number. For more information about the numbering syntax for your networking device, use the question mark (?) online help function.
port	(Optional) Configures a specific port on the gateway.
443	(Optional) Configures the default secure port.
port-number	(Optional) Port number to be configured on the SSL VPN gateway. Range: 1025 to 65535. Default: 443.

Command Default

The command is disabled. The virtual gateway IP address is not configured.

Command Modes

Webvpn gateway configuration (config-webvpn-gateway)

Command History

Release	Modification
12.4(24)T	This command was introduced.

Usage Guidelines

The **ip interface** command is used to configure a interface on a SSL VPN gateway. You can use this command to configure the WebVPN gateway to retrieve the IP address from an interface, and if you do not want to configure the IP address manually. This command is useful when the public interface is Dynamic Host Configuration Protocol (DHCP) and you do not know the IP address or when the IP address gets changed.

If the **ip interface** command is not configured then the WebVPN will use the IP address configured using the **ip address** command.

Examples

The following example shows how to configure a virtual gateway IP interface on port 1036 of an SSL VPN gateway:

```
Router# configure terminal
Router(config)# webvpn gateway gateway1
Router(config-webvpn-gateway)# ip interface FastEthernet 0/1 port 1036
```

Related Commands

Command	Description
ip address	Configures a proxy IP address on an SSL VPN gateway.
webvpn gateway	Defines an SSL VPN gateway and enters WebVPN gateway configuration mode.

ip ips

To apply an Intrusion Prevention System (IPS) rule to an interface, use the **ip ips** command in interface configuration mode. To remove an IPS rule from an interface direction, use the **no** form of this command.

ip ips *ips-name* {**in** | **out**}

no ip ips *ips-name* {**in** | **out**}

Syntax Description

ips-name	Name of IPS signature definition file (SDF).
in	Applies IPS to inbound traffic.
out	Applies IPS to outbound traffic.

Defaults

By default, IPS signatures are not applied to an interface or direction.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(8)T	The command name was changed from the **ip audit** command to the **ip ips** command.

Usage Guidelines

The **ip ips** command loads the SDF onto the router and builds the signature engines when IPS is applied to the first interface.

Note The router prompt disappears while the signatures are loading and the signature engines are building. It will reappear after these tasks are complete.

Depending on your platform and how many signatures are being loaded, building the signature engine can take several of minutes. It is recommended that you enable logging messages so you can monitor the engine building status.

The **ip ips** command replaces the **ip audit** command. If the **ip audit** command is part of an existing configuration, IPS will interpret it as the **ip ips** command.

Examples

The following example shows the basic configuration necessary to load the attack-drop.sdf file onto a router running Cisco IOS IPS. Note that the configuration is almost the same as when you load the default signatures onto a router, except for the **ip ips sdf location** command, which specifies the attack-drop.sdf file.

```
!
ip ips sdf location disk2:attack-drop.sdf
```

```
ip ips name MYIPS
!
interface GigabitEthernet0/1
 ip address 10.1.1.16 255.255.255.0
 ip ips MYIPS in
 duplex full
 speed 100
 media-type rj45
 no negotiation auto
!
```

The following example shows how to configure the router to load and merge the attack-drop.sdf file with the default signatures. After you have merged the two files, it is recommended to copy the newly merged signatures to a separate file. The router can then be reloaded (via the **reload** command) or reinitalized to so as to recognize the newly merged file (as shown the following example)

```
!
ip ips name MYIPS
!
interface GigabitEthernet0/1
 ip address 10.1.1.16 255.255.255.0
 ip ips MYIPS in
 duplex full
 speed 100
 media-type rj45
 no negotiation auto
!
!
! Merge the flash-based SDF (attack-drop.sdf) with the built-in signatures.
copy disk2:attack-drop.sdf ips-sdf
! Save the newly merged signatures to a separate file.
copy ips-sdf disk2:my-signatures.sdf
!
! Configure the router to use the new file, my-signatures.sdf
configure terminal
ip ips sdf location disk2:my-signatures.sdf
! Reinitialize the IPS by removing the IPS rule set and reapplying the rule set.
interface gig 0/1
 no ip ips MYIPS in
!
*Apr 8 14:05:38.243:%IPS-2-DISABLED:IPS removed from all interfaces - IPS disabled
!
 ip ips MYIPS in
!
 exit
```

Related Commands

Command	Description
copy ips-sdf	Loads or saves the SDF in the router.
ip ips sdf location	Specifies the location in which the router should load the SDF.

ip ips auto-update

To enable automatic signature updates for Cisco IOS Intrusion Prevention System (IPS), use the **ip ips auto-update** command in global configuration mode. To revert back to the default value, use the **no** form of this command.

ip ips auto-update

no ip ips auto-update

Syntax Description

This command has no arguments or keywords.

Command Default

The default value is defined in the signature definition XML.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Automatic signature updates allow users to override the existing IPS configuration and automatically keep signatures up to date on the basis of a preset time, which can be configured to a preferred setting.

Use the **ip ips auto-update** command to enable Cisco IOS IPS to automatically update the signature file on the system. When enabling automatic signature updates, it is recommended that you ensure the following configuration guidelines have been met:

- The router's clock is set up with the proper relative time.
- The frequency for Cisco IOS IPS to obtain updated signature information has been defined (through the **occur-at** command).
- Automatic signature updates can be enabled from Cisco.com by using the **cisco** command. This command cannot be used in conjunction with the **url** command.
- The URL in which to retrieve the Cisco IOS IPS signature configuration files has been specified (through the **url** command).
- Optionally, the username and password in which to access the files from the server has been specified (through the **username** command). The **username** command would be optional in this case if the username and password command were previously configured through the **ips signature update cisco** command in Priviledged EXEC mode. The user name and password must be configured for updating signatures directly from Cisco.com.

The Default Value

A user or a management station can override the default value through the **category** command or the **signature** command; a value set with either of these commands will be saved as the delta value. The no form of the ip ips auto-update command will remove the delta value and revert back to the default value in the definition XML.

Setting Time for Auto Updates

Cisco IOS time can be updated through the hardware clock or the software configurable clock (which ever option is available on your system). Although Network Time Protocol (NTP) is typically used for automated time synchronization, Cisco IOS IPS updates use the local clock resources as a reference for update intervals. Thus, NTP should be configured to update the local time server of the router, as appropriate.

Examples

The following example shows how to configure automatic signature updates and issue the **show ip ips auto-update** command to verify the configuration. In this example, the signature package file is pulled from the TFTP server at the third hour of the 5 day of the month, at the 56th minute of this hour. (Note that adjustments are made for months without 31 days and daylight savings time.)

```
Router# clock set ?
    hh:mm:ss Current Time
Router# clock set 10:38:00 20 apr 2006
Router#
*Apr 20 17:38:00.000: %SYS-6-CLOCKUPDATE: System clock has been updated from 10:37:55 MST
Thu Apr 20 2006 to 10:38:00 MST Thu Apr 20 2006, configured from console by cisco on
console.

Router(config)# ip ips auto-update

Related Commands

Command	Description
occur-at	Defines the frequency in which Cisco IOS IPS obtains updated signature information.
cisco	Enables automatic signature updates from Cisco.com.
url (ips-autoupdate)	Defines a location in which to retrieve the Cisco IOS IPS signature configuration files.
username (ips-autoupdate)	Defines a username and password in which to access signature files from the server.

ip ips config location

To specify the location in which the router will save signature information, use the **ip ips config location** command in global configuration mode. To remove the specified location, use the **no** form of this command.

ip ips config location *url*

no ip ips config location

Syntax Description

url	Location where the signature file is saved. Available URL options: • Local flash, such as flash:sig.xml • FTP server, such as ftp://myuser:mypass@ftp_server.sig.xml • rcp, such as rcp://myuser@rcp_server/sig.xml • TFTP server, such as tftp://tftp_server/sig.xml **Note** If the specified location is a URL, such as an FTP server, the user must have writer privileges.

Command Default

No configuration files are saved.

Command Modes

Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Before configuring the **ip ips config location** command, you must create a directory for the config location via the **mkdir** command.

The **ip ips config location** command configures a Cisco IOS Intrusion Prevention System (IPS) signature location, which tells Cisco IOS IPS where to save signature information.

The configuration location is used to restore the IPS configuration in cases such as router reboots or IPS becoming disabled or reenabled. Files, such as signature definitions, signature-type definitions, and signature category information, are written in XML format, compressed, and saved to the specified IPS signature location.

Note If a location is not specified, or if a location is removed via the **no** form, no files will be saved.

Note The **ip ips config location** command replaces the **ip ips sdf location** command.

Examples

The following example shows how to instruct the router to save all signature information to the directory "flash:/ips5":

```
Router# mkdir flash:/ips5
Create directory filename [ips5]?
Created dir flash:/ips5
Router#
Router#
Router#
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip ips name MYIPS
Router(config)# ip ips config location flash:/ips5
Router(config)# ip ips signature-category
Router(config-ips-category)# category all
Router(config-ips-category-action)# retired true
Router(config-ips-category-action)# exit
Router(config-ips-category)# category ios_ips advanced
Router(config-ips-category-action)# retired false
Router(config-ips-category-action)# exit
Router(config-ips-category)# exit
Do you want to accept these changes? [confirm]
Router(config)# d
*Nov 14 2006 17:16:42 MST: Applying Category configuration to signatures ..
Router(config)#
```

ip ips deny-action ips-interface

To create an access control list (ACL) filter for the deny actions ("denyFlowInline" and "denyConnectionInline") on the intrusion prevention system (IPS) interface rather than ingress interface, use the **ip ips deny-action ips-interface** command in global configuration mode. To return to the default, use the **no** form of this command.

ip ips deny-action ips-interface

no ip ips deny-action ips-interface

Syntax Description

This command has no arguments or keywords.

Defaults

ACLs filter for the deny actions are applied to the ingress interface.

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Use the **ip ips deny-action ips-interface** command to change the default behavior of the ACL filters that are created for the deny actions.

Note You should configure this command only if at least one signature is configured to use the supported deny actions (denyFlowInline and denyConnectionInline, if the input interface is configured to for load balancing, and if IPS is configured on the output interface.

Default ACL Filter Approach

By default, ACL filters for the deny actions are created on the ingress interfaces of the offending packet. Thus, if Cisco IOS IPS is configured in outbound direction on the egress interface and the "deny" ACLs are created on the ingress interface, Cisco IOS IPS will drop the matching traffic before it goes through much processing. Unfortunately, this approach does not work in load balancing scenarios for which there is more than one ingress interface performing load-balancing.

Alternative ACL Filter Approach

The **ip ips deny-action ips-interface** command enables ACLs to be created on the same interface and in the same direction as Cisco IOS IPS is configured. This alternative approach supports load-balancing scenarios—assuming that the load-balancing interfaces have the same Cisco IOS IPS configuration. However, all outbound Cisco IOS IPS traffic will go through substantial packet path processing before it is eventually dropped by the ACLs.

Examples

The following example shows how to configure load-balancing between interface e0 and interface e1:

```
ip ips name test
ip ips deny-action ips-interface
! Enables load balancing with e1
interface e0
 ip address 10.1.1.14 255.255.255.0
 no shut
!
! Enables load balancing with e0
interface e1
 ip address 10.1.1.16 255.255.255.0
 no shut
!
interface e2
 ip address 10.1.1.18 255.255.255.0
 ip ips test in
 no shut
```

ip ips enable-clidelta

To enable the signature tuning settings in the clidelta.xmz file on the router to take precedence over the signature settings in the intrusion prevention system (IPS) iosips-sig-delta.xmz file, use the **ip ips enable-clidelta** command in global configuration mode. To restore precedence to the iosips-sig-delta.xmz file settings, use the no form of this command.

ip ips enable-clidelta

no ip ips enable-clidelta

Syntax Description

This command has no arguments or keywords.

Command Default

This command is disabled by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(2)T	This command was introduced.

Usage Guidelines

Most IPS devices and applications provide either a single default configuration or multiple default configurations. Using one of these default configurations is an ideal starting point for deploying IPS. When IOS IPS is deployed, parameters such as severity, active status, or event actions of certain signatures need to be tuned to meet the requirements of an enterprise network traffic profile.

Once the **ip ips enable-clidelta** command is enabled, a local cli-delta.xmz file is generated containing the local tuning signatures configured through the CLI. The settings in the clidelta.xmz file take precedence when a globally administered delta signature update, contained in the iosips-sig-delta.xmz file, is sent from a central repository and applied to the configuration of the local router.

Examples

The following example shows how to enable the clidelta functionality:

```
Router(config)# ip ips enable-clidelta
```

Related Commands

Command	Description
show ip ips sig-clidelta	Displays information about the IPS iosips-sig-clidelta.xmz file on the router to verify signature tuning settings.

ip ips event-action-rules

To enter config-rule configuration mode, which allows users to change the target value rating, use the **ip ips event-action-rules** command in global configuration mode.

ip ips event-action-rules

Syntax Description

This command has no arguments or keywords.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

You must issue the **ip ips event-action-rules** command to define the target value rating via the **target-value** command.

Examples

The following example shows how to change the target value to low for the host 192.168.0.1:

```
configure terminal
ip ips event-action-rules
 target-value low target-address 192.168.0.1
```

Related Commands

Command	Description
target-value	Defines the target value rating for a host.

ip ips fail closed

To instruct the router to drop all packets until the signature engine is built and ready to scan traffic, use the **ip ips fail closed** command in global configuration mode. To return to the default functionality, use the **no** form of this command.

ip ips fail closed

no ip ips fail closed

Syntax Description

This command has no arguments or keywords.

Defaults

All packets are passed without being scanned while the signature engine is being built or if the signature engine fails to build.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Cisco IOS IPS Fails to Load the SDF

By default, the router running Intrusion Prevention System (IPS) will load the built-in signatures if it fails to load the signature definition file (SDF). If this command is issued, the router will drop all packets—unless the user specifies an access control list (ACL) for packets to send to IPS.

IPS Loads the SDF but Fails to Build a Signature Engine

If the router running IPS loads the SDF but fails to build a signature engine, the router will mark the engine "not ready." If an available engine is previously loaded, the IPS will keep the available engine and discard the engine that is not ready for use. If no previous engines have been loaded or "not ready," the router will install the engine that is not ready and rely on the configuration of the **ip ips fail closed** command.

By default, packets destined for an engine marked "not ready" will be passed without being scanned. If this command is issued, the router will drop all packets that are destined for that signature engine.

Examples

The following example shows how to instruct the router to drop all packets if the SME is not yet available:

```
Router(config)# ip ips fail closed
```

ip ips inherit-obsolete-tunings

To enable Cisco IOS Intrusion Prevention System (IPS) signatures to inherit tunings from obsoleted signatures in a Cisco IOS IPS, use the **ip ips inherit-obsolete-tunings** command in global configuration mode. To disable this function, use the **no** form of this command.

ip ips inherit-obsolete-tunings

no ip ips inherit-obsolete-tunings

SyntaxDescription This command has no arguments or keywords.

Command Default Tunings from obsoleted signatures in Cisco IOS IPS are not inherited.

Command Modes Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines The **ip ips inherit-obsolete-tunings** command enables new signatures to obsolete older signatures and inherit the event-action and enabled parameters of the obsolete tuning values without the need to manually tune the new signatures. All other parameter changes, including the “Retire” parameter saved in the old signatures, will be ignored.

After you enter the command, the screen displays a warning message asking you to clarify the intended usage and then asks whether you accept the configuration, By default, old signatures tunings are not inherited by new signatures.

Note The tunings of old signatures will be lost if they are not migrated to new signatures.

Note To enable inheritance of tunings, configure the **ip ips inherit-obsolete-tunings** command before a signature file is loaded.

Note Users of management devices should use those devices and not enable the **ip ips inherit-obsolete-tunings** command.

Examples

The following example shows how to configure a router running Cisco IOS IPS to allow new signatures to inherit the tuning values from the obsoleted signatures, without having to manually tune the new signatures:

```
Router(config)# ip ips inherit-obsolete-tunings
```

Related Commands

Command	Description
ip ips	Applies a IPS rule to an interface.
ip ips memory regex chaining	Enables an Cisco IOS IPS to chain multiple regex tables together and load additional signatures.
ip ips memory threshold	Specifies an Cisco IOS IPS memory threshold.
show ip ips	Displays Cisco IOS IPS information such as configured sessions and signatures.

ip ips memory regex chaining

To enable a Cisco IOS Intrusion Prevention System (IPS) to chain multiple regex tables together and load additional signatures, use the **ip ips memory regex chaining** command in global configuration mode. To disable this function, use the **no** form of this command.

ip ips memory regex chaining

no ip ips memory regex chaining

Syntax Description

This command has no arguments or keywords.

Command Default

Multiple regex table chaining is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Multiple regex table chaining is used to load additional signatures when a Cisco IOS IPS is supporting a large signature set. The default is three chained tables when the **ip ips memory regex chaining** command is enabled. This results in slower performance of Cisco IOS IPS scanning due to scanning packets across more than a single regex table.

When a user tries to load a specific set of signatures that does not fit using a single table, compilation errors will result. A compiler failure error message looks like this:

```
*Sep  9 17:27:46.907: %IPS-4-SIGNATURE_COMPILE_FAILURE: string-tcp 3730:0 - compiles
discontinued for this engine
```

Examples

The following example shows how to enable the **ip ips memory regex chaining** command:

```
Router(config)# ip ips memory regex chaining
```

Related Commands

Command	Description
ip ips	Applies an IPS rule to an interface.
ip ips inherit-obsolete-tunings	Applies tunings from obsoleted signatures to the new versions of the signatures.
ip ips memory threshold	Specifies a Cisco IOS IPS memory threshold.
show ip ips	Displays Cisco IOS IPS information such as configured sessions and signatures.

ip ips memory threshold

To specify a memory threshold when using a Cisco IOS Intrusion Prevention System (IPS), use the **ip ips memory threshold** command in global configuration mode. To disable this function, use the **no** form of this command.

ip ips memory threshold *megabytes*

no ip ips memory threshold

Syntax Description

megabytes	The IPS memory threshold, in megabytes. The valid range is from 0-1024.

Command Default

The default IPS memory threshold is 10 percent of free memory—this is available for router operations other than Cisco IOS IPS.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

The IPS memory threshold defines the amount of free memory unavailable to the IPS.

When you are loading signatures, the default state is that Cisco IOS IPS cannot consume any more memory if the remaining (free) memory becomes less than 10 percent of the size of the total DRAM installed on the router (for example, less than 25.6 MB free memory left on routers with 256 MB DRAM). The 10 percent of free memory unavailable to IPS defines the IPS memory threshold. The IPS memory threshold can be changed using the **ip ips memory threshold** command to force IPS to use less memory, so that other features get access to more memory if they need it.

Setting a memory threshold for Cisco IOS IPS is recommended especially when an arbitrary number of signatures may be added on top of the recommended sets in Cisco IOS IPS Basic or Advanced/Default categories, or when a fully customized signature set is created and loaded.

Examples

The following example shows how to configure a router running Cisco IOS IPS to set the IPS memory threshold to a value of 50 MB:

```
Router(config)# ip ips memory threshold 50
```

Related Commands

Command	Description
ip ips	Applies an IPS rule to an interface.
ip ips inherit-obsolete-tunings	Applies tunings from obsoleted signatures to the newer versions of the signatures.

Command	Description
ip ips memory regex chaining	Enables a Cisco IOS IPS to chain multiple regex tables together and load additional signatures.
show ip ips	Displays Cisco IOS IPS information such as configured sessions and signatures.

ip ips name

To specify an intrusion prevention system (IPS) rule, use the **ip ips name** command in global configuration mode. To delete an IPS rule, use the **no** form of this command.

ip ips name *ips-name* [**list** *acl*]

no ip ips name *ips-name* [**list** *acl*]

Syntax Description

ips-name	Name for IPS rule.
list *acl*	(Optional) Specifies an extended or standard access control list (ACL) to filter the traffic that will be scanned. **Note** All traffic that is permitted by the ACL is subject to inspection by the IPS. Traffic that is denied by the ACL is not inspected by the IPS.

Defaults

An IPS rule does not exist.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(8)T	The command name was changed from the **ip audit name** command to the **ip ips name** command.

Usage Guidelines

The IPS does not load the signatures until the rule is applied to an interface via the **ip ips** command.

Note This command replaces the **ip audit name** global configuration command. If the **ip audit name** command has been issued in an existing configuration and an access control list (ACL) has been defined, IPS will apply the **ip ips name** command and the ACL parameter on all interfaces that applied the rule.

Examples

The following example shows how to configure a router running Cisco IOS IPS to load the default, built-in signatures. Note that a configuration option for specifying an SDF location is not necessary; built-in signatures reside statically in Cisco IOS.

```
!
ip ips po max-events 100
ip ips name MYIPS
!
interface GigabitEthernet0/1
 ip address 10.1.1.16 255.255.255.0
 ip ips MYIPS in
 duplex full
 speed 100
```

```
 media-type rj45
 no negotiation auto
!
```

Related Commands

Command	Description
ip ips	Applies an IPS rule to an interface.
show ip ips	Displays IPS information such as configured sessions and signatures.

ip ips notify

To specify the method of event notification, use the **ip ips notify** command in global configuration mode. To disable event notification, use the **no** form of this command.

ip ips notify [**log** | **sdee**]

no ip ips notify [**log** | **sdee**]

Syntax Description

log	(Optional) Send messages in syslog format. **Note** If an option is not specified, alert messages are sent in syslog format.
sdee	(Optional) Send messages in Security Device Event Exchange (SDEE) format.

Defaults

By default, event notification through syslog is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(8)T	The command name was changed from the **ip audit notify** command to the **ip ips notify** command. Also, support for SDEE was introduced, and the **sdee** keyword was added.
12.3(14)T	The Post Office protocol was deprecated, and the **nr-director** keyword was removed.

Usage Guidelines

SDEE is always running, but it does not receive and process events from Intrusion Prevention System (IPS) unless SDEE notification is enabled. If it is not enabled and a client sends a request, SDEE will respond with a fault response message, indicating that notification is not enabled.

To use SDEE, the HTTP server must be enabled (via the **ip http server** command). If the HTTP server is not enabled, the router cannot respond to the SDEE clients because it cannot not see the requests.

Note The **ip ips notify** command replaces the **ip audit notify** command. If the **ip audit notify** command is part of an existing configuration, the IPS will interpret it as the **ip ips notify** command.

Examples

In the following example, event notifications are specified to be sent in SDEE format:

```
ip ips notify sdee
```

Related Commands

Command	Description
ip http server	Enables the HTTP server on your system.

ip ips sdf location

Note In Cisco IOS Release 12.4(11)T, the **ip ips sdf location** command was replaced with the **ip ips config location** command. For more information, see the **ip ips config location** command.

To specify the location in which the router will load the signature definition file (SDF), use the **ip ips sdf location** command in global configuration mode. To remove an SDF location from the configuration, use the **no** form of this command.

ip ips sdf location *url* [**retries** *number* **wait-time** *seconds*] [**autosave**]

no ip ips sdf location *url* [**retries** *number* **wait-time** *seconds*] [**autosave**]

Syntax Description

url	Location of the SDF. Available URL options: • local flash, such as flash:sig.xml • FTP server, such as ftp://myuser:mypass@ftp_server.sig.xml • rcp, such as rcp://myuser@rcp_server/sig.xml • TFTP server, such as tftp://tftp_server/sig.xml
retries *number*	(Optional) Number of times the router will try to load the SDF after the first attempt fails.
wait-time *seconds*	(Optional) Duration, in seconds, between retry attempts.
autosave	(Optional) Specifies that the router will save a new SDF to the specified location.

Defaults

If an SDF location is not specified, the router will load the default built-in signatures.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(4)T	The **autosave** keyword was added.
12.4(7.20)T	The **retries** *number* and the **wait-time** *seconds* options were added.
12.4(11)T	This command was replaced with the **ip ips config location** command.

Usage Guidelines

When you specify the **ip ips sdf location** command, the signatures are not loaded until the router is rebooted or until the Intrusion Prevention System (IPS) is applied to an interface (through the **ip ips** command). If IPS is already applied to an interface, the signatures are not loaded. If IPS cannot load the SDF, an error message is issued and the router uses the built-in IPS signatures.

You can also specify the **copy ips-sdf** command to load an SDF from a specified location. Unlike the **ip ips sdf location** command, the signatures are loaded immediately after the **copy ips-sdf** command is entered.

When you specify the **autosave** keyword, the router saves a new SDF to the specified location when signatures are loaded using either the **copy** command or an external management platform such as Security Device Manager (SDM), IPS Management Center (IPSMC) or Cisco Incident Control Server (Cisco ICS). You can specify multiple autosave locations. The router will attempt to save to all autosave locations. The URL must have proper write access permissions.

Examples

The following example shows how to configure the router to load and merge the attack-drop.sdf file with the default signatures. After the files are merged, it is recommended that you copy the merged signatures to a separate file. You can then reload the router (by entering the **reload** command) or reinitialize the router so that it recognizes the newly merged file (as shown the following example).

```
!
ip ips name MYIPS
!
interface GigabitEthernet0/1
 ip address 10.1.1.16 255.255.255.0
 ip ips MYIPS in
 duplex full
 speed 100
 media-type rj45
 no negotiation auto
!
!
! Merge the flash-based SDF (attack-drop.sdf) with the built-in signatures.
copy disk2:attack-drop.sdf ips-sdf
! Save the newly merged signatures to a separate file.
copy ips-sdf disk2:my-signatures.sdf
!
! Configure the router to use the new file, my-signatures.sdf
configure terminal
ip ips sdf location disk2:my-signatures.sdf
! Reinitialize the IPS by removing the IPS rule set and reapplying the rule set.
interface gig 0/1
no ip ips MYIPS in
!
*Apr 8 14:05:38.243:%IPS-2-DISABLED:IPS removed from all interfaces - IPS disabled
!
 ip ips MYIPS in
!
exit
```

Related Commands

Command	Description
copy ips-sdf	Loads or saves the SDF in the router.
ip ips	Applies the IPS rule to an interface.

ip ips signature

Note In Cisco IOS Release 12.4(11)T, the **ip ips signature** command was deprecated.

To attach a policy to a signature, use the **ip ips signature** command in global configuration mode. If the policy disabled a signature, use the **no** form of this command to reenable the signature. If the policy attached an access list to the signature, use the **no** form of this command to remove the access list.

ip ips signature *signature-id* {**delete** | **disable** | **list** *acl-list*}

no ip ips signature *signature-id*

Syntax Description

signature-id	Signature within the signature detection file (SDF).
delete	Deleted a specified signature.
disable	Disables a specified signature.
list *acl-list*	A named, standard, or ACL that is associated with the signature.

Defaults

No policy is attached to a signature.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(8)T	The command name was changed from the **ip audit signature** command to the **ip ips signature** command to support SDFs.
12.4(11)T	This command and support for SDFs were removed.

Usage Guidelines

This command allow you to set three policies: delete a signature, disable the audit of a signature, or qualify the audit of a signature with an access list.

If you are attaching an ACL to a signature, then you also need to create an Intrusion Prevention System (IPS) rule with the **ip ips name** command and apply it to an interface with the **ip ips** command.

Note The **ip ips signature** command replaces the **ip audit signature** command. If the **ip audit signature** command is found in an existing configuration, Cisco IOS IPS will interpret it as the **ip ips signature** command.

Examples

In the following example, a signature is disabled, another signature has ACL 99 attached to it, and ACL 99 is defined:

```
ip ips signature 6150 disable
ip ips signature 1000 list 99

access-list 99 deny 10.1.10.0 0.0.0.255
access-list 99 permit any
```

ip ips signature-category

To enter IPS category (config-ips-category) configuration mode, which allows you to tune Cisco IOS Intrusion Prevention System (IPS) signature parameters on the basis of a signature category, use the **ip ips signature-category** command in global configuration mode.

ip ips signature-category

Syntax Description

This command has no arguments or keywords.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Use the **ip ips signature-category** command if you want to tune signature parameters per category.

Examples

The following example shows how to tune event-action parameters for the signature category "adware/spyware." All tuning information will be applied to all signatures that belong to the adware/spyware category.

```
Router(config)# ip ips signature-category
Router(config-ips-category)# category attack adware/spyware
Router(config-ips-category-action)# event-action produce-alert
Router(config-ips-category-action)# event-action deny-packet-inline
Router(config-ips-category-action)# event-action reset-tcp-connection
Router(config-ips-category-action)# retired false
Router(config-ips-category-action)# ^Z
Do you want to accept these changes? [confirm]y
```

Related Commands

Command	Description
category	Specifies a signature category that is to be used for multiple signature actions or conditions.

ip ips signature-definition

To enter signature-definition-signature configuration mode, which allows you to define a signature for command-line interface (CLI) user tunings, use the **ip ips signature-definition** command in global configuration mode. To revert back to the default value, use the **no** form of this command.

ip ips signature-definition

no ip ips signature-definition

Syntax Description

This command has no arguments or keywords.

Command Default

Signature parameters cannot be defined and default values are used.

Command Modes

Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Use the **ip ips signature-definition** command to enter signature-definition-signature configuration mode, which allows you to issue the **signature** command. The **signature** command is used to specify a signature whose CLI user tunings are to be customized. After you issue the **signature** command, you can begin to specify which signature parameters (user tunings) are to be changed.

Examples

The following example shows how to modify signature 5081/0 to “produce alert” and “reset tcp connection”:

```
Router(config)# ip ips signature-definition
Router(config-sigdef-sig)# signature 5081 0
Router(config-sigdef-action)# engine
Router(config-sigdef-action-engine)# event-action produce-alert reset-tcp-connection
Router(config-sigdef-action-engine)# ^Z
Do you want to accept these changes:[confirmm]y
```

Related Commands

Command	Description
signature	Specifies a signature for which the CLI user tunings will be changed.

ip ips signature disable

To instruct the router to scan for a given signature but not take any action if the signature is detected, use the **ip ips signature** command in global configuration mode. To reenable a signature, use the **no** form of this command.

ip ips signature *signature-id* [*sub-signature-id*] **disable** [**list** *acl-list*]

no ip ips signature *signature-id* [*sub-signature-id*] **disable** [**list** *acl-list*]

Syntax Description

signature-id [*sub-signature-id*]	Signature that is disabled.
list *acl-list*	(Optional) A named, standard, or extended access control list (ACL) to filter the traffic that will be scanned. If the packet is permitted by the ACL, the signature will be scanned and reported; if the packet is denied by the ACL, the signature is deemed disabled.

Defaults

All signatures within the signature definition file (SDF) are reported, if detected.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

You may want to disable a signature (or set of signatures) if your deployment scenario deems the signatures unnecessary.

Examples

The following example shows how to instructs the router not to report on signature 1000, if detected:

```
Router(config) ip ips signature 1000 disable
```

Related Commands

Command	Description
ip ips	Applies the IPS rule to an interface.
ip ips name	Specifies an IPS rule.

ip kerberos source-interface

To specify an interface for the source address of the kerberos packets, use the **ip kerberos source-interface** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ip kerberos source-interface *interface-type number*

no ip kerberos source-interface

Syntax Description

interface-type	Interface type. For more information, use the question mark (?) online help function.
number	Interface or subinterface number. For more information about the numbering syntax for your networking device, use the question mark (?) online help function.

Command Default

An interface for the source address of Kerberos packets is not set.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows how to specify an interface for the source address of the Kerberos packets:

```
Router# configure terminal
Router(config)# ip kerberos source-interface FastEthernet 0/0
```

Related Commands

Command	Description
clear kerberos creds	Deletes the contents of the credentials cache.
debug kerberos	Displays information associated with the Kerberos Authentication Subsystem.

ip msdp border

To configure a router that borders a Protocol Independent Multicast (PIM) sparse mode region and dense mode region to use Multicast Source Discovery Protocol (MSDP), use the **ip msdp border** command in global configuration mode. To prevent this action, use the **no** form of this command.

ip msdp [**vrf** *vrf-name*] **border sa-address** *interface-type interface-number*

no ip msdp [**vrf** *vrf-name*] **border sa-address** *interface-type interface-number*

Syntax Description

vrf	(Optional) Supports the multicast VPN routing and forwarding (VRF) instance.
vrf-name	(Optional) Name assigned to the VRF.
sa-address	Specifies the active source IP address.
interface-type interface-number	Interface type and number from which the IP address is derived and used as the rendezvous point (RP) address in Source-Active (SA) messages. Thus, MSDP peers can forward SA messages away from this border. The IP address of the interface is used as the originator ID, which is the RP field in the MSDP SA message. No space is needed between the values.

Defaults

The active sources in the dense mode region will not participate in MSDP.

Command Modes

Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced.
12.0(23)S	The **vrf** keyword and *vrf-name* argument were added.
12.2(13)T	The **vrf** keyword and *vrf-name* argument were added.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(27)SBC	This command was integrated into Cisco IOS Release 12.2(27)SBC.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use this command if you want the router to send SA messages for sources active in the PIM dense mode region to MSDP peers.

Specifying the interface-type and interface-number values allow the MSDP peers to forward source-active messages away from this border. The IP address of the interface is used as the originator ID, which is the rendezvous point field in the MSDP source-active message.

Note We recommend configuring the border router in the sparse mode domain to proxy-register sources in the dense mode domain, and have the sparse mode domain use standard MSDP procedures to advertise these sources.

Note If you use this command, you must constrain the sources advertised by using the **ip msdp redistribute** command. Configure the **ip msdp redistribute** command to apply to only local sources. Be aware that this configuration can result in (S, G) state remaining long after a source in the dense mode domain has stopped sending.

Note The **ip msdp originator-id** command also identifies an interface type and number to be used as the RP address. If both the **ip msdp border** and **ip msdp originator-id** commands are configured, the address derived from the **ip msdp originator-id** command determines the address of the RP.

Examples

In the following example, the local router is not an RP. It borders a PIM sparse mode region with a dense mode region. It uses the IP address of Ethernet interface 0 as the "RP" address in SA messages.

```
ip msdp border sa-address ethernet0
```

Related Commands

Command	Description
ip msdp originator-id	Allows an MSDP speaker that originates an SA message to use the IP address of its interface as the RP address in the SA message.
ip msdp redistribute	Configures which (S, G) entries from the multicast routing table are advertised in SA messages originated to MSDP peers.

ip mtu

To set the maximum transmission unit (MTU) size of IP packets that are sent on an interface, use the **ip mtu** command in interface configuration mode. To restore the default MTU size, use the **no** form of this command.

ip mtu *bytes*

no ip mtu

Syntax Description

bytes	MTU, in bytes.

Command Default

The IP MTU default value depends on the interface medium. Table 38 lists default MTU values according to media type.

Table 38 Default Media MTU Values

Media Type	Default MTU (Bytes)
Ethernet	1500
Serial	1500
Token Ring	4464
ATM	4470
FDDI	4470
HSSI (HSA)	4470
VASI	9216

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4.

Usage Guidelines

If an IP packet exceeds the MTU that is set for the interface, the Cisco IOS software will fragment it.

For VASI interfaces that involve Ethernet type interfaces (Ethernet, Fast Ethernet or Gigabit Ethernet), the IP MTU of the VASI interface must be set the same as the lower default setting of the Ethernet type interface of 1500 bytes. If this adjustment is not made, OSPF reconvergence on the VASI interface will take too long.

Note Changing the MTU value (with the **mtu** interface configuration command) can affect the IP MTU value. If the current IP MTU value is the same as the MTU value, and you change the MTU value, the IP MTU value will be modified automatically to match the new MTU. However, the reverse is not true; changing the IP MTU value has no effect on the value for the **mtu** command.

Examples

The following example sets the maximum IP packet size for the first serial interface to 300 bytes:

```
Router(config)# interface serial 0
Router(config-if)# ip mtu 300
```

Related Commands

Command	Description
mtu	Adjusts the maximum packet size or MTU size.

ip nhrp cache non-authoritative

To turn off authoritative flags on NHRP cache entries, use the **ip nhrp cache non-authoritative** command in interface configuration mode. To turn authoritative flags on again, use the **no** form of this command.

ip nhrp cache non-authoritative

no ip nhrp cache non-authoritative

Syntax Description

This command has no arguments or keywords.

Defaults

Authoritative flags are turned on.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

By default the next hop server (NHS) replies to authoritative Next Hop Resolution Protocol (NHRP) resolution requests if it has a cache entry that is marked as authoritative. The **ip nhrp cache non-authoritative** comand turns off the "authoritative" flag on the cache entries. Thus, the request is forwarded to the next hop client (NHC), which responds to the resolution.

Configuring the **ip nhrp cache non-authoritative** command offloads the resolution replies from the hub to the spokes. It also helps the spokes complete NHRP mapping entries when a spoke-to-spoke tunnel is built, thus alleviating flap conditions in which the IP security (IPsec) tunnel is built but for which there are no corresponding NHRP mappings.

Examples

The following example shows that the authoritative flags have been turned off:

```
interface Tunnel0
 ip nhrp cache non-authoritative
```

ip nhrp nhs

To specify the address of one or more Next Hop Resolution Protocol (NHRP) servers, use the **ip nhrp nhs** command in interface configuration mode. To remove the address, use the **no** form of this command.

Cisco IOS Release 12.2(33)SRA, 12.2SX, and Later Releases

ip nhrp nhs *nhs-address* [*net-address* [*netmask*]]

no ip nhrp nhs *nhs-address* [*net-address* [*netmask*]]

Cisco IOS Release 15.1(2)T and Later Releases

ip nhrp nhs {*nhs-address* [**nbma** {*nbma-address* | *FQDN-string*}] [**multicast**] [**priority** *value*] [**cluster** *value*] | **cluster** *value* **max-connections** *value* | **dynamic nbma** {*nbma-address* | *FQDN-string*} [**multicast**] [**priority** *value*] [**cluster** *value*] | **fallback** *seconds*}

no ip nhrp nhs {*nhs-address* [**nbma** {*nbma-address* | *FQDN-string*}] [**multicast**] [**priority** *value*] [**cluster** *value*] | **cluster** *value* **max-connections** *value* | **dynamic nbma** {*nbma-address* | *FQDN-string*} [**multicast**] [**priority** *value*] [**cluster** *value*] | **fallback** *seconds*}

Syntax Description

nhs-address	Address of the next-hop server being specified.
net-address	(Optional) IP address of a network served by the next-hop server.
netmask	(Optional) IP network mask to be associated with the IP address. The IP address is logically ANDed with the mask.
nbma	(Optional) Specifies the nonbroadcast multiple access (NBMA) address or FQDN.
nbma-address	NBMA address.
FQDN-string	Next hop server (NHS) fully qualified domain name (FQDN) string.
multicast	(Optional) Specifies to use NBMA mapping for broadcasts and multicasts.
priority *value*	(Optional) Assigns a priority to hubs to control the order in which spokes select hubs to establish tunnels. The range is from 0 to 255; 0 is the highest and 255 is the lowest priority.
cluster *value*	(Optional) Specifies NHS groups. The range is from 0 to 10; 0 is the highest and 10 is the lowest. The default value is 0.
max-connections *value*	Specifies the number of NHS elements from each NHS group that needs to be active. The range is from 0 to 255.
dynamic	Configures the spoke to learn the NHS protocol address dynamically.
fallback *seconds*	Specifies the duration, in seconds, for which the spoke must wait before falling back to an NHS of higher priority upon recovery.

Defaults

No next-hop servers are explicitly configured, so normal network layer routing decisions are used to forward NHRP traffic.

Command Modes Interface configuration (config-if)

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(2)T	This command was modified. The *net-address* and *mask* arguments were removed and the **nbma**, *nbma-address*, *FQDN-string*, **multicast**, **priority** *value*, **cluster** *value*, **max-connections** *value*, **dynamic**, and **fallback** *seconds* keywords and arguments were added.

Usage Guidelines Use the **ip nhrp nhs** command to specify the address of a next hop server and the networks it serves. Normally, NHRP consults the network layer forwarding table to determine how to forward NHRP packets. When next hop servers are configured, these next hop addresses override the forwarding path that would otherwise be used for NHRP traffic.

For any next hop server that is configured, you can specify multiple networks by repeating this command with the same *nhs-address* argument, but with different IP network addresses.

Examples The following example shows how to register a hub to a spoke using NBMA and FQDN:

```
Router# configure terminal
Router(config)# interface tunnel 1
Router(config-if)# ip nhrp nhs 192.0.2.1 nbma examplehub.example1.com
```

The following example shows how to configure the desired **max-connections** value:

```
Router# configure terminal
Router(config)# interface tunnel 1
Router(config-if)# ip nhrp nhs cluster 5 max-connections 100
```

The following example shows how to configure the NHS fallback time:

```
Router# configure terminal
Router(config)# interface tunnel 1
Router(config-if)# ip nhrp nhs fallback 25
```

The following example shows how to configure NHS priority and group values:

```
Router# configure terminal
Router(config)# interface tunnel 1
Router(config-if)# ip nhrp nhs 192.0.2.1 priority 1 cluster 2
```

Related Commands

Command	Description
ip nhrp map	Statically configures the IP-to-NBMA address mapping of IP destinations connected to an NBMA network.
show ip nhrp	Displays NHRP mapping information.

ip port-map

To establish port-to-application mapping (PAM), use the **ip port-map** command in global configuration mode. To delete user-defined PAM entries, use the **no** form of this command.

ip port-map *appl-name* **port** [**tcp** | **udp**] [*port_num* | **from** *begin_port_num* **to** *end_port_num*] [**list** *acl-num*] [**description** *description_string*]

no ip port-map *appl-name* **port** [**tcp** | **udp**] [*port_num* | **from** *begin_port_num* **to** *end_port_num*] [**list** *acl-num*] [**description** *description_string*]

Syntax Description

appl-name	Specifies the name of the application with which to apply the port mapping. An application name can contain an underscore or a hyphen. An application can also be system or user-defined. However, a user-defined application must have the prefix **user-** in it; for example, **user-payroll**, **user-sales**, or **user-10**. Otherwise, the following error message appears: "Unable to add port-map entry. Names for user-defined applications must start with 'user-'."
port	Indicates that a port number maps to the application. You can specify up to five port numbers for each port.
tcp | **udp**	(Optional) Specifies the protocol for the application. For well-known applications (and those existing already under PAM), you can omit these keywords and the system assumes the standard protocol for that application. However, for user-defined applications, you must specify either **tcp** or **udp**.
port_num	(Optional) Identifies a port number in the range 1 to 65535.
from *begin_port_num* **to** *end_port_num*	(Optional) Specifies a range of port numbers. You must use the **from** and **to** keywords together.
list *acl-num*	(Optional) Indicates that the port mapping information applies to a specific host or subnet by associating it to an access control list (ACL) number used with PAM.
description *description_string*	(Optional) Specifies a description of up to 40 characters. **Note** Write the text string in the following format: "C *description_string* C," where "C" is a delimiting character.

Defaults

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.3(1)	Skinny Client Control Protocol (SCCP) support was added.

Release	Modification
12.3(14)T	Support was added for the following: • User-defined application names • User-specified descriptions • Port ranges • **tcp** and **udp** keywords • **from** *begin_port_num* **to** *end_port_num* keyword-argument combination • **description** *description_string* keyword-argument combination
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **ip port-map** command associates TCP or User Datagram Protocol (UDP) port numbers with applications or services, establishing a table of default port mapping information at the firewall. This information is used to support network environments that run services using ports that are different from the registered or well-known ports associated with a service or application.

When you issue the **no** form of the command, include all the parameters needed to remove the entry matching that specific set of parameters. For example, if you issued **no ip port-map** *appl-name*, then all entries for that application are removed.

The port mapping information in the PAM table is of one of three types:

- System-defined
- User-defined
- Host-specific

System-Defined Port Mapping

Initially, PAM creates a set of system-defined entries in the mapping table using well-known or registered port mapping information set up during the system start-up. The Cisco IOS Firewall Context-Based Access Control (CBAC) feature requires the system-defined port mapping information to function properly.

You can delete or modify system-defined port mapping information. Use the **no** form of the command for deletion and the regular form of the command to remap information to another application.

You can also add new port numbers to system-defined applications. However, for some system-defined applications like HTTP and Simple Mail Transfer Protocol (SMTP), in which the firewall inspects deeper into packets, their protocol (UDP or TCP) cannot be changed from that defined in the system. In those instances, error messages display.

Table 39 lists some default system-defined services and applications in the PAM table. (Use the **show ip port-map** command for the complete list.)

Table 39 System-Defined Port Mapping

Application Name	Well-Known or Registered Port Number	Protocol Description
cuseeme	7648	CU-SeeMe Protocol
exec	512	Remote Process Execution
ftp	21	File Transfer Protocol (control port)
h323	1720	H.323 Protocol (for example, MS NetMeeting, Intel Video Phone)
http	80	Hypertext Transfer Protocol
login	513	Remote login
msrpc	135	Microsoft Remote Procedure Call
netshow	1755	Microsoft NetShow
real-audio-video	7070	RealAudio and RealVideo
sccp	2000	Skinny Client Control Protocol (SCCP)
smtp	25	Simple Mail Transfer Protocol (SMTP)
sql-net	1521	SQL-NET
streamworks	1558	StreamWorks Protocol
sunrpc	111	SUN Remote Procedure Call
tftp	69	Trivial File Transfer Protocol
vdolive	7000	VDOLive Protocol

Note You can override system-defined entries for a specific host or subnet using the **list** *acl-num* option in the **ip port-map** command.

User-Defined Port Mapping

Network applications that use nonstandard ports require user-defined entries in the mapping table. Use the **ip port-map** command to create default user-defined entries in the PAM table. These entries automatically appear as an option for the **ip inspect name** command to facilitate the creation of inspection rules.

You can specify up to five separate port numbers for each port-map in a single entry. You can also specify a port range in a single entry. However, you may not specify both single port numbers and port ranges in the same entry.

Note If you try to map an application to a system-defined port, a message appears warning you of a mapping conflict. Delete the system-defined entry before mapping it to another application. Deleted system defined mappings appear in the running-configuration in their **no ip port-map** form.

Use the **no** form of the **ip port-map** command to delete user-defined entries from the PAM table. To remove a single mapping, use the **no** form of the command with all its parameters.

To overwrite an existing user-defined port mapping, use the **ip port-map** command to associate another service or application with the specific port.

Multiple commands for the same application name are cumulative.

If you assign the same port number to a new application, the new entry replaces the existing entry and it no longer appears in the running configuration. You receive a message about the remapping.

You cannot specify a port number that is in a range assigned to another application; however, you can specify a range that takes over one singly allocated port, or fully overlaps another range.

You cannot specify overlapping port ranges.

Host-Specific Port Mapping

User-defined entries in the mapping table can include host-specific mapping information, which establishes port mapping information for specific hosts or subnets. In some environments, it might be necessary to override the default port mapping information for a specific host or subnet, including a system-defined default port mapping information. Use the **list** *acl-num* option for the **ip port-map** command to specify an ACL for a host or subnet that uses PAM.

Note If the host-specific port mapping information is the same as existing system-defined or user-defined default entries, host-specific port changes have no effect.

Examples

The following example provides examples for adding and removing user-defined PAM configuration entries at the firewall.

In the following example, nonstandard port 8000 is established as the user-defined default port for HTTP services:

```
ip port-map http port 8000
```

The following example shows PAM entries that establish a range of nonstandard ports for HTTP services:

```
ip port-map http 8001
ip port-map http 8002
ip port-map http 8003
ip port-map http 8004
```

In the following example the command fails because it tries to map port 21, which is the system-defined default port for FTP, with HTTP:

```
ip port-map http port 21
```

In the following example, a specific host uses port 8000 for FTP services. ACL 10 identifies the server address (192.168.32.43), while port 8000 is mapped with FTP services:

```
access-list 10 permit 192.168.32.43
ip port-map ftp port 8000 list 10
```

In the following example, port 21, which is normally reserved for FTP services, is mapped to the RealAudio application for the hosts in list 10. In this configuration, hosts in list 10 do not recognize FTP activity on port 21.

```
ip port-map realaudio port 21 list 10
```

In the following example, the **ip port-map** command fails and generates an error message:

```
ip port-map netshow port 21
Command fail: the port 21 has already been defined for ftp by the system.
              No change can be made to the system defined port mappings.
```

In the following example, the **no** form of this command deletes user-defined entries from the PAM table. It has no effect on the system-defined port mappings. This command deletes the host-specific port mapping of FTP.

```
no ip port-map ftp port 1022 list 10
```

Note All **no** forms of the **ip port-map** command appear before other entries in the running configuration.

In the following example, the command fails because it tries to delete the system-defined default port for HTTP:

```
no ip port-map http port 80
```

In the following example, a specific host uses port 8000 for FTP services. ACL 10 identifies the server address (192.168.32.43), while port 8000 is mapped with FTP services.

```
access-list 10 permit 192.168.32.43
ip port-map ftp port 8000 list 10
```

In the following example, a specific subnet runs HTTP services on port 8080. ACL 50 identifies the subnet, while the PAM entry maps port 8080 with HTTP services.

```
access-list 50 permit 192.168.92.0
ip port-map http 8080 list 50
```

In the following example, a specific host runs HTTP services on port 25, which is the system-defined port number for SMTP services. This requires a host-specific PAM entry that overrides the system-defined default port mapping for HTTP, which is port 80. ACL 15 identifies the host address (192.168.33.43), while port 25 is mapped with HTTP services.

```
access-list 15 permit 192.168.33.43
ip port-map http port 25 list 15
```

In the following example, the same port number is required by different services running on different hosts. Port 8000 is required for HTTP services by host 192.168.3.4, while port 8000 is required for FTP services by host 192.168.5.6. ACL 10 and ACL 20 identify the specific hosts, while PAM maps the ports with the services for each ACL.

```
access-list 10 permit 192.168.3.4
access-list 20 permit 192.168.5.6
ip port-map http port 8000 list 10
ip port-map http ftp 8000 list 20
```

In the following example, five separate port numbers are specified:

```
ip port-map user-my-app port tcp 8085 8087 8092 8093 8094
```

In the following example, multiple commands for the same application name are cumulative and both ports map to the myapp application:

```
ip port-map user-myapp port tcp 3400
ip port-map user-myapp port tcp 3500
```

In the following example, the same port number is assigned to a new application. The new entry replaces the existing entry, meaning that port 5670 gets mapped to user-my-new-app and its mapping to myapp is removed. As a result, the first command no longer appears in the running configuration and you receive a message about the remapping.

```
ip port-map user-myapp port tcp 5670
ip port-map user-my-new-app port tcp 5670
```

In the following example, the second command assigns port 8085 to user-my-new-app because you cannot specify a port number that is in a range assigned to another application. As a result, the first command no longer appears in the running configuration, and you receive a message about the port being moved from one application to another.

```
ip port-map user-my-app port tcp 8085
ip port-map user-my-new-app port tcp from 8080 to 8090
```

Similarly, in the following example the second command assigns port range 8080 to 8085 to user-my-new-app and the first command no longer appears in the running configuration. You receive a message about the remapping.

```
ip port-map user-my-app port tcp from 8080 to 8085
ip port-map user-my-new-app port tcp from 8080 to 8090
```

Related Commands

Command	Description
show ip port-map	Displays the PAM information.

ip radius source-interface

To force RADIUS to use the IP address of a specified interface for all outgoing RADIUS packets, use the **ip radius source-interface** command in global configuration mode. To prevent RADIUS from using the IP address of a specified interface for all outgoing RADIUS packets, use the **no** form of this command.

ip radius source-interface *subinterface-name* [**vrf** *vrf-name*]

no ip radius source-interface

Syntax Description

subinterface-name	Name of the interface that RADIUS uses for all of its outgoing packets.
vrf *vrf-name*	(Optional) Per virtual route forwarding (VRF) configuration.

Defaults

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.3	This command was introduced.
12.2(1)DX	The **vrf** keyword and *vrf-name* argument were implemented on the Cisco 7200 series and Cisco 7401ASR.
12.2(2)DD	This command was integrated into Cisco IOS Release 12.2(2)DD.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

Use this command to set the IP address of a subinterface to be used as the source address for all outgoing RADIUS packets. The IP address is used as long as the subinterface is in the *up* state. The RADIUS server can use one IP address entry for every network access client instead of maintaining a list of IP addresses. Radius uses the IP address of the interface that it is associated to, regardless of whether the interface is in the *up* or *down* state.

The **ip radius source-interface**command is especially useful in cases where the router has many subinterfaces and you want to ensure that all RADIUS packets from a particular router have the same IP address.

If the specified subinterface does not have an IP address or is in the *down* state, then RADIUS reverts to the default. To avoid this, add an IP address to the subinterface or bring the subinterface to the *up* state.

Use the **vrf** *vrf-name* keyword and argument to configure this command per VRF, which allows multiple disjoined routing or forwarding tables, where the routes of one user have no correlation with the routes of another user.

Examples

The following example shows how to configure RADIUS to use the IP address of subinterface s2 for all outgoing RADIUS packets:

```
ip radius source-interface s2
```

The following example shows how to configure RADIUS to use the IP address of subinterface Ethernet0 for VRF definition:

```
ip radius source-interface Ethernet0 vrf vrf1
```

Related Commands

Command	Description
ip tacacs source-interface	Uses the IP address of a specified interface for all outgoing TACACS packets.
ip telnet source-interface	Allows a user to select an address of an interface as the source address for Telnet connections.
ip tftp source-interface	Allows a user to select the interface whose address will be used as the source address for TFTP connections.

ip reflexive-list timeout

To specify the length of time that reflexive access list entries will continue to exist when no packets in the session are detected, use the **ip reflexive-list timeout** command in global configuration mode. To reset the timeout period to the default timeout, use the **no** form of this command.

ip reflexive-list timeout *seconds*

no ip reflexive-list timeout

Syntax Description

seconds	Specifies the number of seconds to wait (when no session traffic is being detected) before temporary access list entries expire. Use a positive integer from 0 to 2,147,483. The default is 300 seconds.

Defaults

300 seconds

Command Modes

Global configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is used with reflexive filtering, a form of session filtering.

This command specifies when a reflexive access list entry will be removed after a period of no traffic for the session (the timeout period).

With reflexive filtering, when an IP upper-layer session begins from within your network, a temporary entry is created within the reflexive access list, and a timer is set. Whenever a packet belonging to this session is forwarded (inbound or outbound) the timer is reset. When this timer counts down to zero without being reset, the temporary reflexive access list entry is removed.

The timer is set to the *timeout period*. Individual timeout periods can be defined for specific reflexive access lists, but for reflexive access lists that do not have individually defined timeout periods, the global timeout period is used. The global timeout value is 300 seconds by default; however, you can change the global timeout to a different value at any time using this command.

This command does not take effect for reflexive access list entries that were already created when the command is entered; this command only changes the timeout period for entries created after the command is entered.

Examples

The following example sets the global timeout period for reflexive access list entries to 120 seconds:

```
ip reflexive-list timeout 120
```

The following example returns the global timeout period to the default of 300 seconds:

```
no ip reflexive-list timeout
```

Related Commands

Command	Description
evaluate	Nests a reflexive access list within an access list.
ip access-list	Defines an IP access list by name.
permit (reflexive)	Creates a reflexive access list and enables its temporary entries to be automatically generated.

ip route (vasi)

To establish a static route on the VRF-Aware Service Infrastructure (VASI) interface, use the **ip route vrf** command in global configuration mode. To remove the static route connection, use the **no** form of this command.

ip route [**vrf** *vrf-name*] *destination-prefix detination-prefix-mask* {**vasileft** | **vasiright**} *number*

no ip route [**vrf** *vrf-name*] *destination-prefix detination-prefix-mask* {**vasileft** | **vasiright**} *number*

Syntax Description

vrf *vrf-name*	Specifies the Virtual Routing and Forwarding (VRF) instance for the static route.
destination-prefix	IP route prefix for the destination, in dotted decimal format.
destination-prefix-mask	Prefix mask for the destination, in dotted decimal format.
vasileft	Configures the vasileft interface.
vasiright	Configures the vasiright interface.
number	Identifier of the VASI interface. The range is from 1 to 256.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 2.6	This command was introduced.

Examples

The following example shows how to configure static route on a VASI interface:

```
router(config)# ip route vrf red 0.0.0.0 0.0.0.0 vasileft 100
```

Related Commands

Command	Description
interface (vasi)	Configures the VASI interface.
debug interface (vasi)	Displays debugging information of VASI interface descriptor block.
debug vasi	Displays debugging information of VASI.
show vasi pair	Displays the status of a VASI pair.

ip scp server enable

To enable the router to securely copy files from a remote workstation, use the **ip scp server enable** command in global configuration mode. To disable secure copy functionality (the default), use the **no** form of this command.

ip scp server enable

no ip scp server enable

Syntax Description

This command has no arguments or keywords.

Defaults

The secure copy function is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)T	This command was introduced.
12.0(21)S	This command was integrated into Cisco IOS Release 12.0(21)S and support for the Cisco 7500 series and Cisco 12000 series routers was added.
12.2(18)SXD	This command was integrated into Cisco IOS Release 12.2(18)SXD.
12.2(25)S	This command was integrated into Cisco IOS Release 12.2(15)S.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.

Usage Guidelines

Use this command to enable secure copying of files from systems using the Secure Shell (SSH) application. This secure copy function is accomplished by an addition to the **copy** command in the Cisco IOS software, which takes care of using the secure copy protocol (scp) to copy to and from a router while logged in to the router itself. Because copying files is generally a restricted operation in the Cisco IOS software, a user attempting to copy such files needs to be at the correct enable level.

The Cisco IOS software must also allow files to be copied to or from itself from a remote workstation running the SSH application (which is supported by both the Microsoft Windows and UNIX operating systems). To get this information, the Cisco IOS software must have authentication and authorization configured in the authentication, authorization, and accounting (AAA) feature. SSH already relies on AAA authentication to authenticate the user username and password. Scp adds the requirement that AAA authorization be turned on so that the operating system can determine whether or not the user is at the correct privilege level.

Examples

The following example shows a typical configuration that allows the router to securely copy files from a remote workstation. Because scp relies on AAA authentication and authorization to function properly, AAA must be configured.

```
aaa new-model
aaa authentication login default tac-group tacacs+
aaa authorization exec default local
username user1 privilege 15 password 0 lab
ip scp server enable
```

The following example shows how to use scp to copy a system image from Flash memory to a server that supports SSH:

```
Router# copy flash:c4500-ik2s-mz.scp scp://user1@host1/

Address or name of remote host [host1]?
Destination username [user1]?
Destination filename [c4500-ik2s-mz.scp]?
Writing c4500-ik2s-mz.scp
Password:
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

Note When using scp, you cannot enter the password into the **copy** command; enter the password when prompted.

Related Commands

Command	Description
aaa authentication login	Sets AAA authentication at login.
aaa authorization	Sets parameters that restrict user access to a network.
copy	Copies any file from a source to a destination.
debug ip scp	Troubleshoots scp authentication problems.
ip ssh port	Enables secure network access to the tty lines.
username	Establishes a username-based authentication system.

ip sdee

To set the Security Device Event Exchange (SDEE) attribute values, use the **ip sdee** command in global configuration mode. To change the current selection or return to the default, use the **no** form of this command.

ip sdee {**alerts** *alert-number* | **messages** *message-number* | **subscriptions** *subscription-number*}

no ip sdee {**alerts** | **messages** | **subscriptions**}

Syntax Description

alerts *alert-number*	Specifies the maximum number of alerts the router must store. The range is from 10 to 2000. The default value is 200. **Note** Storing more alerts uses more router memory.
messages *message-number*	Specifies the maximum number of messages the router must store. The range is from 10 to 500. The default value is 200. **Note** Storing more messages uses more router memory.
subscriptions *subscription-number*	Specifies the maximum number of subscriptions. The range is from 1 to 3. The default value is 1.

Command Default

The default subscription is 1.
The default message is 200.
The default alert is 200.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **alerts** *alert-number* and **messages** *message-number* keywords and arguments were added.

Usage Guidelines

The SDEE messages report on the progress of Cisco IOS Intrusion Prevention System (IPS) initialization and operation. After you have enabled SDEE to receive and process events from IPS, you can issue the **ip sdee subscriptions** command to modify the number of allowed open SDEE subscriptions.

Examples

The following example shows how to change the number of allowed open subscriptions to 2:

```
Router# configure terminal
Router(config)# ip ips notify sdee
Router(config)# ip sdee events 500
Router(config)# ip sdee subscriptions 2
```

The following example shows how to change the number of alerts that must be stored on the router to 10:

```
Router# configure terminal
Router(config)# ip ips notify sdee
Router(config)# ip sdee events 500
Router(config)# ip sdee alerts 10
```

The following example shows how to change the number of messages that must be stored on the router to 10:

```
Router# configure terminal
Router(config)# ip ips notify sdee
Router(config)# ip sdee events 500
Router(config)# ip sdee messages 10
```

Related Commands

Command	Description
ip ips notify	Specifies the method of event notification.

ip sdee events

To set the maximum number of Security Device Event Exchange (SDEE) events that can be stored in the event buffer, use the **ip sdee events** command in global configuration mode. To change the buffer size or return to the default buffer size, use the **no** form of this command.

ip sdee events *events*

no ip sdee events *events*

Syntax Description

events	Maximum number of events; maximum number of allowable events: 1000.

Defaults

200 events

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

When SDEE notification is enabled (via the **ip ips notify sdee** command), 200 hundred events can automatically be stored in the buffer. When SDEE notification is disabled, all stored events are lost. A new buffer is allocated when the notifications are reenabled.

When specifying the size of an events buffer, note the following functionality:

- It is circular. When the end of the buffer is reached, the buffer will start overwriting the earliest stored events. (If overwritten events have not yet been reported, you will receive a buffer overflow notice.)
- If a new, smaller buffer is requested, all events that are stored in the previous buffer will be lost.
- If a new, larger buffer is requested, all existing events will be saved.

Examples

The following example shows how to set the maximum buffer events size to 500:

```
configure terminal
 ip ips notify sdee
 ip sdee events 500
```

Related Commands

Command	Description
ip ips notify	Specifies the method of event notification.

ip security add

To add a basic security option to all outgoing packets, use the **ip security add** command in interface configuration mode. To disable the adding of a basic security option to all outgoing packets, use the **no** form of this command.

ip security add

no ip security add

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled, when the security level of the interface is "Unclassified Genser" (or unconfigured). Otherwise, the default is enabled.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If an outgoing packet does not have a security option present, this interface configuration command will add one as the first IP option. The security label added to the option field is the label that was computed for this packet when it first entered the router. Because this action is performed after all the security tests have been passed, this label will either be the same or will fall within the range of the interface.

Examples

The following example adds a basic security option to each packet leaving Ethernet interface 0:

```
interface ethernet 0
 ip security add
```

Related Commands

Command	Description
ip security dedicated	Sets the level of classification and authority on the interface.
ip security extended-allowed	Accepts packets on an interface that has an Extended Security Option present.
ip security first	Prioritizes the presence of security options on a packet.
ip security ignore-authorities	Causes the Cisco IOS software to ignore the authorities field of all incoming packets.

Command	Description
ip security implicit-labelling	Forces the Cisco IOS software to accept packets on the interface, even if they do not include a security option.
ip security multilevel	Sets the range of classifications and authorities on an interface.
ip security reserved-allowed	Treats as valid any packets that have Reserved1 through Reserved4 security levels.
ip security strip	Removes any basic security option on outgoing packets on an interface.

ip security aeso

To attach Auxiliary Extended Security Options (AESOs) to an interface, use the **ip security aeso** command in interface configuration mode. To disable AESO on an interface, use the **no** form of this command.

ip security aeso *source compartment-bits*

no ip security aeso *source compartment-bits*

Syntax Description

source	Extended Security Option (ESO) source. This can be an integer from 0 to 255.
compartment-bits	Number of compartment bits in hexadecimal.

Defaults

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Compartment bits are specified only if this AESO is to be inserted in a packet. On every incoming packet at this level on this interface, these AESOs should be present.

Beyond being recognized, no further processing of AESO information is performed. AESO contents are not checked and are assumed to be valid if the source is listed in the configurable AESO table.

Configuring any per-interface extended IP Security Option (IPSO) information automatically enables **ip security extended-allowed** (disabled by default).

Examples

The following example defines the Extended Security Option source as 5 and sets the compartments bits to 5:

```
interface ethernet 0
 ip security aeso 5 5
```

Related Commands

Command	Description
ip security eso-info	Configures system-wide defaults for extended IPSO information.
ip security eso-max	Specifies the maximum sensitivity level for an interface.

Command	Description
ip security eso-min	Configures the minimum sensitivity level for an interface.
ip security extended-allowed	Accepts packets on an interface that has an Extended Security Option present.

ip security dedicated

To set the level of classification and authority on the interface, use the **ip security dedicated** command in interface configuration mode. To reset the interface to the default classification and authorities, use the **no** form of this command.

ip security dedicated *level authority* [*authority...*]

no ip security dedicated *level authority* [*authority...*]

Syntax Description

level	Degree of sensitivity of information. The *level* keywords are listed in Table 40.
authority	Organization that defines the set of security levels that will be used in a network. The authority keywords are listed in Table 41.

Defaults

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS release 12.(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

All traffic entering the system on this interface must have a security option that exactly matches this label. Any traffic leaving via this interface will have this label attached to it.

The following definitions apply to the descriptions of the IP Security Option (IPSO) in this section:

- level—The degree of sensitivity of information. For example, data marked TOPSECRET is more sensitive than data marked SECRET. The level keywords and their corresponding bit patterns are shown in Table 40.
