# Application Monitoring Using NetFlow Deployment Guide

● ● ● SMART BUSINESS ARCHITECTURE

August 2012 Series

# Preface

## Who Should Read This Guide

This Cisco® Smart Business Architecture (SBA) guide is for people who fill a variety of roles:

- Systems engineers who need standard procedures for implementing solutions
- Project managers who create statements of work for Cisco SBA implementations
- Sales partners who sell new technology or who create implementation documentation
- Trainers who need material for classroom instruction or on-the-job training

In general, you can also use Cisco SBA guides to improve consistency among engineers and deployments, as well as to improve scoping and costing of deployment jobs.

## Release Series

Cisco strives to update and enhance SBA guides on a regular basis. As we develop a series of SBA guides, we test them together, as a complete system. To ensure the mutual compatibility of designs in Cisco SBA guides, you should use guides that belong to the same series.

The Release Notes for a series provides a summary of additions and changes made in the series.

All Cisco SBA guides include the series name on the cover and at the bottom left of each page. We name the series for the month and year that we release them, as follows:

**month year** Series

For example, the series of guides that we released in August 2012 are the “August 2012 Series”.

You can find the most recent series of SBA guides at the following sites:

Customer access: <http://www.cisco.com/go/sba>

Partner access: <http://www.cisco.com/go/sbachannel>

## How to Read Commands

Many Cisco SBA guides provide specific details about how to configure Cisco network devices that run Cisco IOS, Cisco NX-OS, or other operating systems that you configure at a command-line interface (CLI). This section describes the conventions used to specify commands that you must enter.

Commands to enter at a CLI appear as follows:

```
configure terminal
```

Commands that specify a value for a variable appear as follows:

```
ntp server 10.10.48.17
```

Commands with variables that you must define appear as follows:

```
class-map [highest class name]
```

Commands shown in an interactive example, such as a script or when the command prompt is included, appear as follows:

```
Router# enable
```

Long commands that line wrap are underlined. Enter them as one command:

```
wrr-queue random-detect max-threshold 1 100 100 100 100 100 100 100
```

Noteworthy parts of system output or device configuration files appear highlighted, as follows:

```
interface Vlan64  
ip address 10.5.204.5 255.255.255.0
```

## Comments and Questions

If you would like to comment on a guide or ask questions, please use the [SBA feedback form](#).

If you would like to be notified when new comments are posted, an RSS feed is available from the SBA customer and partner pages.

# What's In This SBA Guide

## Cisco SBA Borderless Networks

Cisco SBA helps you design and quickly deploy a full-service business network. A Cisco SBA deployment is prescriptive, out-of-the-box, scalable, and flexible.

Cisco SBA incorporates LAN, WAN, wireless, security, data center, application optimization, and unified communication technologies—tested together as a complete system. This component-level approach simplifies system integration of multiple technologies, allowing you to select solutions that solve your organization's problems—without worrying about the technical complexity.

Cisco SBA Borderless Networks is a comprehensive network design targeted at organizations with up to 10,000 connected users. The SBA Borderless Network architecture incorporates wired and wireless local area network (LAN) access, wide-area network (WAN) connectivity, WAN application optimization, and Internet edge security infrastructure.

## Route to Success

To ensure your success when implementing the designs in this guide, you should first read any guides that this guide depends upon—shown to the left of this guide on the route below. As you read this guide, specific prerequisites are cited where they are applicable.

## About This Guide

This *deployment guide* contains one or more deployment chapters, which each include the following sections:

- **Business Overview**—Describes the business use case for the design. Business decision makers may find this section especially useful.
- **Technology Overview**—Describes the technical design for the business use case, including an introduction to the Cisco products that make up the design. Technical decision makers can use this section to understand how the design works.
- **Deployment Details**—Provides step-by-step instructions for deploying and configuring the design. Systems engineers can use this section to get the design up and running quickly and reliably.

You can find the most recent series of Cisco SBA guides at the following sites:

Customer access: <http://www.cisco.com/go/sba>

Partner access: <http://www.cisco.com/go/sbachannel>

# Introduction

## Business Overview

WANs are critical infrastructure that enable and support business processes throughout all the functions of an organization. For the staff responsible for planning, operation, and maintenance of the network and network services, it is indispensable to have visibility into the current health of the network from end-to-end. It is also essential to gather short- and long-term information in order to fully understand how the network is performing and what applications are active on the network. NetFlow data from a network is equivalent to the call detail records available from voice and video call control systems.

Items that are of high interest to an organization include:

- What applications are in use and their impact on the network.
- The specifics—who, what, when, where, and how—of the network traffic.
- The efficiency and utilization of network resources.
- The impact of changes to the network.
- Network anomalies that may signal security events.

Capacity planning is one of the most important issues faced by enterprise companies in managing their networks. More of an art than a science until recently, network capacity planning is all about balancing the need to meet user performance expectations against the realities of capital budgeting.

WAN bandwidth is expensive. Many companies attempt to control costs by acquiring the minimum bandwidth necessary to handle traffic on a circuit. This strategy can lead to congestion and degraded application performance.

Visibility into the network enables resource alignment, ensuring that resources are used appropriately in support of organizational goals. It also helps IT staff verify that quality of service (QoS) is implemented properly, so that latency-sensitive traffic, such as voice or video, receives priority. Visibility also plays a vital role in network security as continuous traffic monitoring makes it possible to detect denial-of-service (DoS) attacks, network-propagated worms, and other undesirable network events.

This guide focuses primarily on application visibility within the network.

## Technology Overview

NetFlow is an embedded capability within Cisco IOS Software on routers and switches. It allows an organization to gather traffic flow information.

In general, the key usages of NetFlow data include:

- Network planning and capacity planning.
- Real-time network monitoring.
- Application and user profiling.
- Security incident detection and classification.
- Accounting and billing.
- Network data warehousing, forensics, and data mining.
- Troubleshooting.

The benefits of NetFlow to an organization include the organization's ability to:

- Analyze new applications and their network impact by identifying changes to a known baseline.
- Reduce peak WAN traffic by using NetFlow statistics to measure WAN traffic changes associated with different application policies, and understand who is utilizing the network and who the network top-talkers are.
- Diagnose slow network performance, bandwidth hogs, and bandwidth utilization in real-time with command-line interface (CLI) or reporting tools.
- Detect unauthorized WAN traffic and avoid costly upgrades by identifying the applications that are causing congestion.
- Detect and monitor security anomalies and other network disruptions and their associated sources.
- Validate proper QoS implementation and confirm that appropriate bandwidth has been allocated to each class of service (CoS), and that no CoS is over- or under-subscribed.

## Traditional NetFlow (TNF)

Cisco NetFlow allows network devices that are forwarding traffic to collect data on individual traffic flows. Traditional NetFlow (TNF) refers to the original implementation of NetFlow, which specifically identified a flow as the unique combination of the following seven key fields:

- IPv4 source IP address
- IPv4 destination IP address
- Source port number
- Destination port number
- Layer 3 protocol type
- Type of service (ToS) byte
- Input logical interface

These key fields define a unique flow. If a flow has one different field than another flow, then it is considered a new flow.

NetFlow operates by creating a NetFlow cache entry that contains the information for all active flows on a NetFlow-enabled device. NetFlow builds its cache by processing the first packet of a flow through the standard switching path. It maintains a flow record within the NetFlow cache for all active flows. Each flow record in the NetFlow cache contains key fields, as well as additional non-key fields, that can be used later for exporting data to a collection device. Each flow record is created by identifying packets with similar flow characteristics and counting or tracking the packets and bytes per flow.

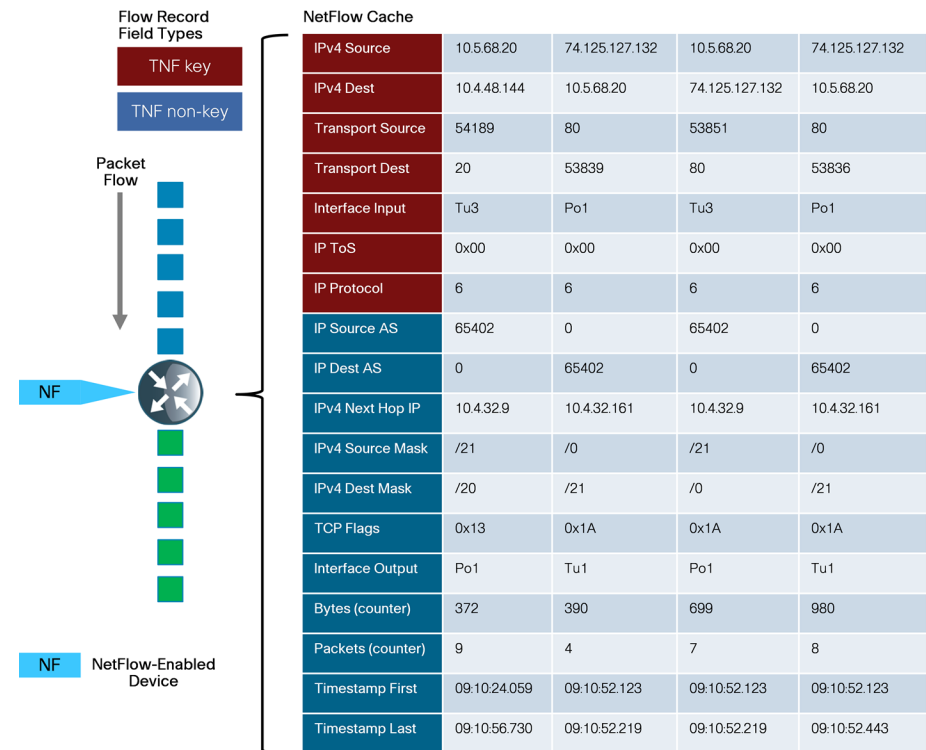

### Tech Tip

NetFlow key fields uniquely determine a flow.

NetFlow non-key fields contain additional information for each flow and are stored along with key field information.

Figure 1 - TNF cache

Originally, TNF used ingress and egress NetFlow accounting features, which are now considered legacy. NetFlow-enabled devices continue to provide backward compatibility with these accounting features implemented within a new configuration framework. These are detailed in the following sections.

## Flexible NetFlow (FNF)

Flexible NetFlow (FNF), unlike TNF, allows you to customize and focus on specific network information. You can use a subset or superset of the traditional seven key fields to define a flow. FNF also has multiple additional fields (both key and non-key). This permits an organization to target more specific information so that the total amount of information and the number of flows being exported is reduced, allowing enhanced scalability and aggregation.

The available key fields are listed in Table 1. The key fields can also be used as non-key fields if desired.

Table 1 - All FNF Key Fields

Key field type	Key field value
application	name
datalink	dot1q vlan input dot1q vlan output dot1q mac destination address input dot1q mac destination address output dot1q mac source address input dot1q mac source address output
flow	direction sampler
interface	input output
IPv4	destination address destination mask destination prefix dscp fragmentationflags fragmentation offset header-length id length header length payload length total option map precedence protocol section header size [value] section payload size [value] source address source mask source prefix tos total-length ttl version

routing	destination as destination traffic-index forwarding-status is-multicast multicast replication-factor next-hop address source as  source traffic-index vrf input
transport	destination-port icmp code icmp type igmp type source-port tcp acknowledgement-number  tcp destination-port  tcp flags  tcp header-length  tcp sequence-number  tcp source-port  tcp urgent-pointer  tcp window-size  udp destination-port  udp message-length  udp source-port

The non-key fields that can be collected for each unique flow are shown in Table 2.

Table 2 - Additional Non-key fields

Non-key field type	Non-key field value
counter	bytes
	packets
timestamp	sys-uptime first
	sys-uptime last
IPv4	total-length maximum
	total-length minimum
	ttl maximum
	ttl minimum

### Migration From TNF to FNF

The introduction of FNF support on network devices requires a new method of configuration for the additional capabilities. You can also use this new configuration CLI to configure legacy TNF, making the original configuration CLI (now referred to as classic CLI) unnecessary.

FNF includes several predefined records that you can use to start monitoring traffic in your network. The predefined records ensure backward compatibility with NetFlow collector configurations that may not include FNF support. They have a unique combination of key and non-key fields that are backward compatible with legacy TNF configurations.

The predefined record **netflow ipv4 original input** used in our deployment is functionally equivalent to the original TNF ingress and egress NetFlow accounting features that predate the usage of flow records. A comparison between the classic and new configuration methods follows.

### Traditional NetFlow—Classic CLI

```
interface GigabitEthernet0/0
 ip flow [ingress|egress]
 !
 ip flow-export destination 10.4.48.171 2055
 ip flow-export source Loopback0
 ip flow-export version 9
 ip flow-cache timeout active 1
 ip flow-cache timeout inactive 15
```

The new configuration CLI example uses the predefined **record ipv4 original-input**, which includes the TNF key and non-key fields listed in Figure 1.

This example should be used to migrate legacy-TNF deployments to the new CLI without changing device behavior.

**Tech Tip**

The predefined flow record is supported only on Cisco Aggregation Services Router 1000 (ASR1000) and Cisco Integrated Services Routers Generation 2 (ISR-G2).

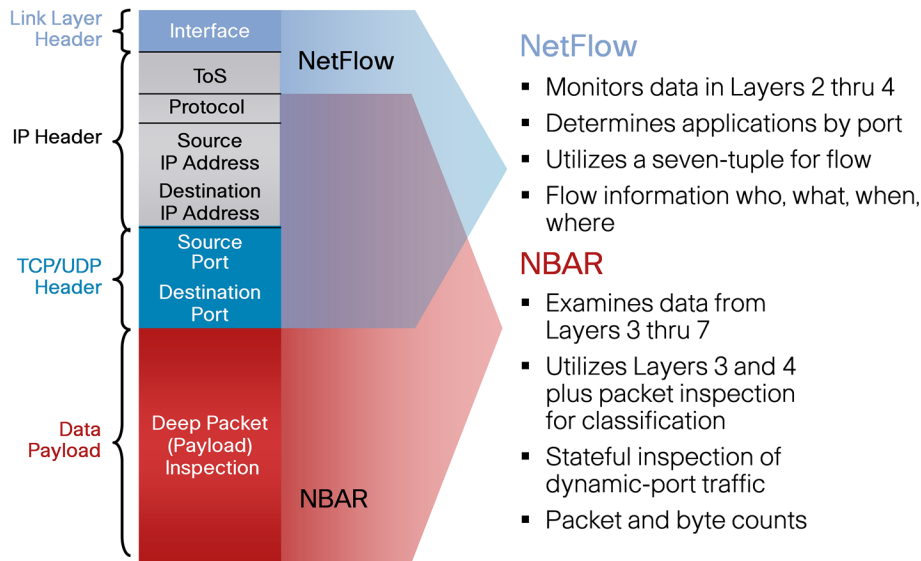

### Traditional NetFlow—New Configuration CLI

```
interface GigabitEthernet0/0
 ip flow monitor Monitor-NF [input|output]
 !
 flow exporter Export-NF-1
 destination 10.4.48.171
 source Loopback0
 transport udp 2055
 export-protocol netflow-v9
 !
 flow monitor Monitor-NF
 record netflow ipv4 original-input
 exporter Export-NF-1
 cache timeout active 1
 cache timeout inactive 15
```

### Network-Based Application Recognition (NBAR)

Network-based application recognition (NBAR) is an intelligent classification engine in Cisco IOS software that can recognize a wide variety of applications, including web-based and client/server applications. NBAR uses deep packet inspection to look within the transport layer payload to determine the associated application, as shown in Figure 2.

Figure 2 - NetFlow and NBAR integration

NBAR can classify applications that use:

- Statically assigned Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) port numbers.
- Non-UDP and non-TCP IP protocols.
- Dynamically assigned TCP and UDP port numbers negotiated during connection establishment; stateful inspection is required for classification of applications and protocols. This is the ability to discover data connections that will be classified, by passing the control connections over the data connection port where assignments are made.
- Sub-port classification; classification of HTTP (URLs, mime or host names) and Citrix applications Independent Computing Architecture (ICA) traffic, based on published application name.
- Classification based on deep-packet inspection and multiple application-specific attributes. Real-time transport protocol (RTP) payload classification is based on this algorithm, in which the packet is classified as RTP, based on multiple attributes in the RTP header.

FNF integrates seamlessly with NBAR and can gather data by using **application name** as either a key field or non-key field within a FNF flow record. The application identification provided by NBAR is more effective than using the TCP/UDP well-known-port mapping.

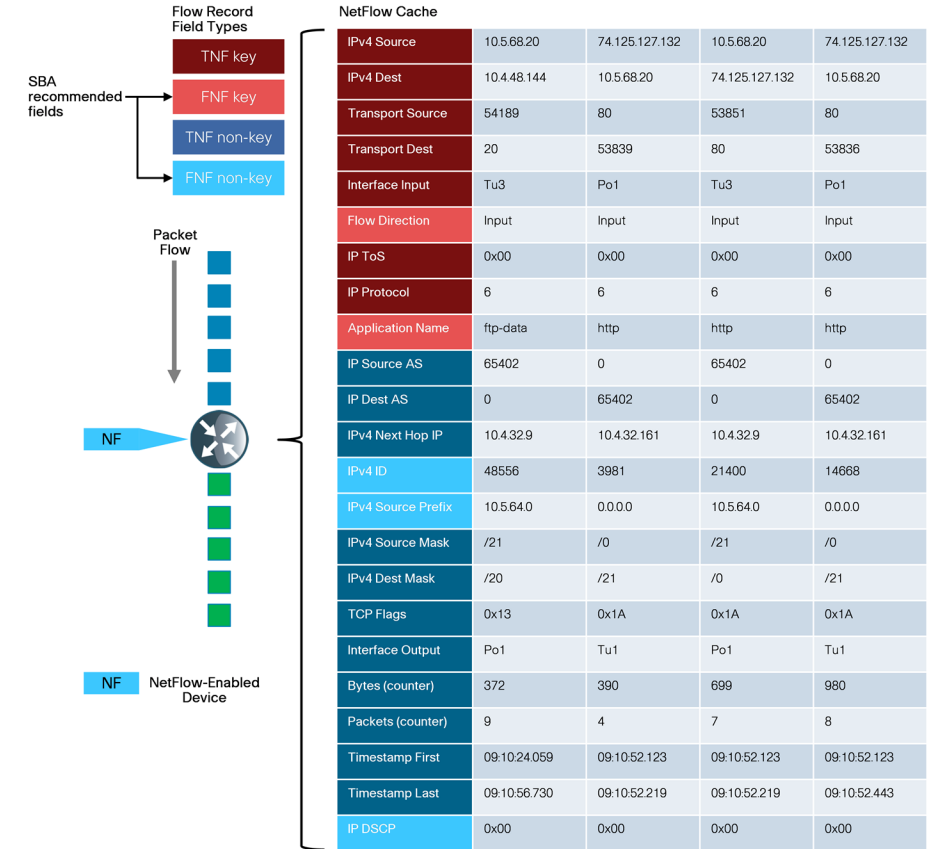

**i Tech Tip**

Application identification with NBAR is one of the key reasons to make the migration from TNF to FNF.

Note that Cisco ASR1000 does not currently support NBAR on port-channel interfaces.

The Cisco SBA implementation of FNF selects additional fields that provide improved application visibility within the deployed architecture. These additional fields are listed in Figure 3.

Figure 3 - FNF cache

## NetFlow Interaction with Encryption

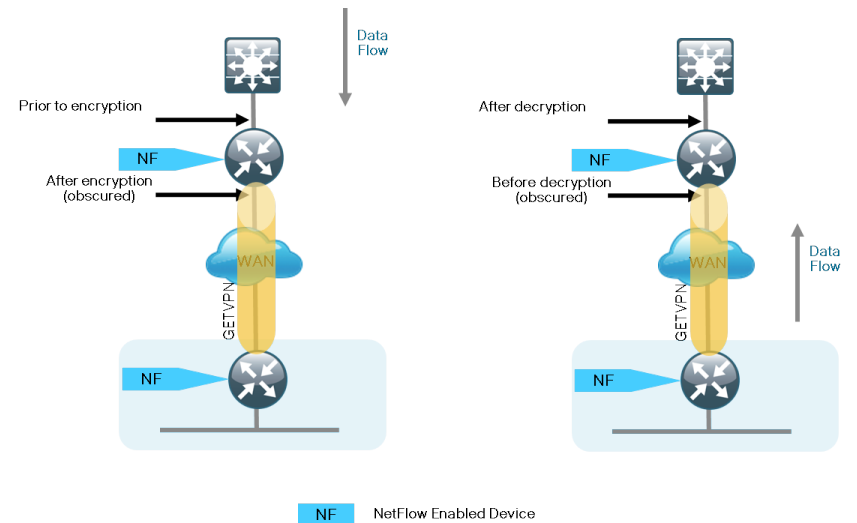

When configuring NetFlow, it is useful to understand how Cisco IOS processes traffic when transmitting and receiving network traffic on an interface. This is best shown as an ordered list, as illustrated in Figure 4.

Figure 4 - IOS order of operations

Ingress Features	Egress Features
1. Virtual Reassembly	1. Output IOS IPS Inspection
2. IP Traffic Export	2. Output WCCP Redirect
3. QoS Policy Propagation through BGP (QPPB)	3. NMI-CIDS
4. Ingress Flexible NetFlow (FNF)	4. NAT Inside-to-Outside or NAT Enable
5. Network Based Application Recognition (NBAR)	5. Network Based Application Recognition (NBAR)
6. Input QoS Classification	6. BGP Policy Accounting
7. Ingress NetFlow (TNF)	7. Lawful Intercept
8. Lawful Intercept	8. Check crypto map ACL and mark for encryption
9. IOS IPS Inspection (inbound)	9. Output QoS Classification
10. Input Stateful Packet Inspection (IOS FW)	10. Output ACL check (if not marked for encryption)
11. Check reverse crypto map ACL	11. Crypto output ACL check (if marked for encryption)
12. Input ACL (unless existing NetFlow record was found)	12. Output Flexible Packet Matching (FPM)
13. Input Flexible Packet Matching (FPM)	13. DoS Tracker
14. IPsec Decryption (if encrypted)	14. Output Stateful Packet Inspection (IOS FW)
15. Crypto inbound ACL check (if packet had been encrypted)	15. TCP Intercept
16. Unicast RPF check	16. Output QoS Marking
17. Input QoS Marking	17. Output Policing (CAR)
18. Input Policing (CAR)	18. Output MAC/Precedence Accounting
19. Input MAC/Precedence Accounting	19. IPsec Encryption
20. Nat Outside-to-Inside	20. Output ACL check (if encrypted)
21. Policy Routing	21. Egress NetFlow (TNF)
22. Input WCCP Redirect	22. Egress Flexible NetFlow (FNF)
	23. Egress RITE
	24. Output Queueing (CBWGQ, LLQ, WRED)

Based on the order of operations, to classify traffic properly NetFlow must monitor prior-to-encryption when transmitting and after-decryption when receiving. Otherwise, the actual protocols in use remain obscured and all traffic appears as IPsec with no other details available. Encrypted traffic from the WAN is properly classified by NetFlow with an outbound monitor on a corresponding LAN interface. Similarly, traffic bound for the WAN is properly classified by NetFlow with an inbound monitor on a corresponding LAN interface. This is illustrated in Figure 5.

Figure 5 - Encryption and NetFlow

## NetFlow Interaction with Application Optimization

The Cisco SBA architecture includes application optimization using Cisco Wide Area Application Services (WAAS) to accelerate and optimize data over a WAN network. Full deployment details are available in the *Cisco SBA—Borderless Networks Application Optimization Deployment Guide*.

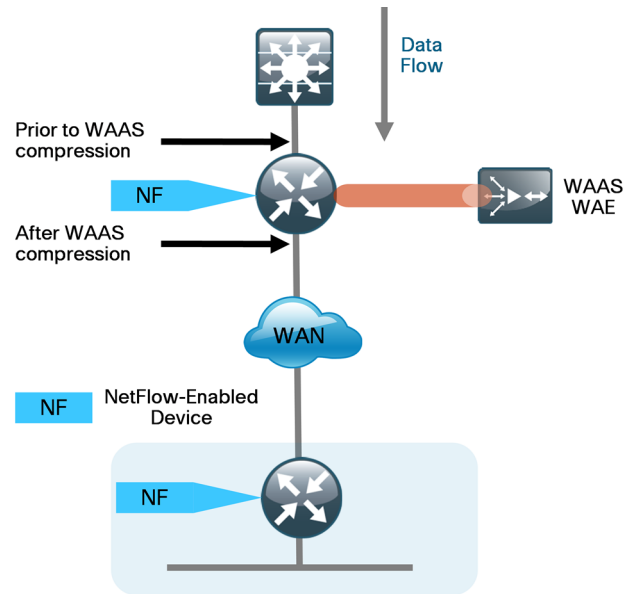

You can configure NetFlow so that information can be gathered at multiple points along the path between a source and destination. When you use application optimization, the interface you select to monitor and the direction being monitored affect the data cached by the network device. The topology in Figure 6 illustrates the potential complexity.

You can monitor traffic bound for a remote site across the WAN in two places. The flows cached inbound on the LAN-facing interface reflect uncompressed data before being optimized by Cisco WAAS. The same flows when cached outbound on the WAN-facing interface reflect compressed data that has been optimized by Cisco WAAS.

### Tech Tip

The Cisco ASR1000 router is unable to classify data using NBAR when using a port-channel interface that connects to the LAN distribution layer and GETVPN encryption on its WAN interface.

Figure 6 - Application optimization and NetFlow

The Cisco SBA recommendation for NetFlow with application optimization is to configure inbound and outbound flow monitoring on both the LAN-facing and WAN-facing interfaces. This ensures that all of the flow information is captured. The flow data that is collected on the LAN-facing interfaces provides an accurate view of the applications in use and their true network usage. The flow data that is collected on the WAN-facing interfaces accurately reflects the amount of network traffic that is transmitted and received to and from the WAN.

### Tech Tip

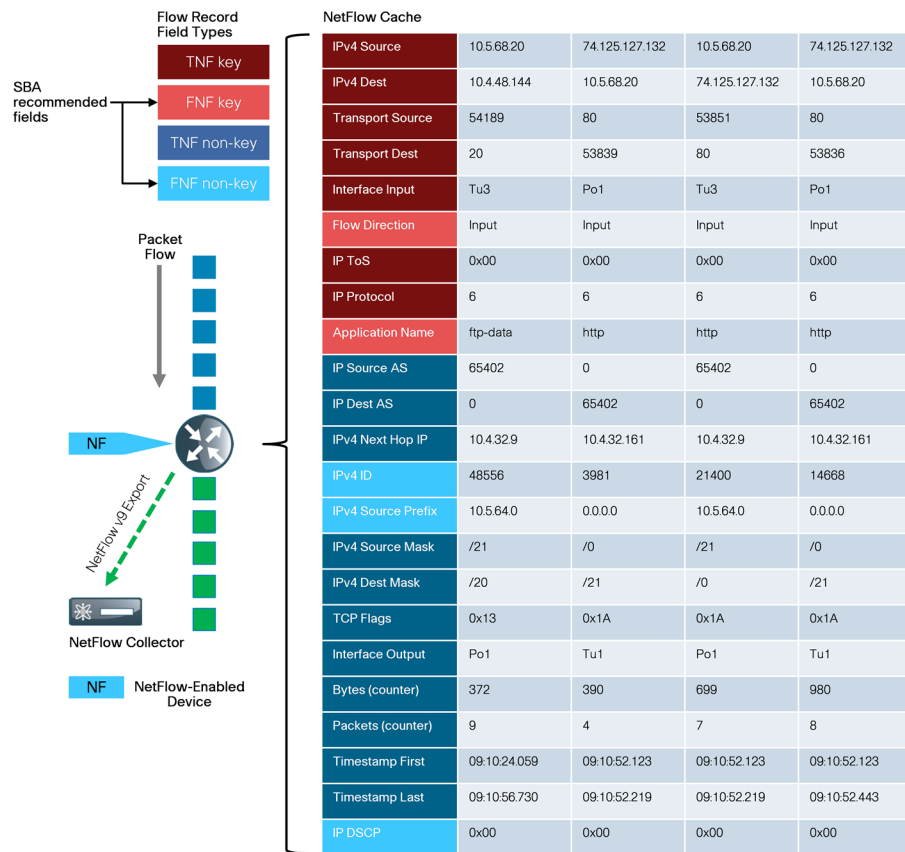

It is necessary to filter data during analysis depending on whether a LAN-facing or WAN-facing analysis is required.

### Monitoring

The NetFlow data can be viewed directly from the NetFlow-enabled device through the use of CLI show commands, but this method is somewhat cumbersome and it is difficult to correlate the data across multiple devices.

The flow details are exported to an external device running a flow collector service, as shown in Figure 7. The cached flow data is sent periodically, based upon configurable timers. The collector is capable of storing an extensive history of flow information that was switched within the NetFlow device. NetFlow is very efficient; the amount of export data is only a small percentage of the actual traffic in the router or switch. NetFlow accounts for every packet (when in non-sampled mode) and provides a highly condensed and detailed view of all network traffic that entered the router or switch. The NetFlow collector should be located in the server room or data center.

Figure 7 - NetFlow export to collector

The most effective way to view NetFlow data is through a dedicated analysis application, which is typically paired with the flow-collector service. The various applications are typically focused on traffic analysis, security (anomaly detection and denial of service), or billing. TNF-monitoring applications expect a standard set of fields to be exported. Each specific FNF-monitoring application will likely have a custom set of NetFlow attributes and a particular export format that must be configured on the NetFlow-enabled device before data can be sent to the collector.

The requirements for implementing FNF are highly dependent on which collector/analysis application you are using. In the Deployment Details section of this guide, example deployment guidance is provided for both TNF and FNF for the following applications.

Traditional NetFlow only:

- SolarWinds Orion NetFlow Traffic Analyzer (NTA)

Flexible NetFlow:

- ActionPacked! LiveAction
- Lancope StealthWatch
- Plixer Scrutinizer
- SevOne Network Management System (NMS)

This guide uses these applications for the following reasons:

- Significant usage within a typical Cisco SBA organization
- Dedicated focus on NetFlow analysis
- Ease of use
- Industry leadership with FNF support

This guide focuses on configuring TNF and FNF within a network topology supported by Cisco SBA and enables NetFlow on all devices that support FNF and NBAR with the tested hardware and software combinations. This includes the headquarters' WAN router and the remote-site routers.

# Deployment Details

Cisco routers support two NetFlow configuration methods: a newer method, which is required for FNF deployments, and an older method, which is limited to TNF deployments only. This guide focuses on the newer method, which you can use to support both FNF and TNF deployment.

FNF and TNF are enabled on the WAN routers used in Cisco SBA architecture. The WAN aggregation routers should monitor both the LAN-facing and WAN-facing interfaces, with the exception of port-channel interfaces on the Cisco ASR1000 series, as shown in Figure 8. Remote-site routers should monitor WAN-facing interfaces and either access-layer or distribution-layer-facing interfaces, as shown in Figure 9. The specific data fields collected and the appropriate timer values used on the NetFlow-enabled devices are documented in the following procedures.

Figure 8 - Where to monitor NetFlow—WAN aggregation

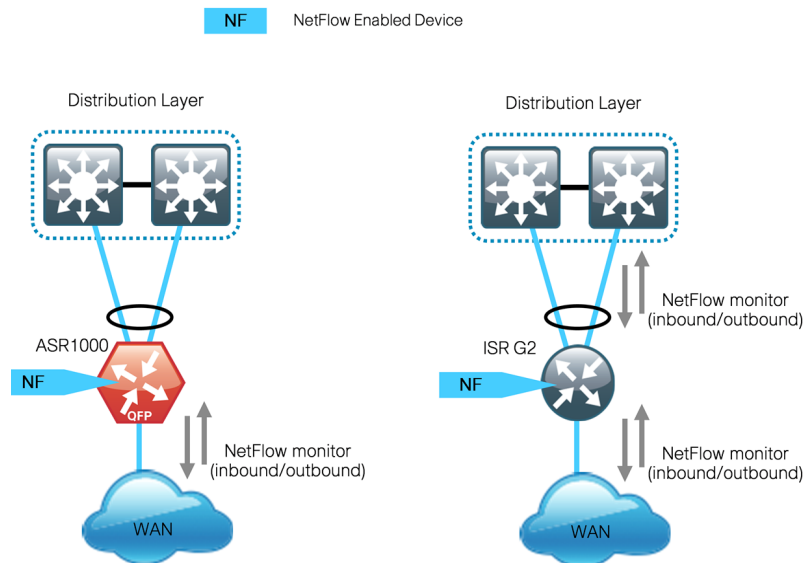

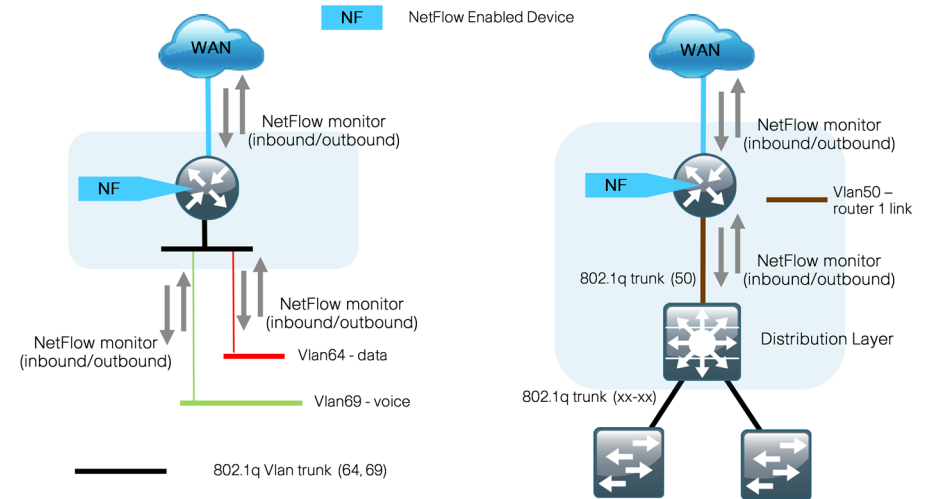

Figure 9 - Where to monitor NetFlow—WAN remote sites

The following process must be completed to enable NetFlow data collection and optional data export.

- Create an FNF flow record or select a built-in flow record to use with TNF.
- Create a flow exporter for each external NetFlow collector.
- Create a flow monitor and associate it with either a custom or built-in flow record. You must also assign one or more flow exporters if you want the data to be analyzed on an external collector.
- Assign the flow monitor to interfaces on the network device.

The procedures that follow include best practice recommendations for which key fields and non-key fields need to be collected to allow for effective application monitoring on your network. This guide includes two sets of examples within the procedures. These examples illustrate how to integrate with NetFlow collectors that support only TNF, as well as NetFlow collectors that support FNF.

## Process

Configuring a Device to Export NetFlow Information

1. Create flexible NetFlow flow record
2. Create flow exporter
3. Create a flow monitor
4. Apply flow monitor to WAN and LAN

### Procedure 1 Create flexible NetFlow flow record

Flexible NetFlow (FNF) requires the explicit configuration of a flow record that consists of both key fields and non-key fields. This procedure provides guidance on how to configure a user-defined flow record that includes all of the TNF fields (key and non-key) as well as additional FNF fields (key and non-key). The resulting flow record includes the full subset of TNF fields used in classic NetFlow deployments.

**Step 1:** Specify key fields. This determines unique flow. Be sure to include a separate match statement for each key field.

#### Tech Tip

It is recommended that you use the TNF key fields, listed in Table 3, and the additional FNF key fields, listed in Table 2.

```
flow record [record name]
description [record description]
match [key field type] [key field value]
```

Table 3 - Recommended TNF key fields (TNF and FNF)

Key field type	Key field value
ipv4	tos
	protocol
	source address
	destination address
transport	source port
	destination port
interface	input
flow	sampler

Table 4 - Recommended additional FNF key fields (FNF only)

Key field type	Key field value	Comments
flow	direction	Allows for ingress/egress flow collection on same interface
application	name	Enables collection of NBAR information for each flow

#### Tech Tip

Cisco ASR1000 does not currently support NBAR on port-channel interfaces, and when using **application name** as a key-field in a flow record, you cannot apply the flow monitor to port-channel interfaces on this platform.

**Step 2:** Specify non-key fields to be collected for each unique flow. Be sure to include a separate collect statement for each non-key field.

Flexible NetFlow allows for the use of additional user specified non-key fields. It is recommended that you use the additional TNF non-key fields listed in Table 5, and the additional FNF non-key fields listed in Table 4.

```
flow record [record name]
  collect [non-key field type] [non-key field value]
```

Table 5 - Recommended TNF non-key fields (TNF and FNF)

Non-key field type	Non-key field value
routing	source as destination as next-hop address ipv4
ipv4	source mask destination mask
transport	tcp flags
Interface	output
counter	bytes packets
timestamp	sys-uptime first sys-uptime last

Table 6 - Recommended additional FNF non-key fields (FNF only)

Non-key field type	Key field value	Comments
ipv4	dscp id source prefix source mask	Additional IPv4 information for each flow

## Example

```
flow record Record-FNF
  description Flexible NetFlow with NBAR Flow Record
  match ipv4 tos
  match ipv4 protocol
  match ipv4 source address
  match ipv4 destination address
  match transport source-port
  match transport destination-port
  match interface input
  match flow direction
  match application name
  collect routing source as
  collect routing destination as
  collect routing next-hop address ipv4
  collect ipv4 dscp
  collect ipv4 id
  collect ipv4 source prefix
  collect ipv4 source mask
  collect ipv4 destination mask
  collect transport tcp flags
  collect interface output
  collect counter bytes
  collect counter packets
  collect timestamp sys-uptime first
  collect timestamp sys-uptime last
```

## Procedure 2

### Create flow exporter

**Step 1:** The NetFlow data that is stored in the cache of the network device can be more effectively analyzed when exported to an external collector.

Creating a flow exporter is only required when exporting data to an external collector. This procedure may be skipped if data is analyzed only on the network device.

## Reader Tip

Most external collectors use SNMP to retrieve the interface table from the network device. Ensure that you have completed the relevant SNMP procedures for your platform.

WAN router procedures are listed in the *Cisco SBA—Borderless Networks MPLS WAN Deployment Guide, Layer 2 WAN Deployment Guide*, or *VPN WAN Deployment Guide*.

**Step 2:** Different NetFlow collector applications support different export version formats (v5 and v9) and expect to receive the exported data on a particular UDP or TCP port. In this deployment, the collector applications used for testing use the parameters designated in Table 7.

Table 7 - Tested NetFlow collector parameters

Vendor	Application	Version	Capability	Export protocol	Destination port
ActionPacked!	LiveAction	2.42	Flexible NetFlow	netflow-v9	UDP 2055
Cisco	Prime Assurance Manager	1.1	Flexible NetFlow	netflow-v9	UDP 9991
Plixer	Scrutinizer	9.01	Flexible NetFlow	netflow-v9	UDP 2055
SevOne	Network Management System	4.1.3.74	Flexible NetFlow	netflow-v9	UDP 9996
SolarWinds	NetFlow Traffic Analyzer	3.9.0	Traditional NetFlow	netflow-v9	UDP 2055

**Step 3:** Configure a basic flow exporter.

```

flow exporter [exporter name]
description [exporter description]
destination [NetFlow collector IP address]
source Loopback0
transport [UDP or TCP] [port number]
export-protocol [export protocol]

```

**Step 4:** If you are exporting FNF records in NetFlow v9 format, export the interface table for FNF.

```

flow exporter [exporter name]
option interface-table

```

**Step 5:** If you are using an NBAR flow record, export the NBAR application table.

```

flow exporter [exporter name]
option application-table

```

**Step 6:** If you are using the Cisco ISR-G2 series routers, enable **output-features**. Otherwise, NetFlow traffic that originates from a WAN remote-site router will not be encrypted or tagged using QoS.

```

flow exporter [exporter name]
output-features

```

### Example (FNF with Plixer)

```

flow exporter Export-FNF-Plixer
description FNF v9
destination 10.4.48.171
source Loopback0
output-features ! this command is not required on ASR1000
routers
transport udp 2055
export-protocol netflow-v9
option interface-table
option application-table

```

### Example (TNF with SolarWinds)

```
flow exporter Export-TNF-Solarwinds
description TNF v9
destination 10.4.48.173
output-features ! this command is not required on ASR1000
routers
source Loopback0
transport udp 2055
export-protocol netflow-v9
```

### Procedure 3 Create a flow monitor

The network device must be configured to monitor the flows through the device on a per-interface basis. The flow monitor must include a flow record and optionally one or more flow exporters if data is to be collected and analyzed. After the flow monitor is created, it is applied to device interfaces. The flow monitor stores flow information in a cache and the timer values for this cache are modified within the flow monitor configuration. It is recommended that you set the timeout active timer to 60 seconds, which exports flow data on existing long-lived flows.

**Step 1:** Create the flow monitor, and then set the cache timers.

```
flow monitor [monitor name]
description [monitor description]
cache timeout active 60
```

**Step 2:** Associate the flow record to the flow monitor. You can use either a custom or a built-in flow record.

```
flow monitor [monitor name]
record [record name]
```

**Step 3:** If you are using an external NetFlow collector, associate the exporters to the flow monitor. If you are using multiple exporters, add additional lines.

```
flow monitor [monitor name]
exporter [exporter name]
```

### Example (FNF with Plixer)

```
flow monitor Monitor-FNF
description FNF/NBAR Application Traffic Analysis
record Record-FNF
exporter Export-FNF-Plixer
cache timeout active 60
```

### Example (TNF using a predefined record with SolarWinds)

#### Tech Tip

**netflow ipv4 original-input** is a predefined built-in record that emulates the classic CLI for TNF.

```
flow monitor Monitor-TNF
description TNF Traffic Analysis
record netflow ipv4 original-input
exporter Export-TNF-Solarwinds
cache timeout active 60
```

## Procedure 4 Apply flow monitor to WAN and LAN

A best practice for NetFlow is to monitor all inbound and outbound traffic to the network device. This method covers all traffic regardless of encryption or application optimization.

### Tech Tip

Be sure to apply the flow monitor to all device interfaces.

The Cisco ASR1000 series routers do not currently support NBAR on port-channel interfaces.

**Step 1:** Apply the flow monitor to the device interface.

```
interface [name]
ip flow monitor [monitor name] input
ip flow monitor [monitor name] output
```

### Example - FNF

```
interface GigabitEthernet0/0
description MPLS WAN Uplink
ip flow monitor Monitor-FNF input
ip flow monitor Monitor-FNF output
interface GigabitEthernet0/2.64
description Wired Data
ip flow monitor Monitor-FNF input
ip flow monitor Monitor-FNF output
```

### Example - TNF

```
interface GigabitEthernet0/0
description MPLS WAN Uplink
ip flow monitor Monitor-TNF input
ip flow monitor Monitor-TNF output
interface GigabitEthernet0/2.64
description Wired Data
```

```
ip flow monitor Monitor-TNF input
ip flow monitor Monitor-TNF output
```

## Process

Monitoring NetFlow Data

1. View raw flow data unfiltered
2. Filter and view flow data
3. Review reports from NetFlow collectors

The data stored in the cache of the network device can be viewed in a number of different ways to address common-use cases. These methods are covered briefly to provide examples of how to access the flow data.

## Procedure 1 View raw flow data unfiltered

The simplest method to view the NetFlow cache is via the following command, which provides a summary of the cache status followed by a series of individual cache entries.

**Step 1:** Display the NetFlow cache.

```
show flow monitor [monitor name] cache
```

### Example

```
Router#show flow monitor Monitor-FNF cache
Cache type:                               Normal
Cache size:                               4096
Current entries:                           55
High Watermark:                            4096
Flows added:                               2188410
Flows aged:                                2188355
- Active timeout      ( 60 secs)  153722
- Inactive timeout    ( 15 secs)  1984047
```

```

- Event aged                                0
- Watermark aged                            37846
- Emergency aged                            12740
IPV4 SOURCE ADDRESS:                        10.11.4.10
IPV4 DESTINATION ADDRESS:                   172.16.50.80
TRNS SOURCE PORT:                           52790
TRNS DESTINATION PORT:                       80
INTERFACE INPUT:                             Po1.64
FLOW DIRECTION:                              Input
IP TOS:                                       0x00
IP PROTOCOL:                                 6
APPLICATION NAME:                            nbar http
ipv4 next hop address:                       192.168.6.134
ipv4 id:                                     355
ipv4 source prefix:                          10.11.4.0
ipv4 source mask:                            /24
ipv4 destination mask:                       /0
tcp flags:                                   0x18
interface output:                            Gi0/0
counter bytes:                               2834
counter packets:                             38
timestamp first:                             14:30:03.102
timestamp last:                              14:30:03.734
ip dscp:                                     0x00

```

Table 8 - NetFlow cache filter parameters

Field type	Available parameters
application	name [value]
counter	bytes [value] flows [value] packets [value]
flow	direction input direction output
interface	input [interface type][number] output [interface type][number]
IPv4	destination address [value] destination mask [value] dscp [value] id [value] protocol [value] source address [value] source mask [value] tos [value]
routing	next-hop address ipv4 [value]
timestamp	sys-uptime first [value] sys-uptime last [value]
transport	destination-port [value] source-port [value] tcp flags [value]

## Procedure 2 Filter and view flow data

### (Optional)

If you know specific fields, such as the source or destination IP-address or the TCP/UDP port number, then you can search the cache for exact matches, or use regular expressions for broader match criteria.

**Step 1:** Display the filtered NetFlow cache.

```
show flow monitor [monitor name] cache filter [filter parameters]
```

### Example

The following command shows how to verify that RTP streams have the proper QoS differentiated-services code point (DSCP) settings.

### Tech Tip

Interactive video is configured to use DSCP cs4 and af41.

```
cs4 = 0x20
af41 = 0x22
```

Router#**show flow monitor Monitor-FNF cache filter application**

**name regexp rtp**

```

IPV4 SOURCE ADDRESS:      10.11.4.40
IPV4 DESTINATION ADDRESS: 10.10.48.27
TRNS SOURCE PORT:        2454
TRNS DESTINATION PORT:   51124
INTERFACE INPUT:         Gi0/0
FLOW DIRECTION:          Input
IP TOS:                   0x88
IP PROTOCOL:             17
APPLICATION NAME:        nbar rtp
ipv4 next hop address:   10.10.32.1
ipv4 id:                  0
ipv4 source prefix:      10.11.0.0
ipv4 source mask:        /16
ipv4 destination mask:   /24
tcp flags:                0x00
interface output:        Po32
counter bytes:           875384
counter packets:         2391
timestamp first:         15:32:52.027
timestamp last:          15:33:39.827
ip dscp:                  0x22

```

**Step 2:** Sort and format flow data.

The same fields that are available for searching the NetFlow cache are also available as simple sort fields. You can select any parameter from Table 9 and sort from either highest to lowest or lowest to highest. Additionally, you can format the command output in multiple ways, as listed in Table 8, with the table output being most suitable for determining top traffic sources or destinations.

```

show flow monitor [monitor name] cache sort [filter
parameters]

```

Table 9 - NetFlow cache sort parameters

Field type	Available parameters
application	name
counter	bytes flows packets
flow	direction input direction output
highest (default)	—
interface	input [interface type][number] output [interface type][number]
IPv4	destination address [value] destination mask [value] dscp [value] id [value] protocol [value] source address [value] source mask [value] tos [value]
lowest	—
routing	next-hop address ipv4 [value]
timestamp	sys-uptime first [value] sys-uptime last [value]
transport	destination-port [value]  source-port [value]  tcp flags [value]

Table 10 - NetFlow cache output formats

Format type	Available parameters
csv	Suitable for cut/paste export
record (default)	Best for viewing individual cache entries
table	Suitable for on-screen display (requires 316 character width)

## Example

The following command shows how to view the cache sorted by **counter bytes** and formatted as a table for on-screen viewing.

```
Router#show flow monitor Monitor-FNF cache sort counter bytes
format table
```

The following is partial output from the **show flow monitor** command. For an example of the full output, see [Appendix B](#).

```
Router#show flow monitor Monitor-FNF cache sort counter bytes
format table
```

```
Processed 57 flows
Aggregated to 57 flows
Showing the top 20 flows
```

### Procedure 3 Review reports from NetFlow collectors

This procedure highlights the types of reports that are available from Plixer Scrutinizer and SolarWinds NTA.

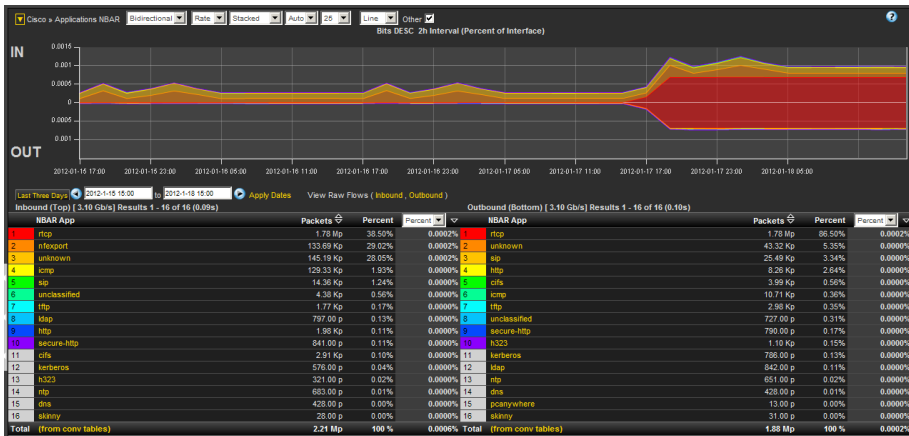

One key advantage of using an external collector is the ability to aggregate the information collected across multiple network devices. A good collector provides the ability to view data collected from a particular device and interface, as well as correlate data collected across multiple devices and interfaces across the network.

Figure 10 - SolarWinds NTA endpoint summary

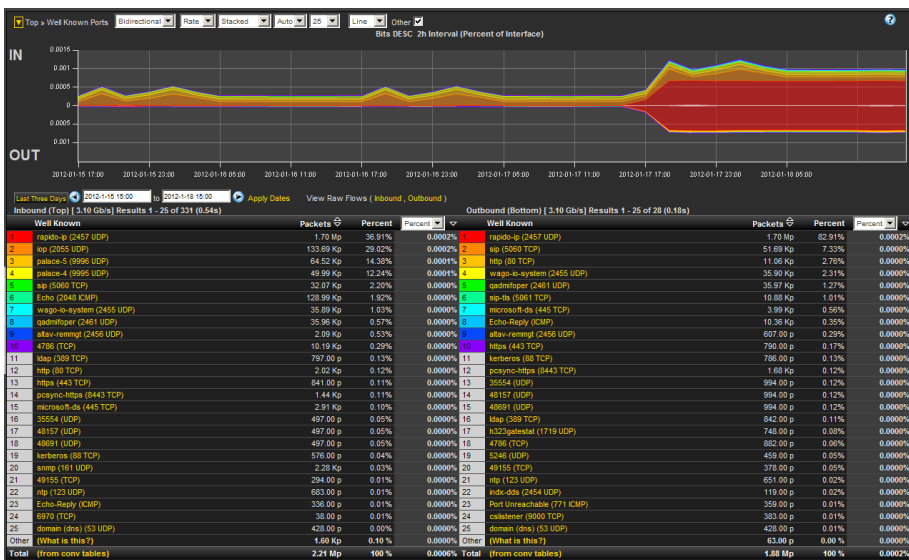

The NetFlow data, cached locally on the network device, is relatively short lived, and is typically aged-out by new flows within minutes. An external collector is essential to maintain a long-term view of the traffic patterns on a network. The applications in use are most accurately determined by using FNF and NBAR.

Figure 11 - Plixer Scrutinizer—applications NBAR report (72-hour timespan)

To fully illustrate the value of NBAR to identify applications requires a comparison, because TNF can only identify applications through the use of either TCP or UDP well-known port (WKP). Since Plixer supports FNF and NBAR, as well as TNF, you can generate the same report by using WKP.

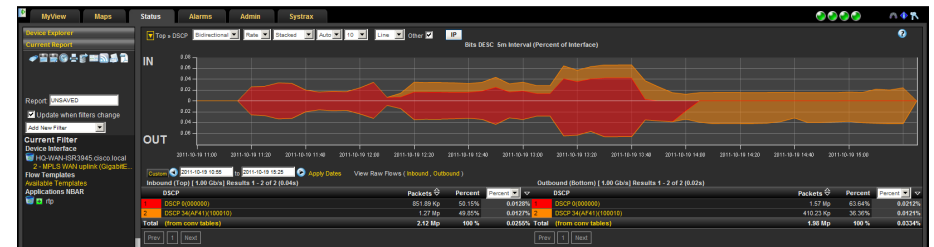

Figure 12 - Plixer Scrutinizer WKP report (72-hour timespan)

The primary difference is that, today, many applications, including video conferencing, tend to use a broad range of TCP or UDP ports that are dynamically chosen within a large, known range. Various WKPs may fall within these ranges, and without additional application awareness provided by NBAR, the NetFlow collectors identify the applications incorrectly.

NetFlow is well-suited for identifying, isolating, and correcting network problems, especially configuration problems that might manifest across multiple devices, such as a misconfigured QoS policy. You can generate a report that filters down to an individual conversation between two endpoints that should be tagged bi-directionally with a specific DSCP value, such as an RTP video stream. If any intermediate devices along the path between the endpoints do not consistently show the data to be properly tagged, then there is likely to be a misconfigured device.

Figure 13 - Plixer Scrutinizer DSCP report (before/after resolving QoS trust boundary)

The report shown in Figure 13 was generated by selecting a DSCP report for a headquarters' WAN router and filtered to show only RTP traffic. The report shows RTP incorrectly tagged with DSCP 0.

This issue was resolved by checking the QoS trust boundaries between LAN switches that connected the router to the video endpoints. After finding and correcting the problem, the report was regenerated to verify that the configuration change worked properly. The report now shows that RTP is properly tagged as AF41 (DSCP 34).

# Appendix A: Product List

## WAN Aggregation

## Notes

# Appendix D: Changes

This appendix summarizes the changes to this guide since the previous Cisco SBA series.

- We added the Cisco ASR1000 Series router as a WAN-aggregation router.
- We added additional NetFlow collector applications.

## Notes

## Feedback

SMART BUSINESS ARCHITECTURE

ALL DESIGNS, SPECIFICATIONS, STATEMENTS, INFORMATION, AND RECOMMENDATIONS (COLLECTIVELY, "DESIGNS") IN THIS MANUAL ARE PRESENTED "AS IS," WITH ALL FAULTS. CISCO AND ITS SUPPLIERS DISCLAIM ALL WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT OR ARISING FROM A COURSE OF DEALING, USAGE, OR TRADE PRACTICE. IN NO EVENT SHALL CISCO OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO DATA ARISING OUT OF THE USE OR INABILITY TO USE THE DESIGNS, EVEN IF CISCO OR ITS SUPPLIERS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. THE DESIGNS ARE SUBJECT TO CHANGE WITHOUT NOTICE. USERS ARE SOLELY RESPONSIBLE FOR THEIR APPLICATION OF THE DESIGNS. THE DESIGNS DO NOT CONSTITUTE THE TECHNICAL OR OTHER PROFESSIONAL ADVICE OF CISCO, ITS SUPPLIERS OR PARTNERS. USERS SHOULD CONSULT THEIR OWN TECHNICAL ADVISORS BEFORE IMPLEMENTING THE DESIGNS. RESULTS MAY VARY DEPENDING ON FACTORS NOT TESTED BY CISCO.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.
