AnnotationTarget

```

Contains the list of possible annotation's retentions.

Determines how an annotation is stored in binary output.

```

public enum class AnnotationRetention {
    /**
     * Annotation isn't stored in binary output
     */
    SOURCE,
    /**
     * Annotation is stored in binary output, but invisible for reflection
     */
    BINARY,
    /**
     * Annotation is stored in binary output and visible for reflection (default retention)
     */
    RUNTIME
}

```

This meta-annotation indicates the kinds of code elements which are possible targets of an annotation.

If the target meta-annotation is not present on an annotation declaration, the annotation is applicable to the following elements: `[CLASS]`, `[PROPERTY]`, `[FIELD]`, `[LOCAL_VARIABLE]`, `[VALUE_PARAMETER]`, `[CONSTRUCTOR]`, `[FUNCTION]`, `[PROPERTY_GETTER]`, `[PROPERTY_SETTER]`.

`@property` allowedTargets list of allowed annotation targets

```

@Target(AnnotationTarget.ANNOTATION_CLASS)
@MustBeDocumented
public annotation class Target(
    vararg val allowedTargets: AnnotationTarget
)

```

This meta-annotation determines whether an annotation is stored in binary output and visible for reflection. By default, both are true.

`@property` value necessary annotation retention (`RUNTIME`, `BINARY` or `SOURCE`)

```

@Target(AnnotationTarget.ANNOTATION_CLASS)
public annotation class Retention(
    val value: AnnotationRetention = AnnotationRetention.RUNTIME
)

```

This meta-annotation determines that an annotation is applicable twice or more on a single code element

```

coroutine is started directly in the invoker's thread without going through the [ContinuationInterceptor] that might be present in the completion's [CoroutineContext]. It is the invoker's responsibility to ensure that a proper invocation context is established. Starts an unintercepted coroutine with receiver type [R] and result type [T] and executes it until its first suspension. Returns the result of the coroutine or throws its exception if it does not suspend or [COROUTINE\_SUSPENDED] if it suspends. In the latter case, the [completion] continuation is invoked when the coroutine completes with a result or an exception. internal actual inline fun <R, P, T> (suspend R.(P) -> T).startCoroutineUninterceptedOrReturn(
 receiver: R, param: P, completion: Continuation<T>): Any? = this.asDynamic()(receiver, param, completion, false)

Creates unintercepted coroutine without receiver and with result type [T]. This function creates a new, fresh instance of suspendable computation every time it is invoked. To start executing the created coroutine, invoke `resume(Unit)` on the returned [Continuation] instance. The [completion] continuation is invoked when coroutine completes with result or exception. This function returns unintercepted continuation. Invocation of `resume(Unit)` starts coroutine immediately in the invoker's call stack without going through the [ContinuationInterceptor] that might be present in the completion's [CoroutineContext]. It is the invoker's responsibility to ensure that a proper invocation context is established. Note that [completion] of this function may get invoked in an arbitrary context. [Continuation.intercepted] can be used to acquire the intercepted continuation. Invocation of `resume(Unit)` on intercepted continuation guarantees that execution of both the coroutine and [completion] happens in the invocation context established by [ContinuationInterceptor]. Repeated invocation of any resume function on the resulting continuation corrupts the state machine of the coroutine and may result in arbitrary behaviour or exception.

```

@SinceKotlin("1.3")
public actual fun <T> (suspend () -> T).createCoroutineUnintercepted(
    completion: Continuation<T>): Continuation<Unit> =
    // Kotlin/JS suspend lambdas have an extra parameter `suspended`

        // When `suspended` is true the continuation is created, but not executed
        this.asDynamic()(completion, true)
    } else {
        createCoroutineFromSuspendFunction(completion) {
            this.asDynamic()(completion)
        }

The compiler produces mangled names for functions with parameters, which is unnatural for usual JavaScript developer.\n \* You can put `@JsName(...)` on functions you want to be available from JavaScript.\n \* \* For some reason you want to rename declaration, e.g. there's common term in JavaScript for a concept provided by the declaration, which is uncommon in Kotlin.\n \* Example:\n \* ``` kotlin\n \* class Person(val name: String) {\n \* fun hello() {\n \* println("Hello \$name!")\n \* }\n \* @JsName("helloWithGreeting")\n \* fun hello(greeting: String) {\n \* println("\$greeting \$name!")\n \* }\n \* }\n \* ```\n \* @property name the name which compiler uses both for declaration itself and for all references to the declaration.\n \* It's required to denote a valid JavaScript identifier.\n \*\n \*/\n@Retention(AnnotationRetention.BINARY)\n@Target(CLASS, FUNCTION, PROPERTY, CONSTRUCTOR, PROPERTY\_GETTER, PROPERTY\_SETTER)\npublic actual annotation class JsName(actual val name: String)\n\n\*\*\n \* Denotes an `external` declaration that must be imported from native JavaScript library.\n \*\n \* The compiler produces the code relevant for the target module system, for example, in case of CommonJS,\n \* it will import the declaration via the `require(...)` function.\n \*\n \* The annotation can be used on top-level external declarations (classes, properties, functions) and files.\n \* In case of file (which can't be `external`) the following rule applies:\n \*\n \* all the declarations in the file must be `external`. By applying `@JsModule(...)` on a file you tell the compiler to import a JavaScript object that contain all the declarations from the file.\n \*\n \* Example:\n \* ``` kotlin\n \* @JsModule("jquery")\n \* external abstract class JQuery() {\n \* // some declarations here\n \* }\n \*\n \* @JsModule("jquery")\n \* external fun JQuery(element: Element): JQuery\n \* ```\n \*\n \* @property import name of a module to import declaration from.\n \* It is not interpreted by the Kotlin compiler, it's passed as is directly to the target module system.\n \*\n \* @see JsNonModule\n \*\n \*/\n@Retention(AnnotationRetention.BINARY)\n@Target(CLASS, PROPERTY, FUNCTION, FILE)\npublic annotation class JsModule(val import: String)\n\n\*\*\n \* Denotes an `external` declaration that can be used without module system.\n \*\n \* By default, an `external` declaration is available regardless your target module system.\n \*\n \* However, by applying [JsModule] annotation you can make a declaration unavailable to plain module system.\n \*\n \* Some JavaScript libraries are distributed both as a standalone downloadable piece of JavaScript and as a module available as an npm package.\n \*\n \* To tell the Kotlin compiler to accept both cases, you can augment [JsModule] with the `@JsNonModule` annotation.\n \*\n \* For example:\n \* ``` kotlin\n \* @JsModule("jquery")\n \* @JsNonModule\n \* @JsName("\$")\n \* external abstract class JQuery() {\n \* // some declarations here\n \* }\n \*\n \* @JsModule("jquery")\n \* @JsNonModule\n \* @JsName("\$")\n \* external fun JQuery(element: Element): JQuery\n \* ```\n \*\n \* @see JsModule\n \*\n \*/\n@Retention(AnnotationRetention.BINARY)\n@Target(CLASS, PROPERTY, FUNCTION, FILE)\npublic annotation class JsNonModule\n\n\*\*\n \* Adds prefix to `external` declarations in a source file.\n \*\n \* JavaScript does not have concept of packages (namespaces). They are usually emulated by nested objects.\n \*\n \* The compiler turns references to `external` declarations either to plain unprefix names (in case of plain modules)\n \* or to plain imports.\n \*\n \* However, if a JavaScript library provides its declarations in packages, you won't be satisfied with this.\n \*\n \* You can tell the compiler to generate additional prefix before references to `external` declarations using the `@JsQualifier(...)` annotation.\n \*\n \* Note that a file marked with the `@JsQualifier(...)` annotation can't contain non-`external` declarations.\n \*\n \* Example:\n \* ```\n \* @file:JsQualifier("my.jsPackageName")\n \* ```

```

extension functions:
- [Iterable.groupingBy]
- [Sequence.groupingBy]
- [Array.groupingBy]
- [CharSequence.groupingBy]

For the list of group-and-fold operations available, see the [extension functions](#extension-functions) for `Grouping`.

    fun sourceIterator(): Iterator<T>
    /** Extracts the key of an [element]. */
    fun keyOf(element: T): K
}

Groups elements from the [Grouping] source by key and applies [operation] to the elements of each group sequentially, passing the previously accumulated value and the current element as arguments, and stores the results in a new map.

The key for each element is provided by the [Grouping.keyOf] function.

@param operation function is invoked on each element with the following parameters:
- `key`: the key of the group this element belongs to;
- `accumulator`: the current value of the accumulator of the group, can be `null` if it's the first `element` encountered in the group;
- `element`: the element from the source being aggregated;
- `first`: indicates whether it's the first `element` encountered in the group.

}

Groups elements from the [Grouping] source by key and applies [operation] to the elements of each group sequentially, passing the previously accumulated value and the current element as arguments, and stores the results in the given [destination] map.

The
```

```
key for each element is provided by the [Grouping.keyOf] function.

@param operation a function that is invoked on each element with the following parameters:

- `element`: the element from the source being aggregated;
- `first`: indicates whether it's the first `element` encountered in the group.

If the [destination] map already has a value corresponding to some key, then the elements being aggregated for that key are never considered as `first`.

Groups elements from the [Grouping] source by key and applies [operation] to the elements of each group sequentially, passing the previously accumulated value and the current element as arguments, and stores the results in a new map.

An initial value of accumulator is provided by [initialValueSelector] function.

@param initialValueSelector a function that provides an initial value of accumulator for each group.

It's invoked with parameters:

- `element`: the first element being encountered in that group.

@param operation a function that is invoked on each element with the following parameters:
- `key`: the key of the group this element belongs to;

elements from the [Grouping] source by key and applies [operation] to the elements of each group sequentially, passing the previously accumulated value and the current element as arguments, and stores the results in the given [destination] map. An initial value of accumulator is provided by [initialValueSelector] function.

@param initialValueSelector a function that provides an initial value of accumulator for each group. It's invoked with parameters:

- key: the key of the group;
- element: the first element being encountered in that group.

If the [destination] map already has a value corresponding to some key, that value is used as an initial value of the accumulator for that group and the [initialValueSelector] function is not called for that group.

@param operation a function that is invoked on each element with the following parameters:

- key: the key of the group this element belongs to;
- accumulator: the current value of the accumulator of the group;
- element: the element from the source being accumulated.

@return the [destination] map associating the key of each group with the result of accumulating the group elements.

inference are either members of the receiver type of an annotated function parameter or\n * extensions for that type.
The extensions must be themselves annotated with `@BuilderInference`.\n *\n * Example: we declare\n * ```\n * fun
<T> sequence(@BuilderInference block: suspend SequenceScope<T>().() -> Unit): Sequence<T>\n * ```\n * and use
it like\n * ```\n * val result = sequence { yield("result") }\n * ```\n * Here the type argument of the resulting
sequence is inferred to `String` from\n * the argument of the [SequenceScope.yield] function, that is called inside
the lambda passed to [sequence].\n *\n * Note: this annotation is experimental, see [ExperimentalTypeInference] on

@OverloadResolutionByLambdaReturnType\n * fun create(intProducer: () -> Int): Int\n * fun
create(doubleProducer: () -> Double): Double\n * val newValue = create { 3.14 }\n * ```\n *\n * The annotation

[Continuation] provided to the [block] shall not be invoked.\n * As the result type of the [block] is declared as
`Any?` and cannot be correctly type-checked,\n * its proper return type remains on the conscience of the suspend
function's author.\n * Invocation of [Continuation.resumeWith] resumes coroutine directly in the invoker's
thread without going through the\n * [ContinuationInterceptor] that might be present in the coroutine's
[CoroutineContext].\n * It is the invoker's responsibility to ensure that a proper invocation context is established.\n

it is not recommended to call either [Continuation.resume] nor [Continuation.resumeWithException] functions synchronously in the same stackframe where suspension function is run. Use [suspendCoroutine] as a safer way to obtain current continuation instance.
