

ISIS - SRv6: uLoop Avoidance

From Cisco IOS XE 17.15.1a, the ISIS - SRv6: uLoop Avoidance feature extends the ISIS Local Microloop Protection feature thereby preventing the occurrences of microloops during network convergence after a link-down event or link-up event.

Prerequisites for ISIS - SRv6: uLoop Avoidance

- When the Topology-Independent Loop-Free Alternate (TI-LFA) feature is configured, IS-IS SRv6 uloop avoidance is enabled automatically.

Restrictions for ISIS - SRv6: uLoop Avoidance

There are no specific restrictions for this feature.

Information About ISIS - SRv6: uLoop Avoidance

Microloops

When changes occur in a network topology because of the failure or restoration of a link or a network device, IP Fast Reroute enables rapid network convergence by moving traffic to precomputed backup paths until regular convergence mechanisms move traffic to a newly computed best path, also known as a post-convergence path. This network convergence may cause short microloops between two directly or indirectly connected devices in the topology. Microloops are caused when different nodes in the network calculate alternate paths at different times and independently of each other. For instance, if a node converges and sends traffic to a neighbor node, which has not converged yet, traffic may loop between the two nodes.

Microloops may or may not result in traffic loss. If the duration of a microloop is short, that is the network converges quickly, packets may loop for a short duration before their time-to-live (TTL) expires. Eventually, the packets will get forwarded to the destination. If the duration of the microloop is long, that is one of the routers in the network is slow to converge, packets may expire their TTL or the packet rate may exceed the bandwidth, or the packets might be out of order, and packets may get dropped.

Microloops that are formed between a failed device and its neighbors are called local uloops, whereas microloops that are formed between devices that are multiple hops away are called remote uloops. Local uloops are usually seen in networks where local loop-free alternate (LFA) path is not available. In such networks, remote LFAs provide backup paths for the network.

The information discussed above can be illustrated with the help of an example topology as shown in the following figure.

Figure 1: Microloop Example Topology

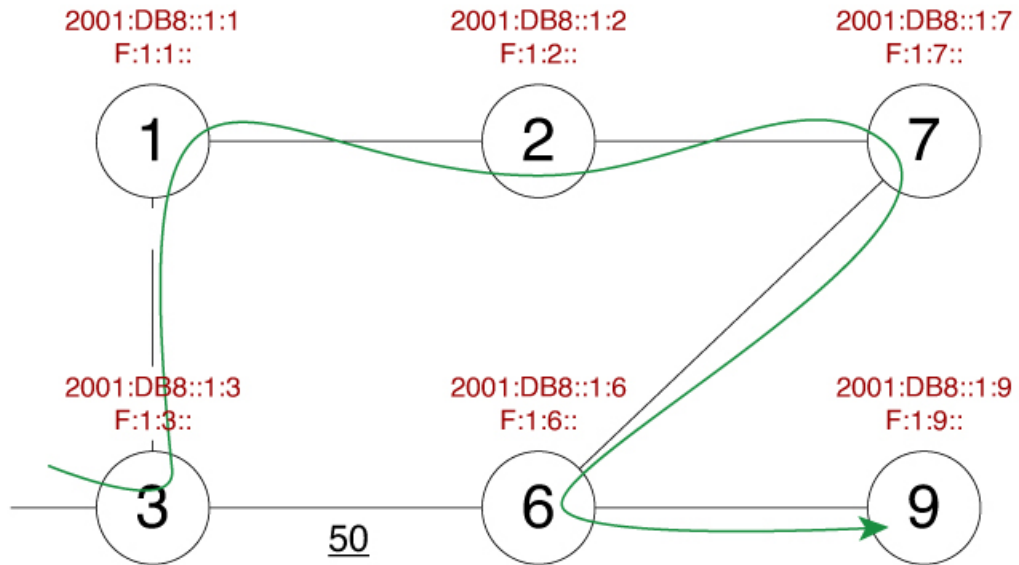

The assumptions in this example are as follows:

- The default metrics is 10 for each link except for the link between Node 3 and Node 6, which has a metric of 50. The order of convergence with SPF backoff delays on each node is as follows:
 - Node 3—50 milliseconds
 - Node 1—500 milliseconds
 - Node 2—1 second
 - Node 7—1.5 seconds

A packet sent from Node 3 to Node 9, the destination, traverses via Node 6.

If a link is established between Node 6 and Node 7, the shortest path for a packet from Node 3 to Node 9 would be Node 1, Node 2, Node 7, and Node 6 before the packet reaches the destination, Node 9.

Figure 2: Microloop Example Topology—Shortest Path

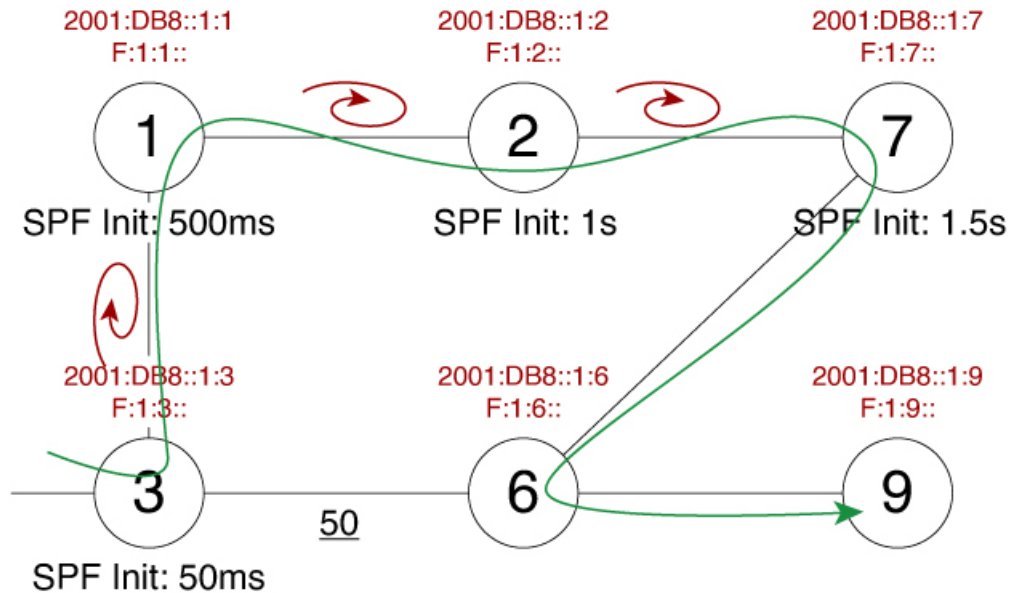

The following figure shows the Forwarding Information Base (FIB) table in each node before the link between Node 6 and Node 7 is established. The FIB entry contains the prefix of the destination node (Node 9) and the next hop.

Figure 3: Microloop Example Topology—FIB Entry

When the link between Node 6 and Node 7 comes up, microloops occur for the links based on the order of convergence of each node. In this example, Node 3 converges first with Node 1 resulting in a microloop between Node 3 and Node 1. Then, Node 1 converges next resulting in a microloop between Node 1 and Node 2. Next, Node 2 converges next resulting in a microloop between Node 2 and Node 7. Finally, Node 7 converges resolving the microloop and the packet reaches the destination Node 9, as shown in the following figure.

Figure 4: Microloop Example Topology—Microloops

Adding the SPF convergence delay, microloop results in a loss of connectivity for 1.5 seconds, which is the convergence duration specified for node 7.

SRv6 and Microloops

The ISIS - SRV6: uLoop Avoidance feature supports the following scenarios, with only one event supported at a time:

- link-up
- link-down
- link cost increase
- link cost decrease
- overload bit set
- overload bit cleared

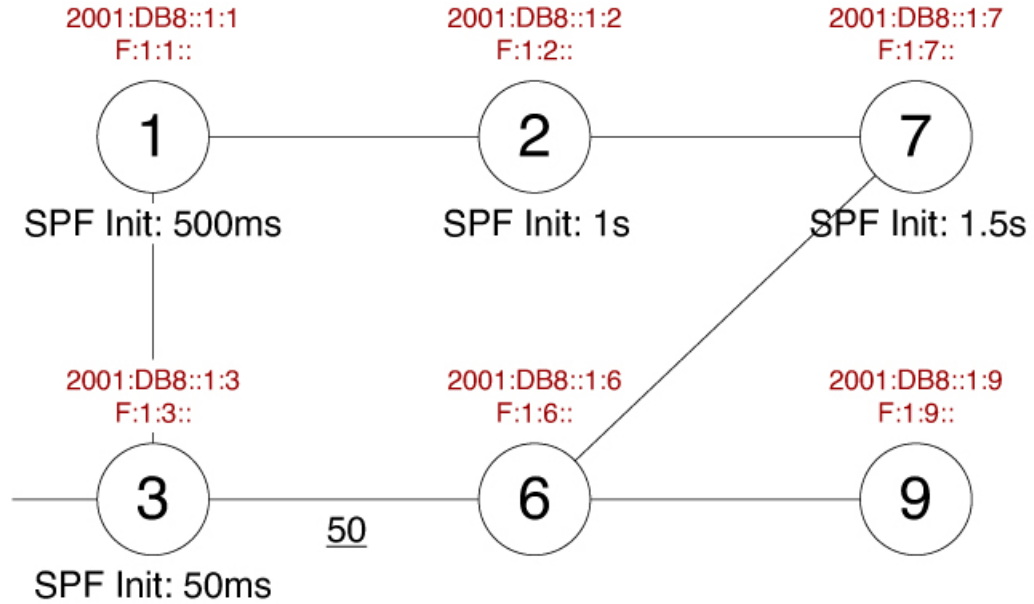

Note Node up/down are not supported as these are multiple events.

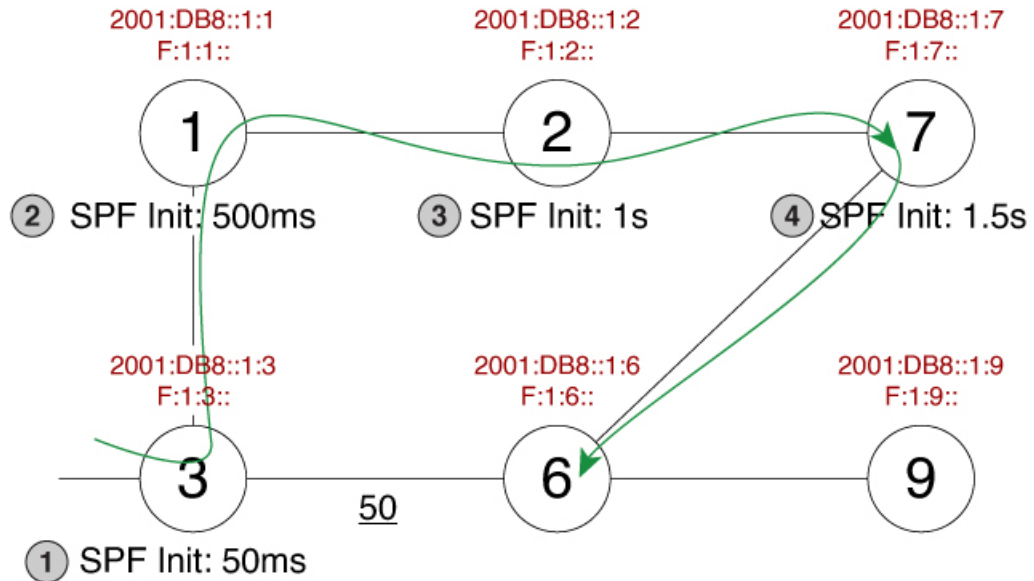

How Segment Routing Prevents Microloops

Using the example used to explain microloops, this section explains how segment routing prevents microloops. Node 3 in the example is enabled with the **microloop avoidance segment-routing** command. After the link between Node 6 and Node 7 comes up, Node 3 computes a new microloop on the network.

Figure 5: Microloop Example Topology—Segment Routing

Instead of updating the FIB table, Node 3 builds a dynamic loop-free alternate (LFA) SRv6 TE policy for the destination (Node 9) using a list of segments IDs, which includes the adjacency segment ID (SID) of Node 6 on Node 7, which is F:1:7:E002::.

So, the SRv6 TE policy enables a packet from Node 3 reaches its destination Node 9, without the risk of microloop until the network converges. Finally, Node 3 updates the FIB for the new path.

Microloop avoidance is available for all IPv6 prefix types, with the **microloop avoidance segment-routing** command, under the **address-family ipv6** configuration. The **microloop avoidance rib-update-delay milliseconds** command can be used to configure the delay in milliseconds for a node to wait before updating the node's forwarding table and stop using the microloop avoidance policy. The default value for the RIB delay is 5000 milliseconds.

Supported Platforms

From Cisco IOS XE 17.15.1a, the ISIS - SRv6: uLoop Avoidance feature is supported on the following platforms:

- Cisco ASR1000 RP3 + ESP100-X, ASR1001-HX, ASR1002-HX
- Cisco Catalyst 8000V Edge Software
- Cisco Catalyst 8200 Series Edge platforms
- Cisco Catalyst 8300 Series Edge platforms
- Cisco Catalyst 8500 and 8500L Series Edge platforms

How to Enable ISIS - SRv6: uLoop Avoidance

Configuring uLoop Avoidance

Use the **microloop avoidance** command under **address-family ipv6** to enable SRv6 uLoop avoidance.

Note SRv6 uLoop avoidance is enabled by default when SRv6 TILFA is enabled.

```
router(config-router-af)# microloop avoidance ?
  disable          Disable Microloop avoidance
  rib-update-delay Microloop avoidance RIB update delay
  segment-routing  Configuring Segment-Routing Microloop Avoidance
```

The following is a sample configuration to enable SRv6 uLoop avoidance:

```
router isis
address-family ipv6
microloop avoidance segment-routing
microloop avoidance rib-update-delay 3000
```

Verifying Microloop Avoidance

Use the **show isis ipv6 rib** command to verify the uLoop configuration.

```
router# show isis ipv6 rib FCCC:CCCL:F1::/48

* FCCC:CCCL:F1::/48
```

```

via ULOOP_EP SRv6-Fwd-Id 25165888, type L1 metric 120 tag 0
  P node: R5 SID FCCC:CC1:E1:: uN (PSP/USD)
  Q node: R6 SID FCCC:CC1:E1:E001:: uA (PSP/USD)
prefix attr: X:0 R:0 N:0
(installed)
- - - - -
via FE80::A8BB:CCFF:FE00:9D21/Ethernet1/2, type L1 metric 120 tag 0
prefix attr: X:0 R:0 N:0
    
```

Use the **show ipv6 microloop-avoidance** commands to display the current uLoop status.

```

router# show isis ipv6 microloop-avoidance
Tag: 1

Algo State Delay Running(L1/L2)
0 Segment-Routing 3000 FALSE/FALSE
router#

router# show isis ipv6 microloop-avoidance log

Feature Information for ISIS - SRv6: uLoop Avoidance

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <https://cfng.cisco.com/>. An account on Cisco.com is not required.
