Configuring SMDS

The Switched Multimegabit Data Service (SMDS) is a WAN service offered by a variety of service providers.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SMDS

You must have already obtained your SMDS addresses from your service provider. You need the following two types of addresses:

- The group address for broadcasts
- The SMDS hardware (individual) address for each router that interfaces directly into the SMDS network (that is, customer premises equipment)

Information About SMDS

SMDS Hardware Requirements

You need the following hardware, equipment, and special software to configure SMDS:

- CSC-MCI or CSC-SCI serial interface controller card, or a HSSI interface on chassis-based systems, or the serial port on a router

To operate on CSC-SCI or CSC-MCI cards, SMDS requires that the appropriate microcode version be installed. Version numbers are 1.2 (or later) for CSC-SCI and 1.7 (or later) for CSC-MCI.

- EIA/TIA-449 or V.35 applique
- SMDS data service unit (SDSU) device

The figure below illustrates the connections among the components.

Figure 1: Typical SMDS Configuration

SMDS Addresses

All addresses for SMDS service are assigned by the service provider and can be assigned to individuals and groups.

You must enter addresses in the Cisco SMDS configuration software using an E prefix for multicast addresses and a C prefix for unicast addresses.

Cisco IOS software expects the addresses to be entered in E.164 format, which is 64 bits (15-digit addressing). The first 4 bits are the address type, and the remaining 60 bits are the address. If the first 4 bits are 1100 (0xC), the address is a unicast SMDS address, which is the address of an individual SMDS host. If the first 4 bits are 1110 (0xE), the address is a multicast SMDS address, which is used to broadcast a packet to multiple end points. The 60 bits of the address are in binary-coded decimal (BCD) format. Each 4 bits of the address field presents a single telephone number digit, allowing for up to 15 digits. At a minimum, you must specify at least 11 digits (44 bits). Unused bits at the end of this field are filled with ones.

Note The **arp smds**command supports 48-bit addresses only (C or E followed by 11 digits). The addresses must be entered in dotted notation--for example, C141.5556.1414.

An example of a 15-digit E.164 address follows:

```
C14155561313FFFF
```

Note Older versions of Cisco IOS software supported 48-bit SMDS addresses. If, when using the current version of the software, you write the configuration to NVRAM, the full 64-bit SMDS address is written. Older versions of the software will no longer be able to read the new SMDS configuration from NVRAM. However, the current version of the software can read previous versions of the configuration in NVRAM.

The addresses can be entered with periods in a manner similar to Ethernet-style notation, or simply as a string of digits.

The following is an example of an individual address entered in Ethernet-style notation:

```
C141.5555.1212.FFFF
```
The following is an example of a group address:

```
E180.0999.9999.FFFF
```
An SMDS network can be thought of in much the same way as an X.25 cloud. The premises equipment (in this case Cisco routers) represents the edge of the cloud. The service provider enables communication across the cloud. However, proper configuration is needed for communication to occur. This configuration will differ from one protocol family to another.

One major difference between protocol families is dynamic versus static routing among the routers (called *remote peers*) on the periphery of the cloud. For IP, routing across the SMDS cloud is fully dynamic. No action on the user's part is needed to map higher-level protocol addresses to SMDS addresses. Both IP and ARP can be configured and a dynamic ARP routing table enabled.

Note The **arp smds** command requires 12-digit dotted-notation SMDS addresses--for example, C141.5678.9012.

Customizing the SMDS Network

Configuring Specific Protocols

Some protocol families are dynamically routed. For IP and CLNS, routing is fully dynamic, and no action on your part is needed to map higher-level protocol addresses to SMDS addresses. But for the other supported protocols, you must make a static entry for each router to communicate with all other peer routers. The static entries need to be made only for those routers that are SMDS remote peers. Nothing additional needs to be done to assure communication with other nodes behind the peer routers.

For an example of how to configure specific protocols, see the section "Typical Multiprotocol Configuration Example, on page 13" later in this chapter.

The table below lists protocol families and the multicasts that are needed.

Table 1: Protocol Families and Types of Multicasts Needed

Protocol Family	Multicasts Needed
IP	IP

Protocol Family	Multicasts Needed
DECnet	DECNET, DECNET_NODE, DECNET_ROUTER-L1, DECNET_ROUTER-L2
CLNS	CLNS, CLNS_ES,CLNS_IS
Novell IPX	IPX
XNS	XNS
AppleTalk	APPLETALK, AARP
Banyan VINES	VINES

Configuring ARP and IP

For both IP and ARP, the multicast address must be configured and ARP must be enabled. ARP multicast is required only for ARP servers; the IP multicast is used for ARP and routing updates.

Configuring DECnet

Static maps must be configured for DECnet. In addition, a separate **smds multicast** command is needed for DECNET, DECNET_NODE, DECNET_ROUTER-L1, and DECNET_ROUTER-L2.

Configuring CLNS

Multicasts must be configured for CLNS_ES and CLNS_IS. No static maps are necessary. End system hello (ESH), intermediate system hello (ISH), and router hello packets are sent to the multicast address, and neighbor entries are created automatically.

Configuring IPX

For Novell IPX, the multicast address must be configured. A static map entry can be made for each remote peer, or you can use the **smds glean** command to dynamically map addresses. Static map entries override any dynamic map entries.

Routing Information Protocol (RIP) routing packets, Service Advertisement Protocol (SAP) packets, NetBIOS Name Lookups, directed broadcasts, and traffic to the helper addresses (if that helper address is a broadcast address) are sent to the SMDS IPX multicast address.

Configuring XNS

For XNS, the multicast address must be configured, and a static map entry must be made for each remote peer. Only RIP, directed broadcasts, and helper traffic are sent to the XNS multicast address.

Configuring AppleTalk

The SMDS cloud must be treated by all AppleTalk routers connected to it as either extended or nonextended. The network types cannot be mixed on the same SMDS cloud. Instead, all AppleTalk routers on an SMDS cloud must agree about the network type: extended or nonextended.

If any router in the SMDS cloud uses Cisco IOS Release 10.3(3) (or earlier), use a nonextended AppleTalk configuration for the SMDS cloud. To use nonextended AppleTalk, use the **appletalk address** command and configure static maps.

If all routers in the SMDS cloud use Cisco IOS Release 10.3(4) (or later), you can use extended AppleTalk to support dynamic AARP for SMDS addresses. To use extended AppleTalk, use the **appletalk cable-range** command.

For information on the **appletalk address** and **appletalk cable-range** commands, refer to the *Cisco IOS AppleTalk and Novell IPX Command Reference* .

For an example of how to configure AppleTalk, see the section "AppleTalk Configuration Examples, on page 14" later in this chapter.

Configuring Banyan VINES

For Banyan VINES, the multicast address must be configured. Also note that VINES works only with static maps.

Transparent Bridging over SMDS

You can enable transparent bridging for SMDS encapsulated serial and HSSI interfaces. Cisco's implementation of IEEE 802.6i transparent bridging for SMDS supports 802.3, 802.5, and FDDI frame formats. The router can accept frames with or without frame check sequence (FCS).

Fast-switched transparent bridging is the default and is not configurable. If a packet cannot be fast switched, it will be process switched.

For more information about bridge groups and the **bridge-group** command, see the "Configuring Transparent Bridging" chapter in the *Cisco IOS Bridging and IBM Networking Configuration Guide* .

SMDS Subinterfaces for Multiple Logical IP Subnetworks

Multiple logical IP subnetworks are supported as defined by RFC 1209. This RFC explains routing IP over an SMDS cloud where each connection is considered a host on one specific private network, and describes cases where traffic must transit from network to network.

This solution allows a single SMDS interface to be treated as multiple logical IP subnetworks and to support routing of packets from one network to the next without using intervening routers. When multiple logical IP subnetworks are enabled, the router performs routing between the subnetworks using IP addresses on an SMDS interface. Each supported subnetwork has an IP address, a unicast SMDS E.164 address, and a multicast SMDS E.164 address configured on the SMDS interface. Broadcast packets are duplicated and transmitted to all IP networks on the specified SMDS interface and use the associated multicast SMDS address for the network.

Only routers that require knowledge of multiple IP networks need to be configured with multipoint subinterfaces that correspond to different networks.

Reenabling Data Exchange Interface Version 3.2 with Heartbeat Support

By default, SMDS provides the Data Exchange Interface (DXI) Version 3.2 *heartbeat* process as specified in the SIG-TS-001/1991 standard. The DXI mechanism encapsulates SMDS packets in a DXI frame before they are transmitted. The heartbeat mechanism automatically generates a heartbeat poll frame every 10 seconds. The Interim Local Management Interface (ILMI) is not supported. See the *Cisco IOS Wide-Area Networking Command Reference* for more information about DXI 3.2.

Note If you are running serial lines back-to-back, disable keepalive on SMDS interfaces. Otherwise, DXI declares the link down.

Pseudobroadcasting

Some hosts do not support multicast E.164 addresses. This is a problem in IP where frequent broadcast packets are sent because routing updates are generally broadcast. IP and ARP depend on the use of multicast addresses to determine a route to a destination IP address. A mechanism was needed to artificially support the use of broadcast where multicast E.164 addresses do not exist; the result is *pseudobroadcasting* . If a multicast address is not available to a destination, pseudobroadcasting can be enabled to broadcast packets to those destinations using a unicast address.

Fast Switching

SMDS fast switching of IP, IPX, and AppleTalk packets provides faster packet transfer on serial links with speeds above 56 kbps. Use fast switching if you use high-speed, packet-switched, datagram-based WAN technologies such as Frame Relay offered by service providers.

By default, SMDS fast switching is enabled.

SMDS Configuration Task List

Enabling SMDS on the Interface

Setting SMDS Encapsulation

To set SMDS encapsulation at the interface level, use the following command in interface configuration mode:

Command	Purpose
`Router(config-if)#` **encapsulation smds**	Enables SMDS on the interface.

Specifying the SMDS Address

To specify the SMDS individual address for a particular interface, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# **smds address** *smds-address*	Enters an individual address provided by the SMDS service provider.

Establishing Address Mapping

Routing tables are configured dynamically when DECnet, extended AppleTalk, IP, IPX, and ISO CLNS routing are configured. However, you can configure static mapping for these protocols, if needed. For other protocols, you must configure a static map between an individual SMDS address and a higher-level protocol address.

To establish address mapping, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# **smds static-map** *protocol protocol-address smds-address* [**broadcast**]	Defines static entries for those routers that are SMDS remote peers. The supported protocols and the keywords to enable them are as follows: • AppleTalk--**appletalk** • Banyan VINES--**vines** • DECnet--**decnet** • IP--**ip** • ISO CLNS--**clns** • Novell IPX--**ipx** • XNS--**xns**

Mapping a Multicast Address to an SMDS Address

You can map an SMDS group address to a broadcast or multicast address used by a higher-level protocol. If you do so, you need not specify the **broadcast** keyword in the **smds static-map** command, and the Cisco IOS software need not replicate each broadcast address.

To map an SMDS group address to a multicast address, use the following command in interface configuration mode:

Command	Purpose
`Router(config-if)#` **smds multicast** *protocol smds-address*	Maps an SMDS group address to a multicast address used by a higher-level protocol. The protocols supported and the keywords to enable them are as follows: • AppleTalk--**appletalk** • AppleTalk ARP address--**aarp** • Banyan VINES--**vines** • Bridging--**bridge** • DECnet--**decnet** • DECnet multicast address for all Level 1 routers--**decnet_router-L1** • DECnet multicast address for all Level 2 routers--**decnet_router-L2** • DECnet multicast address for all end systems--**decnet_node** • IP--**ip** • ISO CLNS--**clns** • Multicast address for all CLNS intermediate systems--**clns_is** • Multicast address for all CLNS end systems--**clns_es** • Novell IPX--**ipx** • XNS--**xns** **Note** Bridging is not a protocol, but the **bridge** keyword is valid for providing a map to a multicast address.

Enabling ARP

When you enable the Address Resolution Protocol (ARP), you can choose to enable either a dynamic ARP cache or one built statically. To enable ARP, use one of the following commands in the specified configuration mode:

Command	Purpose
Router(config-if)# **smds enable-arp**	Enables ARP and dynamic address resolution (interface).
Router(config)# **arp** *ip-address smds-address* **smds**	Enables ARP with a static entry for the remote router (global).

Enabling Broadcast ARP Messages

When an ARP server is present in the network, you can enable broadcast ARP messages that are sent to all ARP SMDS addresses or to all IP SMDS multicast addresses when ARP addresses are not present.

To enable broadcast ARP messages, use the following commands in interface configuration mode:

SUMMARY STEPS

1. Router(config-if)# **smds enable-arp**
2. Router(config-if)# **smds multicast arp** *smds-address*[*ip-address mask*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config-if)# **smds enable-arp**	Enables ARP and dynamic address resolution.
Step 2	Router(config-if)# **smds multicast arp** *smds-address*[*ip-address mask*]	Enables broadcast ARP messages.

Enabling Dynamic Address Mapping for IPX over SMDS

To enable dynamic address mapping for IPX on an SMDS interface, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# **smds glean ipx** [*timeout-value*] [**broadcast**]	Enables dynamic address mapping for IPX.

Customizing Your SMDS Network

Enabling Transparent Bridging over SMDS

To enable transparent bridging, use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. Router(config)# **interface** *type number*
2. Router(config-if)# **encapsulation smds**
3. Router(config-if)# **bridge-group** *bridge-group*
4. Router(config-if)# **smds multicast bridge** *smds-address*

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config)# **interface** *type number*	Specifies a serial or HSSI interface.
Step 2	Router(config-if)# **encapsulation smds**	Configures SMDS encapsulation on the serial interface.
Step 3	Router(config-if)# **bridge-group** *bridge-group*	Associates the interface with a bridge group.
Step 4	Router(config-if)# **smds multicast bridge** *smds-address*	Configures bridging across SMDS.

Configuring SMDS Subinterfaces for Multiple Logical IP Subnetworks

To configure the Cisco IOS software to have multipoint subinterfaces for multiple logical IP subnetworks, use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. Router(config)# **interface serial** *interface* **.** *subinterface* **multipoint**
2. Router(config-if)# **ip address** *ip-address mask*
3. Router(config-if)# **smds address** *smds-address*
4. Router(config-if)# **smds multicast** *protocol smds-address*
5. Router(config-if)# **smds enable-arp**

DETAILED STEPS

	Command or Action	**Purpose**
Step 1	Router(config)# **interface serial** *interface* **.** *subinterface* **multipoint** **Example:** **Example:** Router(config)# **interface serial** *slot* **/** *port* **.** *subinterface* **multipoint** **Example:** (for Cisco 7000 series routers[1])	Defines a logical subinterface for each IP network.
Step 2	Router(config-if)# **ip address** *ip-address mask*	Configures the subinterface as an IP network.
Step 3	Router(config-if)# **smds address** *smds-address*	Assigns unicast SMDS E.164 address to the subinterface.
Step 4	Router(config-if)# **smds multicast** *protocol smds-address*	Assigns multicast SMDS E.164 address for each protocol supported on the subinterface.
Step 5	Router(config-if)# **smds enable-arp**	Enables ARP on the subinterface, if required by the protocol.

[1] Beginning in Cisco IOS Release 11.3, all commands supported on the Cisco 7500 series are also supported on the Cisco 7000 series.

Reenabling Data Exchange Interface Version 3.2 with Heartbeat Support

To reenable the DXI heartbeat, use the following command in interface configuration mode:

Command	**Purpose**
Router(config-if)# **smds dxi**	Enables DXI 3.2.

Configuring Pseudobroadcasting

To configure pseudobroadcasting, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# **smds static-map** *protocol protocol-address smds-address* **broadcast**	Configures pseudobroadcasting.

For an example of how to configure pseudobroadcasting, see the section "Pseudobroadcasting Example, on page 16" later in this chapter.

Enabling Fast Switching

To re-enable fast switching, use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. Router(config)# **interface** *type number*
2. Router(config-if)# **encapsulation smds**
3. Router(config-if)# **ip route-cache**
4. Router(config-if)# **ipx route-cache**
5. Router(config-if)# **appletalk route-cache**

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config)# **interface** *type number*	Defines and enters interface configuration mode.
Step 2	Router(config-if)# **encapsulation smds**	Sets SMDS encapsulation.
Step 3	Router(config-if)# **ip route-cache**	Enables the interface for IP fast switching.
Step 4	Router(config-if)# **ipx route-cache**	Enables the interface for IPX fast switching.
Step 5	Router(config-if)# **appletalk route-cache**	Enables the interface for AppleTalk fast switching.

Monitoring the SMDS Connection

To monitor the SMDS connection, use one or more of the following commands in EXEC mode:

Command	Purpose
`Router#` **show arp**	Monitors ARP activity.
`Router#` **show smds addresses**	Displays the individual addresses and the interface with which they are associated.
`Router#` **show smds map**	Displays all SMDS addresses that are mapped to higher-level protocol addresses.
`Router#` **show smds traffic**	Displays packet traffic activity.

SMDS Configuration Examples

Typical Multiprotocol Configuration Example

The following example is a typical interface configured for IP, DECnet, ISO CLNS, Novell IPX, XNS, and AppleTalk. DECnet needs to be configured globally and at the interface level.

```
interface serial 4
 ip address 1.1.1.2 255.0.0.0
 decnet cost 4
 appletalk address 92.1
 appletalk zone smds
 clns router igrp FOO
 ipx net 1a
 xns net 17
 encapsulation SMDS
! SMDS configuration follows
 smds address c120.1580.4721
 smds static-map APPLETALK 92.2 c120.1580.4592
 smds static-map APPLETALK 92.3 c120.1580.4593
 smds static-map APPLETALK 92.4 c120.1580.4594
 smds static-map NOVELL 1a.0c00.0102.23ca c120.1580.4792
 smds static-map XNS 17.0c00.0102.23ca c120.1580.4792
 smds static-map NOVELL 1a.0c00.0102.23dd c120.1580.4728
 smds static-map XNS 17.0c00.0102.23aa c120.1580.4727
 smds multicast NOVELL e180.0999.9999
 smds multicast XNS e180.0999.9999
 smds multicast ARP e180.0999.9999
 smds multicast IP e180.0999.9999
 smds multicast APPLETALK e180.0999.9999
 smds multicast AARP e180.0999.9999
 smds multicast CLNS_IS e180.0999.9990
 smds multicast CLNS_ES e180.0999.9990
 smds multicast DECNET_ROUTER e180.0999.9992
 smds multicast DECNET_NODE e180.0999.9992
 smds multicast DECNET e180.0999.9992
 smds enable-arp
```

Remote Peer on the Same Network Example

The following example illustrates a remote peer on the same SMDS network. DECnet needs to be configured globally and at the interface level.

```
interface serial 0
 ip address 1.1.1.1 255.0.0.0
 decnet cost 4
 appletalk address 92.2
 appletalk zone smds
 clns router igrp FOO
 ipx net 1a
 xns net 17
 encapsulation SMDS
! SMDS configuration follows
 smds address c120.1580.4792
 smds static-map APPLETALK 92.1 c120.1580.4721
 smds static-map APPLETALK 92.3 c120.1580.4593
 smds static-map APPLETALK 92.4 c120.1580.4594
 smds static-map NOVELL 1a.0c00.0102.23cb c120.1580.4721
 smds static-map XNS 17.0c00.0102.23cb c120.1580.4721
 smds static-map NOVELL 1a.0c00.0102.23dd c120.1580.4728
 smds static-map XNS 17.0c00.0102.23aa c120.1580.4727
 smds multicast NOVELL e180.0999.9999
 smds multicast XNS e180.0999.9999
 smds multicast IP e180.0999.9999
 smds multicast APPLETALK e180.0999.9999
 smds multicast AARP e180.0999.9999
 smds multicast CLNS_IS e180.0999.9990
 smds multicast CLNS_ES e180.0999.9990
 smds multicast DECNET_ROUTER e180.0999.9992
 smds multicast DECNET_NODE e180.0999.9992
 smds multicast DECNET e180.0999.9992
 smds enable-arp
```

IPX Dynamic Address Mapping Example

The following example enables dynamic address mapping for IPX on interface serial 0 and sets the time to live (TTL) to 14 minutes.

```
interface serial 0
 encapsulation smds
 smds address c141.5797.1313
 smds multicast ipx e180.0999.9999
 smds glean ipx 14
```

AppleTalk Configuration Examples

The following two sections provide basic examples of configuration for an extended AppleTalk network and for a nonextended AppleTalk network. For more information on AppleTalk commands, refer to the *Cisco IOS AppleTalk and Novell IPX Command Reference*.

Extended AppleTalk Network Example

If all AppleTalk routers on the SMDS cloud are running Cisco IOS Release 10.3(4) or later releases, you can use an AppleTalk extended network. To do so, use the **appletalk cable-range** interface command.

When SMDS is configured for an extended AppleTalk network, SMDS static maps are not required and not used. Dynamic AARP is supported on the multicast channel.

```
interface Serial0
 ip address 192.168.200.1 255.255.255.0
 encapsulation smds
 appletalk cable-range 10-10
 appletalk zone SMDS
 smds address c151.0988.1923
 smds static-map ip 192.168.200.2 c151.0988.8770
 smds multicast APPLETALK e151.0988.2232
 smds multicast AARP e151.0988.2232
 smds multicast IP e151.0988.2232
 smds multicast ARP e151.0988.2232
 smds enable-arp
```

Nonextended Appletalk Network Example

The following example configures SMDS for a nonextended AppleTalk network. When SMDS is configured for a nonextended AppleTalk network, SMDS static maps are required and the **appletalk address** command is used. Dynamic AppleTalk Address Resolution Protocol (AARP) is not supported on the multicast channel.

```
interface Serial0
 ip address 192.168.200.1 255.255.255.0
 encapsulation smds
 appletalk address 10.1
 appletalk zone SMDS
 smds address c151.0988.1923
 smds static-map ip 192.168.200.2 c151.0988.8770
 smds static-map appletalk 10.2 c151.0988.8770
 smds multicast APPLETALK e151.0988.2232
 smds multicast IP e151.0988.2232
 smds multicast ARP e151.0988.2232
 smds enable-arp
```

Multiple Logical IP Subnetworks over SMDS Example

In the following example, routers A, B, and C are connected to an SMDS cloud by means of two logical subnetworks labeled 1 and 2, as shown in the figure below.

Router A recognizes two IP networks and can communicate with Routers B and C directly. Router B can communicate with router A directly, and with router C through router A. Router C can communicate with router A directly and with router B through router A.

Notice that a packet destined to router B from router C must make two hops on the cloud through the same interface on router A. Notice also that this configuration is nonstandard. This issue was considered when the multiple logical IP subnetworks proposal was made, and was deemed not to be critical.

Figure 2: Multiple Logical IP Subnetworks Configuration
The following example shows all routers as Cisco 7200 routers, but they can be other platforms.

Configuration for Router A

```
interface serial 2/0
 encapsulation smds
!
interface serial 2/0.1 multipoint
 smds addr c111.3333.3333
 ip address 2.2.2.1 255.0.0.0
 smds multicast ip e122.2222.2222
 smds enable-arp
 smds multicast ARP e122.2222.2222
```

Configuration for Router B

```
interface serial 4/0
 encapsulation smds
 smds address c111.2222.2222
 ip address 1.1.1.3 255.0.0.0
 smds multicast ip e180.0999.9999
 smds enable-arp
```

Configuration for Router C

```
interface serial 1/0
 encapsulation smds
 smds address c111.4444.4444
 ip address 2.2.2.2 255.0.0.0
 smds multicast ip e122.2222.2222
 smds enable-arp
```

Pseudobroadcasting Example

In the following example, an ARP broadcast from router A is sent to multicast address E180.0999.9999.FFFF to router B and to unicast address C120.1234.5678.FFFF to router C. The reply from router C uses the unicast address C120.1111.2222.FFFF for the return reply if it is the target of the ARP request. IGRP broadcast updates follow the same rules.

Configuration for Router A

```
interface s 0
 encapsulation smds
 smds address c120.1111.2222
 ip address 172.20.1.30 255.255.255.0
 smds multicast ip e180.0999.9999
 smds static-map ip 172.20.1.10 c120.1234.5678 broadcast
 smds enable-arp
```

Configuration for Router B

```
interface s 4
 smds address c120.9999.8888
 ip address 172.20.1.20
 smds multicast ip e180.0999.9999
 smds enable-arp
```

Configuration for Router C

```
interface serial 2
 smds address c120.1234.5678
 ip address 172.20.1.10
 smds static-map ip 172.20.1.30 c120.1111.2222 broadcast
 smds enable-arp
```

Feature Information for SMDS

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 2: Feature Information for Phrase Based on Module Title
