

# **Provisioning Core ACI Fabric Services**

This chapter contains the following sections:

- Time Synchronization and NTP, on page 1
- Configuring a DHCP Relay Policy, on page 10
- Configuring a DNS Service Policy, on page 14
- Configuring Custom Certificates, on page 20
- Provisioning Fabric Wide System Settings, on page 23
- Provisioning Global Fabric Access Policies, on page 38

# Time Synchronization and NTP

Within the Cisco Application Centric Infrastructure (ACI) fabric, time synchronization is a crucial capability upon which many of the monitoring, operational, and troubleshooting tasks depend. Clock synchronization is important for proper analysis of traffic flows as well as for correlating debug and fault time stamps across multiple fabric nodes.

An offset present on one or more devices can hamper the ability to properly diagnose and resolve many common operational issues. In addition, clock synchronization allows for the full utilization of the atomic counter capability that is built into the ACI upon which the application health scores depend. Nonexistent or improper configuration of time synchronization does not necessarily trigger a fault or a low health score. You should configure time synchronization before deploying a full fabric or applications so as to enable proper usage of these features. The most widely adapted method for synchronizing a device clock is to use Network Time Protocol (NTP).

Prior to configuring NTP, consider what management IP address scheme is in place within the ACI fabric. There are two options for configuring management of all ACI nodes and Application Policy Infrastructure Controllers (APICs), in-band management and/or out-of-band management. Depending upon which management option is chosen for the fabric, configuration of NTP will vary. Another consideration in deploying time synchronization is where the time source is located. The reliability of the source must be carefully considered when determining if you will use a private internal clock or an external public clock.

# **In-Band Management NTP**

Note

See the Adding Management Access section in this guide for information about in-band management access.

• In-Band Management NTP—When an ACI fabric is deployed with in-band management, consider the reachability of the NTP server from within the ACI in-band management network. In-band IP addressing used within the ACI fabric is not reachable from anywhere outside the fabric. To leverage an NTP server external to the fabric with in-band management, construct a policy to enable this communication..

### NTP over IPv6

NTP over IPv6 addresses is supported in hostnames and peer addresses. The gai.conf can also be set up to prefer the IPv6 address of a provider or a peer over an IPv4 address. The user can provide a hostname that can be resolved by providing an IP address (both IPv4 or IPv6, depending on the installation or preference).

# **Configuring NTP Using the GUI**

Note

There is a risk of hostname resolution failure for hostname based NTP servers if the DNS server used is configured to be reachable over in-band or out-of-band connectivity. If you use a hostname, ensure that the DNS service policy to connect with the DNS providers is configured. Also ensure that the appropriate DNS label is configured for the in-band or out-of-band VRF instances of the management EPG that you chose when you configured the DNS profile policy.

### **Procedure**

- Step 1 On the menu bar, choose FABRIC > Fabric Policies.
- Step 2 In the Navigation pane, choose Pod Policies > Policies.
- Step 3 In the Work pane, choose Actions > Create Date and Time Policy.
- **Step 4** In the Create Date and Time Policy dialog box, perform the following actions:
  - a) Enter a name for the policy to distinguish between the different NTP configurations in your environment...
  - b) Click **enabled** for the **Authentication State** field and expand the **NTP Client Authentication Keys** table and enter the key information. Click **Update** and **Next**.
  - c) Click the + sign to specify the NTP server information (provider) to be used.
  - d) In the **Create Providers** dialog box, enter all relevant information, including the following fields: **Name**, **Description**, **Minimum Polling Intervals**, and **Maximum Polling Intervals**.
    - If you are creating multiple providers, check the **Preferred** check box for the most reliable NTP source.
    - In the Management EPG drop-down list, if the NTP server is reachable by all nodes on the fabric through out-of-band management, choose Out-of-Band. If you have deployed in-band management, see the details about In-Band Management NTP. Click **OK**.

Repeat the steps for each provider that you want to create.

- Step 5 In the Navigation pane, choose Pod Policies > Policy Groups.
- Step 6 In the Work pane, choose Actions > Create Pod Policy Group.
- **Step 7** In the **Create Pod Policy Group** dialog box, perform the following actions:

- a) Enter a name for the policy group.
- b) In the **Date Time Policy** field, from the drop down list, choose the NTP policy that you created earlier. Click **Submit**.

The pod policy group is created. Alternatively, you can use the default pod policy group.

- Step 8 In the Navigation pane, choose Pod Policies > Profiles.
- **Step 9** In the **Work** pane, double-click the desired pod selector name.
- **Step 10** In the Properties area, from the **Fabric Policy Group** drop down list, choose the pod policy group you created. Click **Submit**.

# **Configuring NTP Using the NX-OS Style CLI**

When an ACI fabric is deployed with out-of-band management, each node of the fabric is managed from outside the ACI fabric. You can configure an out-of-band management NTP server so that each node can individually query the same NTP server as a consistent clock source.

### **Procedure**

### Step 1 configure

Enters configuration mode.

### **Example:**

apic1# configure

### **Step 2 template ntp-fabric** *ntp-fabric-template-name*

Specifies the NTP template (policy) for the fabric.

### **Example:**

apic1(config)# template ntp-fabric pol1

### Step 3 [no] server dns-name-or-ipaddress [prefer] [use-vrf {inb-default | oob-default}] [key key-value]

Configures an NTP server for the active NTP policy. To make this server the preferred server for the active NTP policy, include the **prefer** keyword. If NTP authentication is enabled, specify a reference key ID. To specify the default management access EPG in-band or out-of-band for management access, include the **use-vrf** keyword with the **inb-default** or **oob-default** keyword.

### Example

apic1(config-template-ntp-fabric) # server 192.0.20.123 prefer use-vrf oob-default

### Step 4 [no] authenticate

Enables (or disables) NTP authentication.

### **Example:**

apic1(config-template-ntp-fabric) # no authenticate

### **Step 5** [no] authentication-key key-value

Configures an authentication NTP authentication. The range is 1 to 65535.

### **Example:**

apic1(config-template-ntp-fabric)# authentication-key 12345 md5 "key\_value"

### Step 6 [no] trusted-key key-value

Configures a trusted NTP authentication. The range is 1 to 65535.

### **Example:**

apic1(config-template-ntp-fabric) # trusted-key 54321

### Step 7 exit

Returns to global configuration mode

### **Example:**

apic1(config-template-ntp-fabric)# exit

### **Step 8 template pod-group** *pod-group-template-name*

Configures a pod-group template (policy).

### **Example:**

apic1(config)# template pod-group allPods

### **Step 9 inherit ntp-fabric** ntp-fabric-template-name

Configures the NTP fabric pod-group to use the previously configured NTP fabric template (policy).

### Example:

apic1(config-pod-group) # inherit ntp-fabric pol1

### Step 10 exit

Returns to global configuration mode

### **Example:**

apic1(config-template-pod-group)# exit

### **Step 11 pod-profile** *pod-profile-name*

Configures a pod profile.

### **Example:**

apic1(config) # pod-profile all

### Step 12 pods $\{pod\text{-}range\text{-}1\text{-}255 \mid all\}$

Configures a set of pods.

### **Example:**

apic1(config-pod-profile) # pods all

### **Step 13 inherit pod-group** *pod-group-name*

Associates the pod-profile with the previously configured pod group.

### **Example:**

apic1(config-pod-profile-pods)# inherit pod-group allPods

### Step 14 end

Returns to EXEC mode.

### **Example:**

```
apic1(config-pod-profile-pods)# end
```

### **Examples**

This example shows how to configure a preferred out-of-band NTP server and how to verify the configuration and deployment.

```
apic1# configure t
apic1(config)# template ntp-fabric pol1
apic1 (config-template-ntp-fabric) # server 192.0.20.123 use-vrf oob-default
apic1(config-template-ntp-fabric) # no authenticate
apic1 (config-template-ntp-fabric) # authentication-key 12345 md5 abcdef1235
apic1(config-template-ntp-fabric)# trusted-key 12345
apic1(config-template-ntp-fabric)# exit
apic1(config) # template pod-group allPods
apic1(config-pod-group) # inherit ntp-fabric pol1
apic1(config-pod-group) # exit
apic1(config) # pod-profile all
apic1(config-pod-profile) # pods all
apic1(config-pod-profile-pods) # inherit pod-group allPods
apic1(config-pod-profile-pods)# end
apic1#
apic1# show ntpq
nodeid
                          refid st
                                            when
                                                   poll
                                                          reach delay
                                                                          offset
            remote
                                                                                    jitter
        * 192.0.20.123 .GPS.
                                           27
                                                   64
                                                          377
                                                                 76.427
                                                                          0.087
```

# **Configuring NTP Using the REST API**

Note

There is a risk of hostname resolution failure for hostname based NTP servers if the DNS server used is configured to be reachable over in-band or out-of-band connectivity. If you use a hostname, ensure that the DNS service policy to connect with the DNS providers is configured. Also ensure that the appropriate DNS label is configured for the in-band or out-of-band VRF instances of the management EPG that you chose when you configured the DNS profile policy.

377

377

64

75.932

75.932 0.001

0.001

### **Procedure**

Step 1 Configure NTP.

### **Example:**

0.067

0.021

0.021

**Step 2** Add the default Date Time Policy to the pod policy group.

### **Example:**

**Step 3** Add the pod policy group to the default pod profile.

### **Example:**

```
POST url:
https://APIC-IP/api/node/mo/uni/fabric/podprof-default/pods-default-typ-ALL/rspodPGrp.xml
payload: <imdata totalCount="1">
<fabricRsPodPGrp tDn="uni/fabric/funcprof/podpgrp-calo1" status="created">
</fabricRsPodPGrp>
</imdata>
```

# **Verifying NTP Operation Using the GUI**

### **Procedure**

- **Step 1** On the menu bar, choose **FABRIC** > **Fabric Policies**.
- Step 2 In the Navigation pane, choose Pod Policies > Policies > Date and Time > ntp\_policy > server\_name.

The *ntp\_policy* is the previously created policy. An IPv6 address is supported in the Host Name/IP address field. If you enter a hostname and it has an IPv6 address set, you must implement the priority of IPv6 address over IPv4 address.

**Step 3** In the **Work** pane, verify the details of the server.

# Verifying NTP Policy Deployed to Each Node Using the NX-OS Style CLI

### **Procedure**

- **Step 1** Log onto an APIC controller in the fabric using the SSH protocol.
- **Step 2** Attach to a node and check the NTP peer status, shown as follows:

apic1# fabric node\_name show ntp peer-status

**Step 3** Repeat step 2 for different nodes in the fabric.

### **NTP Server**

The NTP server enables client switches to also act as NTP servers to provide NTP time information to downstream clients. When the NTP server is enabled, the NTP daemon on the switch responds with time information to all unicast (IPv4/IPv6) requests from NTP clients. NTP server implementation is complaint to NTP RFCv3. As per the NTP RFC, the server will not maintain any state related to the clients.

- The NTP server enables the in-band/out-of-band management IP address of the switches to serve NTP client requests.
- The NTP server responds to incoming NTP requests on both Management VRFs, and responds back using the same VRF.
- The NTP server supports both IPv4/IPv6.
- Switches can sync as an IPv4 client and serve as an IPv6 server, and vice versa.
- Switches can sync as an NTP client using the out-of-band management VRF and serve through the in-band management VRF, and vice versa.
- No additional contracts or IP table configurations are required.
- If the switch is synced to the upstream server, then the server will send time info with the stratum number, and increment to its system peer's stratum.
- If the switch clock is undisciplined (not synced to the upstream server), then the server will send time information with stratum 16. Clients will not be able to sync to this server.

By default, NTP server functionality is disabled. It needs to be enabled explicitly by the configuration policy.

Note

Clients can use the in-band, out-of-band IP address of the leaf switch as the NTP server IP address. Clients can also use the bridge domain SVI of the EPG of which they are part also as the NTP server IP address.

Fabric switches should not sync to other switches of the same fabric. The fabric switches should always sync to external NTP servers.

### **Enabling the NTP Server Using the GUI**

This section explains how to enable an NTP server when configuring NTP in the APIC GUI.

#### **Procedure**

- Step 1 On the menu bar, choose FABRIC > Fabric Policies.
- Step 2 In the Navigation pane, choose Pod Policies > Policies .

The **Date and Time** option appears in the **Navigation** pane.

**Step 3** From the Navigation pane, right-click on Date and Time and choose Create Date and Time Policy.

The Create Date and Time Policy dialog appears in the Work pane.

- **Step 4** In the **Create Date and Time Policy** dialog box, perform the following actions:
  - a) Enter a name for the policy to distinguish between the different NTP configurations in your environment.
  - b) For the Server State option, click enabled.

**Server State** enables switches to act as NTP servers to provide NTP time information to downstream clients.

Note

To support the server functionality, it is always recommended to have a peer setup for the server. This enables the server to have a consistent time to provide to the clients.

When Server State is enabled:

- The NTP server sends time info with a stratum number, an increment to the system peer's stratum number, to switches that are synched to the upstream server.
- The server sends time info with stratum 16 if the switch clock is not synched to the upstream server. Clients are not able to sync to this server.

**Note** To support the server functionality, it is always recommended to have a peer setup for the server. The peer setup allows for a consistent time to provide to the clients.

c) For the Master Mode option, click enabled.

**Master Mode** enables the designated NTP server to provide undisciplined local clock time to downstream clients with a configured stratum number. For example, a leaf switch that is acting as the NTP server can provide undisciplined local clock time to leaf switches acting as clients.

Note

- Master Mode is only applicable when the server clock is undisciplined.
- The default master mode **Stratum Value** is 8.
- d) For the **Stratum Value** field, specify the stratum level from which NTP clients will get their time synchronized. The range is from 1 to 14.
- e) Click Next.
- f) Click the + sign to specify the NTP server information (provider) to be used.
- g) In the Create Providers dialog box, enter all relevant information, including the following fields: Name, Description, Minimum Polling Intervals, and Maximum Polling Intervals.

- If you are creating multiple providers, check the **Preferred** check box for the most reliable NTP source.
- In the Management EPG drop-down list, if the NTP server is reachable by all nodes on the fabric through out-of-band management, choose Out-of-Band. If you have deployed in-band management, see the details about In-Band Management NTP. Click **OK**.

Repeat the steps for each provider that you want to create.

Step 5 In the Navigation pane, choose Pod Policies then right-click on Policy Groups.

The **Create Pod Policy Group** dialog appears.

- Step 6 In the Work pane, choose Actions > Create Pod Policy Group.
- **Step 7** In the **Create Pod Policy Group** dialog box, perform the following actions:
  - a) Enter a name for the policy group.
  - b) In the **Date Time Policy** field, from the drop down list, choose the NTP policy that you created earlier. Click **Submit**.

The pod policy group is created. Alternatively, you can use the default pod policy group.

- Step 8 In the Navigation pane, choose Pod Policies > Profiles.
- **Step 9** In the **Work** pane, double-click the desired pod selector name.
- **Step 10** In the Properties area, from the **Fabric Policy Group** drop down list, choose the pod policy group you created.
- Step 11 Click Submit.

### **Enabling the NTP Server Using the CLI**

This section explains how to enable the NTP server feature using CLI commands.

### Before you begin

### **Procedure**

**Step 1** Enter the global configure mode:

### Example:

apic1#configure t

**Step 2** Configure an NTP server for the active NTP policy.

### **Example:**

apic1(config)#template ntp-fabric default

**Step 3** Specify the NTP server.

### **Example:**

apic1(config-template-ntp-fabric) #server 10.81.254.201 prefer use-vrf oob-default

**Step 4** Enable the switches to act as NTP servers.

### **Example:**

apic1(config-template-ntp-fabric)#server-mode

**Step 5** Enable the switches to act in NTP mastermode with a stratum value of 10.

### **Example:**

apic1(config-template-ntp-fabric)#master stratum 10

**Step 6** Return to global configuration

### **Example:**

aic1(config-template-ntp-fabric)#exit

### **Enabling the NTP Server Using the REST API**

This example demonstrates how to configure the NTP server using the REST API.

### **Procedure**

Enable serverState and masterMode and specify the StratumValue (the StratumValue can be from 1-14.

### **Example:**

POST url: https://APIC-IP/api/node/mo/uni/fabric/time-test.xml <datetimePol name="testdatetime" adminSt="enabled" authSt="enabled" serverState="enabled" masterMode="enabled" StratumValue="10" >

# Configuring a DHCP Relay Policy

A DHCP relay policy may be used when the DHCP client and server are in different subnets. If the client is on an ESX hypervisor with a deployed vShield Domain profile, then the use of a DHCP relay policy configuration is mandatory.

When a vShield controller deploys a Virtual Extensible Local Area Network (VXLAN), the hypervisor hosts create a kernel (vmkN, virtual tunnel end-point [VTEP]) interface. These interfaces need an IP address in the infrastructure tenant that uses DHCP. Therefore, you must configure a DHCP relay policy so that the Cisco Application Policy Infrastructure Controller (APIC) can act as the DHCP server and provide these IP addresses.

When a Cisco Application Centric Infrastructure (ACI) fabric acts as a DHCP relay, it inserts the DHCP Option 82 (the DHCP Relay Agent Information Option) in DHCP requests that it proxies on behalf of clients. If a response (DHCP offer) comes back from a DHCP server without Option 82, it is silently dropped by the fabric. Therefore, when the Cisco ACI fabric acts as a DHCP relay, DHCP servers providing IP addresses to compute nodes attached to the Cisco ACI fabric must support Option 82.

# **Guidelines and Limitations for a DHCP Relay Policy**

• A DHCP relay policy created under the infra or common tenant is not available to other tenants when configuring DHCP relay in a bridge domain. For inter-tenant DHCP relay communications, create a global DHCP relay policy, as described in Create a Global DHCP Relay Policy, on page 39.

- The DHCP relay IP address will always be set to the primary SVI IP address.
- You cannot use a DHCP relay policy if the clients and servers are connected through an L3Out EPG. Either the clients or servers (or both) must be in a regular (non-L3Out) EPG.

# Configuring a DHCP Server Policy for the APIC Infrastructure Using the GUI

- The port and the encapsulation used by the application Endpoint Group must belong to a physical or VM Manager (VMM) domain. If no such association with a domain is established, the APIC continues to deploy the EPG but raises a fault.
- Cisco APIC supports DHCP relay for both IPv4 and IPv6 tenant subnets. DHCP server addresses can be IPv4 or IPv6. DHCPv6 relay will occur only if IPv6 is enabled on the fabric interface and one or more DHCPv6 relay servers are configured.

### **Deploying DHCP Relay Policy for an Endpoint Group**

### Before you begin

Make sure that Layer 2 or Layer 3 management connectivity is configured.

### **Procedure**

- Step 1 On the menu bar, choose TENANTS > infra. In the Navigation pane, under Tenant infra, expand Networking > Protocol Policies > DHCP > Relay Policies.
- Step 2 Right-click Relay Policies and click Create DHCP Relay Policy.
- **Step 3** In the **Create DHCP Relay Policy** dialog box, perform the following actions:
  - a) In the **Name** field, enter the DHCP relay profile name (DhcpRelayP).
  - b) Expand **Providers**. In the **Create DHCP Provider** dialog box, in the **EPG Type** field, click the appropriate radio button depending upon where the DHCP server is connected.
  - c) In the **Application EPG** area, in the **Tenant** field, from the drop-down list, choose the tenant. (infra)
  - d) In the **Application Profile** field, from the drop-down list, choose the application. (access)
  - e) In the **EPG** field, from the drop-down list, choose the EPG. (default)
  - f) In the **DHCP Server Address** field, enter the IP address for the infra DHCP server. Click **Update**.

Note The infra DHCP IP address is the infra IP address of APIC1. You must enter the default IP address of 10.0.0.1 if deploying for vShield controller configuration.

g) Click Submit.

The DHCP relay policy is created.

- Step 4 In the Navigation pane, expand Networking > Bridge Domains > default > DHCP Relay Labels.
- Step 5 Right-click DHCP Relay Labels, and click Create DHCP Relay Label.
- **Step 6** In the Create DHCP Relay Label dialog box, perform the following actions:
  - a) In the **Scope** field, click the tenant radio button.

    This action displays, in the **Name** field drop-down list, the DHCP relay policy created earlier.
  - b) In the **Name** field, from the drop-down list, choose the name of the DHCP policy created (DhcpRelayP) or create a new relay policy by choosing **Create DHCP Relay Policy**.

- c) In the **DHCP Option Policy**, select an existing option policy, or create a new one by choosing **Create DHCP Option Policy**.
- d) Click Submit.

The DHCP server is associated with the bridge domain.

Step 7 In the Navigation pane, expand Networking > Bridge Domains > default > DHCP Relay Labels to view the DHCP server created.

# Configuring a DHCP Server Policy for the APIC Infrastructure Using the NX-OS Style CLI

- The port and the encapsulation used by the application Endpoint Group must belong to a physical or VM Manager (VMM) domain. If no such association with a domain is established, the APIC continues to deploy the EPG but raises a fault.
- Cisco APIC supports DHCP relay for both IPv4 and IPv6 tenant subnets. DHCP server addresses can be IPv4 or IPv6. DHCPv6 relay will occur only if IPv6 is enabled on the fabric interface and one or more DHCPv6 relay servers are configured.

### Before you begin

Ensure that Layer 2 or Layer 3 connectivity is configured to reach the DHCP server address.

### **Procedure**

Configure DHCP server policy settings for the APIC infrastructure traffic.

### Example:

### **DHCP Relay Policy for an Endpoint Group**

```
apic1(config) # tenant infra
apic1(config-tenant) # template dhcp relay policy DhcpRelayP
apic1(config-tenant-template-dhcp-relay) # ip address 10.0.0.1 tenant infra application access epg default
apic1(config-tenant-template-dhcp-relay) # exit
apic1(config-tenant) # interface bridge-domain default
apic1(config-tenant-interface) # dhcp relay policy tenant DhcpRelayP
apic1(config-tenant-interface) # exit
```

### Example:

### **DHCP Relay Policy for Layer 3 Outside**

```
ifav28-ifc2(config) # tenant dhcpTn
ifav28-ifc2(config-tenant) # template dhcp relay policy DhcpRelayPol
ifav28-ifc2(config-tenant) # template-dhcp-relay) # ip address 11.1.1.11 tenant dhcpTn application ap epg serverEpg
ifav28-ifc2(config-tenant-template-dhcp-relay) # exit
ifav28-ifc2(config-tenant) # exit
ifav28-ifc2(config-leaf) # interface ethernet 1/4
ifav28-ifc2(config-leaf) # interface ethernet 1/4
ifav28-ifc2(config-leaf-if) # no switchport
ifav28-ifc2(config-leaf-if) # vrf member tenant dhcpTn vrf vl
ifav28-ifc2(config-leaf-if) # dhcp relay policy tenant DhcpRelayPol
ifav28-ifc2(config-leaf-if) # exit
```

# Configuring a DHCP Server Policy for the APIC Infrastructure Using the REST API

- This task is a prerequisite for users who want to create a vShield domain profile.
- The port and the encapsulation used by the application endpoint group must belong to a physical or VM Manager (VMM) domain. If no such association with a domain is established, the Cisco Application Policy Infrastructure Controller (APIC) continues to deploy the EPG but raises a fault.
- Cisco APIC supports DHCP relay for both IPv4 and IPv6 tenant subnets. DHCP server addresses can be IPv4 or IPv6. DHCPv6 relay will occur only if IPv6 is enabled on the fabric interface and one or more DHCPv6 relay servers are configured.

### Before you begin

Make sure that Layer 2 or Layer 3 management connectivity is configured.

#### **Procedure**

Configure the Cisco APIC as the DHCP server policy for the infrastructure tenant.

Note

This relay policy will be pushed to all the leaf ports that are connected hypervisors using the attach entity profile configuration. For details about configuring with attach entity profile, see the examples related to creating VMM domain profiles.

### Example:

### **DHCP Relay Policy for EPG**

### Example:

### **DHCP Relay Policy for Layer 3 Outside**

**Note** You must specify DHCP Relay label under **13extLIfP** with an appropriate name and owner.

```
<polUni>
  <fvTenant name="dhcpTn">
   <13extOut name="Out1" >
```

# **Configuring a DNS Service Policy**

A DNS policy is required to connect to external servers, for example AAA, RADIUS, vCenter, and services by hostname. A DNS service policy is a shared policy, so any tenant and VRF that uses this service must be configured with the specific DNS profile label. To configure a DNS policy for the ACI fabric, you must complete the following tasks:

 Ensure that the management EPG is configured for the DNS policy, otherwise this policy will not take into effect on the switches.

Note

For the management EPG, only the default DNS policy is supported.

- Create a DNS profile (default) that contains the information about DNS providers and DNS domains.
- Associate the DNS profile (default or another DNS profile) name to a DNS label under the required tenant.

It is possible to configure a per-tenant, per-VRF DNS profile configuration. Additional DNS profiles can be created and applied to specific VRFs of specific tenants using the appropriate DNS label. For example, if you create a DNS profile with a name of acme, you can add a DNS label of acme to the appropriate **Networking** > **VRF** policy configuration in the tenants configuration.

# **Configuring External Destinations with an In-Band DNS Service Policy**

Configure the external destinations for the services as follows:

Source	In-Band Management	Out-of-Band Management	<b>External Server Location</b>
APIC	IP address or Fully Qualified domain name (FQDN)	IP address or FQDN	Anywhere

Source	In-Band Management	Out-of-Band Management		External Server Location  Anywhere
Leaf switches	IP address IP address or FQDN		ess or FQDN	
		Note	The DNS policy must specify the out-of-band management EPG for reachability of the DNS server.	
Spine switches	IP address	IP addre	ess or FQDN	Directly connected to a leaf switch
		Note	The DNS policy must specify the out-of-band management EPG for reachability of the DNS server.	

The following is a list of external servers:

- Call Home SMTP server
- Syslog server
- SNMP Trap destination
- Statistics Export destination
- Configuration Export destination
- Techsupport Export destination
- Core Export destination

The recommended guidelines are as follows:

- The external servers must be atatched to the leaf access ports.
- Use in-band connectivity for the leaf switches to avoid extra cabling for the management port.
- Use out-of-band management connectivity for the spine switches. Connect this out-of-band network for spine switches to one of the leaf ports with in-band management virtual routing and forwarding (VRF) so that the spine switches and the leaf switches can reach the same set of external servers.
- Use IP addresses for the external servers.

### **Dual Stack IPv4 and IPv6 DNS Servers**

DNS servers have primary DNS records which can be A records (IPV4) or AAAA records (IPV6). Both A and AAAA records associate domain name with a specific IP address (IPv4 or IPv6).

The ACI fabric can be configured to use reputable public DNS servers that run on IPv4. These servers are able to resolve and respond with A record (IPv4) or AAAA record (IPv6).

In a pure IPv6 environment, the system administrators must use IPv6 DNS servers. The IPv6 DNS servers are enabled by adding them to /etc/resolv.conf.

A more common environment is to have dual-stack IPv4 and IPv6 DNS servers. In the dual-stack case, both IPv4 and IPv6 name servers are listed in /etc/resolv.conf. However, in a dual-stack environment, simply appending the IPv6 DNS servers to the list may cause a large delay in DNS resolutions. This is because the IPv6 protocol takes precedence by default, and it is unable to connect to the IPv4 DNS servers (if they are listed first in /etc/resolv.conf). The solution is to list IPv6 DNS servers ahead of IPv4 DNS servers. Also add "options single-request-reopen" to enable the same socket to be used for both IPv4 and IPv6 lookups.

Here is an example of resolv.conf in dual-stack IPv4 and IPv6 DNS servers where the IPv6 DNS servers are listed first. Also note the "single-request-reopen" option:

```
options single-request-reopen
nameserver 2001:4860:4680::8888
nameserver 2001:4860:4680::8844
nameserver 8.8.8.8
nameserver 8.8.4.4
```

### **Dual-Stack IPv4 and IPv6 Environment**

If the management network in the ACI fabric supports both IPv4 and IPv6, the Linux system application (glibc) will use the IPv6 network by default because getaddrinfo() will return IPv6 first.

Under certain conditions however, an IPv4 address may be preferred over an IPv6 address. The Linux IPv6 stack has a feature which allows an IPv4 address mapped as an IPv6 address using IPv6 mapped IPv4 address (::ffff/96). This allows an IPv6 capable application to use only a single socket to accept or connect both IPv4 and IPv6. This is controlled by the glibc IPv6 selection preference for getaddrinfo() in /etc/gai.conf.

In order to allow glibc to return multiple addresses when using /etc/hosts, "multi on" should be added to the /etc/hosts file. Otherwise, it may return only the first match.

If an application is not aware whether both IPv4 and IPv6 exist, it may not perform fallback attempts using different address families. Such applications may require a fallback implementation.

# Policy for Priority of IPv4 or IPv6 in a DNS Profile

The DNS profile supports version preference choices between IPv4 and IPv6. Using the user interface, you can enable your preference. IPv4 is the default.

The following is an example of a policy based configuration using Postman REST API:

```
<?xml version="1.0" encoding="UTF-8"?>
<!- api/node/mo/uni/fabric/dnsp-default.xml ->
<dnsProfile dn="uni/fabric/dnsp-default" IPVerPreference="IPv6" childAction="" descr="" >
</dnsProfile>
```

The gai.conf settings control destination address selection. The file has a label table, precedence table, and an IPv4 scopes table. The changes for prioritizing IPv4 or IPv6 over the other need to go into the precedence

table entries. Given below are sample contents of the standard file as it is used in Linux systems for many flavors. A single line of precedence label in the file overrides any default settings.

The following is an example of a gai.conf to prioritize IPv4 over IPv6:

```
# Generated by APIC
label ::1/128
label ::/0
                    1
label 2002::/16
label ::/96
label ::ffff:0:0/96 4
precedence ::1/128
                          50
                          40
precedence ::/0
precedence 2002::/16
                          30
precedence ::/96
                          20
# For APICs prefering IPv4 connections, change the value to 100.
precedence ::ffff:0:0/96 10
```

# Configuring a DNS Service Policy to Connect with DNS Providers Using the GUI

### Before you begin

Make sure that Layer 2 or Layer 3 management connectivity is configured.

### **Procedure**

- Step 1 On the menu bar, choose FABRIC > Fabric Policies. In the Navigation pane, expand Global Policies > DNS Profiles, and click the default DNS profile.
- Step 2 In the Work pane, in the Management EPG field, from the drop-down list, choose the appropriate management EPG (default (Out-of-Band)).
- **Step 3** Expand **DNS Providers**, and perform the following actions:
  - a) In the **Address** field, enter the provider address.
  - b) In the **Preferred** column, check the check box if you want to have this address as the preferred provider. You can have only one preferred provider.
  - c) Click Update.
  - d) (Optional) To add a secondary DNS provider, expand **DNS Providers**, and in the **Address** field, type the provider address. Click **Update**.
- **Step 4** Expand **DNS Domains**, and perform the following actions:
  - a) In the **Name** field, enter the domain name (cisco.com).
  - b) In the **Default** column, check the check box to make this domain the default domain. You can have only one domain name as the default.
  - c) Click Update.
  - d) (Optional) To add a secondary DNS domain, expand **DNS Domains**. In the **Address** field, enter the secondary domain name. Click **Update**.
- Step 5 Click Submit.

The DNS server is configured.

Step 6 On the menu bar, click TENANTS > mgmt.

- Step 7 In the Navigation pane, expand Networking > VRF > oob, and click oob.
- Step 8 In the Work pane, under Properties, in the DNS labels field, enter the appropriate DNS label (default). Click Submit.

The DNS profile label is now configured on the tenant and VRF.

# Configuring a DNS Service Policy to Connect with DNS Providers Using the NX-OS Style CLI

### **Procedure**

**Step 1** In the NX-OS CLI, get into configuration mode, shown as follows:

### **Example:**

```
apic1# configure
apic1(config)#
```

**Step 2** Configure a DNS server policy.

### **Example:**

```
apicl(config) # dns
apicl(config-dns) # address 172.21.157.5 preferred
apicl(config-dns) # address 172.21.157.6
apicl(config-dns) # domain company.local default
apicl(config-dns) # use-vrf oob-default
```

**Step 3** Configure a DNS profile label on any VRF where you want to use the DNS profile.

### **Example:**

```
apic1(config) # tenant mgmt
apic1(config-tenant) # vrf context oob
apic1(config-tenant-vrf) # dns label default
```

# Configuring a DNS Service Policy to Connect with DNS Providers Using the REST API

### Before you begin

Make sure that Layer 2 or Layer 3 management connectivity is configured.

### **Procedure**

**Step 1** Configure the DNS service policy.

### **Example:**

**Step 2** Configure the DNS label under the out-of-band management tenant.

### **Example:**

```
POST URL: https://apic-IP-address/api/node/mo/uni/tn-mgmt/ctx-oob.xml <dnsLbl name="default" tag="yellow-green"/>
```

# Verifying that the DNS Profile is Configured and Applied to the Fabric Controller Switches Using the NX-OS Style CLI

### **Procedure**

**Step 1** Verify the configuration for the default DNS profile.

### **Example:**

```
apic1# show running-config dns
# Command: show running-config dns
# Time: Sat Oct   3 00:23:52 2015
   dns
      address 172.21.157.5 preferred
      address 172.21.157.6
   domain company.local default
   use-vrf oob-default
   exit
```

**Step 2** Verify the configurations for the DNS labels.

### **Example:**

```
apic1# show running-config tenant mgmt vrf context oob
# Command: show running-config tenant mgmt vrf context oob
# Time: Sat Oct    3 00:24:36 2015
    tenant mgmt
    vrf context oob
        dns label default
        exit
    exit
```

**Step 3** Verify that the applied configuration is operating on the fabric controllers.

### **Example:**

```
apic1# cat /etc/resolv.conf
# Generated by IFC
nameserver 172.21.157.5
nameserver 172.21.157.6
```

# **Configuring Custom Certificates**

# **Configuring Custom Certificate Guidelines**

- Exporting a private key that is used to generate a Certificate Signing Request (CSR) on the Cisco
  Application Policy Infrastructure Controller (APIC) is not supported. If you want to use the same certificate
  on multiple servers through a wildcard in the Subject Alternative Name (SAN) field, such as "\*cisco.com,"
  by sharing the private key that was used to generate the CSR for the certificate, generate the private key
  outside of Cisco Application Centric Infrastructure (ACI) fabric and import it to the Cisco ACI fabric.
- You must download and install the public intermediate and root CA certificates before generating a Certificate Signing Request (CSR). Although a root CA Certificate is not technically required to generate a CSR, Cisco requires the root CA certificate before generating the CSR to prevent mismatches between the intended CA authority and the actual one used to sign the CSR. The Cisco APIC verifies that the certificate submitted is signed by the configured CA.
- To use the same public and private keys for a renewed certificate generation, you must satisfy the following guidelines:
  - You must preserve the originating CSR as it contains the public key that pairs with the private key in the key ring.
  - The same CSR used for the originating certificate must be resubmitted for the renewed certificate if you want to re-use the public and private keys on the Cisco APIC.
  - Do not delete the original key ring when using the same public and private keys for the renewed certificate. Deleting the key ring will automatically delete the associated private key used with CSRs.
- Cisco ACI Multi-Site, VCPlugin, VRA, and SCVMM are not supported for certificate-based authentication.
- Only one SSL certificate is allowed per Cisco APIC cluster.
- To terminate the certificate-based authentication session, you must log out and then remove the CAC card.
- The custom certificate configured for the Cisco APIC will be deployed to the leaf and spine switches. If the URL or DN that is used to connect to the fabric node is within the **Subject** or **Subject Alternative**Name field, the fabric node will be covered under the certificate.
- The Cisco APIC GUI can accept a certificate with a maximum size of 4k bytes.

# Configuring a Custom Certificate for Cisco ACI HTTPS Access Using the GUI

CAUTION: PERFORM THIS TASK ONLY DURING A MAINTENANCE WINDOW AS THERE IS A POTENTIAL FOR DOWNTIME. The downtime affects access to the Cisco Application Policy Infrastructure Controller (APIC) cluster and switches from external users or systems and not the Cisco APIC to switch connectivity. The NGINX process on the switches will also be impacted, but that will be only for external connectivity and not for the fabric data plane. Access to the Cisco APIC, configuration, management, troubleshooting, and such will be impacted. The NGINX web server running on the Cisco APIC and switches will be restarted during this operation.

### Before you begin

Determine from which authority you will obtain the trusted certification so that you can create the appropriate Certificate Authority.

#### **Procedure**

- **Step 1** On the menu bar, choose Admin > AAA.
- Step 2 In the Navigation pane, choose Public Key Management > Certificate Authorities.
- Step 3 In the Work pane, choose Actions > Create Certificate Authority.
- **Step 4** In the Create Certificate Authority dialog box, in the Name field, enter a name for the certificate authority.
- Step 5 In the Certificate Chain field, copy the intermediate and root certificates for the certificate authority that will sign the Certificate Signing Request (CSR) for the Cisco APIC.

The certificate should be in Base64 encoded X.509 (CER) format. The intermediate certificate is placed before the root CA certificate. It should look similar to the following example:

```
----BEGIN CERTIFICATE-----
<Intermediate Certificate>
----END CERTIFICATE-----
<ROOT CA CERTIFICATE-----
<ROOT CA CERTIFICATE-----
```

- Step 6 Click Submit.
- Step 7 In the Navigation pane, choose Public Key Management > Key Rings.
- Step 8 In the Work pane, choose Actions > Create Key Ring.

The key ring enables you to manage a private key (imported from external device or internally generated on APIC), a CSR generated by the private key, and the certificate signed via the CSR.

- **Step 9** In the **Create Key Ring** dialog box, in the **Name** field, enter a name.
- In the **Certificate** field, do not add any content if you will generate a CSR using the Cisco APIC through the key ring. Alternately, add the signed certificate content if you already have one that was signed by the CA from the previous steps by generating a private key and CSR outside of the Cisco APIC,
- **Step 11** In the **Modulus** field, click the radio button for the desired key strength.
- Step 12 In the Certificate Authority field, from the drop-down list, choose the certificate authority that you created earlier, then click Submit.
- Step 13 In the Private Key field, do not add any content if you will generate a CSR using the Cisco APIC through the key ring. Alternately, add the private key used to generate the CSR for the signed certificate that you entered in step 10.

**Note** Do not delete the key ring. Deleting the key ring will automatically delete the associated private key used with CSRs.

If you have not entered the signed certificate and the private key, in the **Work** pane, in the **Key Rings** area, the **Admin State** for the key ring created displays **Started**, waiting for you to generate a CSR. Proceed to step 14.

If you entered both the signed certificate and the private key, in the **Key Rings** area, the **Admin State** for the key ring created displays **Completed**. Proceed to step 23.

- Step 14 In the Navigation pane, choose Public Key Management > Key Rings > key\_ring\_name.
- Step 15 In the Work pane, choose Actions > Create Certificate Request.
- **Step 16** In the **Subject** field, enter the common name (CN) of the CSR.

You can enter the fully qualified domain name (FQDN) of the Cisco APICs using a wildcard, but in a modern certificate, we generally recommend that you enter an identifiable name of the certificate and enter the FQDN of all Cisco APICs in the **Alternate Subject Name** field (also known as the *SAN* – Subject Alternative Name) because many modern browsers expect the FQDN in the SAN field.

In the **Alternate Subject Name** field, enter the FQDN of all Cisco APICs, such as "DNS:apic1.example.com,DNS:apic2.example.com,DNS:apic3.example.com" or "DNS:\*example.com".

Alternatively, if you want SAN to match an IP address, enter the Cisco APICs' IP addresses with the following format:

IP:192.168.2.1

You can use DNS names, IPv4 addresses, or a mixture of both in this field. IPv6 addresses are not supported.

**Step 18** Fill in the remaining fields as appropriate.

Note Check the online help information available in the **Create Certificate Request** dialog box for a description of the available parameters.

### Step 19 Click Submit.

Inside the same key ring, the **Associated Certificate Request** area is now displayed with the **Subject, Alternate Subject Name** and other fields you entered in the previous steps along with the new field **Request**, which contains the content of the CSR that is tied to this key ring. Copy the content from the **Request** field to submit the content to the same certificate authority that is tied to this key ring for signing.

- Step 20 In the Navigation pane, choose Public Key Management > Key Rings > key ring name.
- Step 21 In the Work pane, in the Certificate field, paste the signed certificate that you received from the certificate authority.
- Step 22 Click Submit.

**Note** If the CSR was not signed by the Certificate Authority indicated in the key ring, or if the certificate has MS-DOS line endings, an error message is displayed and the certificate is not accepted. Remove the MS-DOS line endings.

The key is verified, and in the **Work** pane, the **Admin State** changes to **Completed** and is now ready for use in the HTTP policy.

- Step 23 On the menu bar, choose Fabric > Fabric Policies.
- Step 24 In the Navigation pane, choose Pod Policies > Policies > Management Access > default.

- Step 25 In the Work pane, in the Admin Key Ring drop-down list, choose the desired key ring.
- **Step 26** (Optional) For Certificate based authentication, in the **Client Certificate TP** drop-down list, choose the previously created Local User policy and click **Enabled** for **Client Certificate Authentication state**.
- Step 27 Click Submit.

All web servers restart. The certificate is activated, and the non-default key ring is associated with HTTPS access.

### What to do next

You must remain aware of the expiration date of the certificate and take action before it expires. To preserve the same key pair for the renewed certificate, you must preserve the CSR as it contains the public key that pairs with the private key in the key ring. Before the certificate expires, the same CSR must be resubmitted. Do not delete or create a new key ring as deleting the key ring will delete the private key stored internally on the Cisco APIC.

# **Provisioning Fabric Wide System Settings**

# **Configuring APIC In-Band or Out-of-Band Connectivity Preferences**

This topic describes how to toggle between in-band and out-of-band connectivity on the APIC server for management access to devices such as authentication servers or SNMP servers external to the ACI fabric. Enabling **inband** executes in-band management connectivity between the APIC server to external devices through leaf switches on the ACI fabric. Enabling **ooband** executes out-of-band management connectivity between the APIC server to external devices through connections external to the ACI fabric.

### Before you begin

Configure in-band and out-of-band management networks. For more information, see *Management* in the *Cisco APIC Basic Configuration Guide, Release 3.x.* 

### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 On the Navigation bar, click APIC Connectivity Preferences.
- **Step 3** To enable the policy, click **inband** or **ooband**.
- Step 4 Click Submit.

# **Configure Quota Management Policies**

Starting in the Cisco Application Policy Infrastructure Controller (APIC) Release 2.3(1), there are limits on number of objects a tenant admin can configure. This enables the admin to limit the number of managed objects that can be added globally across tenants.

This feature is useful when you want to limit any tenant or group of tenants from exceeding ACI maximums per leaf or per fabric or unfairly consuming a majority of available resources, potentially affecting other tenants on the same fabric.

### **Procedure**

- Step 1 On the menu bar, click System > System Settings.
- Step 2 Right-click Quota and choose Create Quota Configuration...
- **Step 3** In the Class field, choose the object type to limit with the quota.
- **Step 4** In the **Container Dn** field, enter the distinguished name (DN) that describes the class.
- Step 5 In the Exceed Action field, choose either Fail Transaction Action or Raise Fault Action.
- **Step 6** In the **Max Number** field, enter the maximum number of the managed objects that can be created after which the exceed action will be applied.
- Step 7 Click Submit.

# **Create an Enforced BD Exception List**

This topic describes how to create a global exception list of subnets which are not subject to an enforced bridge domain. With the Enforced BD feature configured, the endpoints in a subject endpoint group (EPG) can only ping subnet gateways within the associated bridge domain.

The exception IP addresses can ping all of the BD gateways across all of your VRFs.

A loopback interface configured for an L3Out does not enforce reachability to the IP address that is configured for the subject loopback interface.

When an eBGP peer IP address exists in a different subnet than the subnet of the L3Out interface, the peer subnet must be added to the allowed exception subnets. Otherwise, eBGP traffic is blocked because the source IP address exists in a different subnet than the L3Out interface subnet.

### Before you begin

Create an enforced bridge domain (BD).

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click BD Enforced Exception List.
- Step 3 Click the + on Exception List.
- **Step 4** Add the IP address and network mask for the subnet that can ping any subnet gateway.
- **Step 5** Repeat to add more subnets that are exceptions to the enforced bridge domain.
- Step 6 Click Submit.

# Create a BGP Route Reflector Policy and Route Reflector Node Endpoints

This topic describes how to create ACI fabric route reflectors, which use multiprotocol BGP (MP-BGP) to distribute external routes within the fabric. To enable route reflectors in the ACI fabric, the fabric administrator must select the spine switches that will be the route reflectors, and provide the autonomous system (AS) number. Once route reflectors are enabled in the ACI fabric, administrators can configure connectivity to external networks.

### Before you begin

### Required:

- To connect external routers to the ACI fabric, the fabric infrastructure administrator must configure spine nodes as Border Gateway Protocol (BGP) route reflectors.
- For redundancy purposes, more than one spine is configured as a router reflector node (one primary and one secondary reflector).

### **Procedure**

- **Step 1** To create a BGP Route Reflector policy, perform the following steps:
  - a) On the menu bar, click **System** > **System Settings**.
  - b) Click **BGP Route Reflector**.
  - c) Enter the Autonomous System Number.
  - d) Click the + on **Route Reflector Nodes**.
  - e) Enter the spine route reflector node ID endpoint, and click **Submit**.,
- **Step 2** To create external route reflector node endpoints, perform the following steps:
  - a) Click the + on **External Route Reflector Nodes**.
  - b) Choose the spine to serve as external route reflector node endpoint.
  - c) If this is a site managed by Multi-Site, you can also specify an intersite spine route reflector.
  - d) Click Submit.

# **Configure a Fabric Wide Control Plane MTU Policy**

This topic describes how to create a fabric-wide Control Plane (CP) MTU policy, that sets the global MTU size for control plane packets sent by the nodes (APIC and the switches) in the fabric.

In a multipod topology, the MTU setting for the fabric external ports must be greater than or equal to the CP MTU value set. Otherwise, the fabric external ports might drop the CP MTU packets.

Note

If you set the L3Out Interface Profile to inherit the MTU from the IPN, it will be 9150. If you want the MTU to be used across the IPN to be 9216, you must explicitly configure it in the L3Out Interface Profile (at Tenants > tenant-name > Networking > External Routed Networks > Create Routed Outside > Nodes and Interface Profole > Create Node Profile > Create Interface Profile).

If you change the IPN or CP MTU, Cisco recommends changing the CP MTU value first, then changing the MTU value on the spine of the remote pod. This reduces the risk of losing connectivity between the pods due to MTU mismatch.

### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click Control Plane MTU.
- **Step 3** Enter the MTU for fabric ports.
- Step 4 Click Submit.

# **Create a COOP Group Policy**

This topic describes how to create a Council of Oracle Protocol (COOP) Group Policy, which is used to communicate the mapping information (location and identity) to the spine proxy. A leaf switch forwards endpoint address information to the spine switch 'Oracle' using Zero Message Queue (ZMQ). COOP running on the spine nodes will ensure all spine nodes maintain a consistent copy of endpoint address and location information and additionally maintain the distributed hash table (DHT) repository of endpoint identity to location mapping database.

#### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click COOP Group.
- **Step 3** Choose the policy property type. The type can be **Compatible Type** or **Strict Type**.

The Oracle Nodes are the spines in the fabric, automatically populated by the system.

Step 4 Click Submit

# **Configure Endpoint Loop Protection**

The endpoint loop protection policy specifies how loops detected by frequent MAC moves are handled. To configure EP loop protection perform the following steps:

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click Endpoint Controls.
- Step 3 Click the Ep Loop Protection tab.
- Step 4 To enable the policy, click **Enabled** in the **Administrative State** field.

- **Step 5** Optional. Set the loop detection interval, which specifies the time to detect a loop. The interval range is from 30 to 300 seconds. The default setting is 60 seconds.
- Set the loop detection multiplication factor, which is the number of times a single EP moves between ports within the loop detection interval. The range is from 1 to 255. The default is 4.
- **Step 7** Choose the action to take when detecting a loop.

The action can be:

- BD Learn Disable
- Port Disable

The default is **Port Disable**.

Step 8 Click Submit.

# **About the Rogue Endpoint Control Policy**

A rogue endpoint attacks leaf switches through frequently, repeatedly injecting packets on different leaf switch ports and changing 802.1Q tags (thus, emulating endpoint moves) causing learned class and EPG port changes. Misconfigurations can also cause frequent IP and MAC address changes (moves).

Such rapid movement in the fabric causes significant network instability, high CPU usage, and in rare instances, endpoint mapper (EPM) and EPM client (EPMC) crashes due to significant and prolonged messaging and transaction service (MTS) buffer consumption. Also, such frequent moves may result in the EPM and EPMC logs rolling over very quickly, hampering debugging for unrelated endpoints.

The rogue endpoint control feature addresses this vulnerability by quickly:

- Identifying such rapidly moving MAC and IP endpoints.
- Stopping the movement by temporarily making endpoints static, thus quarantining the endpoint.
- Prior to 3.2(6) release: Keeping the endpoint static for the Rogue EP Detection Interval and dropping
  the traffic to and from the rogue endpoint. After this time expires, deleting the unauthorized MAC or IP
  address.
- In the 3.2(6) release and later: Keeping the endpoint static for the **Rogue EP Detection Interval** (this feature no longer drops the traffic). After this time expires, deleting the unauthorized MAC or IP address.
- Generating a host tracking packet to enable the system to re-learn the impacted MAC or IP address.
- Raising a fault to enable corrective action.

The rogue endpoint control policy is configured globally and, unlike other loop prevention methods, functions at the level of individual endpoints (IP and MAC addresses). It does not distinguish between local or remote moves; any type of interface change is considered a move in determining if an endpoint should be quarantined.

The rogue endpoint control feature is disabled by default.

## **Limitations of the Rogue Endpoint Control Policy**

The following limitations apply when using a rogue endpoint control policy:

• Changing rogue endpoint control policy parameters will not affect existing rogue endpoints.

- If a rogue endpoint is enabled, loop detection and bridge domain move frequency will not take effect.
- Disabling the rogue endpoint feature clears all rogue endpoints.
- The endpoint mapper (EPM) has value limits for rogue endpoint parameters. If you set the parameter values outside of this range, the Cisco APIC raises a fault for each mismatched parameter.
- The rogue endpoint feature is not supported on remote leaf switches or Cisco ACI Multi-Site.
- You must disable rogue endpoint control before you upgrade to or from Cisco APIC release 4.1.

### **Configuring the Rogue Endpoint Control Policy Using the GUI**

You can configure the **Rogue EP Control** policy for the fabric, to detect and delete unauthorized endpoints, using the Cisco Application Policy Infrastructure Controller (Cisco APIC) GUI. This topic also includes the steps to clear rogue endpoints on a TOR switch, ad-hoc.

The policy options have the following valid and supported values:

- **Rogue EP Detection Interval**—Sets the rogue endpoint detection interval, which specifies the time to detect rogue endpoints. Valid values are from 0 to 65535 seconds. The default is 60.
- Hold Interval (sec)—Interval in seconds after the endpoint is declared rogue, where it is kept static so learning is prevented and the traffic to and from the Rogue endpoint is dropped. After this interval, the endpoint is deleted. Valid values are from 1800 to 3600. The default is 1800.
- Rogue EP Detection Multiplication Factor—Sets the rogue endpoint detection multiplication factor for determining if an endpoint is unauthorized. If the endpoint moves more times than this number, within the EP detection interval, the endpoint is declared rogue. Valid values are from 2 to 10. The default is 6.

### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 On the navigation bar, click Endpoint Controls and click the Rogue EP Control tab.
- **Step 3** Set the **Administrative State** to **Enabled**.
- Step 4 Optional. Reset the Rogue EP Detection Interval (sec), Rogue EP Detection Multiplication Factor, or the Hold Interval (sec).
- **Step 5** (Optional) To clear rogue endpoints on a TOR switch, perform the following steps:
  - a) On the Cisco APIC menu bar, click **Fabric** > **Inventory**.
  - b) On the Navigation bar, expand the Pod and click the leaf switch where you want to clear rogue endpoints.
  - c) When the leaf switch summary appears in the work pane, right-click the leaf switch name in the Navigation bar, and choose **Clear Rogue Endpoints**.
  - d) Click Yes.

## Configure the Rogue Endpoint Control Policy Using the NX-OS Style CLI

You can configure the rogue endpoint control policy for the fabric to detect and delete unauthorized endpoints using the NX-OS style CLI.

#### **Procedure**

**Step 1** Enter global configuration mode.

### Example:

apic1# configure

**Step 2** Enable the global rogue endpoint control policy.

### Example:

apic1(config) # endpoint rogue-detect enable

**Step 3** Set the hold interval.

The hold interval is a period of time in seconds after the endpoint is declared rogue that the endpoint is kept static so that learning is prevented, and the traffic to and from the endpoint is dropped. After this interval, the endpoint is deleted. Valid values are from 1800 to 3600 seconds. The default is 1800.

### Example

apic1(config) # endpoint rogue-detect hold-interval 1800

**Step 4** Set the detection interval.

The detection interval is a period of time in seconds during which rogue endpoint control counts the number of moves for an endpoint. If the count during this interval exceeds the value specified by the detection multiplication factor, the endpoint is declared rogue. Valid values are from 0 to 65535 seconds. The default is 60.

### **Example:**

apic1(config)# endpoint rogue-detect interval 60

**Step 5** Set the detection multiplication factor.

If an endpoint moves more times than the value specified by the detection multiplication factor during a period of time specified by the detection interval, the endpoint is declared rogue. Valid values are from 2 to 10. The default is 6.

### **Example:**

apic1# endpoint rogue-detect factor 6

## **Configure the Rogue Endpoint Control Policy Using the REST API**

You can configure the rogue endpoint control policy for the fabric to detect and delete unauthorized endpoints using the REST API.

### **Procedure**

**Step 1** To configure the rogue endpoint control policy, send a post with XML similar to the following example:

### **Example:**

- adminst: The administrative state of rogue endpoint control. Specify enable to enable rogue endpoint control.
- holdIntvl: Rogue endpoint hold interval. The hold interval is a period of time in seconds after the endpoint is declared rogue that the endpoint is kept static so that learning is prevented, and the traffic to and from the endpoint is dropped. After this interval, the endpoint is deleted. The valid values are from 1800 to 3600 seconds. The default is 1800.
- rogueEpDetectIntv1: Rogue endpoint detection interval. The detection interval is a period of time in seconds during which rogue endpoint control counts the number of moves for an endpoint. If the count during this interval exceeds the value specified by the detection multiplication factor, the endpoint is declared rogue. Valid values are from 0 to 65535 seconds. The default is 60.
- rogueEpDetectMult: Rogue endpoint detection multiplication factor. If an endpoint moves more times than the value specified by the detection multiplication factor during a period of time specified by the detection interval, the endpoint is declared rogue. Valid values are from 2 to 10. The default is 6.
- **Step 2** In the 3.2(6) release and later, you can revert this feature's behavior so that it once again drops the traffic to and from rogue endpoints by sending a post with XML similar to the following example:

### **Example:**

<infraImplicitSetPol rogueModeAction="quarantine-fault-and-drop" infraDn="uni/infra"/>

# **Configure IP Aging**

This topic describes how to enable an IP Aging policy. When enabled, the IP aging policy ages unused IPs on an endpoint.

When the Administrative State is enabled, the IP aging policy sends ARP requests (for IPv4) and neighbor solicitations (for IPv6) to track IPs on endpoints. If no response is given, the policy ages the unused IPs.

### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click Endpoint Controls.
- Step 3 Click the **Ip Aging** tab.
- Step 4 To enable the policy, click **Enabled** in the **Administrative State** field.

### What to do next

Create an End Point Retention policy, which is required, to specify the timer used for tracking IPs on endpoints. Navigate to **Tenants** > **tenant-name** > **Policies** > **Protocol** > **End Point Retention**.

# **Disable Remote Endpoint Learning**

This topic describes how to enable or disable IP end point learning.

The scope of this policy is fabric-wide. After configuration, a policy is pushed to each leaf switch as it comes up.

You should enable this policy in fabrics which include the Cisco Nexus 9000 series switches, 93128 TX, 9396 PX, or 9396 TX switches with the N9K-M12PQ uplink module, after all the nodes have been successfully upgraded to APIC Release 2.2(2x) or higher.

After any of the following configuration changes, you may need to manually flush previously learned IP endpoints:

- Remote IP endpoint learning is disabled
- The VRF is configured for ingress policy enforcement
- At least one Layer 3 interface exists in the VRF

To manually flush previously learned IP endpoints, enter the following command on both VPC peers: vsh -c "clear system internal epm endpoint vrf <vrf-name> remote"

To enable or disable IP end point learning, perform the following steps:

### **Procedure**

- Step 1 On the menu bar, click System > System Settings.
- Step 2 Click Fabric Wide Setting.
- Step 3 Click the check box on Disable Remote EP Learn.
- Step 4 Click Submit.

# **Globally Enforce Subnet Checks**

This topic describes how to enable or disable subnet checking. When enabled, IP address learning is disabled outside of subnets configured in a VRF, for all other VRFs.

The scope of this policy is fabric-wide. After configuration, a policy is pushed to each leaf switch as it comes up.

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click Fabric Wide Setting.
- **Step 3** Click the check box on **Enforce Subnet Check**.
- Step 4 Click Submit.

## Reallocate a GIPo

This topic describes how to enable reallocating GIPos on non-stretched BDs to make room for stretched BDs.

The scope of this policy is fabric-wide. After configuration, a policy is pushed to each leaf switch as it comes up.

### **Procedure**

- Step 1 On the menu bar, click System > System Settings.
- Step 2 Click Fabric Wide Setting.
- **Step 3** Click the check box on **Reallocate Gipo**.
- Step 4 Click Submit.

# **Globally Enforce Domain Validation**

This topic describes how to enforce domain validation. When enabled, a validation check is performed when a static path is added, to determine if no domain is associated with an EPG.

The scope of this policy is fabric-wide. After configuration, a policy is pushed to each leaf switch as it comes up.

### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click Fabric Wide Setting.
- Step 3 Click the check box on **Enforce Domain Validation**.
- Step 4 Click Submit.

# **Enable OpFlex Client Authentication**

This topic describes how to enable OpFlex client authentication for GOLF and Linux.

To deploy GOLF or Linux Opflex clients in an environment where the identity of the client cannot be guaranteed by the network, you can dynamically validate the client's identity based on a client certificate.

Note

When you enable certificate enforcement, connectivity with any GOLF or Linux Opflex client that does not support client authentication is disabled.

The scope of this policy is fabric-wide. After configuration, a policy is pushed to each leaf switch as it comes up.

#### **Procedure**

- Step 1 On the menu bar, click System > System Settings.
- Step 2 Click Fabric Wide Setting.
- Step 3 Click the check box on **OpFlex Client Authentication** to enable or disable enforcing client certificate authentication for GOLF and Linux Opflex clients.
- Step 4 Click Submit.

# **Fabric Load Balancing**

The ACI fabric provides several load balancing options for balancing the traffic among the available uplink links. This topic describes load balancing for leaf to spine switch traffic.

Static hash load balancing is the traditional load balancing mechanism used in networks where each flow is allocated to an uplink based on a hash of its 5-tuple. This load balancing gives a distribution of flows across the available links that is roughly even. Usually, with a large number of flows, the even distribution of flows results in an even distribution of bandwidth as well. However, if a few flows are much larger than the rest, static load balancing might give suboptimal results.

ACI fabric Dynamic Load Balancing (DLB) adjusts the traffic allocations according to congestion levels. It measures the congestion across the available paths and places the flows on the least congested paths, which results in an optimal or near optimal placement of the data.

DLB can be configured to place traffic on the available uplinks using the granularity of flows or flowlets. Flowlets are bursts of packets from a flow that are separated by suitably large gaps in time. If the idle interval between two bursts of packets is larger than the maximum difference in latency among available paths, the second burst (or flowlet) can be sent along a different path than the first without reordering packets. This idle interval is measured with a timer called the flowlet timer. Flowlets provide a higher granular alternative to flows for load balancing without causing packet reordering.

DLB modes of operation are aggressive or conservative. These modes pertain to the timeout value used for the flowlet timer. The aggressive mode flowlet timeout is a relatively small value. This very fine-grained load balancing is optimal for the distribution of traffic, but some packet reordering might occur. However, the overall benefit to application performance is equal to or better than the conservative mode. The conservative mode flowlet timeout is a larger value that guarantees packets are not to be re-ordered. The tradeoff is less granular load balancing because new flowlet opportunities are less frequent. While DLB is not always able to provide the most optimal load balancing, it is never worse than static hash load balancing.

The ACI fabric adjusts traffic when the number of available links changes due to a link going off-line or coming on-line. The fabric redistributes the traffic across the new set of links.

In all modes of load balancing, static or dynamic, the traffic is sent only on those uplinks or paths that meet the criteria for equal cost multipath (ECMP); these paths are equal and the lowest cost from a routing perspective.

Dynamic Packet Prioritization (DPP), while not a load balancing technology, uses some of the same mechanisms as DLB in the switch. DPP configuration is exclusive of DLB. DPP prioritizes short flows higher than long flows; a short flow is less than approximately 15 packets. Because short flows are more sensitive to latency than long ones, DPP can improve overall application performance.

The ACI fabric default configuration uses a traditional static hash. A static hashing function distributes the traffic between uplinks from the leaf switch to the spine switch. When a link goes down or comes up, traffic on all links is redistributed based on the new number of uplinks.

### **PC/VPC Host Load Balancing**

The following table provides the default (non-configurable) algorithms used in PC/VPC host load balancing.

Table 1: ACI Fabric Dynamic Load Balancing Algorithms

Traffic Type	Hashing Data Points		
IP unicast	Source IP address		
	Destination IP address		
	Protocol type		
	Source port		
	Destination port		
Layer 2 traffic	Source MAC address and Destination MAC address		
End Host (PC and VPC) traffic	For Layer 2 frames: Source MAC address and Destination MAC address		
	For IP traffic:		
	Source IP address		
	Destination IP address		
	Source MAC address		
	Destination MAC address		
	• Layer 4 Source Port		
	Layer 4 Destination Port		
	• Protocol		
	System generated random number		

## **Create a Load Balancer Policy**

This topic describes how to configure the default Load Balancer policy.

The load balancing policy options balance traffic among the available uplink ports. Static hash load balancing is the traditional load balancing mechanism used in networks where each flow is allocated to an uplink based on a hash of its 5-tuple. This load balancing gives a distribution of flows across the available links that is roughly even. Usually, with a large number of flows, the even distribution of flows results in an even distribution of bandwidth as well. However, if a few flows are much larger than the rest, static load balancing might give suboptimal results.

#### **Procedure**

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Click Load Balancer.
- **Step 3** Choose the **Dynamic Load Balancing Mode**.

The dynamic load balancer (DLB) mode adjusts the traffic allocations according to congestion levels. It measures the congestion across the available paths and places the flows on the least congested paths, which results in an optimal or near optimal placement of the data. DLB can be configured to place traffic on the available uplinks using the granularity of flows or of flowlets. Flowlets are bursts of packets from a flow that are separated by intervals. The mode can be **Aggressive**, **Conservative**, or **Off** (the default).

**Step 4** Enable or disable **Dynamic Packet Prioritization** by choosing **On** or **Off** (the default.

Dynamic Packet Prioritization (DPP) prioritizes short flows higher than long flows; a short flow is less than approximately 15 packets. Short flows are more sensitive to latency than long ones. DPP can improve overall application performance.

**Step 5** Choose the Load Balancing Mode. The mode can be **Link Failure** or **Traditional** (the default).

The load balancer administrative state. In all modes of load balancing, static or dynamic, the traffic is sent only on those uplinks or paths that meet the criteria for equal cost multipath (ECMP); these paths are equal and the lowest cost from a routing perspective.

Step 6 Click Submit.

### **Creating a Load Balancer Policy Using the CLI**

### Creating a Dynamic Load Balancer Policy Using the CLI

There are two dynamic load balancer modes: **dynamic-aggressive** and **dynamic-conservative**. The **dynamic-aggressive** mode enables a shorter flowlet timeout interval, and the **dynamic-conservative** mode enables a longer flowlet timeout interval. For more information about these commands, see the *Cisco APIC NX-OS Style CLI Command Reference*.

This section demonstrates how to configure a dynamic load balancer policy using the CLI.

### **Procedure**

**Step 1** To enable aggressive mode dynamic load balancing:

```
apic1# conf t
apic1# (config)# system dynamic-load-balance mode dynamic-aggressive
```

**Step 2** To enable conservative mode dynamic load balancing:

```
apic1# conf t
apic1# (config)# system dynamic-load-balance mode dynamic-conservative
```

### **Creating a Dynamic Packet Prioritization Policy Using the CLI**

This section demonstrates how to enable dynamic packet prioritization using the CLI. For more information about this command, see the *Cisco APIC NX-OS Style CLI Command Reference*.

### **Procedure**

Enable dynamic packet prioritization:

```
apic1# conf t
apic1# (config)# system dynamic-load-balance mode packet-prioritization
```

### **Creating a GTP Load Balancer Policy Using the CLI**

This section demonstrates how to create a GTP load balancer policy using the CLI. For more information about this command, see the *Cisco APIC NX-OS Style CLI Command Reference*.

### **Procedure**

Enable dynamic packet prioritization:

```
apic1# conf t
apic1# (config)# ip load-sharing address source_destination gtpu
```

## **Creating a Load Balancer Policy Using the REST API**

This section demonstrates how to enable a DLB, DPP, and a GTP load balancer policy. For a list of all possible property values, see the *Cisco APIC Management Information Model Reference*.

### **Procedure**

To enable a DLB, DPP, and GTP load balancer policy:

# **Enable a Time Precision Policy**

This topic describes how to enable Precision Time Protocol (PTP), a time synchronization protocol for nodes distributed across a network. Its hardware timestamp feature provides greater accuracy than other time synchronization protocols such as Network Time Protocol (NTP).

PTP is a distributed protocol that specifies how real-time PTP clocks in the system synchronize with each other. These clocks are organized into a master-member synchronization hierarchy with the grandmaster clock, the clock at the top of the hierarchy, determining the reference time for the entire system. Synchronization is achieved by exchanging PTP timing messages, with the members using the timing information to adjust their clocks to the time of their master in the hierarchy. PTP operates within a logical scope called a PTP domain.

### **Procedure**

- Step 1 On the menu bar, click System > System Settings.
- Step 2 Click Precision Time Protocol.
- Step 3 Choose Enabled or Disabled.

If you choose disable PTP, NTP time is used to sync the fabric. If you enable PTP, a spine is automatically chosen as a master to which the entire site gets synced.

Step 4 Click Submit.

# **Enable a Global System GIPo Policy**

This topic describes how to use the infra tenant GIPo as the system GIPo.

An ACI multipod deployment requires the 239.255.255.240 system Global IP Outside (GIPo) to be configured on the inter-pod network (IPN) as a PIM BIDIR range. This 239.255.255.240 PIM BIDIR range configuration on the IPN devices can be avoided by using the infra GIPo as System GIPo.

### Before you begin

Upgrade all of the switches in the ACI fabric, including the leaf switches and spine switches, to the latest APIC release.

- **Step 1** On the menu bar, click **System > System Settings**.
- Step 2 Choose Enabled or Disabled (the default) on Use Infra GIPo as System GIPo
- Step 3 Click Submit.

# **Provisioning Global Fabric Access Policies**

# **Create a Global Attachable Access Entity Profile**

An Attachable Entity Profile (AEP) represents a group of external entities with similar infrastructure policy requirements. The infrastructure policies consist of physical interface policies that configure various protocol options, such as Cisco Discovery Protocol (CDP), Link Layer Discovery Protocol (LLDP), or Link Aggregation Control Protocol (LACP).

An AEP is required to deploy VLAN pools on leaf switches. Encapsulation blocks (and associated VLANs) are reusable across leaf switches. An AEP implicitly provides the scope of the VLAN pool to the physical infrastructure.

The following AEP requirements and dependencies must be accounted for in various configuration scenarios, including network connectivity, VMM domains, and multipod configuration:

- The AEP defines the range of allowed VLANs but it does not provision them. No traffic flows unless an EPG is deployed on the port. Without defining a VLAN pool in an AEP, a VLAN is not enabled on the leaf port even if an EPG is provisioned.
- A particular VLAN is provisioned or enabled on the leaf port that is based on EPG events either statically binding on a leaf port or based on VM events from external controllers such as VMware vCenter or Microsoft Azure Service Center Virtual Machine Manager (SCVMM).
- Attached entity profiles can be associated directly with application EPGs, which deploy the associated application EPGs to all those ports associated with the attached entity profile. The AEP has a configurable generic function (infraGeneric), which contains a relation to an EPG (infraRsFuncToEpg) that is deployed on all interfaces that are part of the selectors that are associated with the attachable entity profile.

A virtual machine manager (VMM) domain automatically derives physical interface policies from the interface policy groups of an AEP.

### Before you begin

Create the tenant, VRF instance, application profiles, and EPGs to associate to the attached entity profile.

- **Step 1** On the menu bar, click **Fabric** > **Access Policies**.
- Step 2 On the navigation bar, expand Policies and Global.
- Step 3 Right-click Attachable Access Entity Profile and choose Create Attachable Access Entity Profile.
- **Step 4** Enter a name for the policy.
- **Step 5** Click the + icon on **Domains** table.
- **Step 6** Enter a physical domain, a previously created physical, Layer 2, Layer 3, or Fibre Channel domain, or create one
- **Step 7** Enter the encapsulation for the domain and click **Update**.
- Step 8 Click the + icon on the EPG DEPLOYMENT table.

- Step 9 Enter the tenant, application profile, EPG, encapsulation (such as vlan-1), primary encapsulation (primary encapsulation number) and interface mode (trunk, Access (802.1P, or Access (Untagged).
   Step 10 Click Update.
   Step 11 Click Next.
- **Step 12** Choose the interfaces to associate to the attachable entity profile.
- Step 13 Click Finish.

# **Configure the Global QoS Class Policy**

The global QoS Class policy can be used to:

- Preserve the CoS priority level, to guarantee that the CoS value in 802.1P packets which enter and transit the ACI fabric is preserved. 802.1P CoS preservation is supported in single pod and multipod topologies. In multipod topologies, CoS Preservation can be used where you want to preserve the QoS priority settings of 802.1P traffic entering POD 1 and egressing out of POD 2, but you are not concerned with preserving the CoS/DSCP settings in interpod network (IPN) traffic between the pods. To preserve CoS/DSCP settings when multipod traffic is transitting an IPN, use a DSCP policy (configured at Tenants > infra > Policies > Protocol > DSCP class-cos translation policy for L3 traffic)
- Reset the properties for the default QoS class levels, such as the MTU, Queue Limit, or Scheduling Algorithm.

### **Procedure**

- **Step 1** On the menu bar, click **Fabric** > **External Access Policies**.
- Step 2 On the navigation bar, expand Policies and Global.
- Step 3 Click QOS Class.
- **Step 4** To enable 802.1P CoS preservation, click the **Preserve COS** check box.
- **Step 5** To change the default settings for a QoS class, double-click on it. Enter the new settings and click **Submit**.

## **Create a Global DHCP Relay Policy**

The global DHCP Relay policy identifies the DHCP Server for the fabric.

- Step 1 On the menu bar, click Fabric > External Access Policies.
- Step 2 On the navigation bar, expand Policies and Global.
- Step 3 Right-click DHCP Relay and choose Create DHCP Relay Policy.
- **Step 4** Enter a name for the policy.
- **Step 5** Click the + icon on **Providers**.

- **Step 6** Choose the EPG type, and for an application EPG, choose the tenant, application profile, and the EPG to be the provider
- **Step 7** In the **DHCP Server Address** field, enter the IP address for the server.
- Step 8 Click OK.

# **Enable a Global MCP Instance Policy**

Enable a global Mis-Cabling Protocol (MCP) instance policy. In the current implementation, only one instance of MCP runs in the system.

### **Procedure**

- **Step 1** On the menu bar, click **Fabric** > **External Access Policies**.
- Step 2 On the navigation bar, expand Policies and Global.
- Step 3 Click MCP Instance Policy default.
- **Step 4** Change the **Admin State** to **Enabled**.
- **Step 5** Set other properties as needed for your fabric.
- Step 6 Click Submit.

### What to do next

# **Create an Error Disabled Recovery Policy**

The error disabled recovery policy specifies the policy for re-enabling a port that was disabled due to one or more pre-defined error conditions.

- Step 1 On the menu bar, click Fabric > External Access Policies.
- Step 2 On the navigation bar, expand Policies and Global.
- Step 3 Click Error Disabled Recovery Policy..
- **Step 4** Double-click on an event to enable it for the recovery policy.
- **Step 5** Click the check box and click **Update**.
- **Step 6** Optional. Repeat steps 4 and 5 for more events.
- Step 7 Optional. Reset the Error disable recovery interval (sec).
- Step 8 Click Submit.

# **Configure a Fabric Port Tracking Policy**

Uplink failure detection can be enabled in the fabric access fabric port tracking policy. The port tracking policy monitors the status of links between leaf switches and spine switches. When an enabled port tracking policy is triggered, the leaf switches take down all access interfaces on the switch that have EPGs deployed on them. For more information about fabric port tracking, see the *Cisco APIC Layer 2 Networking Configuration Guide*.

- **Step 1** In the 3.2(1) release or earlier, navigate to the following location:
  - a) On the menu bar, choose **Fabric** > **Access Policies**.
  - b) In the Navigation pane, choose **Policies** > **Global**.
  - c) Click Port Tracking.
- **Step 2** In the 3.2(2) release, navigate to the following location:
  - a) On the menu bar, choose **System** > **System Settings**.
  - b) In the Navigation pane, choose **Port Tracking**.
- **Step 3** Enable port tracking by setting the **Port tracking state** to **on**.
- **Step 4** (Optional) Change the **Daily restore timer** value.
- Step 5 Configure the Number of active spine links that triggers port tracking parameter.
- Step 6 Click Submit.

**Configure a Fabric Port Tracking Policy**
