Session Recovery

With robust hardware failover and redundancy protection, any hardware or software failures on the system can quickly be corrected. However, software failures can occur for numerous reasons, often without prior indication.

This chapter describes the Session Recovery feature that provides seamless failover and reconstruction of subscriber session information in the event of a hardware or software fault.

☞

Important Session Recovery is a licensed Cisco feature. A separate feature license may be required. Contact your Cisco account representative for detailed information on specific licensing requirements. For information on installing and verifying licenses, refer to the *Managing License Keys* section of *Software Management Operations*.

This chapter includes the following sections:

How Session Recovery Works

This section provides an overview of how this feature is implemented and the recovery process.

The Session Recovery feature provides seamless failover and reconstruction of subscriber session information in the event of a hardware or software fault within the system preventing a fully connected user session from being disconnected.

Session recovery is performed by mirroring key software processes (for example, session manager and AAA manager) within the system. These mirrored processes remain in an idle state (standby-mode) wherein they perform no processing, until they may be needed in the event of a software failure (for example, a session manager task aborts).

There are some situations wherein session recovery may not operate properly. These include:

- Additional software or hardware failures occur during the session recovery operation. For example, an AAA manager fails while the state information it contained was being used to populate the newly activated session manager task.

• A lack of hardware resources (packet processing card memory and control processors) to support session recovery.

☞

Important After a session recovery operation, some statistics, such as those collected and maintained on a per manager basis (AAA Manager, Session Manager, etc.) are in general not recovered, only accounting and billing related information is checkpointed and recovered.

Session Recovery is available for the following functions:

• Any session needing L2TP LAC support (excluding regenerated PPP on top of an HA or GGSN session)

• ASR 5500 only – Closed RP PDSN services supporting simple IP, Mobile IP, and Proxy Mobile IP

• ASR 5500 only – eHRPD service (evolved High Rate Packet Data)

• ASR 5500 only – ePDG service (evolved Packet Data Gateway)

• GGSN services for IPv4 and PPP PDP contexts

• HA services supporting Mobile IP and/or Proxy Mobile IP session types with or without per-user Layer 3 tunnels

• ASR 5500 only – HNB-GW: HNB Session over IuH

• ASR 5500 only – HNB-GW: HNB-CN Session over IuPS and IuCS

• ASR 5500 only – HNB-GW: SeGW Session IPSec Tunnel

• ASR 5500 only – HSGW services for IPv4

• IPCF (Intelligent Policy Control Function)

• ASR 5500 only – IPSG-only systems (IP Services Gateway)

• LNS session types (L2TP Network Server)

• MME (Mobility Management Entity)

• ASR 5500 only – NEMO (Network Mobility)

• P-GW services for IPv4

• ASR 5500 only – PDIF (Packet Data Interworking Function)

• PDSN services supporting simple IP, Mobile IP, and Proxy Mobile IP

• S-GW (Serving Gateway)

• SaMOG (S2a Mobility over GTP) Gateway (CGW and MRME)

• ASR 5500 only – SAE-GW (System Architecture Evolution Gateway)

• ASR 5500 only – SGSN services (3G and 2.5G services) for IPv4 and PPP PDP contexts

Session recovery is **not supported** for the following functions:

• Destination-based accounting recovery

• GGSN network initiated connections

- GGSN session using more than 1 service instance

- MIP/L2TP with IPSec integration

- MIP session with multiple concurrent bindings

- Mobile IP sessions with L2TP

- Multiple MIP sessions

☞

Important   Always refer to the Administration Guides for individual products for other possible session recovery and Interchassis Session Recovery (ICSR) support limitations.

When session recovery occurs, the system reconstructs the following subscriber information:

- Data and control state information required to maintain correct call behavior.

- A minimal set of subscriber data statistics; required to ensure that accounting information is maintained.

- A best-effort attempt to recover various timer values such as call duration, absolute time, and others.

- The idle time timer is reset to zero and the re-registration timer is reset to its maximum value for HA sessions to provide a more conservative approach to session recovery.

☞

Important   Any partially connected calls (for example, a session where HA authentication was pending but has not yet been acknowledged by the AAA server) are not recovered when a failure occurs.

✎

Note   Failure of critical tasks will result in restarting StarOS. Kernel failures, hypervisor failures or hardware failures will result in the VM restarting or going offline. The use of ICSR between two VPC-DIs or two VPC-SIs is the recommended solution for these types of failure.

Configuring the System to Support Session Recovery

The following procedures allow you to configure the session recovery feature for either an operational system that is currently in-service (able to accept incoming calls) or a system that is out-of-service (not part of your production network and, therefore, not processing any live subscriber/customer data).

☞

Important   The session recovery feature, even when the feature use key is present, is disabled by default on the system.

Enabling Session Recovery

As noted earlier, session recovery can be enabled on a system that is out-of-service (OOS) and does not yet have any contexts configured, or on an in-service system that is currently capable of processing calls. However, if the system is in-service, it must be restarted before the session recovery feature takes effect.

Enabling Session Recovery on an Out-of-Service System

The following procedure is for a system that does not have any contexts configured.

To enable the session recovery feature on an out-of-service system, follow the procedure below. This procedure assumes that you begin at the Exec mode prompt.

Step 1   At the Exec mode prompt, verify that the session recovery feature is enabled via the session and feature use licenses on the system by running the **show license info** command.
If the current status of the Session Recovery feature is Disabled, you cannot enable this feature until a license key is installed in the system.

Step 2   Use the following configuration example to enable session recovery.
configure
  require session recovery
    end

Step 3   Save your configuration as described in *Verifying and Saving Your Configuration*.
The system, when started, enables session recovery, creates all mirrored "standby-mode" tasks, and performs packet processing card reservations and other operations automatically.

Step 4   After the system has been configured and placed in-service, you should verify the preparedness of the system to support this feature as described in Viewing Session Recovery Status, on page 5

Enabling Session Recovery on an In-Service System

When enabling session recovery on a system that already has a saved configuration, the session recovery commands are automatically placed before any service configuration commands in the configuration file.

To enable the session recovery feature on an in-service system, follow the procedure below. This procedure assumes that you begin at the Exec mode prompt.

Step 1   At the Exec mode prompt, verify that the session recovery feature is enabled via the session and feature use licenses on the system by running the **show license info** command:
If the current status of the Session Recovery feature is Disabled, You cannot enable this feature until a license key is installed in the system.

Step 2 Use the following configuration example to enable session recovery.

configure
  require session recovery
  end

This feature does <u>not</u> take effect until after the system has been restarted.

Step 3 Save your configuration as described in *Verifying and Saving Your Configuration*.

Step 4 Perform a system restart by entering the **reload** command:
The following prompt appears:

```
Are you sure&quest; [Yes|No]:
```

Confirm your desire to perform a system restart by entering **yes**.

The system, when restarted, enables session recovery and creates all mirrored "standby-mode" tasks, performs packet processing card reservations, and other operations automatically.

Step 5 After the system has been restarted, you should verify the preparedness of the system to support this feature as described in Viewing Session Recovery Status, on page 5
More advanced users may opt to simply insert the **require session recovery** command syntax into an existing configuration file using a text editor or other means, and then applying the configuration file manually. Exercise caution when doing this to ensure that this command is placed among the first few lines of any existing configuration file; it must appear before the creation of any non-local context.

Disabling the Session Recovery Feature

To disable the session recovery feature on a system, enter the **no require session recovery** command from the Global Configuration mode prompt.

☞

Important If this command is issued on an in-service system, then the system must be restarted by issuing the **reload** command.

Viewing Session Recovery Status

To determine if the system is capable of performing session recovery, when enabled, enter the **show session recovery status verbose** command from the Exec mode prompt.

The output of this command should be similar to the examples shown below.

```
[local]host_name# show session recovery status
Session Recovery Status:
    Overall Status          :  SESSMGR Not Ready For Recovery
    Last Status Update      :  1 second ago

[local]host_name# show session recovery status
Session Recovery Status:
    Overall Status          :  Ready For Recovery
    Last Status Update      :  8 seconds ago
```

```
[local]host_name# show session recovery status verbose
Session Recovery Status:
    Overall Status            :  Ready For Recovery
    Last Status Update        :  2 seconds ago

               ----sessmgr----       ----aaamgr----     demux
    cpu state  active   standby    active   standby    active   status
    ---- ------- ------   -------    ------   -------    ------   ------------
    1/1 Active   2        1         1        1          0        Good
    1/2 Active   1        1         0        0          0        Good
    1/3 Active   1        1         3        1          0        Good
    2/1 Active   1        1         1        1          0        Good
    2/2 Active   1        1         0        0          0        Good
    2/3 Active   2        1         3        1          0        Good
    3/0 Active   0        0         0        0          1        Good (Demux)
    3/2 Active   0        0         0        0          1        Good (Demux)
    4/1 Standby  0        2         0        1          0        Good
    4/2 Standby  0        1         0        0          0        Good
    4/3 Standby  0        2         0        3          0        Good
[local]host_name#
```

Viewing Recovered Session Information

To view session state information and any session recovery status, enter the following command:

[local]*host_name*# **show subscriber debug-info { callid** *id* **| msid** *id* **| username** *name* **}**

The following example shows the output of this command both before and after a session recovery operation has been performed. The "Redundancy Status" fields in this example have been bold-faced for clarity.

```
username: user1                callid: 01ca11b1                msid: 0000100003
    Card/Cpu: 4/2
    Sessmgr Instance: 7
    Primary callline:
```
Redundancy Status: Original Session
```

```

Recovery Control Task Statistics

Recovery Control Task (RCT) statistics show the following:

- Recovery action taken – Migration, Shutdown, Switchover

- Type of event – Planned or Unplanned

- From card to card – slot numbers

- Start time – YYYY-MMM-DD+hh:mm:sss.sss

- Duration – seconds

- Card failure device (such as CPU*n*)

- Card failure reason

- Card is in usable state or not failed

- Recovery action status – Success or failure reason

- If recovery action failed, failure time stamp

- If recovery action failed, failure task facility name

- If recovery action failed, failure instance number

show rct stats Command

The Exec mode **show rct stats** command employs the following syntax:

[local]*host_name*# **show rct stats [verbose]**

<u>Without</u> the **verbose** keyword, a summary output is displayed as show in the example below:

```
RCT stats details (Last 1 Actions)

 #  Action        Type      From  To  Start Time               Duration    Status
--- ------------- --------- ----  ---- ----------------------- ----------  -------
 1  Migration(st) Planned     2    1  2016-Jul-12+13:12:21.865  0.003 sec  Success

RCT stats summary
-----------------
Migrations  =            0
  Management Card:     0           Average time: 0.000 sec
  Packet Card    :     1           Average time: 0.006 sec
Switchovers =          1, Average time - 25.855 sec
```

With the verbose keyword the detailed statistics show in are provided.

Sample Output for show rct stats verbose

[local]*host_name*# **show rct stats verbose**

```
RCT stats Details (Last 5 Actions)
