CONTENTS

PART I

Basic Configuration 75

CHAPTER 1

Start Up Configuration of the Cisco cBR Router	1
Prerequisites for Configuring the Cisco CMTS	2
Booting and Logging onto the Cisco CMTS	3
First Time Boot Up with ROMMON	3
Configuration Register	4
Setting Environment Variables	5
Unsetting Environment Variables	5
Booting from the TFTP on the Cisco cBR	6
Listing Supported Devices	6
Booting from the Device on the Cisco cBR	7
Setting AUTOBOOT image in ROMMON	7
Verifying the ROMMON Version	8
Resetting the Cisco cBR	8
Configuring PTP	9
Overview of PTP	9
Configuring a PTP Subordinate Through DPIC	11
Verifying the PTP Subordinate Configuration	12
PTP Subordinate Configuration Examples	13
Feature Information for PTP Subordinate	14
File Systems	15
Verification of Hardware Bring Up	15
Monitoring the Cisco cBR Chassis Using CLI	15
Gigabit Ethernet Management Interface Overview	23
Gigabit Ethernet Port Numbering	23

IP Address Handling in ROMMON and the Management Ethernet Port	24
Gigabit Ethernet Management Interface VRF	24
Common Ethernet Management Tasks	24
Viewing the VRF Configuration	24
Setting a Default Route in the Management Ethernet Interface VRF	25
Setting the Management Ethernet IP Address	25
Telnetting over the Management Ethernet Interface	25
Pinging over the Management Ethernet Interface	25
Copy Using TFTP or FTP	26
NTP Server	26
SYSLOG Server	26
SNMP-Related Services	26
Domain Name Assignment	27
DNS service	27
RADIUS or TACACS+ Server	27
VTY lines with ACL	27
Configuring the AUX Port for Network Management	27
Preprovisioning the Supervisor in the Cisco cBR Chassis	28
Configuring the Gigabit Ethernet Interface for Network Management	28
Configuring the DTI Port on the Supervisor PIC	29
Configuring the TenGigabit Ethernet Interface for Network Management	30
Connecting the New Router to the Network	31
Setting Password Protection on the Cisco CMTS	32
Recovering Lost Password on the Cisco CMTS	32
Saving Your Configuration Settings	35
Reviewing Your Settings and Configurations	35
Recovering Unresponsive Modems	35

CHAPTER 2

Cisco Smart Licensing	37
Hardware Compatibility Matrix for the Cisco cBR Series Routers	37
Prerequisites for Cisco Smart Licensing	38
Information About Cisco Smart Licensing	39
Downstream License	40
Out of Compliance Enforcement	40

How to Configure Cisco Smart Licensing	41
Using Cisco Smart Licensing Agent on the Router	41
Setting Up a Cisco Smart Account	41
Creating Virtual Accounts	48
Creating a Product Instance Registration Token	49
Registering the Router with the Cisco Licensing Cloud Using the Registration Token	50
Re-establishing Connectivity to Cisco Smart Call Home Server	51
How to Configure Cisco Smart Licensing using Transport Gateway Solution	51
Configuring 100G Licenses for Supervisor 250G	53
Overview of 100G License for Supervisor 250G	53
Applying 10G WAN License to the 100G WAN Ports	53
Displaying the License Information	54
Feature Information for 100G License for Supervisor 250G	57
Verifying Cisco Smart Licensing Configuration	58
Troubleshooting Cisco Smart Licensing	64
Manually Renewing the Smart License Registration	64
Unregistering the Router from Cisco Smart Licensing	65
Additional References	65
Feature Information for Cisco Smart Licensing	65

CHAPTER 3

Core Peak Bandwidth Licensing	67
Core Peak Bandwidth License	67
CPB Calculation	67
Configure CPB on Cisco cBR Routers	68
Enable CPB Licensing	68
View CPB Usage Details	68
Example: Show CPB Usage Details	68
View Details of All Licenses	68
Example: View Details of All Licenses	68
View CPB Sample History	69
Example: View CPB Sample History	69
Feature Information for Core Peak Bandwidth Licensing	69

CHAPTER 4

Capped License Enforcement	71
-----------------------------------	-----------

Hardware Compatibility Matrix for the Cisco cBR Series Routers	71
Information About Capped License Support	72
SNMP-MIB-based Capped Enforcement	72
Use Case Scenarios	73
How to Configure Capped License Enforcement	73
Configuring Capped License Enforcement	74
Viewing the License Usage Count	74
Configuration Examples	74
Feature Information for Capped License Enforcement	74

CHAPTER 5**Consolidated Packages and SubPackages Management 75**

Finding Feature Information	75
Running the Cisco cBR Series Routers Using Individual and Optional SubPackages: An Overview	75
Running the Cisco cBR Series Routers Using a Consolidated Package: An Overview	76
Running the Cisco cBR Series Routers: A Summary	76
Software File Management Using Command Sets	77
Managing and Configuring the Router to Run Using Consolidated Packages and Individual SubPackages	78
Cable Line Card Process Restart	78
Cable Line Card Control Plane Process Restart	79
Cable Line Card Upstream Scheduler Process Restart	85
Quick Start Software Upgrade	91
Managing and Configuring a Consolidated Package Using the copy Command	92
Managing and Configuring a Router to Run Using Individual SubPackages From a Consolidated Package	93
Extracting a Consolidated Package and Booting Using the Provisioning File	93
Copying a Set of Individual SubPackage Files, and Booting Using a Provisioning File	96
Installing an Optional SubPackage	96
Upgrading Individual SubPackages	98
Patch Installation	98
Installing a Patch that Affects Both Line Card and Supervisor Card	98
Installing a Patch that Affects Only Line Cards	98
Installing a Patch that Affects Only Supervisor Cards	98
Upgrading a Line Card SubPackage	99

Additional References	106
Feature Information for Consolidated Packages and SubPackages Management	106

CHAPTER 6

G.8275.2 Telecom Profile	107
G.8275.2 Telecom Profile	107
Information About G.8275.2 Telecom Profile	107
Why G.8275.2 Telecom Profile?	108
PTP Clocks	108
PTP Domain	108
PTP Messages and Transport	109
PTP Ports	109
Alternate BPCA	109
Benefits	109
Restrictions for Using the G.8275.2 Profile	109
How to Configure the G.8275.2 Profile	110
Creating an Ordinary Subordinate (T-TSC-P)	110
Configuring Dual PTP Primary Clocks	110
Configuring the G.8275.2 Profiles	110
Configuring an IPv4 Single Clock Source	111
Configuring an IPv6 Single Clock Source	111
Verifying the G.8275.2 Profile	111
Configuration Examples	111
Feature Information for G.8275.2 Profile	112

PART II**High Availability Configuration 113****CHAPTER 7**

Cisco IOS-XE In-Service Software Upgrade Process	115
Hardware Compatibility Matrix for the Cisco cBR Series Routers	115
Information about In-Service Software Upgrade	116
How to Configure In-Service Software Upgrade	117
Configuring Subpackage Upgrade	117
Subpackages Upgrade	117
Linecard Only In-Service Software Upgrade	118
ISSU Upgrade Across Major Releases	119

Additional References	119
Feature Information for In-Service Software Upgrade	120

CHAPTER 8

Supervisor Redundancy	121
Hardware Compatibility Matrix for the Cisco cBR Series Routers	121
Prerequisites for Supervisor Redundancy	122
Information About Supervisor Redundancy	122
Switchover Procedure	123
Using Redundant File Systems	124
Console Port Usage After Supervisor Switchover	125
Benefits	126
How to Configure Supervisor Redundancy	126
Forcing Switchover	126
Changing the System Boot Behavior	127
Saving a Configuration File to the Bootflash or Hard Disk	130
Verifying the Supervisor Redundancy Configuration	131
Verifying Supervisor Redundancy	131
Verifying Supervisor Switchover	133
Configuration Example for Supervisor Redundancy	135
Additional References	135
Feature Information for Supervisor Redundancy	136

CHAPTER 9

Line Card Redundancy	137
Hardware Compatibility Matrix for the Cisco cBR Series Routers	137
Prerequisites for Line Card Redundancy	138
Restrictions for Line Card Redundancy	138
Information About Line Card Redundancy	139
How to Configure Line Card Redundancy	140
Configuring Line Card Manual Switchover	140
Configuring N+1 Line Card Redundancy	140
Verifying the Line Card Redundancy Configuration	141
Additional References	145
Feature Information for Line Card Redundancy	146

PART III**Layer 2 and DOCSIS 3.0 Configuration 147**

CHAPTER 10**Downstream Interface Configuration 149**

- Finding Feature Information 149
- Hardware Compatibility Matrix for the Cisco cBR Series Routers 149
- Information About Downstream Interface Configuration 150
- How to Configure Downstream Interfaces 152
 - Configuring the Cisco CMTS Manually Using Configuration Mode 152
 - Configuring the QAM Profile on the Downstream Channels 152
 - Configuring the Frequency Profile on the Downstream Channels 153
 - Configuring the Controller on the Downstream Channels 154
 - Troubleshooting Tips 155
 - Configuring the RF Channel on a Controller 155
- Configuration Examples 157
- Additional References 160
- Feature Information for Downstream Interface Configuration on the Cisco cBR Router 160

CHAPTER 11**Upstream Interface Configuration 163**

- Finding Feature Information 163
- Hardware Compatibility Matrix for the Cisco cBR Series Routers 163
- Information About Upstream Interface Configuration 164
- How to Configure Upstream Interfaces 165
 - Configuring the Cisco CMTS Manually Using Configuration Mode 165
 - Configuring the Modulation Profile and Assigning to an Upstream Channel 165
 - Configuring the Upstream Channel with PHY Layer 166
 - Associating Upstream Channels with a MAC Domain and Configuring Upstream Bonding 167
- Configuration Examples 168
- Additional References 169
- Feature Information for Upstream Interface Configuration on the Cisco cBR Router 169

CHAPTER 12**DOCSIS Interface and Fiber Node Configuration 171**

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 171
- Overview of DOCSIS Interfaces and Fiber Node Configurations 172

- Downstream Features **172**
- Upstream Features **173**
- MAC Domains (Cable Interfaces) **173**
- Fiber Nodes **173**
- Configuring DOCSIS Interfaces and Fiber Nodes **173**
 - Configuring Upstream Channels **173**
 - Verifying the Controller Configuration **173**
 - Binding Upstream Channels to MAC Domain **174**
 - Configuring Primary Capable Downstream Channels **175**
 - Verifying Downstream Configuration in Controller **175**
 - Configuring Integrated-cable Interface **176**
 - Binding Primary Capable Downstream Channels to a MAC Domain **177**
- Configuring MAC Domain Service Groups **179**
 - Configuring the Fiber Nodes **179**
 - Verify MD-DS-SG Channel Membership **181**
 - Verify MD-US-SG Channel Membership **181**
- Downstream Bonding Group Configuration **182**
 - Configuring Wideband-cable Interface (Downstream Bonding Grouping) **182**
 - Verifying the Bonding Group Interfaces **184**
- Upstream Bonding Group Configuration **186**
 - Restrictions for Upstream Bonding Groups **186**
 - Configuring Upstream Bonding Groups **186**
 - Verifying Upstream Bonding Groups **188**
- Additional References **189**
- Feature Information for DOCSIS Interface and Fiber Node Configuration **189**

CHAPTER 13

- Service Group Based Configuration of the Cisco cBR Router **191****
 - Service Group Profile Based Configuration **191**
 - Service Profile Configuration for 16x8 with One MAC Domain **193**
 - Service Profile Configuration for 16x8 with Two MAC Domains **195**
 - MAC-Domain Split Configuration **197**

CHAPTER 14

- Hardware Compatibility Matrix for the Cisco cBR Series Routers **201****
 - Hardware Compatibility Matrix for the Cisco cBR Series Routers **202**

Prerequisites for DOCSIS Load Balancing Groups	203
Restrictions for DOCSIS Load Balancing Groups	204
Information About DOCSIS Load Balancing Groups	205
Service-Based Load Balancing	205
RLBG/GLBG Assignment	206
Channel Assignment	207
Upstream Load Balancing for DOCSIS 3.0 Cable Modems in Single Upstream Mode	210
Auto-generate DOCSIS 2.0 GLBG	210
Independent Upstream/Downstream Throughput Rules	210
How to Configure DOCSIS Load Balancing Groups	211
Configuring DOCSIS 3.0 and 2.0 RLBG and DOCSIS 2.0 GLBG	212
Configuring DOCSIS 3.0 GLBG	214
Configuring a DOCSIS 3.0 General Load Balancing Group	215
Configuring Default Values of DOCSIS 3.0 Load Balancing Group	216
Configuring Cable Modems to RLBG or a Service Type ID	217
Configuring Rules and Policies	218
Troubleshooting Tips	218
Configuring Load Balancing Parameter for a Cable Modem Movement Failure	219
Creating and Configuring TLV type Tag	219
Configuration Examples for DOCSIS Load Balancing Groups	221
Example: Configuring a Tag	221
Example: Disabling Load Balancing	222
How to Configure Load Balancing with Operational Simplification	222
Load Balancing Groups with Operational Simplification	225
Verifying DOCSIS Load Balancing Groups	226
Additional References	231
Feature Information for DOCSIS Load Balancing Groups	231
Prerequisites for DOCSIS Load Balancing Groups	232
Restrictions for DOCSIS Load Balancing Groups	232
Information About DOCSIS Load Balancing Groups	233
Service-Based Load Balancing	233
RLBG/GLBG Assignment	234
Channel Assignment	235
Upstream Load Balancing for DOCSIS 3.0 Cable Modems in Single Upstream Mode	238

Auto-generate DOCSIS 2.0 GLBG	238
Independent Upstream/Downstream Throughput Rules	238
How to Configure DOCSIS Load Balancing Groups	239
Configuring DOCSIS 3.0 and 2.0 RLBG and DOCSIS 2.0 GLBG	240
Configuring DOCSIS 3.0 GLBG	242
Configuring a DOCSIS 3.0 General Load Balancing Group	243
Configuring Default Values of DOCSIS 3.0 Load Balancing Group	244
Configuring Cable Modems to RLBG or a Service Type ID	245
Configuring Rules and Policies	246
Troubleshooting Tips	246
Configuring Load Balancing Parameter for a Cable Modem Movement Failure	247
Creating and Configuring TLV type Tag	247
Configuration Examples for DOCSIS Load Balancing Groups	249
Example: Configuring a Tag	249
Example: Disabling Load Balancing	250
Verifying DOCSIS Load Balancing Groups	250
Additional References	255
Feature Information for DOCSIS Load Balancing Groups	255

CHAPTER 15
DOCSIS Load Balancing Movements 257

Hardware Compatibility Matrix for the Cisco cBR Series Routers	258
Prerequisites	259
Prerequisites for Load Balancing	259
Prerequisites for Dynamic Channel Change for Load Balancing	259
Prerequisites for Dynamic Bonding Change for DOCSIS 3.0 Static Modem Count-Based Load Balancing	260
Restrictions	260
Restrictions for Load Balancing	260
Restrictions for Dynamic Channel Change for Load Balancing	261
DCC Restrictions with N+1 Redundancy and Inter-Card Load Balancing	262
Restrictions for DOCSIS 3.0 Static Modem Count-Based Load Balancing	263
Restrictions for Dynamic Bonding Change for DOCSIS 3.0 Static Modem Count-Based Load Balancing	263
Restrictions for MRC-Only Cable Modems	264

Information on the Load Balancing on the Cisco CMTS	264
Feature Overview	264
Methods to Determine When Interfaces Are Balanced	265
Modems Method	265
Utilization Method	266
Load Balancing Parameters	267
Configurable Minimum Threshold under Utilization Method	267
Single Channel Load Balancing	267
Error Handling of Channel Assignment	267
Downstream Load Balancing Distribution with Upstream Load Balancing	267
Upstream Load Balancing for DOCSIS 3.0 Cable Modems in Single Upstream Mode	268
Interaction with Spectrum Management	269
Using Dynamic Channel Change	269
Multiple Channel Load Balancing	270
Algorithm for Bonded Channel Cable Modem Load Balancing	270
DOCSIS 3.0 Static Modem Count-Based Load Balancing	270
Dynamic Load Balancing for DOCSIS 3.0 Cable Modems	272
Multiple Channel Load Balancing Operation	273
Using DBC for DOCSIS 3.0 Load Balancing Movement	277
Benefits of Load Balancing	279
Exclude Cable Modems from Load Balancing Groups	280
How to Configure Load Balancing	280
Enabling Single Channel Load Balancing	281
Configuring Dynamic Bonding Change for DOCSIS 3.0 Static Load Balancing	281
Excluding Cable Modems from a Load Balancing Group	281
Distributing Downstream Load Balancing with Upstream Load Balancing	282
How to Configure Dynamic Channel Change for Load Balancing	283
Configuring Dynamic Channel Change for Load Balancing	284
Verifying Load Balancing Operations	285
Example	286
Troubleshooting Tips	287
Configuration Examples for Load Balancing	289
Example: Configuring Dynamic Channel Change for Load Balancing	290
Additional References	293

Feature Information for DOCSIS Load Balancing Movements 293

CHAPTER 16

DOCSIS 3.0 Downstream Bonding 295

Hardware Compatibility Matrix for the Cisco cBR Series Routers 295

Information About DOCSIS 3.0 Downstream Bonding 296

Receive Channel Profile 296

Receive Channel Configuration 297

RCC Template 297

Channel Assignment 297

Downstream Traffic Forwarding 298

Service Flow Priority in Downstream Extended Header 298

How to Configure RCP and RCC Encoding 298

Configuring the RCP ID 298

Configuring the RCC Templates 301

Assigning an RCC Template to a MAC Domain (Cable Interface) 303

Verifying the RCC Configuration 306

How to Configure Attribute Masks 307

Configuring Provisioned Attributes for an Integrated Cable Interface 308

Configuring Provisioned Attributes for a Wideband Cable Interface 309

Verifying the Attribute-Based Service Flow Assignments 309

How to Enable Service Flow Priority in Downstream Extender Header 311

Enabling Service Flow Priority in Downstream Extender Header 311

Verifying the Enablement of the Service Flow Priority in Downstream Extended Header 311

Enabling Verbose Reporting for Receive Channel Profiles 313

Configuration Example for an RCC Template 314

Additional References 315

Feature Information for DOCSIS 3.0 Downstream Bonding 315

CHAPTER 17

DOCSIS 2.0 A-TDMA Modulation Profiles 317

Hardware Compatibility Matrix for the Cisco cBR Series Routers 317

Prerequisites for DOCSIS 2.0 A-TDMA Modulation Profiles 318

Restrictions for DOCSIS 2.0 A-TDMA Services 319

Information About DOCSIS 2.0 A-TDMA Services 319

Modes of Operation 320

Modulation Profiles	321
Benefits	321
How to Configure DOCSIS 2.0 A-TDMA Services	322
Creating Modulation Profiles	322
Creating a TDMA Modulation Profile	322
Creating a Mixed Mode Modulation Profile	323
Creating an A-TDMA Modulation Profile	324
Configuring the DOCSIS Mode and Profile on an Upstream	325
Monitoring the DOCSIS 2.0 A-TDMA Services	326
Displaying Modulation Profiles	326
Displaying Cable Modem Capabilities and Provisioning	327
Configuration Examples for DOCSIS 2.0 A-TDMA services	328
Creating Modulation Profiles Examples	329
Example: DOCSIS 1.0/DOCSIS 1.1 TDMA Modulation Profiles	329
Example: Mixed TDMA/A-TDMA Modulation Profiles	329
Example: DOCSIS 2.0 A-TDMA Modulation Profiles	330
Assigning Modulation Profiles to Upstreams Examples	330
Example: Assigning DOCSIS 1.0/DOCSIS 1.1 TDMA Modulation Profiles	330
Example: Assigning Mixed TDMA/A-TDMA Modulation Profiles	331
Example: Assigning DOCSIS 2.0 A-TDMA Modulation Profiles	331
Additional References	332
Feature Information for DOCSIS 2.0 A-TDMA Modulation Profile	333

CHAPTER 18

Downstream Resiliency Bonding Group	335
Hardware Compatibility Matrix for the Cisco cBR Series Routers	335
Prerequisites for Downstream Resiliency Bonding Group	336
Restrictions for the Downstream Resiliency Bonding Group	336
Information About Downstream Resiliency Bonding Group	338
Finding a Best-Fit RBG for the Cable Modem	338
How to Configure Downstream Resiliency Bonding Group	339
Enabling Downstream Resiliency Bonding Group	339
Reserving a Resiliency Bonding Group for a Line Card	340
Verifying Downstream Resiliency Bonding Group Configuration	341
Verifying the Downstream Resiliency Bonding Group	341

- Verifying a Reserved Resiliency Bonding Group 341
- Downstream Resiliency Narrowband Mode Versus Resiliency Bonding Group 341
- Troubleshooting the Downstream Resiliency Bonding Group Configuration 345
- Configuration Examples for the Downstream Resiliency Bonding Group 345
- Additional References 349
- Feature Information for Downstream Resiliency Bonding Group 349

CHAPTER 19

Downstream Channel ID Assignment 351

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 351
- Information About Downstream Channel ID Assignment on the Cisco CMTS Routers 352
 - Manual Downstream Channel ID Assignment 353
 - Automatic Downstream Channel ID Assignment on the Cisco CMTS Routers 354
- How to Configure Downstream Channel ID Assignment on the Cisco CMTS Routers 355
 - Configuring Manual Downstream Channel ID Assignment 355
 - Configuring Automatic Downstream Channel ID Assignment 356
- Additional References 358
- Feature Information for Downstream Channel ID Assignment 358

CHAPTER 20

Upstream Channel Bonding 359

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 359
- Prerequisites for Upstream Channel Bonding 360
- Restrictions for Upstream Channel Bonding 360
- Information About Upstream Channel Bonding 361
 - Multiple Transmit Channel Mode 362
 - Multiple Receive Channel Mode 362
- Dynamic Range Window and Transmit Power Levels for Upstream Channel Bonding 362
 - Extended Transmit Power 363
 - Reduced Transmit Channel Set 364
- T4 Multiplier 364
- Fiber Node Configuration for Upstream Channel Bonding 365
- New TLVs for Upstream Channel Bonding 365
- Upstream Weighted Fair Queuing 366
 - Class-Based Weighted Fair Queuing 366
 - Activity-Based Weighted Fair Queuing 366

Custom Weight for Service Flow Priorities	366
Upstream Scheduler and Service Flows	367
Upstream Service Flow Fairness	368
Distribution of Traffic across all Channels in a USBG	368
DOCSIS 3.0 Load Balancing with USBG Smaller than Cable Modem Capabilities	368
Cisco cBR-8 CCAP Line Card Rate Limiting	369
SID Tracking	369
Service ID Clusters	369
How to Configure Upstream Channel Bonding	370
Enabling MTC Mode on a Cisco CMTS Router	370
Default MTC Mode Configuration on a Cisco CMTS Router	370
Enabling MTC Mode for All CMs	370
Configuring UCSB Required Attribute	371
Creating a Bonding Group	372
Adding Upstream Channels to a Bonding Group	373
Adding Upstream Channel Ports to a Fiber Node	374
Configuring the Class-Based Weighted Fair Queuing	375
Configuring the Activity-Based Weighted Fair Queuing	376
Configuring Custom Weights for Service Flow Priorities	376
Configuring the SID Cluster	377
Configuring the Channel Timeout for a Cable Modem	379
Configuring Cable Upstream Resiliency	379
Configuring Rate Limiting on the Cisco cBR-8 CCAP Line Card	381
Enabling Upstream Related Events for CM Status Reports	382
Modifying the Bonding Group Attributes	382
Modifying the Ranging Poll Interval on Upstream Channels	383
Configuring the Reduced Channel Set Assignment	384
Configuring DOCSIS Extended Transmit Power Feature	385
Troubleshooting Tips	385
Configuration Example for Upstream Channel Bonding	385
Example: Enabling MTC Mode for a Single CM Using the CM Configuration File	387
Verifying the Upstream Channel Bonding Configuration	387
Verifying Weighted Fair Queuing for Upstream Service Flows	388
Verifying Rate Limiting for Upstream Bonded Service Flows	388

Verifying Extended Power Transmission	388
Additional References	388
Feature Information for Upstream Channel Bonding	389

CHAPTER 21**Dynamic Bonding Group 391**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	391
Information About Dynamic Bonding Group	392
Overview of Dynamic Bonding Group	392
How to configure Dynamic Bonding Group	393
Enable Dynamic Bonding Group	393
Enable DS-Resiliency and Configure Resiliency Bonding Group	393
Enable ACFE	394
Configure Interface Mac-Domain and Fiber-Node	394
Enable Load Balancing for DOCSIS 3.0 and DOCSIS 3.1	395
Enable DOCSIS 3.0 and DOCSIS 3.1 Static Load Balance	396
Enable DOCSIS 3.0 and DOCSIS 3.1 General Load Balance Group	396
Enable Dynamic Load Balance and Fixed-Primary Channel Movement	396
Verifying Dynamic Bonding Group Configuration	397
Verifying Static Load Balancing Configuration	399
Verifying Dynamic Load Balancing Configuration	401
Feature Information for Dynamic Bonding Group	403

CHAPTER 22**Spectrum Management and Advanced Spectrum Management 405**

Finding Feature Information	405
Hardware Compatibility Matrix for the Cisco cBR Series Routers	406
Prerequisites for Spectrum Management	406
Restrictions for Spectrum Management	407
Shared Spectrum Groups	407
Dynamic Upstream Modulation	407
Fixed-Frequency Spectrum Groups with Advanced Spectrum Management	408
Limitations on Upstream Modulation Parameters for PacketCable VoIP Calls	408
N+1 Redundancy Support	408
Intelligent and Advanced Spectrum Management Support	408
Information About Spectrum Management	409

Spectrum Management Measurements	410
Signal and Carrier Noise Ratios	410
Differences Between the MER (SNR) and CNR (CNIr) Values	411
Additional Measurements	412
Upstream Signal Channel Overview	413
Upstream Segments and Combiner Groups	414
Frequency Management Policy	415
Noise Impairments	416
Spectrum Groups and Frequency Hopping	416
Guidelines for Spectrum Management	417
Guided and Scheduled Spectrum Management	417
Frequency Hopping Capabilities	417
Dynamic Upstream Modulation (MER [SNR]-Based)	419
Input Power Levels	421
Intelligent and Advanced Hardware-Based Spectrum Management	422
Intelligent Spectrum Management Enhancements	422
Benefits	422
Guided and Scheduled Spectrum Management Benefits	422
Intelligent and Advanced Spectrum Management Benefits	423
How to Configure Spectrum Management	424
Guided and Scheduled Spectrum Management Configuration Tasks	425
Creating and Configuring Spectrum Groups	425
Assigning a Spectrum Group to One or More Upstream Ports	427
Configuring Shared Spectrum Groups (Fiber Node Groups) for DOCSIS 3.0	428
Configuring Dynamic Upstream Modulation (MER [SNR]-Based)	428
Verifying Frequency Hopping	431
Intelligent and Advanced Spectrum Management Configuration Tasks	434
Configuring and Assigning Spectrum Groups	434
Configuring Dynamic Upstream Modulation (CNR-Based)	435
Configuring Proactive Channel Management	437
Verifying the Spectrum Management Configuration	439
Monitoring Spectrum Management	442
Using CLI Commands	442
Using SNMP	443

	ccsSNRRRequestTable	443
	ccsSpectrumRequestTable	444
	ccsSpectrumDataTable	445
	ccsUpSpecMgmtTable	445
	ccsHoppingNotification	447
Configuration Examples		447
	Spectrum Group and Combiner Group Examples	448
	Example: Verifying Spectrum Group Creation	448
	Example: Time-Scheduled Spectrum Group	448
	Example: Verifying Spectrum Group Configuration	448
	Example: Determining the Upstream Ports Assigned to a Combiner Group	448
	Example: Combiner Group	449
	Example: Other Spectrum Management Configurations	450
Dynamic Upstream Modulation Examples		451
	Verifying Your Settings	451
	Example: Modulation Profiles	452
	Example: Input Power Level	453
	Advanced Spectrum Management Configuration Examples	453
	Example: Advanced Spectrum Management for the Cisco cBR Series Routers	453
Additional References		454
Feature Information for Spectrum Management and Advanced Spectrum Management		455

CHAPTER 23**Upstream Scheduler Mode** 457

	Finding Feature Information	457
	Hardware Compatibility Matrix for the Cisco cBR Series Routers	457
	Restrictions for Upstream Scheduler Mode	458
	Information About Upstream Scheduler Mode for the Cisco CMTS Routers	459
	How to Configure Upstream Scheduler Modes	459
	Additional References	460
	Feature Information for Upstream Scheduler Mode	461

CHAPTER 24**Generic Routing Encapsulation** 463

	Finding Feature Information	463
	Hardware Compatibility Matrix for the Cisco cBR Series Routers	464

Restrictions for Implementing Tunnels	464
Restrictions for GRE IPv6 Tunnels	465
Information About Implementing Tunnels	466
Tunneling Versus Encapsulation	466
Tunnel ToS	466
Path MTU Discovery	466
QoS Options for Tunnels	467
Information About IPv6 over IPv4 GRE Tunnels	467
Overlay Tunnels for IPv6	467
GRE IPv4 Tunnel Support for IPv6 Traffic	469
Information About GRE IPv6 Tunnels	470
Overview of GRE IPv6 Tunnels	470
How to Implement Tunnels	470
Determining the Tunnel Type	470
Configuring an IPv4 GRE Tunnel	471
GRE Tunnel Keepalive	471
What to Do Next	473
Configuring 6to4 Tunnels	474
What to Do Next	475
Verifying Tunnel Configuration and Operation	475
Configuration Examples for Implementing Tunnels	477
Example: Configuring a GRE IPv4 Tunnel	477
Configuring QoS Options on Tunnel Interfaces Examples	478
Policing Example	479
How to Configure IPv6 over IPv4 GRE Tunnels	480
Configuring GRE on IPv6 Tunnels	480
Configuration Examples for IPv6 over IPv4 GRE Tunnels	481
Example: GRE Tunnel Running IS-IS and IPv6 Traffic	481
Example: Tunnel Destination Address for IPv6 Tunnel	482
How to Configure GRE IPv6 Tunnels	482
Configuring GRE IPv6 Tunnels	482
Configuration Examples for GRE IPv6 Tunnels	484
Example: Configuring GRE IPv6 Tunnels	484
Additional References	484

Feature Information for Generic Routing Encapsulation 485

CHAPTER 25

Transparent LAN Service over Cable 487

Hardware Compatibility Matrix for the Cisco cBR Series Routers 487

Prerequisites for Transparent LAN Service over Cable 488

Restrictions for Transparent LAN Service over Cable 488

Information About Transparent LAN Service over Cable 489

Feature Overview 489

Transparent LAN Service and Layer 2 Virtual Private Networks 490

IEEE 802.1Q Mapping 490

Overview 490

Details of IEEE 802.1Q Mapping 490

Benefits 491

How to Configure the Transparent LAN Service over Cable 491

Configuring IEEE 802.1Q VLAN Mapping 492

Enabling and Configuring Layer 2 Tunneling for IEEE 802.1Q Mapping 492

Creating the IEEE 802.1Q VLAN Bridge Group 492

Configuration Examples for Transparent LAN Service over Cable 494

Example: Configuring IEEE 802.1Q VLAN Mapping 494

Example: Configuring IEEE 802.1Q Bridge Aggregator 494

Verifying the Transparent LAN Service over Cable Configuration 495

Additional References 496

Feature Information for Transparent LAN Service over Cable 497

CHAPTER 26

Downgrading Channel Bonding in Battery Backup Mode 499

Hardware Compatibility Matrix for the Cisco cBR Series Routers 499

Prerequisites for Downgrading Channel Bonding in Battery Backup Mode 500

Restrictions for Downgrading Channel Bonding in Battery Backup Mode 501

Information About Downgrading Channel Bonding in Battery Backup Mode 501

How to Configure Downgrading Channel Bonding in Battery Backup Mode 502

Configuring Channel Bonding Downgrade in Battery Backup Mode Globally 502

Configuring Channel Bonding Downgrade in Battery Backup Mode for MAC Domain 503

Verifying the Configuration for Channel Bonding Downgrade in Battery Backup Mode 504

Additional References 507

Feature Information for Downgrading Channel Bonding in Battery Backup Mode 508

CHAPTER 27

Upstream Bonding Support for D-PON 509

Hardware Compatibility Matrix for the Cisco cBR Series Routers 509

Prerequisites for Upstream Bonding Support for D-PON 510

Restrictions for Upstream Bonding Support for D-PON 510

Information About Upstream Bonding Support for D-PON 511

D-PON on Upstream Scheduling 512

How to Configure Upstream Bonding Support for D-PON 512

DOCSIS 3.0 Cable Modems Upstream Bonding Enters Partial Bonding 514

Verifying the Upstream Bonding Support for D-PON 514

Additional References 515

Feature Information for Upstream Bonding Support for D-PON 515

CHAPTER 28

Energy Management Mode 517

Information About Energy Management Mode 517

Dynamic Downstream Bonding Group 517

Flow Chart of the CM Power State 518

Interaction with the Battery Mode 519

Handling Energy Management Request Load 521

Supervisor High Availability and Line Card Switchover 521

Prerequisites for Energy Management Mode 521

Restrictions for the Energy Management Mode 521

Restrictions for CMTS High Availability 521

Restrictions for Dynamic Bonding Group 522

Restrictions for Interaction of CMTS with Other Features 522

Voice 522

Dynamic Bonding Change and Dynamic Channel Change and Related Applications 522

Multicast 522

Committed Information Rate 522

Admission Control 523

Battery Mode 523

Attribute Mask 523

Dynamic Service Addition 523

Restrictions for Configuration Change and Interface Shutdown	523
How to Configure the Energy Management Mode	524
Enabling Energy Management Mode	524
Enabling Energy Management Mode per MAC Domain	525
Configuring Initialization Ranging Technique in Dynamic Bonding Channel	525
Configuring the Percentage for the Dynamic Channel Bandwidth	525
Configuring the Queue Size for Energy Management	525
Verifying the Energy Management Mode	525
Viewing the Basic Statistics for Energy Management Receive Request	526
Verifying the Configuration Parameters	526
Viewing Information Regarding a Cable Modem	526
Feature Information for Energy Management Mode	528

CHAPTER 29**Cable Modem Steering 529**

Cable Modem Steering on the Cisco cBR Series Converged Broadband Routers	529
Prerequisites for Cable Modem Steering	530
Restrictions for Cable Modem Steering	530
Information About Cable Modem Steering	530
Upstream Channel Descriptor TLV for Ranging Hold-off	531
Ranging Class ID	531
Cable Modem Exclusion for DOCSIS Load Balance	531
How to Configure Cable Modem Steering on the CMTS Router	532
Configuring an Upstream Channel Class ID	532
Configuring an Upstream Ranging Hold-off Priority Value	533
Verifying and Troubleshooting Cable Modem Steering	534
Verifying an Upstream Ranging Class ID Configuration	534
Additional References	536
Feature Information for Cable Modem Steering	537

PART IV**Layer 2 and DOCSIS 3.1 Configuration 539****CHAPTER 30****DOCSIS 3.1 OFDM Channel Configuration 541**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	541
Information about OFDM Channel Configuration	542

OFDM Channels	542
Channel Profile	543
Modulation Profile	543
OFDM Channel Exclusion Band	543
How to Configure OFDM Channel	543
Configuring OFDM Modulation Profile	543
Verifying OFDM Modulation Profile Configuration	543
Configuring OFDM Channel Profile	545
Verifying OFDM Channel Profile Configuration	545
Configuring OFDM Channel as Primary Channel	546
Verifying OFDM Primary Channel Configuration	546
Configuring Port/Controller and Channel	547
Verifying Port/Controller and Channel Configuration	548
Configuration Examples	551
Additional References	552
Feature Information for DOCSIS 3.1 OFDM Channel Configuration	553

CHAPTER 31**OFDM Channel Power Profile 555**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	555
Information About OFDM Channel Power Profile	556
Restrictions for Configuring OFDM Power Profile	557
How to Configure the OFDM Channel Power Profile	557
Configuring OFDM Power Profile Using Band-index	557
Verifying the Power Profile Configuration	558
Configuring OFDM Power Profile with Linear Power-tilt	558
Verifying the Power Profile Using show controller Command	558
Configuration Example for OFDM Power Profile	559
Feature Information for OFDM Channel Power Profile	559

CHAPTER 32**DOCSIS 3.1 Path Selection 561**

Information about Path Selection	561
How to Configure Path Selection	561
Configuring Downstream Bonding Group with OFDM Channel	561
Verifying Downstream Bonding Group with OFDM Channel Configuration	562

Configuring Upstream Bonding Group with OFDMA Channel	562
Verifying Upstream Bonding Group with OFDMA Channel Configuration	562
Verifying the Path Selection Status	563
Clearing the Path Selection Status	563
Verifying the RCC Configuration	563
Additional References	565
Feature Information for DOCSIS 3.1 Path Selection	565

CHAPTER 33**DOCSIS 3.1 Downstream Profile Selection 567**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	567
Information about Downstream Profiles	568
Default Data Profile	569
Recommended Profile	569
Unfit Profile	569
How to Configure Profiles	569
Configuring Profile Downgrade	569
Configuring RxMER to Bit Loading Mapping	570
Additional References	571
Feature Information for Downstream Profile Selection	571

CHAPTER 34**DOCSIS 3.1 Commanded Power for Upstream SC-QAMs 573**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	573
Information About Commanded Power Feature for Upstream SC-QAMs	574
Feature TLVs	575
TLVs Affected by Commanded Power for US SC-QAMs	575
Commanded Power Sub-TLVs	575
Additional References	576
Feature Information for Commanded Power for US SC-QAMs	576

CHAPTER 35**DOCSIS3.1 Downstream Resiliency for OFDM channel 577**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	577
Information about DOCSIS3.1 Downstream Resiliency for OFDM Channel	578
How to Configure DOCSIS3.1 Downstream Resiliency for OFDM Channel	579
Configuring DOCSIS3.1 Downstream Resiliency for OFDM Channel	579

Displaying OFDM Specific CM-STATUS Events	580
Feature Information for DOCSIS3.1 Downstream Resiliency for OFDM Channel	581

CHAPTER 36**DOCSIS 3.1 OFDMA Channel Configuration 583**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	583
Information about OFDMA Channel Configuration	584
OFDMA Channels	584
Modulation Profile	585
OFDMA Channel Exclusion Band	585
Configure OFDMA Channel	585
Configuring OFDMA Controller Profile	585
Verifying OFDMA Modulation Profile Configuration	586
Configuring OFDMA Channel	587
Verifying OFDMA Channel Configuration	588
Configure Exclusion / Unused Bands	590
Verifying Exclusion / Unused Bands	590
Override OFDMA Profile Per Channel	591
Verifying Override Configuration	592
Apply OFDMA Upstream To Cable Interface	593
Determine DOCSIS 3.1 Cable Modems and the Cable Modems Using OFDMA Upstreams	594
Verifying DOCSIS 3.1 Upstream OFDMA channel bonding across DOCSIS 3.0 ATDMA channels	595
Feature Information for DOCSIS 3.1 OFDMA Channel Configuration	596

CHAPTER 37**Time and Frequency Division Multiplexing Configuration 597**

Information About TaFDM Support	597
Prerequisites for Configuring TaFDM Support	597
How to Configure cBR for TaFDM Support	598
Configuring TaFDM Modulation Profile	598
Configuring I/O Controller for TaFDM	598
Enhancing OFDMA Channel Throughput	599
Enhancing SC-QAM Channel UGS Flow Performance	599
Configuring Cable Interface-MAC Domain	599
Configuring Service Class	600

Excluding a Frequency Band from TaFDM 600
 Verifying TaFDM Configuration 600
 Configuration Example 600
 Feature Information for TaFDM Configuration 601

CHAPTER 38

DOCSIS 3.1 Upstream Profile Selection 603

Hardware Compatibility Matrix for the Cisco cBR Series Routers 603
 Information about Upstream Profiles 604
 Default Data IUC 605
 Recommended Interval Usage Code (IUC) 605
 How to Configure Upstream Profiles 605
 Configuring RxMER to Bit Loading Mapping 605
 Feature Information for Upstream Profile Selection 606

CHAPTER 39

DOCSIS 3.1 Upstream Triggered Spectrum Capture - Proactive Network Management 607

Hardware Compatibility Matrix for the Cisco cBR Series Routers 607
 Information About Upstream Triggered Spectrum Capture – Proactive Network Management 608
 Proactive Network Management for Supervisor High Availability, Line Card High Availability and
 containers 609
 Proactive Network Management Using Upstream Triggered Spectrum Capture 609
 Proactive Network Management Interface Index 611
 Upstream Triggered Spectrum Capture Configuration Parameters – Proactive Network Management
 614
 Upstream Triggered Spectrum Capture Configuration Objects 614
 Upstream Triggered Spectrum Capture Configuration MIB Objects 615
 Upstream Triggered Spectrum Capture Control Objects and MIBs 624
 Upstream Triggered Spectrum Capture Status Objects and MIBs 625
 Upstream Triggered Spectrum Capture Capability Objects and MIBs 626
 Upstream Triggered Spectrum Capture Bulk Data Control Objects and MIBs 627
 Configuring the PNM MAX-HOLD Trigger Mode 629
 Proactive Network Management MAX-HOLD trigger mode 630
 Debugging the PNM feature on cBR8 630
 Quick Install Guide - Proactive Network Management 632
 Troubleshooting Upstream Triggered Spectrum Capture – Proactive Network Management Issues 634

 Feature Information for Upstream Triggered Spectrum Capture – Proactive Network Management 635

CHAPTER 40
Downstream Power Tilt 637

Hardware Compatibility Matrix for the Cisco cBR Series Routers 637

Information about Downstream Power Tilt 638

Restrictions for Configuring Downstream Power Profile 638

How to Configure the Downstream Power Tilt 639

Configuring Downstream Power Tilt 639

Verifying Downstream Power Tilt Configuration 640

Feature Information for Downstream Power Tilt 640

CHAPTER 41
Controller Profile Configuration 643

Hardware Compatibility Matrix for the Cisco cBR Series Routers 643

Information about Controller Profile Configuration 644

How to Configure the Controller Profile 645

Configuring Downstream Controller Profile 645

Verifying Downstream Controller Profile Configuration 646

Configuring Upstream Controller Profile 647

Verifying Upstream Controller Profile Configuration 648

Feature Information for Controller Profile Configuration 648

CHAPTER 42
Voltage Thresholds for AC Power Supply Module Mode Control 651

Hardware Compatibility Matrix for the Cisco cBR Series Routers 651

Information about Voltage Thresholds for AC PSM Mode Control 652

Overview of Voltage Thresholds for AC PSM Mode Control 652

How to Configure Voltage Thresholds for AC PSM Mode Control 653

Configuring Voltage Thresholds for AC PSM Mode Control 653

Verifying Voltage Thresholds for AC PSM Mode Control 653

Configuration Examples 654

Example: Configuring Voltage Thresholds for AC PSM Mode Control 654

Feature Information for Voltage Thresholds for AC PSM Mode Control 654

CHAPTER 43
DOCSIS3.1 Downstream Zero Bit Loading 655

Hardware Compatibility Matrix for the Cisco cBR Series Routers 655

Information about DOCSIS3.1 Downstream Zero Bit Loading	656
How to Configure DOCSIS3.1 Downstream Zero Bit Loading	657
Configuring Downstream Zero Bit Loading	657
Verifying Downstream Zero Bit Loading	658
Feature Information for DOCSIS3.1 Downstream Zero Bit Loading	659

CHAPTER 44**Reducing Power Consumption 661**

Finding Feature Information	661
Hardware Compatibility Matrix for the Cisco cBR Series Routers	661
Information About Reducing Power Consumption	662
Restrictions for Setting Up Power-Saving Configuration	662
Configure Reduction of Power Consumption	663
Verifying the Power-Saving Configuration	663
Feature Information for Reducing Power Consumption	664

PART V**Layer 2 and Layer 3 VPN Configuration 665****CHAPTER 45****L2VPN Support over Cable 667**

Finding Feature Information	667
Hardware Compatibility Matrix for the Cisco cBR Series Routers	668
Prerequisites for L2VPN Support over Cable	668
Restrictions for L2VPN Support over Cable	669
VPN ID Restrictions	669
Information About L2VPN Support over Cable	670
Point-to-Point L2VPN Forwarding Mode	670
L2VPN Encodings in the CM Configuration File	672
Supported L2VPN Encodings	672
Voice-Call Support on L2VPN CM	673
How to Configure L2VPN Support over Cable	673
Configuring the Ethernet Network System Interface	673
Preparing the DOCSIS Configuration File for L2VPN Support	674
Manual Switchover Command Line Interface	674
Verifying L2VPN Support over Cable	675
Enabling Voice-Call on a L2VPN CM	677

Verifying Dynamic Service Flows	678
Configuration Examples for L2VPN over Cable	678
Example: Specifying the Ethernet NSI Interface	678
Example: Enabling Voice Call Support on MPLS L2VPN	679
Example: Enabling Voice Call Support on 802.1q L2VPN	680
Example: Enabling Voice Call Support on CLI-based L2VPN	680
Additional References	681
Feature Information for L2VPN Support over Cable	682

CHAPTER 46**L2VPN Over Port-Channel 685**

Information About L2VPN Over Port-Channel	685
TLS L2VPN	685
DOCSIS L2VPN	685
Benefits of L2VPN Over Port-Channel	686
Restrictions for L2VPN Over Port-Channel	686
How to Configure the L2VPN Over Port-Channel	686
Configuring the Port-Channel Uplink Port for TLS L2VPN	686
Configuring the Port-Channel Uplink Port for DOCSIS L2VPN	686
Verifying Port-Channel Configuration	686
Feature Information for L2VPN Over Port-Channel	687

CHAPTER 47**MPLS Pseudowire for Cable L2VPN 689**

Finding Feature Information	689
Hardware Compatibility Matrix for the Cisco cBR Series Routers	690
Prerequisites for MPLS Pseudowire for Cable L2VPN	690
Restrictions for MPLS Pseudowire for Cable L2VPN	691
Information About MPLS Pseudowire for Cable L2VPN	691
How MPLS Transports Layer 2 Packets	692
Supported Ethernet Encapsulation on UNI	693
MPLS Pseudowire	694
Bundle254 Interface	694
Ingress Process	694
Egress Process	694
MPLS Pseudowire Control Plane Process	695

L2VPN Pseudowire Redundancy	695
MPLS Pseudowire Provisioning Methods	695
Static Provisioning Method for MPLS Pseudowires	695
Dynamic Provisioning Method for MPLS Pseudowires	696
Cisco-Specific L2VPN TLVs	697
How to Enable MPLS on a Cisco CMTS Router	699
Configuring an LDP Router ID	700
Configuring MPLS on a Gigabit Ethernet Interface	701
Configuring an MPLS Label Distribution Protocol	702
Enabling the Cisco CMTS Support for MPLS Pseudowire for Cable L2VPN	703
How to Provision MPLS Pseudowires	704
Dynamic Provisioning of MPLS Pseudowires	704
Static Provisioning Method for MPLS Pseudowires	704
How to Configure L2VPN Pseudowire Redundancy	705
Configuring the Backup Pseudowire	705
Configuring Backup Delay	706
Performing Manual Switchover	707
Troubleshooting Tips	708
Configuration Examples for MPLS Pseudowire for Cable L2VPN	708
Configuration Example for Static Provisioning of MPLS Pseudowires	708
Configuration Examples for Dynamic Provisioning of MPLS Pseudowires	709
BSOD Specification-Based MPLS Pseudowire Provisioning: Example	709
Type-4 MPLS Pseudowire Provisioning Using the CM Configuration File: Example	710
Type-5 MPLS Pseudowire Provisioning Using the CM Configuration File: Example	713
Configuration Examples for L2VPN Pseudowire Redundancy	713
Example: Configuring Backup Pseudowire Peer and VC ID	713
Example: Configuring Backup Delay	714
Example: L2VPN Backup MPLS Pseudowire Provisioning Using the CM Configuration File	714
Verifying the MPLS Pseudowire Configuration	714
Additional References	718
Feature Information for MPLS Pseudowire for Cable L2VPN	719
<hr/>	
CHAPTER 48	MPLS VPN Cable Enhancements 721
	Finding Feature Information 721

Hardware Compatibility Matrix for the Cisco cBR Series Routers	721
Feature Overview	722
Benefits	725
Restrictions	726
Prerequisites	726
Other Important Information	727
Configuration Tasks	727
Creating VRFs for each VPN	727
Defining Subinterfaces on a Virtual Bundle Interface and Assigning VRFs	729
Configuring Cable Interface Bundles	730
Configuring Subinterfaces and MPLS VPNs on a Virtual Bundle Interface	730
Configuring MPLS in the P Routers in the Provider Core	730
Verifying the MPLS VPN Configuration	731
Configuration Examples	732
VRF Definition Configuration	732
Cable Bundle SubInterface Configuration	733
PE WAN Interface Configuration	734
PE BGP Configuration	734
Additional References	736
Feature Information for MPLS VPN Cable Enhancements	737
CHAPTER 49	Multicast VPN and DOCSIS 3.0 Multicast QoS Support 739
Finding Feature Information	739
Hardware Compatibility Matrix for the Cisco cBR Series Routers	740
Restrictions for the Multicast VPN and DOCSIS 3.0 Multicast QoS Support	740
Information About the Multicast VPN and DOCSIS 3.0 Multicast QoS Support	741
Enhanced Quality of Service	741
Intelligent Multicast Admission Control	741
Multicast Session Limit Support	742
Multicast Virtual Private Network	742
How to Configure the Multicast VPN and DOCSIS 3.0 Multicast QoS Support	742
Configuring a QoS Profile for a Multicast Group	743
Configuring a Multicast QoS Group	743
Configuring a Default Multicast QoS Group for VRF	744

Verifying Configuration of the Multicast VPN and DOCSIS 3.0 Multicast QoS Support	745
Configuration Examples for the Multicast VPN and DOCSIS 3.0 Multicast QoS Support	746
Example: Configuring Group QoS and Group Encryption Profiles	747
Example: Configuring a QoS Group	747
Additional References	747
Feature Information for Multicast VPN and DOCSIS3.0 Multicast QoS Support	748

CHAPTER 50**EtherChannel for the Cisco CMTS 751**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	752
Restrictions for EtherChannel on the Cisco CMTS	752
Information About EtherChannel on the Cisco CMTS	753
Introduction to EtherChannel on the Cisco CMTS	753
Cisco Ten Gigabit EtherChannel on the Cisco cBR Series Routers	753
How to Configure EtherChannel on the Cisco CMTS	753
Configuring Ten Gigabit EtherChannel on the Cisco CMTS	754
Troubleshooting Tips	756
What to Do Next	756
Verifying EtherChannel on the Cisco CMTS	756
Configuration Examples for EtherChannel on the Cisco CMTS	757
Additional References	758
Feature Information for EtherChannel on Cisco CMTS	759

CHAPTER 51**Flow-Based per Port-Channel Load Balancing 761**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	761
Restrictions for Flow-Based per Port-Channel Load Balancing	762
Information About Flow-Based per Port-Channel Load Balancing	762
Flow-Based Load Balancing	762
Buckets for Flow-Based Load Balancing	763
Load Balancing on Port Channels	763
How to Enable Flow-Based per Port-Channel Load Balancing	765
Configuring Load Balancing on a Port Channel	765
Verifying Load Balancing Configuration on a Ten GEC Interface	766
Configuration Examples for Flow-Based per Port-Channel Load Balancing	768
Example: Flow-Based Load Balancing	768

Additional References	769
Feature Information for Flow-Based per Port-Channel Load Balancing	769

CHAPTER 52**MPLS QoS via TLV for non-L2VPN Service Flow 771**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	771
Restrictions for MPLS QoS via TLV for non-L2VPN Service Flow	772
Information About MPLS QoS via TLV for non-L2VPN Service Flow	773
Configuring MPLS QoS via TLV for non-L2VPN Service Flow	773
Traffic Class for MPLS Imposition Packets	773
Traffic Classification for MPLS Disposition Packets	773
Using Vendor-Specific TLVs with AToM L2VPN and MPLS L3VPN	774
Configuration Examples	774
Example: Upstream Service Flow Marking TLV	774
Example: Downstream Packet Classification TLV	774
Example: MPLS QoS Configuration File	775
Additional References	777
Feature Information for MPLS QoS via TLV for non-L2VPN Service Flow	778

PART VI**Layer 3 Configuration 779****CHAPTER 53****DHCP, ToD, and TFTP Services for CMTS Routers 781**

Prerequisites for DHCP, ToD, and TFTP Services	781
Restrictions for DHCP, ToD, and TFTP Services	781
Information About DHCP, ToD, and TFTP Services	782
Feature Overview	782
External DHCP Servers	782
Cable Source Verify Feature	782
Smart Relay Feature	783
GIADDR Field	784
DHCP Relay Agent Sub-option	784
Time-of-Day Server	784
TFTP Server	786
Benefits	786
How to Configure ToD, and TFTP Services	787

Configuring Time-of-Day Service	787
Enabling Time-of-Day Service	787
Disabling Time-of-Day Service	788
Configuring TFTP Service	789
Optimizing the Use of an External DHCP Server	791
Configuring Cable Source Verify Option	792
Configuring Prefix-based Source Address Verification	793
Configuring Optional DHCP Parameters	794
How to Configure ToD, and TFTP Services	798
Configuration Examples	798
ToD Server Example	798
TFTP Server Example	798
Additional References	799
Feature Information for the DHCP, ToD, and TFTP Services for the CMTS Routers	799

CHAPTER 54**Virtual Interface Bundling 801**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	801
Information About Virtual Interface Bundling	802
Overview of Virtual Interface Bundling	802
Guidelines for Virtual Interface Bundling	803
Virtual Interface Bundle-aware and Bundle-unaware Support	804
Configuring Virtual Interface Bundling	805
Verifying the Virtual Interface Bundling Configuration	807
Additional References	809
Feature Information for Virtual Interface Bundling	809

CHAPTER 55**IPv6 on Cable 811**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	812
Restrictions for IPv6 on Cable	813
Multicast Restrictions	813
QoS Restrictions	813
Information About IPv6 on Cable	814
Features Supported	814
Overview of the DOCSIS 3.0 Network Model Supporting IPv6	814

Overview of Cable Modem IPv6 Address Provisioning	816
Overview of IPv6 Dual Stack CPE Support on the CMTS	817
Overview of IPv6 over Subinterfaces	817
Overview of High Availability on IPv6	817
DOCSIS PRE HA	818
DOCSIS Line Card HA	818
Dynamic Channel Change	818
Overview of IPv6 VPN over MPLS	819
Cable Monitor	820
Overview of IPv6 CPE Router Support on the Cisco CMTS	820
Support for IPv6 Prefix Stability on the CMTS	821
Configurable DHCPv6 Relay Address	821
Support for Multiple IAPDs in a Single Advertise	822
IPv6 Neighbor Discovery Gleaning	822
How to Configure IPv6 on Cable	822
Configuring IPv6 Switching Services	822
Implementing IPv6 Addressing and Basic Connectivity for Cable Interfaces and Bundles	824
Configuring the Cable Virtual Bundle Interface	824
Configuring the IP Provisioning Mode and Bundle on the Cable Interface	826
Configuring IPv6 Cable Filter Groups	827
Configuring IPv6 Cable Filter Groups	827
Cable Filter Groups and the DOCSIS Subscriber Management MIB	827
Troubleshooting Tips	832
Configuring IPv6 Domain Name Service	832
Configuring IPv6 Source Verification	834
Configuring IPv6 VPN over MPLS	835
Configuring DHCPv6 Relay Agent	835
Configuring IPv6 Source Address and Link Address	836
Configurable DOCSIS CMTS Capabilities DHCPv6 Field	837
Disabling IPv6 ND Gleaning	837
How to Verify IPv6 Dual Stack CPE Support	838
Examples	838
Configuration Examples for IPv6 on Cable	839
Example: IPv6 over Subinterfaces	839

Example: Basic IPv6 Cable Filter Groups	840
Example: Complete Cable Configuration with IPv6	840
Example: BGP Configuration for 6VPE	848
Example: Subinterface Configuration for 6VPE	849
Example: Cable Interface Bundling	849
Example: VRF Configuration for 6VPE	849
Verifying IPv6 on Cable	850
Verifying IPv6 VRF Configuration	850
Verifying IPv6 BGP Status	850
Verifying MPLS Forwarding Table	850
Verifying IPv6 Cable Modem and its Host State	851
Verifying Multiple IAPDs in a Single Advertise	851
Supported MIBs	852
Additional References	852
Feature Information for IPv6 on Cable	852

CHAPTER 56
Cable DHCP Leasequery 855

Hardware Compatibility Matrix for the Cisco cBR Series Routers	855
Prerequisites for Cable DHCP Leasequery	856
Restrictions for Cable DHCP Leasequery	856
Information About Cable DHCP Leasequery	857
DHCP MAC Address Exclusion List	858
Unitary DHCPv6 Leasequery	858
How to Configure Filtering of Cable DHCP Leasequery Requests	858
Enabling DHCP Leasequery Filtering on Downstreams	858
Enabling DHCP Leasequery Filtering on Upstreams	859
Configuring Unitary DHCPv6 Leasequery Filtering	860
Enabling DHCPv6 Leasequery Filtering on Downstreams	862
Configuration Examples for Filtering of DHCP Leasequery	862
Example: DHCP Leasequery Filtering	862
Example: Unitary DHCPv6 Leasequery Filtering	863
Additional References	863
Feature Information for Cable DHCP Leasequery	863

CHAPTER 57**Layer 3 CPE Mobility 865**

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 865
- Prerequisites for Layer 3 CPE Mobility 866
- Restrictions for Layer 3 CPE Mobility 866
- Information About Layer 3 CPE Mobility 867
 - Benefits of Layer 3 CPE Mobility 867
- How to Configure Layer 3 Mobility 868
 - Configuring CPE Mobility 868
 - Configure Source-Based Rate Limit (SBRL) for L3-mobility 869
 - Disabling CPE Mobility 870
 - Verifying Layer 3 Mobility Configuration 871
- Configuration Examples for Layer 3 Mobility 871
 - Example: Configuring CPE Layer 3 Mobility 871
 - Example: Configuring SBRL for L3-mobility 872
- Additional References 872
- Feature Information for Layer 3 CPE Mobility 872

CHAPTER 58**DOCSIS 3.0 Multicast Support 873**

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 873
- Prerequisites for the DOCSIS 3.0 Multicast Support 874
- Restrictions for the DOCSIS 3.0 Multicast Support 874
- Information About the DOCSIS 3.0 Multicast Support 875
 - Multicast DSID Forwarding 875
 - Multicast Forwarding on Bonded CM 876
 - Static TLV Forwarding 876
 - Explicit Tracking 876
 - Multicast Quality of Service Enhancement 877
 - Multicast Secondary Bonding Group 877
 - Load Balancing 878
 - Multicast DSID Forwarding Disabled Mode 878
 - MDF1 Support for DOCSIS 2.0 Hybrid Cable Modems 879
 - DSG Disablement for Hybrid STBs 879
 - Benefits of MDF1 Support 879

Dynamic Multicast Replication Sessions	879
Cache Multicast Replication Sessions	879
How to Configure the DOCSIS 3.0 Multicast Support	880
Configuring Basic Multicast Forwarding	880
Configuring Multicast DSID Forwarding	881
Configuring Explicit Tracking	881
Configuring Multicast QoS	881
Selecting a Forwarding Interface Based on Service Flow Attribute	883
Configuring Multicast DSID Forwarding Disabled Mode	885
Configuring Multicast Replication Session Globally	886
Configuring Multicast Replication Sessions on Forwarding Interface	887
Clearing Multicast Replication Cache	887
How to Monitor the DOCSIS 3.0 Multicast Support	887
Verifying the Basic Multicast Forwarding	888
Verifying the Multicast DSID Forwarding	888
Verifying the Explicit Tracking Feature	890
Verifying the Multicast QoS Feature	890
Verifying the Service Flow Attributes	890
Verifying the Multicast Group Classifiers	891
Troubleshooting Tips	891
Viewing Current Cache	891
Configuration Examples for DOCSIS 3.0 Multicast Support	893
Example: Configuring Basic Multicast Forwarding	893
Example: Configuring Multicast QoS	893
Example: Configuring Forwarding Interface Selection Based on Service Flow Attribute	893
Example: Configuring Multicast Replication Session	894
Additional References	894
Feature Information for DOCSIS 3.0 Multicast Support	895

CHAPTER 59
IPv6 Segment Routing on Cisco cBR 897

Hardware Compatibility Matrix for the Cisco cBR Series Routers	897
Information about IPv6 Segment Routing	898
Restriction for Configuring IPv6 Segment Routing	898
How to Configure IPv6 Segment Routing	899

Configuring IPv6 Segment Routing on cBR	899
Verifying IPv6 Segment Routing Configuration	899
Configure Multiple IPv6 Addresses for Segment Routing	899
Verifying IPv6 Segment Routing Configuration on Multiple IPv6 Addresses	899
Disabling Prefix SID	900
Verifying whether Prefix SID is Disabled	900
Disabling SRv6 for a Prefix-SID	900
Verifying whether SRv6 is Disabled and Prefix SID Removed	901
Configuration Examples	901
Example: Configuring IPv6 Segment Routing on Cisco cBR	901
Example: Configure Multiple IPv6 Addresses for SRv6	901
Example: Disabling Prefix SID	901
Example: Disabling SR with an Active Prefix SID	902
Feature Information for IPv6 Segment Routing	902

PART VII
Layer 3 Configuration—IP Access Control Lists 903

CHAPTER 60
IP Access Control Lists 905

Hardware Compatibility Matrix for the Cisco cBR Series Routers	905
Information About IP Access Lists	906
Benefits of IP Access Lists	906
Border Routers and Firewall Routers Should Use Access Lists	907
Definition of an Access List	908
Access List Rules	908
Helpful Hints for Creating IP Access Lists	909
Named or Numbered Access Lists	910
Standard or Extended Access Lists	910
IP Packet Fields You Can Filter to Control Access	911
Wildcard Mask for Addresses in an Access List	911
Access List Sequence Numbers	912
Access List Logging	912
Alternative to Access List Logging	913
Additional IP Access List Features	913
Where to Apply an Access List	913

Additional References	914
Feature Information for IP Access Lists	915

CHAPTER 61**Creating an IP Access List and Applying It to an Interface 917**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	917
Information About Creating an IP Access List and Applying It to an Interface	918
Helpful Hints for Creating IP Access Lists	918
Access List Remarks	919
Additional IP Access List Features	919
How to Create an IP Access List and Apply It to an Interface	920
Creating a Standard Access List to Filter on Source Address	920
Creating a Named Access List to Filter on Source Address	920
Creating a Numbered Access List to Filter on Source Address	922
Creating an Extended Access List	924
Creating a Named Extended Access List	924
Creating a Numbered Extended Access List	926
Applying an Access List to an Interface	928
Configuration Examples for Creating an IP Access List and Applying It to an Interface	929
Example: Filtering on Host Source Address	929
Example: Filtering on Subnet Source Address	929
Example: Filtering on Source and Destination Addresses and IP Protocols	929
Example: Filtering on Source Addresses Using a Numbered Access List	930
Example: Preventing Telnet Access to a Subnet	930
Example: Filtering on TCP and ICMP Using Port Numbers	930
Example: Allowing SMTP E-mail and Established TCP Connections	930
Example: Preventing Access to the Web by Filtering on Port Name	931
Example: Filtering on Source Address and Logging the Packets	931
Example: Limiting Debug Output	932
Additional References Creating an IP Access List and Applying It to an Interface	932
Feature Information Creating an IP Access List and Applying It to an Interface	933

CHAPTER 62**Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports 935**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	935
Prerequisites for Creating an IP Access List to Filter IP Options TCP Flags Noncontiguous Ports	936

Information About Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports	937
IP Options	937
Benefits of Filtering IP Options	937
Benefits of Filtering on TCP Flags	937
TCP Flags	938
Benefits of Using the Named ACL Support for Noncontiguous Ports on an Access Control Entry Feature	938
How Filtering on TTL Value Works	938
Benefits of Filtering on TTL Value	939
How to Create an IP Access List to Filter IP Options TCP Flags Noncontiguous Ports	940
Filtering Packets That Contain IP Options	940
What to Do Next	941
Filtering Packets That Contain TCP Flags	941
Configuring an Access Control Entry with Noncontiguous Ports	944
Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry	945
What To Do Next	947
Filtering Packets Based on TTL Value	947
Enabling Control Plane Policing to Filter on TTL Values 0 and 1	948
Configuration Examples for Filtering IP Options, TCP Flags, Noncontiguous Ports	951
Example: Filtering Packets That Contain IP Options	951
Example: Filtering Packets That Contain TCP Flags	952
Example: Creating an Access List Entry with Noncontiguous Ports	952
Example: Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports	952
Example: Filtering on TTL Value	953
Example: Control Plane Policing to Filter on TTL Values 0 and 1	953
Additional References	954
Feature Information for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values	955

CHAPTER 63**Refining an IP Access List 957**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	957
Information About Refining an IP Access List	958
Access List Sequence Numbers	958

Benefits of Access List Sequence Numbers	959
Sequence Numbering Behavior	959
Benefits of Time Ranges	959
Benefits Filtering Noninitial Fragments of Packets	960
Access List Processing of Fragments	960
How to Refine an IP Access List	961
Revising an Access List Using Sequence Numbers	962
Restricting an Access List Entry to a Time of Day or Week	964
What to Do Next	966
Configuration Examples for Refining an IP Access List	966
Example Resequencing Entries in an Access List	966
Example Adding an Entry with a Sequence Number	967
Example Adding an Entry with No Sequence Number	967
Example Time Ranges Applied to IP Access List Entries	968
Example Filtering IP Packet Fragments	968
Additional References	969
Feature Information for Refining an IP Access List	970

CHAPTER 64
IP Named Access Control Lists 971

Hardware Compatibility Matrix for the Cisco cBR Series Routers	971
Information About IP Named Access Control Lists	972
Definition of an Access List	972
Named or Numbered Access Lists	973
Benefits of IP Access Lists	973
Access List Rules	974
Helpful Hints for Creating IP Access Lists	975
Where to Apply an Access List	976
How to Configure IP Named Access Control Lists	976
Creating an IP Named Access List	976
Applying an Access List to an Interface	978
Additional References for IP Named Access Control Lists	979
Feature Information for IP Named Access Control Lists	979

CHAPTER 65
IPv4 ACL Chaining Support 981

Hardware Compatibility Matrix for the Cisco cBR Series Routers	981
Restrictions for IPv4 ACL Chaining Support	982
Information About IPv4 ACL Chaining Support	982
ACL Chaining Overview	982
IPv4 ACL Chaining Support	983
How to Configure IPv4 ACL Chaining Support	983
Configuring an Interface to Accept Common ACL	983
Configuration Examples for IPv4 ACL Chaining Support	984
Example: Configuring an Interface to Accept a Common ACL	984
Additional References for IPv4 ACL Chaining Support	985
Feature Information for IPv4 ACL Chaining Support	986

CHAPTER 66**IPv6 ACL Chaining with a Common ACL 987**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	987
Information About IPv6 ACL Chaining with a Common ACL	988
ACL Chaining Overview	988
IPv6 ACL Chaining with a Common ACL	989
How to Configure IPv6 ACL Chaining with a Common ACL	989
Configuring IPv6 ACL to an Interface	989
Configuration Examples for IPv6 ACL Chaining with a Common ACL	990
Example: Configuring an Interface to Accept a Common ACL	990
Additional References for IPv6 ACL Chaining with a Common ACL	991
Feature Information for IPv6 ACL Chaining with a Common ACL	992

CHAPTER 67**Commented IP Access List Entries 993**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	993
Information About Commented IP Access List Entries	994
Benefits of IP Access Lists	994
Access List Remarks	995
How to Configure Commented IP Access List Entries	995
Writing Remarks in a Named or Numbered Access List	995
Additional References for Commented IP Access List Entries	996
Feature Information for Commented IP Access List Entries	997

CHAPTER 68**Standard IP Access List Logging 999**

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 999
- Restrictions for Standard IP Access List Logging 1000
- Information About Standard IP Access List Logging 1000
 - Standard IP Access List Logging 1000
- How to Configure Standard IP Access List Logging 1001
 - Creating a Standard IP Access List Using Numbers 1001
 - Creating a Standard IP Access List Using Names 1002
- Configuration Examples for Standard IP Access List Logging 1003
 - Example: Limiting Debug Output 1003
- Additional References for Standard IP Access List Logging 1004
- Feature Information for Standard IP Access List Logging 1004

CHAPTER 69**IP Access List Entry Sequence Numbering 1005**

- Hardware Compatibility Matrix for the Cisco cBR Series Routers 1005
- Restrictions for IP Access List Entry Sequence Numbering 1006
- Information About IP Access List Entry Sequence Numbering 1006
 - Purpose of IP Access Lists 1006
 - How an IP Access List Works 1007
 - IP Access List Process and Rules 1007
 - Helpful Hints for Creating IP Access Lists 1008
 - Source and Destination Addresses 1009
 - Wildcard Mask and Implicit Wildcard Mask 1009
 - Transport Layer Information 1009
 - Benefits IP Access List Entry Sequence Numbering 1009
 - Sequence Numbering Behavior 1010
- How to Use Sequence Numbers in an IP Access List 1010
 - Sequencing Access-List Entries and Revising the Access List 1010
- Configuration Examples for IP Access List Entry Sequence Numbering 1014
 - Example: Resequencing Entries in an Access List 1014
 - Example: Adding Entries with Sequence Numbers 1014
 - Example: Entry Without Sequence Number 1015
- Additional References 1015

Feature Information for IP Access List Entry Sequence Numbering 1016

CHAPTER 70

ACL IP Options Selective Drop 1017

Hardware Compatibility Matrix for the Cisco cBR Series Routers 1017

Restrictions for ACL IP Options Selective Drop 1018

Information About ACL IP Options Selective Drop 1018

Using ACL IP Options Selective Drop 1018

Benefits of Using ACL IP Options Selective Drop 1019

How to Configure ACL IP Options Selective Drop 1019

Configuring ACL IP Options Selective Drop 1019

Configuration Examples for ACL IP Options Selective Drop 1020

Example Configuring ACL IP Options Selective Drop 1020

Example Verifying ACL IP Options Selective Drop 1020

Additional References for IP Access List Entry Sequence Numbering 1021

Feature Information for ACL IP Options Selective Drop 1021

CHAPTER 71

ACL Syslog Correlation 1023

Hardware Compatibility Matrix for the Cisco cBR Series Routers 1023

Prerequisites for ACL Syslog Correlation 1024

Information About ACL Syslog Correlation 1024

ACL Syslog Correlation Tags 1024

ACE Syslog Messages 1025

How to Configure ACL Syslog Correlation 1025

Enabling Hash Value Generation on a Device 1025

Disabling Hash Value Generation on a Device 1026

Configuring ACL Syslog Correlation Using a User-Defined Cookie 1027

Configuring ACL Syslog Correlation Using a Hash Value 1029

Changing the ACL Syslog Correlation Tag Value 1030

Troubleshooting Tips 1032

Configuration Examples for ACL Syslog Correlation 1032

Example: Configuring ACL Syslog Correlation Using a User-Defined Cookie 1032

Example: Configuring ACL Syslog Correlation using a Hash Value 1032

Example: Changing the ACL Syslog Correlation Tag Value 1033

Additional References for IPv6 IOS Firewall 1033

Feature Information for ACL Syslog Correlation 1034

CHAPTER 72

IPv6 Access Control Lists 1035

Hardware Compatibility Matrix for the Cisco cBR Series Routers 1035

Information About IPv6 Access Control Lists 1036

Access Control Lists for IPv6 Traffic Filtering 1036

IPv6 Packet Inspection 1037

Access Class Filtering in IPv6 1037

How to Configure IPv6 Access Control Lists 1037

Configuring IPv6 Traffic Filtering 1037

Creating and Configuring an IPv6 ACL for Traffic Filtering 1037

Applying the IPv6 ACL to an Interface 1039

Controlling Access to a vty 1039

Creating an IPv6 ACL to Provide Access Class Filtering 1039

Applying an IPv6 ACL to the Virtual Terminal Line 1041

Configuration Examples for IPv6 Access Control Lists 1042

Example: Verifying IPv6 ACL Configuration 1042

Example: Creating and Applying an IPv6 ACL 1042

Example: Controlling Access to a vty 1042

Additional References 1043

Feature Information for IPv6 Access Control Lists 1043

CHAPTER 73

IPv6 Template ACL 1045

Hardware Compatibility Matrix for the Cisco cBR Series Routers 1046

Information About IPv6 ACL—Template ACL 1046

IPv6 Template ACL 1046

How to Enable IPv6 ACL—Template ACL 1047

Enabling IPv6 Template Processing 1047

Configuration Examples for IPv6 ACL—Template ACL 1048

Example: IPv6 Template ACL Processing 1048

Additional References 1048

Feature Information for IPv6 Template ACL 1049

CHAPTER 74

IPv6 ACL Extensions for Hop by Hop Filtering 1051

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1051
Information About IPv6 ACL Extensions for Hop by Hop Filtering	1052
ACLs and Traffic Forwarding	1052
How to Configure IPv6 ACL Extensions for Hop by Hop Filtering	1053
Configuring IPv6 ACL Extensions for Hop by Hop Filtering	1053
Configuration Example for IPv6 ACL Extensions for Hop by Hop Filtering	1054
Example: IPv6 ACL Extensions for Hop by Hop Filtering	1054
Additional References	1055
Feature Information for IPv6 ACL Extensions for Hop by Hop Filtering	1056

PART VIII
Application—Voice and Video Configuration 1057

CHAPTER 75
Unique Device Identifier Retrieval 1059

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1059
Unique Device Identifier Overview	1060
Benefits of the Unique Device Identifier Retrieval Feature	1061
Retrieving the Unique Device Identifier	1061
Troubleshooting Tips	1064
Additional References	1064
Feature Information for Unique Device Identifier Retrieval	1065

CHAPTER 76
Advanced-Mode DOCSIS Set-Top Gateway 1.2 for the Cisco CMTS Routers 1067

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1068
Prerequisites for Advanced-Mode DSG Issue 1.2	1068
Restrictions for Advanced-Mode DSG Issue 1.2	1068
DSG Configuration File Transfer Operations	1069
Multicast Configuration Restrictions	1069
NAT for DSG Unicast-only Mapping	1069
PIM and SSM for Multicast	1069
Subinterfaces	1069
Information About Advanced-Mode DSG Issue 1.2	1069
DSG 1.2 Clients and Agents	1070
FQDN Support	1070
DSG Name Process and DNS Query	1070

A-DSG Forwarding on the Primary Channel	1071
DOCSIS 3.0 DSG MDF Support	1071
Source Specific Multicast Mapping	1071
How to Configure Advanced-Mode DSG Issue 1.2	1072
Configuring the Default Multicast Quality of Service	1072
Configuring Global Tunnel Group Settings for Advanced-Mode DSG 1.2	1073
Global A-DSG 1.2 Tunnel Settings	1073
Adding DSG Tunnel Group to a Subinterface	1075
Configuring the DSG Client Settings for Advanced-Mode DSG 1.2	1075
Configuring Downstream DSG 1.2 Settings for Advanced-Mode DSG 1.2	1077
Configuring IP Multicast Operations	1078
Enabling DNS Query and DSG Name Process	1079
Configuring NAT to Support Unicast Messaging	1080
Configuring WAN Interfaces for Multicast Operations	1082
Configuring a Standard IP Access List for Packet Filtering	1082
Configuring a Standard IP Access List for Multicast Group Filtering	1084
Disabling A-DSG Forwarding on the Primary Channel	1085
How to Monitor and Debug the Advanced-mode DOCSIS Set-Top Gateway Feature	1085
Displaying Global Configurations for Advanced-Mode DSG 1.2	1086
show cable dsg cfr	1086
show cable dsg host	1086
show cable dsg tunnel	1086
show cable dsg tg	1086
show running-config interface	1087
show cable dsg static-group bundle	1087
Displaying Interface-level Configurations for Advanced-Mode DSG 1.2	1087
show cable dsg tunnel interfaces	1087
show interfaces cable dsg downstream	1087
show interfaces cable dsg downstream dcd	1087
show interfaces cable dsg downstream tg	1088
show interfaces cable dsg downstream tunnel	1088
Debugging Advanced-Mode DSG	1088
Configuration Examples for Advanced-Mode DSG	1088
Example: Enabling DNS Query	1090

Example: Disabling A-DSG Forwarding on the Primary Channel	1091
Additional References	1091
Feature Information for Advanced-Mode DSG 1.2 for the Cisco CMTS Routers	1091

CHAPTER 77**Cisco Network Registrar for the Cisco CMTS Routers 1093**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1094
Servers Required on the HFC Network	1094
Cisco Network Registrar Description	1095
Overview of DHCP Using CNR	1096
How Cisco Converged Broadband Routers and Cable Modems Work	1097
DHCP Fields and Options for Cable Modems	1097
Cisco Network Registrar Sample Configuration	1098
Cable Modem DHCP Response Fields	1101
DOCSIS DHCP Fields	1101
DHCP Relay Option (DOCSIS Option 82)	1101
Overview of Scripts	1102
Two-way Cable Modem Scripts	1102
Telco Return Cable Modem Scripts	1102
Placement of Scripts	1102
Windows NT	1102
Solaris	1103
Activating Scripts in Cisco Network Registrar	1103
Configuring the Cisco CMTS Routers to Use Scripts	1103
Configuring the System Default Policy	1103
Cable Modems	1104
PCs	1104
Creating Selection Tag Scopes	1104
General	1104
Telco Return for the Cisco cBR-8 Router	1104
Creating Network Scopes	1105
Creating Policies for Class of Service or for Upgrading Cable Modem Cisco IOS Images	1105
CNR Steps to Support Subinterfaces	1106
Additional References	1107

PART IX

PacketCable and PacketCable Multimedia Configuration 1109

CHAPTER 78

PacketCable and PacketCable Multimedia 1111

- Finding Feature Information 1111
- Hardware Compatibility Matrix for the Cisco cBR Series Routers 1112
- Restrictions for PacketCable Operations 1112
- Information About PacketCable Operations 1113
 - Feature Overview 1113
 - Emergency 911 Features 1113
 - PacketCable Emergency 911 Cable Interface Line Card Prioritization 1113
 - PacketCable Emergency 911 Services Listing and History 1114
 - PacketCable Network Components 1114
 - Dynamic Quality of Service 1115
 - Two-Stage Resource Reservation Process 1115
 - Making a Call Using DQoS 1116
 - DQoSLite Based IPv6 Voice Support 1116
 - Dynamic Service Transaction ID Support 1117
 - PacketCable Subscriber ID Support 1117
 - Benefits 1118
- How to Configure PacketCable Operations 1119
 - Enabling PacketCable Operation 1119
 - Disabling PacketCable Operation 1119
 - Configuring PacketCable Operation 1120
 - Enabling Both PacketCable and Non-PacketCable UGS Service Flows 1121
 - Enabling PacketCable Subscriber ID Support 1122
 - Configuring RADIUS Accounting for RKS Servers 1123
 - PacketCable Client Accept Timeout 1125
- Configuration Examples for PacketCable 1126
 - Example: Typical PacketCable Configuration 1126
- Verifying PacketCable Operations 1128
 - Verifying Emergency 911 Calls 1130
- Information About PacketCable Multimedia Operations 1132
 - PCMM Overview 1132

PCMM Enhancements over PacketCable 1.x	1133
PCMM and High Availability Features on the Cisco CMTS Router	1134
PCMM Gates	1134
PCMM Gate Overview and PCMM Dynamic Quality of Service	1134
PCMM Persistent Gate	1134
PCMM Interfaces	1135
PCMM to COPS Interface	1135
PCMM and Distributed Cable Interface Line Cards	1135
PCMM Unicast and Multicast	1135
PCMM Multicast Session Range	1135
How to Configure PCMM Operations	1135
Enabling PCMM Operations on the Cisco CMTS Router	1135
Configuring a PCMM Multicast Session Range	1137
Configuration Examples for PacketCable Multimedia	1137
Example: Enabling PCMM Operations on the Cisco CMTS Router	1138
Example: Enabling a Multicast Session Range on the Cisco CMTS Router	1138
Verifying PCMM Operations	1138
High Availability Stateful Switchover (SSO) for PacketCable and PacketCable MultiMedia	1140
PacketCable and PCMM with Admission Control	1140
Voice MGPI Support	1140
Voice Support Over DOCSIS 3.0 E-MTAs	1141
PacketCable and PCMM Call Trace	1141
Verifying PacketCable and PCMM Statistics	1141
Additional References	1143
Feature Information for PacketCable and PacketCable Multimedia	1144

CHAPTER 79
COPS Engine Operation 1147

Finding Feature Information	1147
Hardware Compatibility Matrix for the Cisco cBR Series Routers	1147
Prerequisites for the COPS Engine on the Cisco CMTS Routers	1148
Restrictions for the COPS Engine on the Cisco CMTS	1148
Information About the COPS Engine on the Cisco CMTS	1149
How to Configure the COPS Engine on the Cisco CMTS	1149
Configuring COPS TCP and DSCP Marking	1149

Configuring COPS TCP Window Size	1151
Configuring Access Control List Support for COPS Engine	1151
Restricting RSVP Policy to Specific Access Control Lists	1152
Displaying and Verifying COPS Engine Configuration on the Cisco CMTS	1153
Show Commands for COPS Engine Information	1153
Displaying COPS Servers on the Network	1154
Displaying COPS Policy Information on the Network	1154
Displaying Access Lists for COPS	1154
COPS Engine Configuration Examples for Cable	1154
Example: COPS Server Specified	1154
Example: COPS Server Display	1154
Additional References	1155
Feature Information for COPS Engine Operation	1156

PART X**Quality of Services Configuration** 1157

CHAPTER 80**Dynamic Bandwidth Sharing** 1159

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1159
Information About Dynamic Bandwidth Sharing	1160
How to Configure Dynamic Bandwidth Sharing	1161
Configuring DBS for a Wideband Cable Interface	1161
Configuring DBS for an Integrated Cable Interface	1161
Verifying the Dynamic Bandwidth Sharing Configuration	1162
Additional References	1165
Feature Information for Dynamic Bandwidth Sharing	1166

CHAPTER 81**Modular Quality of Service Command-Line Interface QoS** 1167

Finding Feature Information	1167
Hardware Compatibility Matrix for the Cisco cBR Series Routers	1167
Restrictions for Applying QoS Features Using the MQC	1168
About	1170
The MQC Structure	1170
Elements of a Traffic Class	1170
Elements of a Traffic Policy	1172

Nested Traffic Classes	1174
match-all and match-any Keywords of the class-map Command	1174
input and output Keywords of the service-policy Command	1175
Benefits of Applying QoS Features Using the MQC	1175
How to Apply QoS Features Using the MQC	1175
Creating a Traffic Class	1175
Creating a Traffic Policy	1177
Attaching a Traffic Policy to an Interface Using the MQC	1178
Verifying the Traffic Class and Traffic Policy Information	1179
Configuration Examples for Applying QoS Features Using the MQC	1180
Creating a Traffic Class	1180
Creating a Policy Map	1180
Example: Attaching a Traffic Policy to an Interface	1180
Using the match not Command	1181
Configuring a Default Traffic Class	1181
How Commands "class-map match-any" and "class-map match-all" Differ	1181
Establishing Traffic Class as a Match Criterion (Nested Traffic Classes)	1182
Example: Nested Traffic Class for Maintenance	1182
Example: Nested Traffic Class to Combine match-any and match-all Characteristics in One Traffic Class	1183
Example: Traffic Policy as a QoS Policy (Hierarchical Traffic Policies)	1183
How to Configure Input MQC on the Port-Channel Interfaces	1184
Creating a Traffic Class	1184
Creating a Policy Map	1184
Defining QoS Actions in a Policy Map	1185
Set Actions	1185
Configuring Aggregate Port-Channel Interface	1185
Attaching a Traffic Policy to an Interface	1185
Example: Configuring Input MQC on the Port-Channel Interfaces	1185
Additional References	1186
Feature Information for Modular Quality of Service Command-Line Interface QoS	1187

Prerequisites for DOCSIS 1.1 Operations	1190
Restrictions for DOCSIS 1.1 Operations	1191
Information about DOCSIS 1.1	1193
Baseline Privacy Interface Plus	1193
Concatenation	1194
Dynamic MAC Messages	1194
Enhanced Quality of Service	1194
Fragmentation	1195
Interoperability	1195
Payload Header Suppression	1195
Downstream ToS Overwrite	1195
DOCSIS 1.1 Quality of Service	1196
Service Flow	1196
Service Class	1197
Packet Classifiers	1198
Packet Header Suppression Rules	1199
Quality of Service Comparison	1199
Enhanced Rate Bandwidth Allocation (ERBA) Support for DOCSIS 1.0 Cable Modems	1201
DOCSIS 3.0 Downstream Peak Traffic Rate TLV Support for ERBA	1202
Suppressing Upstream and Downstream Peak Rate TLVs for pre DOCSIS 3.0 Cable Modems	1203
Downstream Classification Enhancement with MAC Addresses	1204
Benefits	1204
How to Configure the Cisco CMTS for DOCSIS 1.1 Operations	1206
Configuring Baseline Privacy Interface	1206
Downloading the DOCSIS Root Certificate to the CMTS	1209
Adding a Manufacturer's Certificate as a Trusted Certificate	1211
Adding a Certificate as a Trusted Certificate Using SNMP Commands	1211
Adding a Manufacturer's or CM Certificate to the Hotlist	1213
Adding a Certificate to the Hotlist Using SNMP Commands	1213
Enabling Concatenation	1214
Enabling DOCSIS Fragmentation	1215
Enabling DOCSIS 1.1 Downstream Maximum Transmit Burst on the Cisco cBR-8 Router	1217
Monitoring DOCSIS Operations	1218
Monitoring the DOCSIS Network	1218

Displaying the Status of Cable Modems	1218
Displaying a Summary Report for the Cable Modems	1220
Displaying the Capabilities of the Cable Modems	1221
Displaying Detailed Information About a Particular Cable Modem	1221
Monitoring the RF Network and Cable Interfaces	1221
Displaying Information About Cloned Cable Modems	1221
Denying RF Access For Cable Modems	1221
Displaying Information About the Mac Scheduler	1221
Displaying Information About QoS Parameter Sets	1222
Displaying Information About Service Flows	1222
Displaying Information About Service IDs	1222
Monitoring BPI+ Operations	1222
Displaying the Current BPI+ State of Cable Modems	1222
Displaying the BPI+ Timer Values on the CMTS	1223
Displaying the Certificate List on the CMTS	1223
Configuration Examples for DOCSIS 1.1 Operations	1224
Example: DOCSIS 1.1 Configuration for Cisco cBR-8 Router (with BPI+)	1224
Additional References	1227
Feature Information for DOCSIS 1.1 for Cisco CMTS Routers	1228

CHAPTER 83**Default DOCSIS 1.0 ToS Overwrite 1229**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1229
Restrictions for Default DOCSIS 1.0 ToS Overwrite	1230
Information About Default DOCSIS 1.0 ToS Overwrite	1230
Default DOCSIS 1.0 ToS Overwrite Overview	1231
DOCSIS	1231
Type-of-Service (ToS)	1231
How to Configure Default DOCSIS 1.0 ToS Overwrite	1231
Enabling Default DOCSIS 1.0 ToS Overwrite	1231
Editing QoS Profiles	1233
Additional References	1233
Feature Information for Default DOCSIS 1.0 ToS Overwrite	1234

CHAPTER 84**DOCSIS WFQ Scheduler on the Cisco CMTS Routers 1235**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1235
Prerequisites for DOCSIS WFQ Scheduler	1236
Restrictions for DOCSIS WFQ Scheduler	1236
Information About DOCSIS WFQ Scheduler	1236
Queue Types	1237
Priority Queues	1238
CIR Queues	1238
Best Effort Queues	1238
DOCSIS QoS Support	1238
Traffic Priority	1239
Maximum Sustained Traffic Rate	1240
Minimum Reserved Traffic Rate	1240
High Priority Traffic	1240
Enhanced Rate Bandwidth Allocation	1240
Peak Traffic Rate	1241
DOCSIS 3.0 Downstream Bonding Support with Bonding Group Dynamic Bandwidth Sharing	1242
How to Configure DOCSIS WFQ Scheduler	1242
Mapping DOCSIS Priority to Excess Ratio	1242
Verifying the Downstream Queues Information	1243
Additional References	1243
Feature Information for DOCSIS WFQ Scheduler	1244

CHAPTER 85

Fairness Across DOCSIS Interfaces	1245
Hardware Compatibility Matrix for the Cisco cBR Series Routers	1245
Prerequisites for Fairness Across DOCSIS Interfaces	1246
Restrictions for Fairness Across DOCSIS Interfaces	1246
Information About Fairness Across DOCSIS Interfaces	1247
On-demand CIR Acquisition	1247
Fairness Across Bonding Groups	1247
OFDM Channels	1248
Interface Bandwidth	1248
How to Configure Fairness Across DOCSIS Interfaces	1248
Configuring Fairness Across DOCSIS Interfaces	1248
Configuring Maximum Excess Information Rate Ratio	1249

Configuring Constant Excess Information Rate Demand	1250
Configuring Maximum Bonus Bandwidth	1251
Verifying the Fairness Across DOCSIS Interfaces	1252
Verifying Reservable Bandwidth	1252
Verifying Global Fairness Across DOCSIS Interfaces Status and Statistics	1253
Verifying Per-Controller Fairness Across DOCSIS Interfaces Status and Statistics	1254
Verifying Per-Interface Fairness Across DOCSIS Interfaces Status and Statistics	1254
Configuration Examples for Fairness Across DOCSIS Interfaces	1255
Example: Fairness Across DOCSIS Interfaces	1255
Example: Maximum EIR Demand Ratio	1255
Example: Constant EIR Demand	1256
Example: Maximum Bonus Bandwidth	1256
Additional References	1257
Feature Information for Fairness Across DOCSIS Interfaces	1257

CHAPTER 86

Service Group Admission Control	1259
Finding Feature Information	1259
Hardware Compatibility Matrix for the Cisco cBR Series Routers	1259
Restrictions for Service Group Admission Control	1260
Information About Service Group Admission Control	1260
Overview	1260
SGAC and Downstream Bandwidth Utilization	1261
Categorization of Service Flows	1261
Thresholds for Downstream Bandwidth	1262
Overview of Bonding Group Admission Control	1262
How to Configure, Monitor, and Troubleshoot Service Group Admission Control	1262
Defining Rules for Service Flow Categorization	1262
Naming Application Buckets	1265
Preempting High-Priority Emergency 911 Calls	1265
Calculating Bandwidth Utilization	1266
Enabling SGAC Check	1267
Configuration Examples for SGAC	1268
Example: SGAC Configuration Commands	1268
Example: SGAC for Downstream Traffic	1270

Additional References	1270
Feature Information for Service Group Admission Control	1271
<hr/>	
CHAPTER 87	Subscriber Traffic Management 1273
Hardware Compatibility Matrix for the Cisco cBR Series Routers	1274
Restrictions for Subscriber Traffic Management on the Cisco CMTS Routers	1274
Information About Subscriber Traffic Management on the Cisco CMTS Routers	1275
Feature Overview	1275
Feature List	1276
Sliding Window for Monitoring Service Flows	1277
Weekend Monitoring	1278
SNMP Trap Notifications	1278
Cable Modem Interaction with the Subscriber Traffic Management Feature	1279
How to Configure the Subscriber Traffic Management Feature on the Cisco CMTS Routers	1280
Creating and Configuring an Enforce-Rule	1280
Examples	1283
Configuring Weekend Monitoring	1285
Prerequisites	1285
Restrictions	1285
Configuring Different Legacy Monitoring Conditions for Weekends	1285
Configuring Different Peak-Offpeak Monitoring Conditions for Weekends	1286
Disabling Weekend Monitoring	1287
Removing Weekend Monitoring Conditions and Use the Same Monitoring Criteria Every Day	1288
Disabling an Enforce-Rule	1288
Removing an Enforce-Rule	1289
Changing a Cable Modem Service Class	1290
Monitoring the Subscriber Traffic Management Feature on the Cisco CMTS Routers	1291
Displaying the Currently Defined Enforce-Rules	1291
Displaying the Current Subscriber Usage	1293
Configuration Examples for Subscriber Traffic Management on the Cisco CMTS Routers	1294
Example: DOCSIS Configuration File and STM Service Classes	1294
Example: Downstream Configuration	1295
Example: Upstream Configuration	1296
Example: Downstream and Upstream Configuration	1296

Example: Weekend Monitoring Configuration	1297
Additional References	1297
Feature Information for Subscriber Traffic Management	1298

CHAPTER 88**Narrowband Digital Forward And Narrowband Digital Return 1301**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1301
Information About NDF and NDR	1302
Restrictions for Configuring NDF and NDR	1302
1x2 RPD	1303
Configure NDF and NDR	1303
Configure Static-Pseudowires for NDF and NDR	1303
Configure NDF and NDR Profile	1306
Bind NDF Static-Pseudowire and NDF Profile with Rf-Port	1307
Bind NDR Static-Pseudowire and NDR Profile with Rf-Port	1307
Display TLV Status	1307
Example: NDF Configuration	1309
Example: NDR Configuration	1309
Feature Information for Narrowband Digital Forward And Narrowband Digital Return	1310

PART XI**Security and Cable Monitoring Configuration 1311****CHAPTER 89****Dynamic Shared Secret 1313**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1314
Prerequisites for Dynamic Shared Secret	1314
Restrictions for Dynamic Shared Secret	1315
General Restrictions for Dynamic Shared Secret	1315
Cable Modem Restrictions for Dynamic Shared Secret	1316
DHCP Restriction for Incognito Server and Thomson Cable Modems	1316
DOCSIS Compliance	1317
TFTP Restrictions	1318
Information About Dynamic Shared Secret	1318
Modes of Operation	1319
Operation of the Dynamic Shared Secret	1320
Interaction with Different Commands	1320

Performance Information	1321
SNMP Support	1321
System Error Messages	1322
Benefits	1323
Related Features	1324
How to Configure the Dynamic Shared Secret Feature	1324
Enabling and Configuring the Dynamic Shared Secret Feature	1324
Disabling the Dynamic Shared Secret on a Cable Interface	1326
Excluding Cable Modems from the Dynamic Shared Secret Feature	1327
Clearing the Lock on One or More Cable Modems	1328
Upgrading Firmware on the Cable Modems	1329
How to Monitor the Dynamic Shared Secret Feature	1330
Displaying Marked Cable Modems	1330
Displaying the Current Dynamic Secrets	1331
Troubleshooting Cable Modems with Dynamic Shared Secret	1333
Configuration Examples for Dynamic Shared Secret	1334
Mark Configuration: Example	1334
Lock Configuration: Example	1335
Reject Configuration: Example	1335
Disabled Configuration: Example	1336
Additional References	1336
Feature Information for Dynamic Shared Secret	1337

CHAPTER 90**Lawful Intercept Architecture 1339**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1339
Prerequisites for Lawful Intercept	1340
Restrictions for Lawful Intercept	1341
Information About Lawful Intercept	1341
Introduction to Lawful Intercept	1341
Cisco Service Independent Intercept Architecture	1342
PacketCable Lawful Intercept Architecture	1342
Cisco cBR Series Routers	1342
VRF Aware LI	1343
Lawful Intercept- Redundant Mediation Devices	1344

Lawful Intercept MIBs	1344
Restricting Access to the Lawful Intercept MIBs	1344
Service Independent Intercept	1345
Restricting Access to Trusted Hosts (without Encryption)	1345
How to Configure Lawful Intercept	1345
Creating a Restricted SNMP View of Lawful Intercept MIBs	1345
Where to Go Next	1347
Enabling SNMP Notifications for Lawful Intercept	1347
Disabling SNMP Notifications	1348
Provisioning a MAC Intercept for Cable Modems Using SNMPv3	1349
Provisioning a MAC Intercept for a CPE Device Using SNMPv3	1349
Configuration Examples for Lawful Intercept	1349
Example: Enabling Mediation Device Access Lawful Intercept MIBs	1349
Example: Configuring Lawful Intercept- Redundant Mediation Devices	1350
Additional References	1351
Feature Information for Lawful Intercept	1352

CHAPTER 91	Cable Monitoring Feature for Cisco cBR Series Routers	1353
	Overview of Cable Monitor Command for cBR	1354
	Configuring Cable Monitoring for cBR Routers	1354
	Capturing Sniffed Packets	1356
	Capturing Sniffed Packets on an External Host	1356
	Capturing Sniffed Packets on a Local Hard Drive	1357
	Cable Monitor Packet Struct	1359
	Feature Information for Cable Monitoring	1359

CHAPTER 92	Source-Based Rate Limit	1361
	Hardware Compatibility Matrix for the Cisco cBR Series Routers	1361
	Prerequisites for Source-Based Rate Limit	1362
	Restrictions for Source-Based Rate Limit	1362
	Information About Source-Based Rate Limit	1363
	How to Configure Source-Based Rate Limit	1363
	Configuring WAN-Side Source-Based Rate Limit	1363
	Configuring Control Plane Policing	1364

Enabling WAN-Side Source-Based Rate Limit	1366
Configuring WAN-Side Quarantine	1366
Configuring Subscriber-Side Source-Based Rate Limit	1367
Configuring Source-Based Rate Limit Ping-Bypass	1368
Configuring Punt Policing	1369
Verifying the Source-Based Rate Limit Configuration	1369
Configuration Example for Source-Based Rate Limit	1374
Default SBRL Configuration	1375
Conversion of SBRL Subscriber-side Configuration from 16.8.x to 16.9.x	1375
Conversion of Divert Rate Limit Configuration on the Cisco uBR10012 Router to SBRL Configuration on the Cisco cBR Series Routers	1376
Additional References	1379
Feature Information for Source-Based Rate Limit	1379

CHAPTER 93
Cable Duplicate MAC Address Reject 1381

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1381
Prerequisites for Cable Duplicate MAC Address Reject	1382
Restrictions for Cable Duplicate MAC Address Reject	1383
Information About Cable Duplicate MAC Address Reject	1383
Early Authentication and Encryption	1383
EAE Enforcement Policies	1383
EAE Exclusion	1384
BPI+ Security and Cloned Cable Modems	1384
Logging of Cloned Cable Modems	1384
DOCSIS 3.0 BPI+ Policy Enforcement	1385
BPI+ Policy Enforcement Exclusion	1386
How to Configure EAE and BPI+ Enforcement Features	1386
Configuring EAE Enforcement Policies	1386
Configuring BPI+ Enforcement Policies	1387
Configuring AES-128 for non-MTC DOCSIS3.0 Cable Modem	1388
Verifying AES-128 for non-MTC DOCSIS3.0 Cable Modem	1388
Troubleshooting Tips	1388
Configuration Example for EAE and BPI+ Enforcement Policies	1388
Verifying EAE and BPI+ Enforcement Policies	1389

What to Do Next	1389
System Messages Supporting Cable Duplicate MAC Address Reject	1389
Additional References	1390
Feature Information for Cable Duplicate MAC Address Reject	1390

CHAPTER 94**Cable ARP Filtering 1393**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1393
Prerequisites for Cable ARP Filtering	1394
Restrictions for Cable ARP Filtering	1394
Information About Cable ARP Filtering	1395
Overview	1395
Filtering ARP Traffic	1395
Monitoring Filtered ARP Traffic	1396
Linksys Wireless-Broadband Router (BEFW11S4)	1396
ARP Filtering in FP	1396
Filtering ARP Traffic in FP	1397
How to Configure Cable ARP Filtering	1397
Monitoring ARP Processing	1397
Enabling ARP Filtering	1398
Identifying the Sources of Major ARP Traffic	1400
Examples	1402
Clearing the Packet Counters	1403
Identifying ARP Offenders in FP	1403
cBR-8 Outputs in FP	1403
Configuration Examples for Cable ARP Filtering	1404
ARP Filtering Configuration on an Individual Cable Interface: Example	1404
ARP Filtering Configuration on Bundled Cable Interfaces: Example	1405
ARP Filtering in FP Default Configuration: Example	1406
Additional References	1406
Feature Information for Cable ARP Filtering	1407

CHAPTER 95**Subscriber Management Packet Filtering Extension for DOCSIS 2.0 1409**

Hardware Compatibility Matrix for the Cisco cBR Series Routers	1409
Prerequisites for Configuring Subscriber Management Packet Filtering	1410

Restriction for Configuring Subscriber Management Packet Filtering 1410

Information About Configuring Subscriber Management Packet Filtering 1411

How to Configure Subscriber Management Packet Filtering 1411

- Configuring the Filter Group 1411
- Defining the Upstream and Downstream MTA Filter Group 1412
- Defining the Upstream and Downstream STB Filter Group 1413
- Defining the Upstream and Downstream PS Filter Group 1413

Configuration Examples for Subscriber Management Packet Filtering 1414

- Configuring the Filter Group: Example 1414
- Defining the Upstream and Downstream MTA Filter Group: Example 1415
- Defining the Upstream and Downstream STB Filter Group: Example 1415
- Defining the Upstream and Downstream PS Filter Group: Example 1415

Additional References 1415

Feature Information for Subscriber Management Packet Filtering 1416

	Overview of Online Offline Diagnostics	1633
	Benefits of Online Offline Diagnostics	1633
	Prerequisites for Online Offline Diagnostics	1634
	Restrictions for Online Offline Diagnostics	1634

How to Configure Online Offline Diagnostics 1634

- Configuring Field Diagnostic Test 1634
- Verifying the Testing Process 1634
- Removing the Field Diagnostic Image from a Line Card 1635

Configuration Example for Online Offline Diagnostics 1635

Feature Information for Online Offline Diagnostics 1635

PART I

Basic Configuration

- [Start Up Configuration of the Cisco cBR Router, on page 1](#)
- [Cisco Smart Licensing, on page 37](#)
- [Core Peak Bandwidth Licensing, on page 67](#)
- [Capped License Enforcement, on page 71](#)
- [Consolidated Packages and SubPackages Management, on page 75](#)
- [G.8275.2 Telecom Profile, on page 107](#)

CHAPTER 1

Start Up Configuration of the Cisco cBR Router

This document describes the basic start up configuration tasks that must be completed on a Cisco cBR Series Converged Broadband Router.

- [Prerequisites for Configuring the Cisco CMTS, on page 2](#)
- [Booting and Logging onto the Cisco CMTS , on page 3](#)

Prerequisites for Configuring the Cisco CMTS

Complete these prerequisite steps before you power on and configure the Cisco CMTS:

- Ensure that your network supports reliable broadband data transmission. Your plant must be swept, balanced, and certified based on National Television Standards Committee (NTSC) or appropriate international cable plant recommendations. Ensure your plant meets all Data-over-Cable Service Interface Specifications (DOCSIS) downstream and upstream radio frequency (RF) requirements.
- Ensure that your Cisco CMTS is installed according to the instructions in the hardware installation guide available on Cisco.com.
- Ensure that all other required headend or distribution hub routing and network interface equipment is installed, configured, and operational (based on the supported services). This includes:
 - All routers
 - Servers (Dynamic Host Configuration Protocol (DHCP) servers, Trivial File Transfer Protocol (TFTP) servers, and time-of-day (ToD) servers)
 - Network management systems
 - Other configuration or billing systems
- Ensure that DHCP and DOCSIS configuration files have been created and pushed to appropriate servers so that each CM, when initialized, can:
 - Transmit a DHCP request
 - Receive an IP address
 - Obtain TFTP and ToD server addresses
 - Download a DOCSIS configuration file (or updated software image if using Cisco uBR924 cable access routers or Cisco uBR910 cable data service units (DSUs) in your network)
- Ensure that customer premises equipment (CPE)—CMs or set-top boxes (STBs), PCs, telephones, or facsimile machines—meet requirements for your network and service offerings.
- Be familiar with your channel plan to assign appropriate frequencies. Outline your strategies for setting up bundling, if applicable to your headend or distribution hub. As appropriate, obtain:
 - Passwords
 - IP addresses
 - Subnet masks

- Device names

After these prerequisites are met, you are ready to configure the Cisco CMTS. This includes, at a minimum:

- Configuring a host name and password for the Cisco CMTS
- Configuring the CMTS to support IP over the cable plant and network backbone

Note If you plan to use service-class-based provisioning, the service classes must be configured at the CMTS before CMs attempt to make a connection.

Note Do not configure the **logging event link-status** command during system initialization. It may take long time or even stop the standby SUP from booting up.

Booting and Logging onto the Cisco CMTS

The Cisco CMTS is administered using the Cisco command interpreter, called the EXEC. You must boot and log in to the router before you can enter an EXEC command.

Step 1 [Connect to the console port on the Supervisor PIC](#) and the [Supervisor card](#).

Step 2 Establish a terminal session. You can open terminal application (Hyper Terminal) on a PC as follows:

- Connect using: Direct to Com 1
- Set bits per second:9600
- Set data bits: 8
- Set parity: none
- Set stop bit: 1
- Set flow control: none

Type **no** when the following message is displayed:

```
Would you like to enter the initial dialog?[yes]: no
Router>
```

First Time Boot Up with ROMMON

The Cisco cBR-8 boots up with ROMMON on the console with 9600 baud default configuration. It boots image either from TFTP or from local device. Local devices supported include the bootflash and USB.

Example of the boot up display:

```
Initializing Hardware ...~
```

```

```

Setting Environment Variables

No Environment variables are required to boot the Cisco IOS-XE image.

There are variables set by default. The ROMMON command **set** displays the default variables.

```
rommon > set
PS1=rommon ! >
?=0
rommon >
```

To set a variable, the format is VARIABLE="value".

The **set** command displays the new variable and the **sync** command saves the variable to NVRAM.

Note If the variable value has a space in between, specify the value within quotes.

```
rommon > set
PS1=rommon ! >
?=0
rommon > IP_ADDRESS=1.2.3.4
rommon > IP_SUBNET_MASK=255.255.255.128
rommon > DEFAULT_GATEWAY=1.2.9.10
rommon > TFTP_SERVER=1.2.3.6
rommon > sync
```

Unsetting Environment Variables

The **unset** ROMMON command removes the Environment variables and the **sync** command saves the variable to NVRAM.

```
rommon 1 > set
PS1=rommon ! >
?=0
BSI=0
BOOT=bootflash:cbrsup-adventerprisek9.SSA.bin,12;
RANDOM_NUM=1357042312
RET_2_RTS=17:45:06 PDT Sat Dec 31 2011
RET_2_RCALTS=1325378706
rommon 2 > unset BOOT
rommon 3 > sync
rommon 4 > set
PS1=rommon ! >
?=0
BSI=0
RANDOM_NUM=1357042312
RET_2_RTS=17:45:06 PDT Sat Dec 31 2011
RET_2_RCALTS=1325378706
rommon 5 >
```

Booting from the TFTP on the Cisco cBR

ROMMON boots up with default environment variables. The BinOS image is booted up from TFTP over the management port. This requires a minimum set of environment variables: IP_ADDRESS, IP_SUBNET_MASK, DEFAULT_GATEWAY, and TFTP_SERVER.

Step 1 Type the **set** command and define the required environment variables.

```
rommon > set
PS1=rommon ! >
?=0
rommon > IP_ADDRESS=1.2.3.4
rommon > IP_SUBNET_MASK=255.255.255.128
rommon > DEFAULT_GATEWAY=1.2.9.10
rommon > TFTP_SERVER=1.2.3.6
rommon > sync
```

Step 2 Type the **sync** command to save the variables to NVRAM.

```
rommon 6 > sync
```

Step 3 Type the **boot** command to load the image.

```
rommon 7 > boot tftp://tftpboot/username/cbrsup-universalk9.SSA.bin

IP_ADDRESS: 1.2.3.4
IP_SUBNET_MASK: 255.255.255.128
DEFAULT_GATEWAY: 1.2.9.10
TFTP_SERVER: 1.2.3.6
TFTP_FILE: /tftpboot/username/cbrsup-universalk9.SSA.bin
TFTP_MACADDR: c4:14:3c:17:e8:00
TFTP_VERBOSE: Progress
TFTP_RETRY_COUNT: 18
TFTP_TIMEOUT: 7200
TFTP_CHECKSUM: Yes
ETHER_PORT: 2

ETHER_SPEED_MODE: Auto Detect
link up.....
Receiving /tftpboot/username/cbrsup-universalk9.SSA.bin from 172.19.211.47
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

Listing Supported Devices

The **dev** command lists the devices supported on the router.

```
rommon 1 > dev
Devices in device table:
  id name
  harddisk: Internal hard disk
  bootflash: Internal flash drive
  usb0: External USB drive 0
```

```
usb1: External USB drive 1
rommon 2 >
```

Booting from the Device on the Cisco cBR

Step 1 Type the **dir bootflash:** command.

```
rommon > dir bootflash:
File System: EXT2/EXT3

12          691955580 -rw-r--r--      cbrsup-xe315.SSA.bin
45          83475     -rw-r--r--      reload.log.20120103004502
```

Step 2 Type the **boot bootflash:imagenam** command.

```
rommon > boot bootflash:cbrsup-xe315.bin
File size is 0x293e67bc
Located cbrsup-xe315.bin
Image size 691955644 inode num 145153, bks cnt 168935 blk size 8*512
#####
```

Setting AUTOBOOT image in ROMMON

To set AUTOBOOT of an image from bootflash:, add the Environment Variable BOOT and then change the configuration register boot characteristics to boot and reset the system.

Step 1 Type the **boot=bootflash:imagenam** command to load the image.

```
rommon > BOOT=bootflash:cbrsup-xe315-20150131.bin
```

Step 2 Type the **sync** command to copy the variables to NVRAM.

```
rommon > sync
```

Step 3 Type the **confreg** command to configure and modify the settings.

```
rommon > confreg

Configuration Summary
(Virtual Configuration Register: 0x0)
enabled are:
[ 0 ] break/abort has effect
[ 1 ] console baud: 9600
boot: ..... the ROM Monitor

do you wish to change the configuration? y/n [n]: y
enable "diagnostic mode"? y/n [n]:
enable "use net in IP bcast address"? y/n [n]:
enable "load rom after netboot fails"? y/n [n]:
enable "use all zero broadcast"? y/n [n]:
```

```

disable "break/abort has effect"? y/n [n]:
enable "ignore system config info"? y/n [n]:
change console baud rate? y/n [n]: n
change the boot characteristics? y/n [n]: y

enter to boot:
0 = ROM Monitor
1 = the boot helper image
2-15 = boot system
[0]: 2

Configuration Summary
(Virtual Configuration Register: 0x2)
enabled are:
[ 0 ] break/abort has effect
[ 1 ] console baud: 9600
boot: ..... image specified by the boot system commands or default to: cisco2-Cisco cBR-8

do you wish to change the configuration? y/n [n]:

You must reset or power cycle for new config to take effect

```

Step 4 Type the **reset** command for the new configuration to take effect.

```
rommon > reset
```

What to do next

Verifying the ROMMON Version

Use the **showmon** command to display the version of ROMMON.

```

rommon > showmon
Current image running (0/1): Boot ROM0

Configuring PTP

The Cisco cBR supports Precision Time Protocol (PTP) boundary or ordinary clock (OC) subordinate mode when connected to the Ethernet ports of the DPIC card or Supervisor PIC card. This topic provides you with an overview of PTP, configuration options, commands to verify the configuration settings, and configuration examples.

Cisco cBR supports DPIC PTP subordinate configuration with the following restraints:

- Only subordinate mode is supported.
- Only one-step timestamping is supported

Overview of PTP

PTP is a packet-based two-way message exchange protocol for synchronizing clocks between nodes in a network, thereby enabling an accurate time distribution over a network. PTP support is based on the IEEE 1588-2008 standard.

IEEE Standard 1588-2008 defines a method for distributing time around a network using the Precision Time Protocol (PTP) version 2. IEEE 1588-2008 is designed to provide precise timing and synchronization over packet-based ethernet infrastructures without layer-1 support along the clocking path. PTP ensures that the best available clock is selected as the source of time (the grandmaster clock) for the network and that other clocks in the network are synchronized to the grandmaster.

PTP consists of two parts:

- The port state machine and best primary clock algorithm, which provides a method to determine which ports in the network will run as primary (providing time to other clocks to the network), which will run as subordinate (receiving time from other clocks in the network), and which will be passive (neither primary nor subordinate).
- Mechanisms for subordinate ports to calculate the difference between the time of their own clocks and the time of their primary clock. To calculate the differences, PTP uses a delay request/response mechanism and a peer delay mechanism.

An overview of clock synchronization is explained.

Figure 1: Clock synchronization

After the primary-subordinate clock hierarchy is established, the clock synchronization process starts. The message exchange occurs in this sequence:

1. The primary clock sends a Sync message. The time at which the Sync message leaves the primary is time-stamped as t1.
2. The subordinate clock receives the Sync message and is time-stamped as t2.
3. The subordinate sends the Delay request, which is time-stamped as t3 when it leaves the subordinate, and as t4 when the primary receives it.
4. The primary responds with a Delay request that contains the time stamp t4.

PTP employs a hierarchy of clock types to ensure that precise timing and synchronization is maintained between the source and the numerous PTP clients that are distributed throughout the network. The clock types are:

- Grandmaster clock

This is the highest-ranking clock within its PTP domain. PTP grandmasters can be deployed as either standalone devices or as plug in modules or “blades” that can be integrated into an existing synchronization supply unit (SSU) or building integrated timing supply (BITS) shelf. Grandmasters are the primary reference source (PRS) for all other PTP elements within their PTP domain.

- Primary clock

A PTP primary will have a very precise clock, from a PRC or GPS. This clock drives the timestamp engine to derive accurate timestamps. The primary hosts PTP sessions with a number of subordinates.

- Subordinate clock

The subordinate is a network element that can recover the (Frequency and phase) clock from the timestamps obtained by messages exchanged with the PTP primary clock.

- Boundary clock

The Boundary clock acts as both PTP primary and subordinate. It will be a subordinate to a grandmaster and derive the reference from the grandmaster. It then starts its own PTP sessions with a number of

downstream subordinates. The advantage of placing a boundary clock is that it mitigates the number of network hops and resulting delays that occur in the packet network between the grandmaster and subordinates.

- Transparent clock

They maintain precise internal clocking by measuring the exact time difference between the packet entry and exit and the correction field of PTP packet is updated accordingly. Hence, the delay introduced by the node will not affect the PTP subordinate.

Configuring a PTP Subordinate Through DPIC

Before you begin

You can configure the PTP ports on Cisco cBR through the DPIC. An [Overview of PTP](#), on page 9 is essential to have an understanding of the utility.

Procedure

	Command or Action	Purpose
Step 1	<p>Configure the PTP subordinate using any of the following options:</p> <ul style="list-style-type: none"> • Subordinate mode with single source <pre> config t ptp clock ordinary domain <domain id> servo tracking-type R-DTI clock-port <name> slave delay-req interval < Interval> sync interval < Interval> sync one-step transport <ipv4/ipv6> unicast interface <loopback name> negotiation clock source <clock ip> </pre> <ul style="list-style-type: none"> • Subordinate mode with single source with profile G8275.2 <pre> config t ptp clock ordinary domain <domain id> servo tracking-type R-DTI clock-port <name> slave profile g8275.2 delay-req interval < Interval> sync interval < Interval> sync one-step transport <ipv4/ipv6> unicast interface <loopback name> negotiation clock source <clock ip> </pre> <ul style="list-style-type: none"> • Subordinate mode with multiple clock source <pre> config t ptp clock ordinary domain <domain id> servo tracking-type R-DTI clock-port <name> slave delay-req interval < Interval> sync interval < Interval> </pre>	

	Command or Action	Purpose
	<pre> sync one-step transport <ipv4/ipv6> unicast interface <loopback name> negotiation clock source <clock ip> clock source <clock ip> <local priority> • Subordinate mode with multiple clock source with profile G8275.2 config t ptp clock boundary domain <domain id> servo tracking-type R-DTI clock-port <name> profile g8275.2 delay-req interval < Interval> sync interval < Interval> sync one-step transport ipv6 unicast interface <loopback name> negotiation clock source <clock ip> clock-port <name> profile g8275.2 delay-req interval < Interval> sync interval < Interval> sync one-step transport ipv6 unicast interface <loopback name> negotiation clock source <clock ip> </pre>	

Verifying the PTP Subordinate Configuration

You can verify the PTP subordinate configuration by going through the following steps.

Procedure

	Command or Action	Purpose
Step 1	<p>Verify the PTP configuration by running the show run se ptp command. For example:</p> <p>Example:</p> <pre> router# show run se ptp ptp clock ordinary domain 55 servo tracking-type R-DTI clock-port slave-from-903 slave delay-req interval -5 sync interval -5 sync one-step transport ipv4 unicast interface Lo1588 negotiation clock source 10.90.3.93 </pre>	
Step 2	<p>To verify the PTP clock working state, use the show ptp clock running command. The state “PHASE_ALIGNED”, confirms a successful locking. For example:</p> <p>Example:</p>	

Command or Action	Purpose
<pre> router# show ptp clock running PTP Ordinary Clock [Domain 55] State Ports Pkts sent Pkts rcvd Redundancy Mode PHASE_ALIGNED 1 68938 138822 Hot standby PORT SUMMARY PTP Master Name Tx Mode Role Transport State Sessions Port Addr slave-from-903 unicast slave Lo1588 Slave 1 10.90.3.93 L06# </pre>	

PTP Subordinate Configuration Examples

The PTP subordinate example configurations are as follows:

- PTP subordinate mode with ipv4

```

config t
ptp clock ordinary domain 0
servo tracking-type R-DTI
clock-port slave-from-903 slave
delay-req interval -5
sync interval -5
sync one-step
transport ipv4 unicast interface Lo1588 negotiation
clock source 10.90.3.93

```

- PTP subordinate mode with ipv6

```

config t
ptp clock ordinary domain 0
servo tracking-type R-DTI
clock-port slave-from-903 slave
delay-req interval -4
sync interval -5
sync one-step
transport ipv6 unicast interface Lo1588 negotiation
clock source ipv6 2001:10:90:3::93

```

- PTP subordinate mode with ipv4 with profile G8275.2

```

config t
ptp clock ordinary domain 55
servo tracking-type R-DTI
clock-port slave-from-903 slave profile g8275.2
delay-req interval -4
sync interval -5
sync one-step
transport ipv4 unicast interface Lo1588 negotiation
clock source 10.90.3.93

```

- PTP subordinate mode with ipv6 with profile G8275.2

```

config t
ptp clock ordinary domain 55
servo tracking-type R-DTI

```

```
clock-port slave-from-903 slave profile g8275.2
delay-req interval -4
sync interval -5
sync one-step
transport ipv6 unicast interface Lo1588 negotiation
clock source ipv6 2001:10:90:3::93
```

- PTP subordinate mode with ipv4 with 2 clock sources

```
config t
ptp clock ordinary domain 0
servo tracking-type R-DTI
clock-port slave-from-903 slave
delay-req interval -5
sync interval -5
sync one-step
transport ipv4 unicast interface Lo1588 negotiation
clock source 10.90.3.93
clock source 10.1.1.1 2
```

- PTP subordinate mode with ipv6 with 2 clock sources and with profile G8275.2

```
config t
ptp clock boundary domain 55
servo tracking-type R-DTI
clock-port 22 profile g8275.2
delay-req interval -4
sync interval -5
sync one-step
transport ipv6 unicast interface Lo1588 negotiation

clock source ipv6 2001:158:158:158::7
```

Feature Information for PTP Subordinate

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfnng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 1: Feature Information for PTP Subordinate Through DPIC

Feature Name	Releases	Feature Information
PTP Subordinate Through DPIC	Cisco IOS-XE Release 16.8.1	This feature was introduced in Cisco IOS-XE Release 16.8.1 on Cisco cBR Series Converged Broadband Router.

File Systems

The Cisco cBR-8 router runs on the Cisco IOS-XE image. Supported file systems include:

1. IOS File System (IFS) in IOS
2. ext2, vfs, jffs2, tmpfs, autofs, and such common file systems in Linux

Features of the File Systems:

1. Both the Harddisk and USB are hot pluggable.
2. Harddisk is not accessible under Rommon.
3. Bootflash and USB disk are accessible under Rommon.
4. The **dir**, **show**, **copy**, **delete**, **mkdir**, **rmdir**, and **fsck** commands are supported for bootflash, harddisk and USB.

File System Table in the Supervisor

Name	Device	Size	Type	Visible	Usage	Physical Description
bootflash	/dev/bootflash1	7800705024	ext2	IOS/Binos	image,IOScrasinfo,etc	Partition1 of bootflash (eUSB flash).
flash	/dev/bootflash1	7800705024	ext2	IOS	image	A copy of bootflash.
nvrnm	/dev/bootflash2	32M	N/A	IOS	configuration, etc	Partition2 of bootflash (eUSB flash).
harddisk	/dev/harddisk1	98394218496	ext2	IOS/Binos	tracelog,corefile,etc	Partition1 of the 100G harddisk.
usb0	/dev/usb11	8G	vfat	IOS/Binos	image	Two USBs can be inserted into one SUP.

Verification of Hardware Bring Up

Monitoring the Cisco cBR Chassis Using CLI

- **show platform**—Verify if the installed cards are in **Ok** or **Inserted** state.

```
Router# show platform
```

```
Chassis type: CBR-8-CCAP-CHASS

```

- **show platform hardware slot *slot* serdes status**—Verify if all the links are in **locked** state.

```
Router# show platform hardware slot F1 serdes status
```

```

Slot R1-Link A
  RX link locked
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 3-Link A
  RX link locked
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link A
  RX link locked
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link B
  RX link locked
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link C
  RX link locked
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link D
  RX link locked
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link E
  RX link Init
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

```

```

Slot 5-Link F
  RX link Init
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link G
  RX link Init
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

Slot 5-Link H
  RX link Init
  58-bit scrambler, 20 Gbps
  0 Overruns, 0 Underruns
  0 Reframe, 0 Disparity
  0 Out of band, 0 Illegal control codes

```

- **show environment all**—Verify the environmental status of each FRU after installation.

This command displays the system temperature, voltage, fan, and power supply conditions.

```
Router# show environment all
```

```

Sensor List: Environmental Monitoring

Gigabit Ethernet Management Interface Overview

The purpose of this interface is to allow users to perform management tasks on the router; it is basically an interface that should not and often cannot forward network traffic but can otherwise access the router, often via Telnet and SSH, and perform most management tasks on the router.

The following aspects of the Management Ethernet interface should be noted:

- Each SUP has a Management Ethernet interface, but only the active SUP has an accessible Management Ethernet interface (the standby SUP can be accessed using the console port, however).
- IPv4, IPv6, and ARP are the only routed protocols supported for the interface.
- The interface provides a method of access to the router even when some software processes are down.
- The Ethernet Management Interface cannot be used as a Lawful Intercept MD source interface.
- The Management Ethernet interface is part of its own VRF.

Gigabit Ethernet Port Numbering

The Gigabit Ethernet Management port is always GigabitEthernet0.

In a dual SUP configuration, the Management Ethernet interface on the active SUP will always be Gigabit Ethernet 0, while the Management Ethernet interface on the standby SUP will not be accessible using the Cisco IOS-XE CLI in the same telnet session. The standby SUP can be telnetted to through the console port, however.

The port can be accessed in configuration mode like any other port on the Cisco cBR Series Routers:

```
Router#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)#interface gigabitethernet0
Router(config-if)#
```

IP Address Handling in ROMMON and the Management Ethernet Port

Assuming the IOS-XE process has not begun running on the Cisco cBR Series Router, the IP address that was set in ROMMON acts as the IP address of the Management Ethernet interface. In cases where the IOS-XE process is running and has taken control of the Management Ethernet interface, the IP address specified when configuring the Gigabit Ethernet 0 interface in the IOS-XE CLI becomes the IP address of the Management Ethernet interface. The ROMMON-defined IP address is only used as the interface address when the IOS-XE process is inactive.

For this reason, the IP addresses specified in ROMMON and in the IOS-XE CLI can be identical and the Management Ethernet interface will function properly in single SUP configurations.

In dual SUP configurations, however, users should never configure the IP address in the ROMMON on either SUP0 or SUP1 to match each other or the IP address as defined by the IOS-XE CLI. Configuring matching IP addresses introduces the possibility for an active and standby Management Ethernet interface having the same IP address with different MAC addresses, which will lead to unpredictable traffic treatment.

Gigabit Ethernet Management Interface VRF

Placing the management Ethernet interface in its own VRF has the following effects on the Management Ethernet interface:

- Many features must be configured or used inside the VRF, so the CLI may be different for certain Management Ethernet functions on the Cisco cBR Series Routers than on Management Ethernet interfaces on other routers.
- The VRF prevents route leakage and avoids unnecessary traffic through the management port.

The Management Ethernet interface VRF supports both IPv4 and IPv6 address families.

Common Ethernet Management Tasks

Because users can perform most tasks on a router through the Management Ethernet interface, many tasks can be done by accessing the router through the Management Ethernet interface.

This section documents tasks that might be common or slightly tricky on the Cisco cBR Series Routers. It is not intended as a comprehensive list of all tasks that can be done using the Management Ethernet interface.

Viewing the VRF Configuration

The VRF configuration for the Management Ethernet interface is viewable using the **show running-config vrf** command.

This example shows the default VRF configuration:

```
Router# show running-config vrf
```

```
Building configuration...

Current configuration : 351 bytes
vrf definition Mgmt-intf
!
address-family ipv4
exit-address-family
!
address-family ipv6
exit-address-family
!
(some output removed for brevity)
```

Setting a Default Route in the Management Ethernet Interface VRF

To set a default route in the Management Ethernet Interface VRF, use the **ip route vrf Mgmt-intf 0.0.0.0 0.0.0.0 next-hop-IP-address** command.

Setting the Management Ethernet IP Address

The IP address of the Management Ethernet port is set like the IP address on any other interface.

Below are two simple examples of configuring an IPv4 address and an IPv6 address on the Management Ethernet interface.

IPv4 Example

```
Router(config)# interface GigabitEthernet 0
Router(config-if)# ip address A.B.C.D A.B.C.D
```

IPv6 Example

```
Router(config)# interface GigabitEthernet 0
Router(config-if)# ipv6 address X:X:X:X::X /prefix-length
```

Telnetting over the Management Ethernet Interface

Telnetting can be done through the VRF using the Management Ethernet interface.

In the following example, the router telnets to 172.17.1.1 through the Management Ethernet interface VRF:

```
Router# telnet 172.17.1.1 /vrf Mgmt-intf
```

Pinging over the Management Ethernet Interface

Pinging other interfaces using the Management Ethernet interface is done through the VRF.

In the following example, the router pings the interface with the IP address of 172.17.1.1 through the Management Ethernet interface:

```
Router# ping vrf Mgmt-intf 172.17.1.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 172.17.1.1, timeout is 2 seconds:
.!!!!
Success rate is 80 percent (4/5), round-trip min/avg/max = 1/1/1 ms
```

Copy Using TFTP or FTP

To copy a file using TFTP through the Management Ethernet interface, the **ip tftp source-interface GigabitEthernet 0** command must be entered before entering the **copy tftp** command because the **copy tftp** command has no option of specifying a VRF name.

Similarly, to copy a file using FTP through the Management Ethernet interface, the **ip ftp source-interface GigabitEthernet 0** command must be entered before entering the **copy ftp** command because the **copy ftp** command has no option of specifying a VRF name.

TFTP Example

```
Router(config)# ip tftp source-interface gigabitethernet 0
```

FTP Example

```
Router(config)# ip ftp source-interface gigabitethernet 0
```

NTP Server

To allow the software clock to be synchronized by a Network Time Protocol (NTP) time server over the Management Ethernet interface, enter the **ntp server vrf Mgmt-intf** command and specify the IP address of the device providing the update.

The following CLI provides an example of this procedure.

```
Router(config)# ntp server vrf Mgmt-intf 172.17.1.1
```

SYSLOG Server

To specify the Management Ethernet interface as the source IP or IPv6 address for logging purposes, enter the **logging host ip-address vrf Mgmt-intf** command.

The following CLI provides an example of this procedure.

```
Router(config)# logging host ip-address vrf Mgmt-intf
```

SNMP-Related Services

To specify the Management Ethernet interface as the source of all SNMP trap messages, enter the **snmp-server source-interface traps gigabitEthernet 0** command.

The following CLI provides an example of this procedure:

```
Router(config)# snmp-server source-interface traps gigabitEthernet 0
```

Domain Name Assignment

The IP domain name assignment for the Management Ethernet interface is done through the VRF.

To define the default domain name as the Management Ethernet VRF interface, enter the **ip domain-name vrf Mgmt-intf domain** command.

```
Router(config)# ip domain-name vrf Mgmt-intf cisco.com
```

DNS service

To specify the Management Ethernet interface VRF as a name server, enter the **ip name-server vrf Mgmt-intf IPv4/IPv6 address** command.

RADIUS or TACACS+ Server

To group the Management VRF as part of a AAA server group, enter the **ip vrf forward Mgmt-intf** command when configuring the AAA server group.

The same concept is true for configuring a TACACS+ server group. To group the Management VRF as part of a TACACS+ server group, enter the **ip vrf forwarding Mgmt-intf** command when configuring the TACACS+ server group.

RADIUS Server Group Configuration

```
Router(config)# aaa group server radius hello
Router(config-sg-radius)# ip vrf forwarding Mgmt-intf
```

TACACS+ Server Group Configuration

```
Router(config)# aaa group server tacacs+ hello
Router(config-sg-tacacs+)# ip vrf forwarding Mgmt-intf
```

VTY lines with ACL

To ensure an access control list (ACL) is attached to vty lines that are and are not using VRF, use the **vrf-also** option when attaching the ACL to the vty lines.

```
Router(config)# line vty 0 4
Router(config-line)# access-class 90 in vrf-also
```

Configuring the AUX Port for Network Management

- Step 1** AUX port is used for IOSd command prompt. Type the **set** command at the rommon prompt.
- Step 2** Verify if **BOOT_PARAM** is defined. It must not be defined.

- Step 3** If the `BOOT_PARAM` is defined, do the following:
- Type `unset BOOT_PARAM`.
 - Type `sync`.
 - Type `reset`.
- Step 4** Boot with the latest image. The AUX port will show IOS command prompt.

Preprovisioning the Supervisor in the Cisco cBR Chassis

Preprovisioning on the Cisco cBR allows you to configure the Supervisors without their physical presence in the chassis.

Procedure

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Router> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<code>configure terminal</code> Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	<code>card slot/1 sup-pic-8x10g</code> Example: Router(config)# <code>card 4/1 sup-pic-8x10g</code>	Preprovisions the Supervisor in the Cisco cBR chassis. <ul style="list-style-type: none"> <code>slot</code>—Identifies the chassis slot number for the Supervisor PIC. The valid values are 4 and 5.

Configuring the Gigabit Ethernet Interface for Network Management

You must configure the GigabitEthernet0 interface and enable it to use the NME port.

Procedure

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Router> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<code>configure terminal</code> Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# <code>configure terminal</code>	
Step 3	interface GigabitEthernet0 Example: Router(config)# <code>interface GigabitEthernet0</code>	Enters the Gigabit Ethernet interface configuration mode.
Step 4	vrf forwarding vrf-name Example: Router(config-if)# <code>vrf forwarding Mgmt-intf</code>	Associates a Virtual Routing and Forwarding (VRF) instance with the interface. <ul style="list-style-type: none"> • <i>vrf-name</i>—The interface name to be associated with the specified VRF.
Step 5	ip address ip-address subnet-mask Example: Router(config-if)# <code>ip address 192.71.0.1 255.255.255.0</code>	Sets the IP address of the Gigabit Ethernet interface. <ul style="list-style-type: none"> • <i>ip-address</i>—IP address of the Gigabit Ethernet interface. • <i>subnet -mask</i>—Subnet mask for the network.
Step 6	no shutdown Example: Router(config-if)# <code>no shutdown</code>	Enables the Gigabit Ethernet interface.
Step 7	speed 1000 [negotiate] Example: Router(config-if)# <code>speed 1000</code>	Configures the speed for the Gigabit Ethernet interface.
Step 8	duplex full Example: Router(config-if)# <code>duplex full</code>	Configures full duplex operation on the Gigabit Ethernet interface.
Step 9	negotiation auto Example: Router(config-if)# <code>negotiation auto</code>	Selects the auto-negotiation mode.
Step 10	end Example: Router(config-if)# <code>end</code>	Exits Gigabit Ethernet interface configuration mode. Returns to privileged EXEC mode.

Configuring the DTI Port on the Supervisor PIC

The Cisco cBR router can run in standalone mode, which uses internal clock and does not require any external reference clock source. The Cisco cBR router also supports DTI server as an external clocking source. To use a DTI server as a reference clock source, you must enable the DTI port on the Supervisor PIC.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable clock dti Example: Router(config)# cable clock dti	Configures the DTI clock reference mode for the Supervisor PIC.

Configuring the TenGigabit Ethernet Interface for Network Management

You must configure the TenGigabitEthernet interface and enable it to use the NME port.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface TenGigabitEthernet Example: Router(config)# interface TenGigabitEthernet4/1/0	Enters the TenGigabit Ethernet interface configuration mode.
Step 4	ip address <i>ip-address subnet-mask</i> Example: Router(config-if)# ip address 1.2.3.4 255.255.255.0	Sets the IP address of the TenGigabit Ethernet interface.
Step 5	load-interval <i>seconds</i> Example: Router(config-if)# load-interval 30	Changes the length of time for which data is used to compute load statistics.

	Command or Action	Purpose
Step 6	no shutdown Example: Router(config-if) # no shutdown	Enables the TenGigabit Ethernet interface.
Step 7	end Example: Router(config-if) # end	Exits TenGigabit Ethernet interface configuration mode. Returns to privileged EXEC mode.

Connecting the New Router to the Network

Connect the new router to the network using a n Ethernet interface. After the router successfully resolves its host name, new router sends a TFTP broadcast requesting the file name-config or name.cfg. The router name must be in all lowercase, even if the true host name is not. The file is downloaded to the new router, where the configuration commands take effect immediately. If the configuration file is complete, the new router should be fully operational.

To save the complete configuration to NVRAM, use the following commands in privileged EXEC mode:

Procedure

	Command or Action	Purpose
Step 1	enable password	Enters privileged mode on the new router.
Step 2	copy running-config startup-config	<p>Saves the information from the name-config file into your startup configuration. On most platforms, this step saves the configuration to NVRAM.</p> <p>Note Verify that the existing and new routers (or access servers) are connected before entering the copy running-config startup-config EXEC command to save configuration changes. Use the ping EXEC command to verify connectivity. If an incorrect configuration file is downloaded, the new router will load NVRAM configuration information before it can enter AutoInstall mode.</p> <p>If the configuration file is a minimal configuration file, the new router comes up, but with only one interface operational. Use the following commands to connect to the new router and configure it.</p>
Step 3	telnet existing	Establishes a Telnet connection to the existing router.
Step 4	telnet newrouter	From the existing router, establishes a Telnet connection to the new router.

	Command or Action	Purpose
Step 5	enable password	Enters privileged EXEC mode.
Step 6	setup	Enters setup mode to configure the new router.

Setting Password Protection on the Cisco CMTS

Note For security purposes, the EXEC has two levels of access to commands: user EXEC mode and privileged EXEC mode. The commands available at the user level are a subset of those available at the privileged level.

Tip Because many privileged-level EXEC commands are used to set operating parameters, password-protect these commands to prevent unauthorized use.

Note An enable secret password can contain from 1 to 25 uppercase and lowercase alphanumeric characters. An enable password can contain any number of uppercase and lowercase alphanumeric characters. A number cannot be the first character. Spaces are valid password characters; for example, “two words” is a valid password. Leading spaces are ignored. Trailing spaces are recognized. Alphanumeric characters are recognized as uppercase or lowercase.

Passwords should be different for maximum security. If you enter the same password for both during the setup script, the system accepts it, but you receive a warning message indicating that you should enter a different password.

At the EXEC prompt, enter one of the following two commands to set password protection:

- **enable secret password**—a very secure encrypted password.
- **enable**—is a less secure and nonencrypted password.

To gain access to privileged-level commands, enter the desired password.

Recovering Lost Password on the Cisco CMTS

Complete the following steps to recover or replace a lost enable, enable secret, or console login password:

-
- Step 1** Attach an ASCII terminal to the console port on your Cisco CMTS.
- Step 2** Configure the terminal to operate at 9600 baud, 8 data bits, no parity, and 1 stop bits.
- Step 3** If you can log in to the router as a nonprivileged user, enter the **show version** command to display the existing configuration register value. Note the value for later use. If you cannot log in to the router at all, continue with the next step.

- Step 4** Press the **Break** key or send a **Break** from the console terminal.
- If Break is enabled, the router enters the ROM monitor, indicated by the ROM monitor prompt (rommon n>), where n is the number of the command line. Proceed to configuring the register.
 - If Break is disabled, power cycle the router (turn the router off or unplug the power cord, and then restore power). Within 60 seconds of restoring the power to the router, press the **Break** key or send a **Break**. This action causes the router to enter the ROM monitor and display the ROM monitor prompt (rommon 1>).

- Step 5** To set the configuration register on a Cisco CMTS, use the configuration register utility by entering the **confreg** command at the ROM monitor prompt as follows:

```
rommon 1> confreg
```

Answer **yes** to the *enable ignore system config info?* prompt and note the current configuration register settings.

- Step 6** Initialize the router by entering the **reset** command as follows:

```
rommon 2> reset
```

The router initializes, the configuration register is set to 0x142, the router boots the system image from Flash memory and enters the System Configuration dialog (setup), as follows:

```
--- System Configuration Dialog ---
```

- Step 7** Enter **no** in response to the System Configuration dialog prompts until the following message appears:

```
Press RETURN to get started!
```

- Step 8** Press **Return**. The user EXEC prompt appears as follows:

```
Router>
```

- Step 9** Enter the **enable** command to enter privileged EXEC mode.

- Step 10** Enter the **show startup-config** command to display the passwords in the configuration file as follows:

```
Router# show startup-config
```

- Step 11** Scan the configuration file display looking for the passwords; the enable passwords are usually near the beginning of the file, and the console login or user EXEC password is near the end. The passwords displayed will look something like this:

```
enable secret 5 $1$ORPP$s9syZt4uKn3SnpuLDrhuei
enable password 23skiddoo
.
.
line con 0
 password onramp
```

Note The enable secret password is encrypted and cannot be recovered; it must be replaced. The enable and console passwords can be encrypted text or clear text.

Proceed to the next step to replace an enable secret, console login, or enable password. If there is no enable secret password, note the enable and console login passwords if they are not encrypted and proceed to set the configuration register to the original value.

Caution Do not perform the next step unless you have determined that you must change or replace the enable, enable secret, or console login passwords. Failure to follow the steps as presented here could cause your router configuration to be erased.

Step 12 (Optional) Enter the `configure memory` command to load the startup configuration file into running memory. This action allows you to modify or replace passwords in the configuration.

```
Router# configure memory
```

Step 13 Enter the `configure terminal` command for configuration mode:

```
Router# configure terminal
```

Step 14 To change all three passwords, enter the following commands:

```
Router(config)# enable secret newpassword1
Router(config)# enable password newpassword2
Router(config)# line con 0
Router(config)# password newpassword3
```

Change only the passwords necessary for your configuration. You can remove individual passwords by using the `no` form of the previous commands. For example, entering the `no enable secret` command removes the enable secret password.

Step 15 You must configure all interfaces to not be administratively shut down as follows:

```
Router(config)# interface gigabitethernet 0
Router(config)# no shutdown
```

Enter the equivalent commands for all interfaces that were originally configured. If you omit this step, all interfaces are administratively shut down and unavailable when the router is restarted.

Step 16 Use the `config-register` command to set the configuration register to the original value noted earlier.

Step 17 Press `Ctrl-Z` or type `end` to exit configuration mode:

```
Router(config)# end
```

Caution Do not perform the next step unless you have changed or replaced a password. If you skipped changing or replacing the enable, enable secret, or console login passwords previously, then proceed now to reload. Failure to observe this sequence causes the system to erase your router configuration file.

Step 18 Enter the `copy running-config startup-config` command to save the new configuration to nonvolatile memory:

```
Router# copy running-config startup-config
```

Step 19 Enter the `reload` command to reboot the router:

```
Router# reload
```

Step 20 Log in to the router with the new or recovered passwords.

Saving Your Configuration Settings

To store the configuration or changes to your startup configuration in NVRAM, enter the **copy running-config startup-config** command at the *Router#* prompt.

This command saves the configuration settings you set using configuration mode, the Setup facility, or AutoInstall.

Note If you do not save your settings, your configuration will be lost the next time you reload the router.

Example

```
Router# copy running-config startup-config
```

Reviewing Your Settings and Configurations

- To view the current configuration of a Cisco CMTS, run the **show running-config** command at the command-line interface (CLI) prompt in EXEC mode or privileged EXEC mode.
- To review changes you make to the configuration, use the EXEC **show startup-config** command to display the information stored in NVRAM.

Recovering Unresponsive Modems

If the cable modem does not respond to pings from the Cisco Converged Broadband Router, the modem DSBG, DSID, and the BPI index values on the Cisco Converged Broadband Router may be incorrect. To recover the unresponsive modem, run the **cable reconciliation enable** command to generate the correct DSBG, DSID, and the BPI index values. The following CLI provides an example of this procedure:

```
Router# configure terminal
Router# cable reconciliation enable
Router# end
```

To set the time when the **cable reconciliation enable** command should run, run the **cable reconciliation time hours** command, where *hours* is the time in the 24 hour format. The following CLI provides an example of this procedure:

```
Router# configure terminal
Router# cable reconciliation time 23
Router# end
```

CHAPTER 2

Cisco Smart Licensing

A new licensing model, based on a single technology, has been designed for Cisco called Smart Licensing that is intended to provide Enterprise Level Agreement-like capabilities for all Cisco products. The Cisco Smart Licensing is based on the Trust but Verify model.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Hardware Compatibility Matrix for the Cisco cBR Series Routers

Note The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

Table 2: Hardware Compatibility Matrix for the Cisco cBR Series Routers

Cisco CMTS Platform	Processor Engine	Interface Cards
Cisco cBR-8 Converged Broadband Router	<p>Cisco IOS-XE Release 16.5.1 and Later Releases</p> <p>Cisco cBR-8 Supervisor:</p> <ul style="list-style-type: none"> • PID—CBR-SUP-250G • PID—CBR-CCAP-SUP-160G • PID—CBR-CCAP-SUP-60G • PID—CBR-SUP-8X10G-PIC 	<p>Cisco IOS-XE Release 16.5.1 and Later Releases</p> <p>Cisco cBR-8 CCAP Line Cards:</p> <ul style="list-style-type: none"> • PID—CBR-LC-8D30-16U30 • PID—CBR-LC-8D31-16U30 • PID—CBR-RF-PIC • PID—CBR-RF-PROT-PIC • PID—CBR-CCAP-LC-40G • PID—CBR-CCAP-LC-40G-R <p>Cisco cBR-8 Downstream PHY Modules:</p> <ul style="list-style-type: none"> • PID—CBR-D30-DS-MOD • PID—CBR-D31-DS-MOD <p>Cisco cBR-8 Upstream PHY Modules:</p> <ul style="list-style-type: none"> • PID—CBR-D30-US-MOD • PID—CBR-D31-US-MOD

Prerequisites for Cisco Smart Licensing

- You must configure the DNS server using the **ip name-server** global configuration command.
- You must configure the IP DNS-based hostname-to-address translation using the **ip domain-lookup** global configuration command.
- Cisco Smart Licensing is enabled by default on the Cisco cBR router. However, you must ensure that the CiscoTAC-1 call-home profile points to the Cisco Smart Software Manager at the following URL using the **show call-home profile CiscoTAC-1** command:

<https://tools.cisco.com/its/service/oddce/services/DDCEService>

The following is a sample output of the **show call-home profile CiscoTAC-1** command:

```
Router# show call-home profile CiscoTAC-1

Load for five secs: 10%/1%; one minute: 9%; five minutes: 8%
Time source is NTP, 16:49:35.525 PDT Thu Oct 29 2015

Profile Name: CiscoTAC-1

- Ensure that you can ping the DNS server. If you are unable to ping the server, verify the connectivity to the NME port on the Cisco cBR router.

Note If you are using a Virtual Routing and Forwarding (VRF) instance, ensure that you can ping the VRF instance.

Information About Cisco Smart Licensing

Cisco Smart Licensing is software-based licensing that consists of tools and processes to authorize the customers for the usage and reporting of the Cisco products. The feature has the capability to capture the customer order and communicate with the Cisco Cloud License Service through Smart Call Home transport media to complete the product registration and authorization. If the Cisco products stop communicating with the Cisco Cloud License Service for 90 days, the cable interfaces in the Cisco products will be locked, which means the customer can no longer enable/disable the cable interfaces.

The Cisco Smart Licensing feature is aimed at giving users an experience of a single, standardized licensing solution for all Cisco products.

In the Cisco Smart Licensing Model, you can activate licensed features (also known as entitlements) without the use of a special software key or upgrade license file. You can activate the new functionality using the appropriate product commands and configurations and the functionality is activated. A software reboot is not required for the Cisco cBR router.

The Cisco cBR router supports software activation using Cisco Smart Licensing. The Cisco Smart Licensing is enabled by default on the Cisco cBR router.

Note The **no http secure server-identity-check** option was default in versions 16.7.2 and earlier, and was not configurable. Ensure that you configure the **no http secure server-identity-check** option after upgrading to maintain parity with images earlier than 16.7.3. The default option is **http secure server-identity-check**.
A LCHA license is needed for each working linecard that is protected by the protect linecard.

Downstream License

The DOCSIS 3.1 license scheme provides support to identify the DOCSIS 3.1 channels and their width. The DOCSIS 3.1 entitlement is DOCSIS 3.1 Downstream Channel License.

Note Configuration of DOCSIS 3.1 Downstream OFDM channel consumes both DOCSIS 3.0 and DOCSIS 3.1 license in a 1:1 ratio with license units of 6 MHz.

Out of Compliance Enforcement

The following two events are responsible for triggering a DOCSIS configuration lock enforcement.

Eval-Expired (Evaluation Period Expired)

When a router is not registered with Smart License Manager for more than ninety days.

Auth-Expired (authorization Period Expired)

When a registered router fails to communicate with the Smart License Manager for more than ninety days.

When either of the above mentioned events occur, the Smart Agent sends a notification to the platform. The platform, upon receiving such notification, **locks** the following CLI commands:

- **[no] cable upstream shutdown** *upstream-port-number*
- **contoller upstream-cable** *slot/subslot/controller-port-number*
- **rf-ch***channel-number*

Any attempt to configure the above mentioned CLIs in this condition would fail and a warning message will be displayed. Under this condition all other CLIs are configurable, some of which may be required to configure Cisco License Call Home, connect to cisco and register the device to come out of either of the above two events and enter into authorized or Out of Compliance (OOC) state.

You can copy the modified configuration file to the startup configuration file and reload the device to make that configuration effective. However, when the device is in enforced state, you can only copy the running configuration file to the startup configuration file.

Note Any attempt to copy any other file fails and a warning message is displayed.

How to Configure Cisco Smart Licensing

This section contains the following:

Using Cisco Smart Licensing Agent on the Router

Step 1 Set up a Cisco Smart Account. See [Setting Up a Cisco Smart Account, on page 41](#).

Step 2 Log in to the [Cisco Smart Software Manager](#).

Step 3 (Optional) Create a virtual account. See [Creating Virtual Accounts, on page 48](#).

Note A single default virtual account is always available.

Step 4 Create a product instance registration token. See [Creating a Product Instance Registration Token, on page 49](#).

Step 5 Register the router with the Cisco Licensing Cloud using the product instance registration token. See [Registering the Router with the Cisco Licensing Cloud Using the Registration Token, on page 50](#).

Step 6 Log in to the [Cisco Smart Software Manager](#) for managing licenses.

For more information, see the *Cisco Smart Software Manager User Guide*, which is accessible from the Cisco Smart Software Manager tool.

Setting Up a Cisco Smart Account

Cisco Smart Account enables you to fully utilize the license management features of the smart-enabled products.

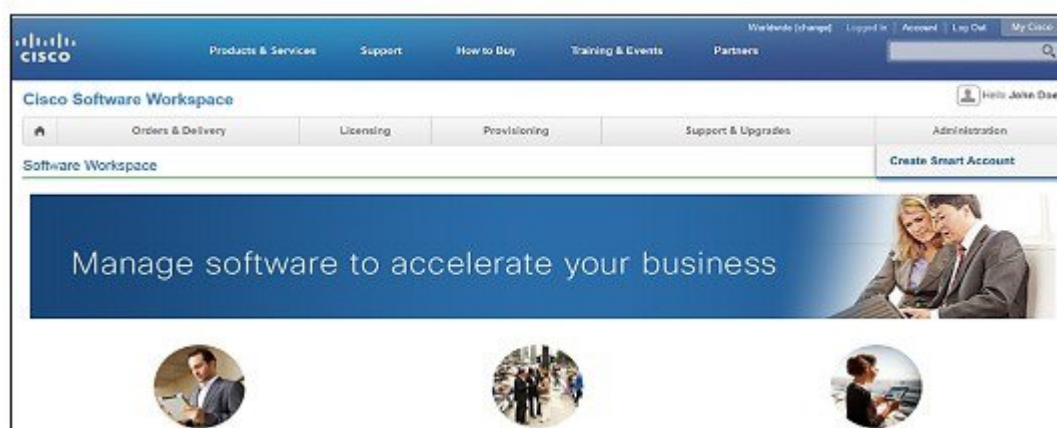

Before you begin

- Ensure that you have a CCO ID.

Step 1 Log in to [Cisco Software Workspace \(CSW\)](#) with your CCO ID.

Step 2 Hover the cursor over the *Administration* tab and click **Create Smart Accounts**.

Figure 2: Creating Smart Account

Step 3 Perform one of the following to select the Account Approver:

- To select yourself as the Approver, click the **Yes, I will be the Approver for the account** radio button.
- To select other person as the Approver, click the **No, the person specified below will be the Approver for the account** radio button and specify the person's e-mail ID.

Note The specified Approver must have the authority to enter legal agreements. The Approver serves as the primary owner and nominates account administrators.

Figure 3: Selecting the Approver

Step 4 If you are the Approver, perform the following:

- Enter the Account Name, Company/Organization Name, Country, and State/Province/Region information.
- (Optional) Click **Edit**. In the *Edit Account Identifier* window, enter a valid Proposed Domain Identifier and Contact Phone Number. Click **OK**.

Note The default domain identifier is the Approver e-mail domain. If you edit the domain identifier, the change goes through a manual approval process.

- c) Click **Continue** to select the legal address to be linked to your Cisco Smart Account.

Figure 4: Setting Up Account Information When You Are The Approver

The screenshot shows the 'Account Information' page with the following details:

- Account Domain Identifier:** test.lsg-u.edu (with an 'Edit' link)
- Account Name:** big-u.edu
- Buttons:** Continue

The 'Edit Account Identifier' dialog box contains:

- Text:** This Account Domain Identifier is generated based on the domain of the primary email address in your Cisco.com profile and will need to undergo an approval process if you change it. Cisco will contact you by telephone to complete this process, so please verify or enter your desired contact phone number below.
- Text:** If you do decide to change the Account Domain Identifier, it must maintain domain format and can include subdomains to the left of the domain, e.g., east.example.com or west.example.com.
- Proposed Domain Identifier:** twister.big-u.edu
- Contact Phone Number:** +1 408-853-1221
- Buttons:** OK, Cancel

Step 5 If you are not the Approver, perform the following:

- Enter the Account Name and an optional Message to Approver.
- (Optional) Click **Edit**. In the *Edit Account Identifier* window, enter a valid Proposed Domain Identifier. Click **OK**.

Note The default domain identifier is the Approver e-mail domain. If you edit the domain identifier, the change goes through a manual approval process.

- c) Click **Continue**.

Figure 5: Setting Up Account Information When You Are Not The Approver

The screenshot shows the 'Account Information' page with the following details:

- Account Domain Identifier:** company.com (with an 'Edit' link)
- Account Name:** Company ABC
- Message to Approver:** A text area for entering a message.
- Buttons:** Continue

The 'Edit Account Identifier' dialog box contains:

- Text:** The Account Domain Identifier is generated based on the domain of the approver's email address and will require the Approver to complete an approval process via telephone if you change it.
- Text:** If you do decide to change the Account Domain Identifier, it must maintain domain format and can include subdomains to the left of the domain, e.g., east.example.com or west.example.com.
- Proposed Domain Identifier:** (Empty field)
- Error Message:** Please enter a valid domain, i.e. example.com or west.example.com
- Buttons:** OK, Cancel

Step 6 If you are not the Approver, the Approver will receive an e-mail and must perform the following:

- Click **Complete Smart Account Setup** in the received e-mail.

Figure 6: Complete Smart Account Setup Link in E-mail

New Cisco Smart Account - NTT Demo Account (Pending)

A new Cisco Smart Account has been requested for "NTT Demo Account" and you have been designated as an "Approver" for this account. A Smart Account is used for managing your company's relationship with Cisco, including initiatives such as Smart Licensing. This account is currently in a Pending state, as it requires a person designated as an "Approver" to complete the process. Review the Account Summary information below and click the Complete Smart Account Setup link to continue. As a part of this process, you will be asked to accept a Smart Account Agreement. If you'd like to look at the agreement beforehand, you can [preview the agreement](#).

[Complete Smart Account Setup »](#)

Note: You will need to log in with a Cisco.com ID. If you don't have one, you will need to [register for a new account](#).

- b) Click the appropriate radio button to accept, decline, or nominate another Approver. To nominate another Approver, enter the person's e-mail address. Click **Continue**.

Note If the Approver declines, the Cisco Smart Account is deleted. If the Approver nominates another approver, the new Approver must accept the role.

Figure 7: Accepting the Account Approver Role

Cisco Software Workspace
Smart Accounts

Smart Account Setup

A Cisco Smart Account has been set up for "NTT Demo Account" and you have been nominated as the Approver for the account. This Smart Account will be used for managing the company's relationship with Cisco, including initiatives such as Smart Licensing. The account is currently in a Pending state and will remain so until the approver completes the setup process.

Account Approver

You have been nominated as the Approver for the "NTT Demo Account" Smart Account. Do you accept this role? This person will approve terms and conditions for the account and will be the one completing the account setup process. [Learn More](#)

Yes, I accept the role of Account Approver
 No, I do not accept the role of Account Approver
 No, but I nominate the person specified below to be the Account Approver

Account Summary

Account Domain Identifier: intcsia.com
 Account Name: NTT Demo Account
 Requested By: Heather Deng (hdeng@csco.com)

[Continue](#)

- c) After accepting the Approver role, click the appropriate radio button to select the Account Domain Identifier or specify a different Account Domain Identifier.

Figure 8: Completing the Account Information

Cisco Software Workspace
Smart Accounts

Account Information

Below is the information for the company. The Account Domain Identifier is based on the email address of the Approver and must belong to the company that will own this account. [Learn More](#)

Account Domain Identifier: ntt.com - this was entered by person requesting the account, because it does not match your email address, it will require an approval process with Cisco. [Learn More](#)

cisco.com - this is based on the email address in your Cisco.com profile, if you want to change it, you can: [Edit your Cisco.com Profile](#)

[Specify a different Account Domain Identifier](#)

Account Name:

Back

d) Enter the Account Name and click **Continue**.

The Approver role is accepted and Cisco Smart Account is pending Account Domain approval.

Step 7

After the Account Domain is approved, the Approver will receive an e-mail and must perform the following:

a) Click **Complete Smart Account Setup** in the received e-mail.

Figure 9: Cisco Smart Account Identifier Approved E-mail

Cisco Smart Account Identifier Approved - Mail

The Account Domain Identifier for the Cisco Smart Account Gmail has completed the review process. You can continue the account creation process via the Complete Smart Account Setup link below. As a part of this process, you will be asked to accept a Smart Account Agreement. If you'd like to look at the agreement beforehand, you can [preview the agreement](#).

[Complete Smart Account Setup](#)

Cisco Smart Account Summary

Account Domain Identifier:	twister.big-u.edu
Account Name:	big-u.edu
Account Status:	Pending Smart Account Agreement Acceptance
Account Approver:	John Doe(SSLMTester1@mail.com)
Requested by:	John Doe(SSLMTester1@mail.com)

b) Enter the Account Name, Company/Organization Name, Country, and State/Province/Region information.

Figure 10: Completing the Account Information and Company/Organization Information

Cisco Software Workspace
Smart Accounts

Smart Account Setup

Account Information

The Account Domain Identifier has been approved and the account process can be completed, just a few more steps are required.

Account Domain Identifier: lwa@big-u.edu

* Account Name: big-u.edu

Company/Organization Information

Enter information about the company that will own the account. This information will be used in the next step to search for the company or organization's **primary address** in Cisco's customer database.

* Company/Organization Name: Big U

* Country: United States

State/Province/Region: California

Continue

- c) Click **Continue** to select the legal address to be linked to the Cisco Smart Account.
- d) Select the Company/Organization Primary Address using the Refine Search option and click **Continue**.

Figure 11: Selecting the Company/Organization Primary Address

Cisco Software Workspace
Smart Accounts

Smart Account Setup

In order to validate the identity of the new account, Cisco requires that the account be associated with an existing primary address in its customer database. All matching results are displayed below but only primary addresses can be associated with the Smart Account.

Select Company/Organization Primary Address: [Refine Search](#)

* Company/Organization Name: Big U

* Country: United States

Address: Street address where company is headquartered

City: City where the company is headquartered

State/Province/Region: Arizona

Search

BIG U 170 W TASMAN DR, SAN JOSE, CA, UNITED STATES - [Primary Address]
 BIG U FOR US INTERNAL DEMO EVAL ONLY 2601 BRANARD RD BLDG 0 57305, FORT HUACHUCA, AZ, UNITED STATES
 BIG U FOR US INTERNAL DEMO EVAL ONLY 3133 N MADERA MESA PL, TUCSON, AZ, UNITED STATES

- e) (Optional) Enter the e-mail addresses of the Additional Account Approvers and Additional Account Administrators. The initial Approver automatically becomes an Administrator. Additional Administrators can be created or assigned separately from the Approver creation process.

Figure 12: Nominating Additional Account Approvers and Administrators

CUSTOMER-C2A-OCT14, v1.0

CUSTOMER-C2A - SAMPLE

The Licensed Software is owned and copyrighted by the Individual Software Vendor. The Software is licensed, not sold, only on the terms of this EULA. Acceptance and installation of the software indicates your acceptance of the terms and conditions of this EULA.

Upon receipt and installation of the software and payment of the license fee, you will acquire the right to use the Software in object code form. You assume responsibility for the selection of the program to achieve your intended results, and for the installation, use and results obtained from the Licensed Software.

In consideration of your acceptance of the terms and conditions combined in this EULA, you are granted a non-exclusive license to use the Licensed Software and the associated documentation for your own needs on one device. You are not licensed to rent, lease, transfer or distribute the Software. You may not allow any third party to access or view the Software for any reason other than to install, you professionally in your business where the software is currently being used.

Title and copyright in the Software, including object code media and documentation, remain with the Individual Software Manufacturer. You may not copy, reproduce or make data transmissions, in whole or in part, except as is necessary for back-up or archival purposes. You may not reverse engineer, translate, disassemble or decompile the Software, in whole or in part.

In the case of some Special Licensed software a fee to use, or continue to use, the Software is payable is charged either quarterly or annually. More information on charge-back costs and how they are applied can be found at Software Charge-Back FAQs - WebEx Social.

The license is effective upon acceptance and installation of the Licensed Software and shall continue until terminated. You may terminate it at any time by uninstalling the Licensed Software. ES&S has the right to terminate this Agreement if you fail to comply with any term or condition of this EULA.

I agree to the terms above

You will receive an e-mail confirming the creation of the Cisco Smart Account.

Creating Virtual Accounts

This procedure is optional. Virtual accounts are collections of licenses and product instances. You can create virtual accounts in Cisco Smart Software Manager to organize the licenses for your company into logical entities. A single virtual account is available by default.

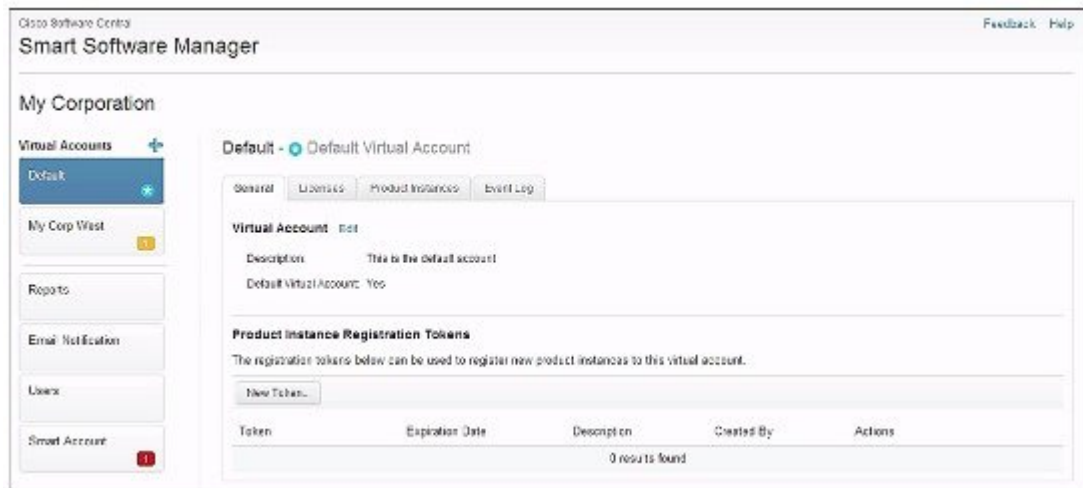

Before you begin

Set up a Cisco Smart Account. See [Setting Up a Cisco Smart Account, on page 41](#).

Step 1 Log in to the [Cisco Smart Software Manager](#).

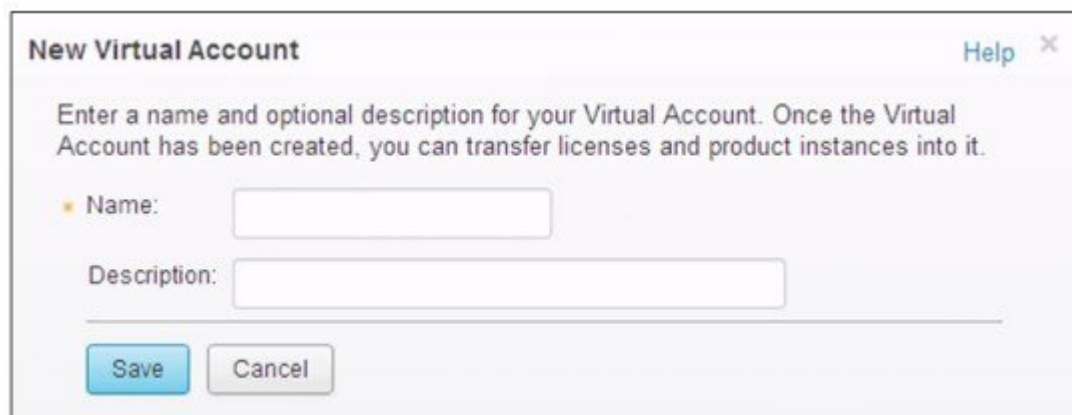

Step 2 Click the + (plus) symbol to create a virtual account.

Figure 14: Creating a Virtual Account

Step 3 In the **New Virtual Account** dialog box, enter the Name and Description.

Figure 15: New Virtual Account Dialog Box

Step 4 Click **Save**.

Creating a Product Instance Registration Token

Product instance registration tokens are used to register and consume a product for Cisco Smart Licensing. You must generate a token to register the product and add the product instance to a specified virtual account. Registration tokens can be valid from 1 to 365 days.

Step 1 Log in to the [Cisco Smart Software Manager](#).

Step 2 Click an existing virtual account.

Step 3 In the **General** tab, click **New Token**.

Figure 16: Creating a New Registration Token

Step 4 In the **Create Registration Token** dialog box, enter the Description and Expire After information and click **Create Token**.

Figure 17: Create Registration Token Dialog Box

What to do next

Register the router with the Cisco Licensing Cloud. For more details, see the [Registering the Router with the Cisco Licensing Cloud Using the Registration Token, on page 50](#) section.

Registering the Router with the Cisco Licensing Cloud Using the Registration Token

The router registration is performed only once for each product instance.

Note Ensure that you have the product instance registration token.

To register the router with the Cisco Licensing Cloud using a registration token, use the following commands:

```
enable
license smart register idtoken id-token
```

For example:

```
Router#license smart register idtoken
YjBkOwM5YtItMDFiOS00ZjBmLT1lY2YtODEzMzg1YTMzZDVhLTEz
ODE0MjE0%0ANzc5NDF8U1BDUTAySWFRtmJqa1NnbmlzRUIyaGLYU
053L0pHZTNvUW9VTfPE%0AekxCOD0%3D%0A
```

The system contacts the Cisco Smart Licensing servers to obtain authorization for Smart Licensing.

The license agent registers the product with Cisco and receives an identity certificate. This certificate is saved and automatically used for all future communications with Cisco. The license agent automatically renews the registration information with Cisco every 30 days.

Note Smart licensing may fail if IPv6 is configured on any interface, and the router does not have IPv6 connectivity to the Internet or Cisco Smart Software Agent (at tools.cisco.com). Log file error messages similar to the following may appear.

(These messages may also appear as a result of other conditions being true.)

```
%SMART_LIC-3-AGENT_REG_FAILED: Smart Agent for Licensing Registration with Cisco licensing cloud failed: Fail to send out Call Home HTTP message.  
%SMART_LIC-3-COMM_FAILED: Communications failure with Cisco licensing cloud: Fail to send out Call Home HTTP message.
```

If connectivity fails due to this issue, see the [Re-establishing Connectivity to Cisco Smart Call Home Server](#) section.

After connectivity is established, register the router with the Cisco Licensing Cloud.

Re-establishing Connectivity to Cisco Smart Call Home Server

This section describes what to do when the router fails to connect to the Cisco Smart Call Home Server and IPv6 is configured.

The following scenarios are applicable:

- If the interface is configured using the **ip http client source-interface interface** CLI and has the IPv6 address, the router establishes a session with the remote server with IPv6 connectivity.
- If the interface is configured using the **ip http client source-interface interface** command and has the IPv4 address, the router establishes a session with the remote server with IPv4 connectivity.
- If the interface is configured using **ip http client source-interface interface** command, and has an IPv6 address and an IPv4 address, the router establishes a session with the remote server with IPv6 connectivity.
- If the interface is not configured using the **ip http client source-interface interface**, the router establishes a session with the remote server with the IPv6 address.

For Cisco IOS XE Everest 16.5.1 or later, if an IPv6 address is available for an interface and the device cannot connect to the Internet or Cisco Smart Software Agent, configure the interface to only use IPv4 for smart licensing, by running the following configuration mode command.

```
ip http client source-interface interface
```

How to Configure Cisco Smart Licensing using Transport Gateway Solution

The steps below describe how to configure Cisco smart licensing using transport gateway solution.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto pki trustpoint Example: Router(config)# crypto pki trustpoint cisco	Declare the trustpoint that the router should use.
Step 4	enrollment terminal Example: Router(ca-trustpoint)# enrollment terminal	Specify manual cut-and-paste certificate enrollment.
Step 5	revocation-check <i>method</i> Example: Router(ca-trustpoint)# revocation-check none	Check the revocation status of a certificate. Method none means certificate checking is not required.
Step 6	crypto pki authenticate Example: Router(config)# crypto pki authenticate cisco	Authenticate the certification authority.
Step 7	no reporting smart-licensing-data Example: Router(config)# call-home Router(cfg-call-home)# profile CiscoTAC-1 Router(cfg-call-home-profile)# no reporting smart-licensing-data	Configure the default profile to not to communicate with tools.cisco.com.
Step 8	destination address <i>http address</i> Example: Router(config)# call-home Router(cfg-call-home)# profile Custom-Profile-1 Router(cfg-call-home-profile)# reporting smart-licensing-data Router(cfg-call-home-profile)# destination transport-method http Router(cfg-call-home-profile)# no destination transport-method email Router(cfg-call-home-profile)# destination address http https://IDS.IP.HERE:8443/Transportgateway/services/DeviceRequestHandler	Configure the custom profile to communicate with the transport server, here we use Custom Profile 1 as the name of the custom profile.

Configuring 100G Licenses for Supervisor 250G

The Cisco cBR Smart Account supports both 100G WAN licenses and 10G WAN licenses.

You need to configure the Cisco cBR to consume 100G WAN licenses for Supervisor 250G. This would accommodate existing 10G WAN licenses for 100G port, in addition to the 100G WAN license.

Starting from Cisco cBR release IOS-XE 16.8.1, there will be two types of WAN licenses in the Smart Account for WAN ports on the Cisco cBR Supervisor 250G module:

- 100G WAN license: By default, the Smart Account will consume the 100G WAN license for 100G WAN port.
- 10G WAN license: Can be applied to 10G and 100G WAN ports.

Overview of 100G License for Supervisor 250G

With the 100G WAN licenses, you can facilitate the ordering and management of WAN license for Supervisor 250G. This would help avoid the overhead of maintaining multiple 10G WAN licenses, and you can manage a single 100G WAN license for one 100G port of Supervisor 250G, instead of ten individual 10G WAN licenses.

However, there is no auto-conversion between 10G WAN licenses and 100G WAN licenses. They must be ordered and managed separately. If you are an existing customer using 10G WAN license for Supervisor 250G and have not purchased any 100G WAN licenses, the Cisco Smart Licensing will report out of compliance when attempting to upgrade to Cisco cBR release IOS-XE 16.8.1.

For information on configuring the Cisco cBR to consume 10G WAN licenses on 100G port for Supervisor 250G, see [Applying 10G WAN License to the 100G WAN Ports, on page 53](#).

Note

- In Supervisor 160, there is no 100G WAN interface and WAN 100G License. The display is same as the previous release.
 - The 100G license feature does not support an ISSU downgrade. This might cause a standby SUP crash.
-

Applying 10G WAN License to the 100G WAN Ports

Ensure that you go through [Overview of 100G License for Supervisor 250G, on page 53](#) for an understanding of the feature and the restrictions.

The Smart Account will consume the 100G WAN license for 100G WAN port by default. To apply the 10G WAN licenses for the 100G WAN port, complete the following step.

SUMMARY STEPS

1. You can apply the 10G WAN license to the 100G WAN ports using the following command:

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>You can apply the 10G WAN license to the 100G WAN ports using the following command:</p> <p>Example:</p> <pre>Router(config)# cable license 100G-conversion</pre> <p>To disable the 10G WAN license for 100G WAN ports, run the command with the <i>no</i> option. This would enable the 100G WAN ports to consume 100G WAN license.</p> <pre>Router(config)# no cable license 100G-conversion</pre>	

Displaying the License Information

You can use the following command options to display the license information, based on whether the license has been configured or not:

SUMMARY STEPS

1. Run either of the following command options to display license information.

- By default, or with the *no* option, the ports will consume a 100G WAN license for a 100G WAN port.

For example if the **no cable license 100G-conversion** command has been issued, the responses to the **show cable license wan** and **show license summary** commands would be in the following format:

```
Router(config)# show cable license wan
-----
Entitlement:  WAN License
Consumed count: 0
Consumed count reported to SmartAgent: 0
Enforced state: No Enforcement

-----

Entitlement:  WAN 100G License
Consumed count: 2
Consumed count reported to SmartAgent: 2
Enforced state: No Enforcement

Router(config)# show license summary
Smart Licensing is ENABLED

Registration:
  Status: REGISTERED
  Smart Account: CBR8_DEV_1
  Virtual Account: cbr8-dev-test
  Export-Controlled Functionality: Allowed

-----
regid.2017-09.com.ci... (WAN_100G_License)                2 AUTHORIZED
```

- With the **cable license 100G-conversion** command, it will consume 10G WAN license for 100G WAN port.

For example if the **cable license 100G-conversion** command has been issued, the responses to the **show cable license wan** and **show license summary** commands would be in the following format:

```
Router(config)# show cable licenses wan
-----
Entitlement: WAN License
Consumed count: 20
Consumed count reported to SmartAgent: 20
Enforced state: No Enforcement

-----

Entitlement: WAN 100G License
Consumed count: 0
Consumed count reported to SmartAgent: 0
Enforced state: No Enforcement

Router(config)# show license summary
Smart Licensing is ENABLED

Registration:
Status: REGISTERED

Feature Information for 100G License for Supervisor 250G

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 3: Feature Information for 100G License for Supervisor 250G

Feature Name	Releases	Feature Information
100G License for Supervisor 250G	Cisco IOS-XE Release 16.8.1	This feature was integrated into Cisco IOS-XE Release 16.8.1 on the Cisco cBR Series Converged Broadband Routers.

Verifying Cisco Smart Licensing Configuration

Use the following commands to verify the Cisco Smart Licensing Configuration on the Cisco cBR router:

- **show license all**—Displays all the license information.

The following is a sample output of this command:

```
Router# show license all

Smart Licensing Status
=====

Smart Licensing is ENABLED

Registration:
  Status: REGISTERED
  Virtual Account: auto-test-1
  Initial Registration: SUCCEEDED on Mar  5 02:01:03 2015 UTC
  Last Renewal Attempt: None
  Next Renewal Attempt: Sep  1 02:03:51 2015 UTC
  Registration Expires: Never

License Authorization:
  Status: OUT OF COMPLIANCE on Mar  5 03:34:54 2015 UTC
  Last Communication Attempt: SUCCEEDED on Mar  5 03:35:57 2015 UTC
  Next Communication Attempt: Mar  5 15:35:57 2015 UTC
  Communication Deadline: Jun  3 03:32:51 2015 UTC

License Usage

Entitlement: DOCSIS 3.1 Downstream Channel License
Consumed count: 31
Consumed count reported to SmartAgent: 0
Enforced state: No Enforcement
```

Use the following commands to verify the DOCSIS 3.1 Upstream Exclusive License on the Cisco cBR router:

- **show cable licenses us_d31_exclusive**—Displays the DOCSIS 3.1 upstream exclusive license information.

The following is a sample output of this command:

```
Router# show cable licenses us_d31_exclusive

Load for five secs: 99%/2%; one minute: 21%; five minutes: 6%
Time source is NTP, *10:14:30.935 CST Tue Jun 6 2017
-----
Entitlement: DOCSIS 3.1 Upstream Channel Exclusive License
Total Licensed Spectrum: 188000000Hz
Consumed count: 188
Consumed count reported to SmartAgent: 188
Enforced state: No Enforcement
```

Troubleshooting Cisco Smart Licensing

Before taking the steps below to troubleshoot the Cisco Smart Licensing, the customers should first make sure the configuration is correct and see if they are able to ping the HTTP address they have configured for the smart license. The output of the **show call-home smart-licensing statistics** command should have REGISTERED and ACKNOWLEDGE information. And check the output of **show logging | include SMART | CALL**.

Manually Renewing the Smart License Registration

The license agent automatically renews the registration information with Cisco every 30 days. You may need to manually renew the registration if the license is out of compliance and it needs to be registered immediately.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	license smart renew Example: Router# license smart renew	Manually renews the license registration of the device instance with Cisco.

Unregistering the Router from Cisco Smart Licensing

You can unregister the router from Cisco Smart Licensing. You may need to unregister the router for the Return Material Authorization (RMA) of the router.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	license smart deregister Example: Router# license smart deregister	Removes the Cisco Smart Licensing registration for the device instance. All Cisco Smart Licensing certificates and entitlements are removed.

Feature Information for Cisco Smart Licensing

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 4: Feature Information for Cisco Smart Licensing

Feature Name	Releases	Feature Information
Cisco Smart Licensing	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.
DOCSIS 3.1 US Channel Licensing	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 3

Core Peak Bandwidth Licensing

The Core Peak Bandwidth (CPB) license enables you to manage Cisco cBR-8 routers with one comprehensive license, unlike the multiple license types associated with the traditional licensing models. This document provides information on CPB and how to configure the license on Cisco cBR-8 routers.

- [Core Peak Bandwidth License, on page 67](#)
- [Configure CPB on Cisco cBR Routers, on page 68](#)
- [Feature Information for Core Peak Bandwidth Licensing , on page 69](#)

Core Peak Bandwidth License

The CPB licensing plan functions on a quarterly basis. In this plan, you pay for additional Core Peak Bandwidth licenses that you require. The cost of the CPB licenses is proportional to the number of subscribers on the Cisco cBR-8 router, as the network traffic through a CCAP core is proportional to the number of subscribers on the router.

In each quarter, as the CPB grows, additional CPB licenses equal to the growth are automatically billed and added to your existing CPB license inventory.

CPB Calculation

The total CPB is calculated by measuring the core traffic through all the CCAP cores, taking the 95th percentile of the monthly peak, and reporting the quarterly value on the first day of the next quarter to the Smart License server to automatically manage the licensing process. The Smart License server automatically invoices for additional licensing needs and then delivers the licenses when you pay.

The traffic rate is measured every 5 minutes. Cisco cBR-8 routers save this data for a minimum of three months. The monthly CPB value is calculated and the maximum monthly value is considered as the quarterly CPB.

When you enable CPB on Cisco cBR-8, the initial CPB value is measured as 1.

For measuring the CPB, 12 samples are collected in every hour, which is one sample every 5 minutes. Due to a maintenance window or a shutdown, which approximately is less than 5 hours, if samples are lost and the number of lost samples is more than 60 in a month, the cable operator is notified with an error message. If the chassis serial number does not match the local chassis serial number, these sample records are deleted when starting the router or rebooting it. The sample history is also cleared when a Supervisor card is replaced.

To calculate the monthly CPB value, the Cisco cBR router rates all samples collected in one month based on the speed. For example, if 8767 samples are collected in a month, and the 8767th sample is the fastest, then the 95th percentile is the 8329th sample rated by speed (consider the first sample as the slowest and the 8767th the fastest). Hence, the CPB value for that month is the value of the 8329th sample divided by 100 (100Mbps).

Configure CPB on Cisco cBR Routers

Enable CPB Licensing

To enable CPB and show only the CPB usage, use the following command. When you enable CPB, the other existing licensing features are canceled automatically.

```
cable license enable-CPB
```

Use the `no cable license enable-CPB` command to disable CPB. By default, CPB is disabled on Cisco cBR routers.

View CPB Usage Details

To display CPB usage information, use the following command:

```
show cable licenses cpb
```

Example: Show CPB Usage Details

The following example shows CPB usage details:

```
show cable licenses cpb
Entitlement: CPB License
Consumed count: 987
Consumed count reported to SmartAgent: 987
Enforced state: No Enforcement
Quarterly CPB is 987 (100Mbps) in the First quarter of 2018.
First monthly CPB is: 103585495480 bps, 987 (100Mbps).
Second monthly CPB is: 103595095264 bps, 987 (100Mbps).
Third monthly CPB is: 103595124064 bps, 987 (100Mbps).
```

View Details of All Licenses

To display the usage information of all licenses, use the following command.

If you enable CPB, this command displays only the CPB usage information. If CPB is disabled, the command displays the usage information of all existing licenses.

```
show cable licenses all
```

Example: View Details of All Licenses

The following example shows the usage information of all licenses, when CPB is enabled.

```
show cable licenses all
Entitlement: CPB License
Consumed count: 987
Consumed count reported to SmartAgent: 987
Enforced state: No Enforcement
```

```

Quarterly CPB is 987 (100Mbps) in the First quarter of 2018.
First monthly CPB is: 103585495480 bps, 987 (100Mbps).
Second monthly CPB is: 103595095264 bps, 987 (100Mbps).
Third monthly CPB is: 103595124064 bps, 987 (100Mbps).

```

View CPB Sample History

To display the details of the CPB sample history, use the following command.

```
show cable licenses cpb-records year <year> month <month> day <day>
```

Example: View CPB Sample History

The following example CPB sample history.

```

show cable licenses cpb-records year 2018 month 4 day 28
index: 34626, timestamp: 28-April-2018 05:30:02 UTC, 5min rate: 105291741536 bps, 1004
(100Mbps)
index: 34627, timestamp: 28-April-2018 05:35:02 UTC, 5min rate: 104006310312 bps, 991
(100Mbps)
index: 34628, timestamp: 28-April-2018 05:40:02 UTC, 5min rate: 104006237736 bps, 991
(100Mbps)
index: 34629, timestamp: 28-April-2018 05:45:02 UTC, 5min rate: 104006156168 bps, 991
(100Mbps)
index: 34650, timestamp: 28-April-2018 07:30:03 UTC, 5min rate: 47644177216 bps, 454
(100Mbps)
index: 34651, timestamp: 28-April-2018 07:35:03 UTC, 5min rate: 83840688424 bps, 799
(100Mbps)
-----
There are 6 cpb records in Apr 28 2018 UTC.

```

Feature Information for Core Peak Bandwidth Licensing

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 5: Feature Information for Core Peak Bandwidth Licensing

Feature Name	Releases	Feature Information
Core Peak Bandwidth Licensing	Cisco IOS XE Fuji 16.9.1a	This feature was introduced on Cisco cBR Series Converged Broadband Routers.

CHAPTER 4

Capped License Enforcement

This document provides information on the Capped License feature and on how to configure it on Cisco cBR Series Routers.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

- [Hardware Compatibility Matrix for the Cisco cBR Series Routers, on page 71](#)

Hardware Compatibility Matrix for the Cisco cBR Series Routers

Note The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

Table 6: Hardware Compatibility Matrix for the Cisco cBR Series Routers

Cisco CMTS Platform	Processor Engine	Interface Cards
Cisco cBR-8 Converged Broadband Router	<p>Cisco IOS-XE Release 16.5.1 and Later Releases</p> <p>Cisco cBR-8 Supervisor:</p> <ul style="list-style-type: none"> • PID—CBR-SUP-250G • PID—CBR-CCAP-SUP-160G • PID—CBR-CCAP-SUP-60G • PID—CBR-SUP-8X10G-PIC 	<p>Cisco IOS-XE Release 16.5.1 and Later Releases</p> <p>Cisco cBR-8 CCAP Line Cards:</p> <ul style="list-style-type: none"> • PID—CBR-LC-8D30-16U30 • PID—CBR-LC-8D31-16U30 • PID—CBR-RF-PIC • PID—CBR-RF-PROT-PIC • PID—CBR-CCAP-LC-40G • PID—CBR-CCAP-LC-40G-R <p>Cisco cBR-8 Downstream PHY Modules:</p> <ul style="list-style-type: none"> • PID—CBR-D30-DS-MOD • PID—CBR-D31-DS-MOD <p>Cisco cBR-8 Upstream PHY Modules:</p> <ul style="list-style-type: none"> • PID—CBR-D30-US-MOD • PID—CBR-D31-US-MOD

Information About Capped License Support

The capped license enforcement feature allows you to set a limit to the number of licenses for each licensed feature on Cisco cBR-8. Hence, with this feature, the uncontrolled usage of licensed features and the accidental consumption of more resources are kept under check. It also enables the users to track the usage per device and controls the usage of resources upfront.

If any of the capped enforcement limit is lower than the current usage number, you cannot apply the capped license option.

If capped enforcement is already in effect, the user cannot access more resources than the capped limit. The number of feature licenses accessed must be less than or equal to the capped count.

Smart License feature, which is a Reporting Model, discourages license enforcement. Hence, the Capped License Enforcement feature is disabled by default and is not publicized to every customer.

SNMP-MIB-based Capped Enforcement

Set the cap for the features and enable the Capped-Enforcement feature using the SNMP set command. The SNMP set command is successful only when the cap enforcement count for all the features are greater than

or equal to the current usage count. If the usage count for any feature is above the cap count, shutdown those resources and make sure that they are below or equal to the cap limit before issuing the SET command.

Platform, after synchronizing those values with the standby RP, enables the capped enforcement. So if the user tries to increase the usage beyond the CAP values, the resource are blocked and warning messages appear.

During the Return Material Authorization (RMA) of the SUP and when the SUP is moved across chassis, the stored cap numbers and the values configured while enabling cap enforcement are cleared. However, in a system with standby RP, if the standby RP has taken over, when the new RP is plugged in during RMA, the values are synced. In a non-redundant system, reissue the SNMP SET command after an RMA or when an SUP is moved across the chassis.

You cannot enable capped enforcement on Cisco cBR-8, which is already in a configuration lock state. However, a Cisco cBR8 that is cap enabled or not when fails to communicate with the license server for more than 90 days, moves to configuration lock state.

If you do not set the CAP count for a feature, the value is set to the default 0xffff_ffff (268435455).

Use Case Scenarios

The following table shows the use cases for SNMP-MIB-based capped enforcement.

If the entitlement usage is less than or equal to the CAP count	You can configure the limit and turn on additional resources. When the feature usage reaches the CAP count, the platform prevents the additional usage.
If the entitlement usage is greater than the CAP count	Stops the SNMP command from running. A message appears to inform you about this scenario and the difference in the count.

The following table shows the conditions under which you must set the CAP enable and the CAP count options.

Scenario	Non Redundant Cisco cBR	Redundant Cisco cBR
First-time boot	Yes	Yes
System reload	No	No
SSO	N/A	No
SUP RMA	Yes	No
Moving SUP across chassis	Yes	No

How to Configure Capped License Enforcement

This section contains the following:

Configuring Capped License Enforcement

To configure the Capped License Enforcement, use the SNMP command as given in the following example. Change the MIB value by running the following command from a Linux server:

```
snmpget -v <snmp_version_information> -c <snmp_readonly_community>
  <cBR8_Server_IP> <MIB_OID>
snmpset -v <snmp_version_information> -c <snmp_read_write_community>
  <cBR8_Server_IP> <MIB_OID> <object_type> <value>
```

Viewing the License Usage Count

To view the license usage count of the current configuration, use the show cable license all command as given in the following example.

```
Router-config# show cable license all
```

Configuration Examples

The following example shows how to get the **EnforcementEnabled** Global value using the community private on the server 172.25.15.210 using SNMP version 2c:

```
$ snmpget -v 2c -c public 172.25.15.210 1.3.6.1.4.1.9.9.839.1.1.3.0
```

The following example shows how to set the **EnforcementEnabled** Global value using the community private on the server 172.25.15.210 using SNMP version 2c.

```
$ snmpset -v 2c -c private 172.25.15.210 1.3.6.1.4.1.9.9.839.1.1.3.0 i 1
```

The following example shows how to set the DS license cap limit to 999999.

```
$ snmpset -v 2c -u private 123 172.25.15.210 1.3.6.1.4.1.9.9.839.1.1.4.1 u 999999
```

Feature Information for Capped License Enforcement

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 7: Feature Information for Capped License Enforcement

Feature Name	Releases	Feature Information
Capped License Enforcement	Cisco IOS XE Everest 16.6.1	This feature was introduced in Cisco IOS XE Everest 16.6.1 on Cisco cBR Series Converged Broadband Router.

CHAPTER 5

Consolidated Packages and SubPackages Management

This document discusses how consolidated packages and software subpackages (individual and optional) are run and managed on the Cisco cBR Series Converged Broadband Router. It contains the following sections:

- [Finding Feature Information, on page 75](#)
- [Running the Cisco cBR Series Routers Using Individual and Optional SubPackages: An Overview , on page 75](#)
- [Running the Cisco cBR Series Routers Using a Consolidated Package: An Overview , on page 76](#)
- [Running the Cisco cBR Series Routers: A Summary , on page 76](#)
- [Software File Management Using Command Sets , on page 77](#)
- [Managing and Configuring the Router to Run Using Consolidated Packages and Individual SubPackages, on page 78](#)
- [Upgrading Individual SubPackages, on page 98](#)
- [Additional References, on page 106](#)
- [Feature Information for Consolidated Packages and SubPackages Management, on page 106](#)

Finding Feature Information

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Running the Cisco cBR Series Routers Using Individual and Optional SubPackages: An Overview

The Cisco cBR Series Converged Broadband Router can be configured to run using individual subpackages and optional subpackages.

When the router is configured to run using individual and optional subpackages:

- Each individual subpackage within a consolidated package is extracted onto the router as its own file.
- Additionally, any optional subpackages must be separately downloaded and stored in the same directory with the provisioning file and the other individual subpackages that have been extracted.
- The router then runs by accessing each file as needed for operational purposes. All individual and optional subpackage files must be stored in the same directory on the router for the router to run properly using individual subpackages.

When the router runs using the individual and optional subpackages, the router needs to be configured to boot using the provisioning file that was included in the consolidated package with the individual subpackage files. This provisioning file must also be in the same directory as the individual and optional subpackage files. The router boots faster when configured to run using individual and optional subpackages than it does when configured to run using a consolidated package.

A Cisco cBR Series Router cannot be configured to run individual and optional subpackages stored on a TFTP or any other network server. To use this method of running the router, copy the individual and optional subpackages along with the provisioning file onto the bootflash: file system.

Running the Cisco cBR Series Routers Using a Consolidated Package: An Overview

The Cisco cBR Series Converged Broadband Router can also be configured to run using a consolidated package.

Note Booting the router from a consolidated package is not supported for installation of optional subpackages.

When the router is configured to run using a consolidated package, the entire consolidated package file is copied onto the router or accessed by the router via TFTP or another network transport method. The router runs using the consolidated package file.

A router configured to run using a consolidated package is booted by booting the consolidated package file. Because this file is large, the boot process for routers running using the consolidated package is slower than the boot process for routers running individual subpackages.

A router configured to run using a consolidated package does have some advantages over a router configured to run individual subpackages. First, a consolidated package can be booted and utilized using TFTP or another network transport method. Secondly, configuring the router to use the one consolidated package file is easier than managing several individual subpackage files. Running the router using a consolidated package may be the right method of running the router in certain networking environments.

The consolidated package should be stored on bootflash:, usb[0-1]:, or a remote file system when this method is used to run the router.

Running the Cisco cBR Series Routers: A Summary

The advantages of running your router using individual subpackages include:

- The router boots fastest when booted using the individual subpackage boot approach.

- Individual subpackages can be upgraded instead of the complete consolidated image.

The advantages of running your router using a consolidated package include:

- Simplified installation—Only one software file needs to be managed instead of several separate images.
- Storage—A consolidated package, unlike individual subpackages, can be used to run the router while being stored in bootflash:, on a USB Flash disk, or on a network server. A consolidated package can be booted and utilized using TFTP or another network transport method, while the individual subpackage method requires the individual subpackage files to be copied into the bootflash: file directory on the router.

Approach	Advantages	Disadvantages
Individual and optional subpackages Note This method is required if you need to install any optional subpackages for your system.	Faster boot time.	<ul style="list-style-type: none"> • Multiple software subpackages more difficult to manage. • Cannot be booted from TFTP or any other network server. If you are going to use the individual subpackage boot method, each individual subpackage file must be placed in the bootflash: directory. • Individual and optional subpackage files and the provisioning file must be stored in bootflash:.
Consolidated Package	<ul style="list-style-type: none"> • Easier management. Only have to manage one file instead of many files. • A consolidated package file can be stored in bootflash:, on any TFTP or other network server. 	Slower boot times and lessened maximum system scalability because the larger image must be processed at all times.

Software File Management Using Command Sets

Software files can be managed on the Cisco cBR Series Converged Broadband Router using the following distinct command sets.

The request platform Command Set

The **request platform software package** command is part of the larger request platform command set being introduced on the Cisco cBR Series Converged Broadband Router.

The **request platform software package** command, which can be used to upgrade individual subpackages and a complete consolidated package, is used to upgrade software on the Cisco cBR Series Converged Broadband Router. Notably, the **request platform software package** command is the recommended way of performing an individual subpackage upgrade, and also provides the only method of no-downtime upgrades of individual subpackages on the router when the router is running individual subpackages.

The **request platform software package** command requires that the destination device or process be specified in the command line, so the commands can be used to upgrade software on both an active or a standby processor.

Command Syntax

request platform software package install rp *rp-slot-number* file *file-URL*

where

- *rp-slot-number* is the number of the RP slot and
- *file-URL* is the path to the file being used to upgrade the Router.

The copy Command

The **copy** command can be used to move consolidated packages and individual subpackages onto the router, though using this command to move individual subpackage files from one storage area to another is often inefficient (in these scenarios, it is almost always preferable to move the consolidated package, then extract the subpackages, or to extract the subpackages without moving the consolidated package).

To upgrade a consolidated package on the Cisco cBR Series Converged Broadband Router, copy the consolidated package onto a file system, usually bootflash: , using the **copy** command as you would on most other Cisco routers. After making this copy, configure the router to boot using the consolidated package file.

To upgrade the router and reboot using individual subpackages, copy the consolidated package onto the router using the **copy** command, enter the **request platform software package expand** command to extract the individual subpackages, and configure the router to boot using subpackages. Other methods, such as copying each individual subpackage in the same consolidated package from a directory or using the request platform software package command to extract the subpackages onto a router directory are also usable, though copying individual subpackages is often inefficient.

Managing and Configuring the Router to Run Using Consolidated Packages and Individual SubPackages

This section describes methods that are used to manage and configure the packages, sub-packages and patches on the router.

Cable Line Card Process Restart

The last step, in many of the methods used to upgrade and manage the packages and sub-packages, is to reload the router or the component for which the software is being configured or upgraded. Reloading the router or the components involves the following disadvantages:

- service disruption (limited)
- loss of modem configuration data

- time consumption in rebooting the line cards and other components

The N+1 line card high availability (LCHA) system reboots the active and the standby line cards whenever a package is upgraded on a line card. This occurs for sub-package upgrade for Field Replaceable Units (FRUs) on the line card as well. Every time an upgrade is done to a package or sub-package, the line card must be rebooted. The time taken for the package upgrade on N number of active line cards, the total number of reboots would be 2xN. This is time-consuming and may affect services on the rebooting line cards.

To avoid the disadvantages of reloading the router and the line cards, use the Cable Line Card Process Restart features when you upgrade packages on the RF line cards.

Note Do not use the process restart features without upgrading or installing packages on the RF line cards.

Primarily there are two features that allow you to restart Cable Line Card processes:

- Cable Line Card Control Plane Process Restart
- Cable Line Card Upstream Scheduler Process Restart

Cable Line Card Control Plane Process Restart

The Cable Line Card Control Plane Process Restart feature provides the following advantages:

- Simplified package upgrade without LCHA based reboot of active and standby line cards.
- Restart of specific processes without service disruption.
- All the modem configuration data is recovered after the IOSd process restarts.
- Changes in the modem configuration data during the IOSd process restart is reconciled after the IOSd process is restarted.
- The secondary line card shutdown and un-shutdown processes occur automatically.

Restrictions:

- To upgrade a line card IOS using the Cable Line Card Control Plane Process Restart feature, the sub-package must have the patches for cbrsup-clcios and cbrsup-clciosdb.
- IOSd and us-scheduler restart are supported. You can restart IOSd only, which requires IOSd/IOSdb packages or restart the us-scheduler only, which requires clc-docsis package. You can also restart both using a single command, where the us-scheduler is restarted first and then the IOSd is restarted. In this case, IOSd/IOSdb and clc-docsis packages are required.

Other restrictions include the following:

- The IOSd process can be restarted only on the primary active RF line cards.
- Any secondary RF line card must be shut down before restarting the IOSd process.
- The IOSd process restart does not work when double failures (i.e. termination of IOSd and one or more process at the same time) occur. The double failures result in line card reload.
- The restart of the next IOSd (i.e. IOSd process on the next RF line card) does not occur until the current IOSd process recovers fully.

The Cable Line Card Control Plane Process Restart feature provides the following restart options:

- Restart a specific slot using the **request platform software process restart** command with the **slot slot number** option.
- Restart all the line cards without specifying a specific slot, using the **request platform software process restart** command without the **slot slot number** option.
- Interval based restart option of all line card using the **request platform software process restart** command with the **interval secs** option.

Important points to remember:

- Before using the Cable Line Card Control Plane Process Restart feature, shut down the secondary line card, using the **hw-module slot shutdown** command.
- When the Cable Line Card Control Plane Process Restart feature is started, the secondary line card shuts down automatically.
- Before using the Cable Line Card Control Plane Process Restart feature, shut down the secondary line card, using the **hw-module slot shutdown** command.
- When the Cable Line Card Control Plane Process Restart feature is started, the secondary line card shuts down automatically.
- To prevent reloading the line card after sub-package upgrade, use the **request platform software package install node file** command with the **noreload linecard** option.
- Verify the restart process using the **show platform software ios slot slot number restart info** command.

Restart on Crash

The cable line card control plane and upstream scheduler process restarts automatically after a crash. After restarting process, secondary line card is reset.

Restrictions:

- Restart on crash supported only on primary active line cards

The table below lists the cable line card behaviors when crash happens under different rules.

Table 8: Cable Line Card Process Restart Policy Matrix

	Secondary Cable Line Card Present	Crash	Secondary Cable Line Card state
LCHA or LCPR	Yes	Cable line card reset	Active after switchover
Process restart enabled	No	Restart	N/A
LCHA or LCPR	Yes	Cable line card reset	Active after switchover
Process restart Disabled	No	Cable line card reset	N/A
No LCHA Preferred or LCPR	Yes	Process restart	Secondary cable line card resets after process restart on primary cable line card

	Secondary Cable Line Card Present	Crash	Secondary Cable Line Card state
Process restart Enabled	No	Process restart	N/A
No LCHA Preferred or LCPR	Yes	Cable line card reset	Active after switchover
Process restart Disabled	No	Cable line card reset	N/A

- Note**
- Manual process restart does not depend on policy configured, and will shut/unshut secondary cable line card if present.
 - “LCHA preferred” and “process restart enable” are default. User can set these two parameters using `disable-auto-restart` and `lcha-preferred` commands. For the details, see http://www.cisco.com/c/en/us/td/docs/cable/cmts/cmd_ref/b_cmts_cable_cmd_ref.html.
 - Behavior is the same for Control Plane Process Restart and Upstream Scheduler Process Restart.
 - Secondary cable line card in standby mode is considered present.

The restart retry limit feature is added to the Cable Line Card Process Restart, it is applicable only to restart on crash. Using this feature, the customer can set a restart retry time limit, if the process cannot restart successfully within this limit, the line card will reload. This feature can prevent the line card from continuous restart when restart failed.

Using the Cable Line Card Control Plane Process Restart Feature

To use the Cable Line Card Control Plane Process Restart Feature, install the RF line card sub-package upgrade using the command.

- Step 1** Install the RF line card sub-package upgrade using the **request platform software package install node file noreload linecard** command.

```
Router#request platform software package install node file bootflash:sp/cbr_patch.9.0.tar noreload linecard
```

- Step 2** Use the **request platform software process restart** command to restart the RF line card IOSd process on all the cable line cards sequentially.

```
Router# request platform software process restart
```

- Step 3** Use the **request platform software process restart slot slot#** command to restart the RF line card IOSd process on a specific cable line card.

```
Router# request platform software process restart slot 7
```

Configuring the Cable Line Card Control Plane Process Restart Retry Limit

To configure the Cable Line Card Control Plane Process Restart Retry Limit, complete the following procedure:

```
enable
configure terminal
process-restart
lc-control-plane-timeout time
restart-retry retry-times
exit
```

Examples for Cable Line Card Control Plane Process Restart Feature

This section provides the sample outputs for the commands used in the Cable Line Card Control Plane Process.

This example shows the output of the **request platform software package install node file** command with the **noreload linecard** option that installs the sub-package upgrade:

```
Router# request platform software package install node file bootflash:sp/cbr_patch.9.0.tar
noreload linecard
Image file expanded and copied
Expanding image file: stby-bootflash:sp/cbr_patch.9.0.tar
Image file expanded and copied
Finished image file expansion
Found clc package

Cable Line Card Upstream Scheduler Process Restart

The Cable Line Card Upstream Scheduler Process Restart feature is used to restart the upstream scheduler process on the RF line cards.

The Cable Line Card Upstream Scheduler Process Restart feature provides the following advantages:

- Allows to restart line card US- Scheduler (CDMAN) process with minimum impact to upstream traffic and no impact to downstream traffic.
- All modem configuration data recovered to the state before restart.
- Changes in modem configuration data during restart are reconciled.
- New modems coming online are blocked during restart.
- The **request platform software package restart** command is used to upgrade the new DOCSIS sub-pkg patch without reloading the line card.
- Effective with Cisco IOS-XE Release 3.18.0S, the card restarts automatically after a crash. For more information, see [Restart on Crash, on page 80](#) section.

Restrictions:

The following restrictions apply to the :

- The Upstream Scheduler process can be restarted only on the primary active RF line cards.
- The Upstream Scheduler process restart does not work when double failures (i.e. termination of Upstream Scheduler and one or more process at the same time) occur. The double failures result in line card reload.
- The restart of the next Upstream Scheduler (i.e. Upstream Scheduler process on the next RF line card) does not occur until the current Upstream Scheduler process recovers fully.

Important points to remember:

- With Cisco IOS-XE Release 3.17.0S, when the Cable Line Card Upstream Scheduler Process Restart feature is started, the secondary line card shuts down automatically.
- To prevent reloading the line card after sub-package upgrade, use the **request platform software package install node file** command with the **noreload linecard** option.
- Verify the restart process using the **show platform software us-scheduler restart info** command.

```
Router# show platform software us-scheduler 3 restart info
us-scheduler process restart info:
Process restartable : Yes
us-scheduler state : RESTART_OPERATIONAL
Features bit map : 0x001e
us-scheduler restart count : 4
```

Using the Cable Line Card Upstream Scheduler Process Restart Feature

To use the Cable Line Card Upstream Scheduler Process Restart Feature, install the RF line card sub-package upgrade using the command.

-
- Step 1** Install the RF line card sub-package upgrade using the **request platform software package install node file noreload linecard** command.

```
Router#request platform software package install node file bootflash:sp/cbr_patch.9.0.tar noreload
linecard
```

- Step 2** Use the **request platform software process restart** command to restart the Upstream Scheduler process on all the cable line cards sequentially.

```
Router# request platform software process restart
```

- Step 3** Use the **request platform software process restart slot slot#** command to restart the Upstream Scheduler process on a specific cable line card.

```
Router# request platform software process restart slot 7
```

Configuring the Cable Line Card Control Plane Process Restart Retry Limit

To configure the Cable Line Card Control Plane Process Restart Retry Limit, complete the following procedure:

```

enable
configure terminal
process-restart
lc-us-scheduler-timeout time
restart-retry retry-times
exit

```

Examples for Cable Line Card Upstream Scheduler Process Restart Feature

This section provides the sample outputs for the commands used in the Cable Line Card Upstream Scheduler Process Restart Feature.

This example shows the output of the **show platform software us-scheduler restart info** command.

```

Router#show platform software us-scheduler 6 restart info
us-scheduler process restart info:
Process restartable : Yes
us-scheduler state : RESTART_OPERATIONAL
Features bit map : 0x001e
us-scheduler restart count : 1

```

This example shows the output when the upstream scheduler process is restarted.

```

Router#

```

You can specify a time interval in seconds using the **interval** keyword, between the restarting of two line card processes in the sequence. The default interval is five seconds.

This example shows the configuration of an interval of six seconds.

```
Router#request platform software process restart interval 6
```

Quick Start Software Upgrade

The following instructions provide a quick start version of upgrading the software running the Cisco cBR Series Converged Broadband Router. These instructions assume you have access to the consolidated package and that the files will be stored in a bootflash: file system that is not storing any previously installed subpackages or consolidated packages and that has enough room for the file or files.

-
- Step 1** Copy the consolidated package into bootflash: using the **copy URL-to-image bootflash:** command.
 - Step 2** If you want to run the router using individual subpackages, enter the **request platform software package expand file bootflash:/sub_dir/base_image** command. If you want to run the router using a consolidated package, skip this step.
 - Step 3** Enter the **dir bootflash:** command to verify your consolidated package or your extracted subpackages are in the directory.
 - Step 4** If you are trying to run individual subpackages, use the **delete bootflash:base_image** to delete the consolidated package. If you want to run the router using the consolidated package, skip this step.
 - Step 5** Set up the boot parameters for your boot. Set the configuration register to 0x2 by entering the **config-register 0x2102** global configuration command, and enter the **boot system flash bootflash:base_image** (if running using the consolidated package) or **boot system flash bootflash:provisioning-file-name** (if running using individual subpackages) global configuration command.
 - Step 6** Enter **copy running-config startup-config** to save your configuration.

- Step 7** Enter the **reload** command to reload the router and finish the boot. The upgraded software should be running when the reload completes.

Managing and Configuring a Consolidated Package Using the copy Command

To upgrade a consolidated package on the Cisco cBR Series Routers using the **copy** command, copy the consolidated package into the bootflash: directory on the router using the **copy** command as you would on most other Cisco routers. After making this copy, configure the router to boot using the consolidated package file.

In the following example, the consolidated package file is copied onto the bootflash: file system from TFTP. The config-register is then set to boot using **boot system** commands, and the **boot system** commands instruct the router to boot using the consolidated package stored in the bootflash: file system. The new configuration is then saved using the **copy running-config startup-config** command, and the system is then reloaded to complete the process.

```
Router# dir bootflash:
Directory of bootflash:/

Managing and Configuring a Router to Run Using Individual SubPackages From a Consolidated Package

To run the router using individual subpackages from a consolidated package, follow one of the following procedures:

Extracting a Consolidated Package and Booting Using the Provisioning File

To extract a consolidated package and to boot using provisioning file, perform the following steps:

Step 1 Perform one of the following tasks:

- a) Copy the consolidated package file (or, in cases where you have every individual subpackage and a provisioning file for the subpackages available, each individual subpackage and the provisioning file) onto the bootflash: file system using the **copy** command. Make sure to copy the consolidated package into the bootflash: file system and directory where you want to store the provisioning file and the individual image subpackages. Enter the **request platform software package expand file bootflash:url-to-Cisco-IOS-XE-imagename** command with no other option to extract the provisioning file and the individual subpackages out of the consolidated package file and into the current directory in bootflash:. We recommend that you extract the sub packages to an empty directory to simplify the management of these files.
- b) Copy the consolidated package file onto any file system on your router, then enter the **request platform software package expand file file-system:url-to-Cisco-IOS-XE-imagename to bootflash:** command to extract the provisioning file and the individual image subpackages onto the bootflash: file system.

Note After performing this step, do not move any of the files. The bootup process cannot function properly unless all of the subpackages and the provisioning file are located in the same directory. Also, do not rename the subpackage files. Only the provisioning file can be renamed, and the renaming of the provisioning file, if desired, should be done at this step before the router is rebooted.

Step 2 Configure the router to boot using the provisioning file.

The sequence below provides an example that would boot the router using the provisioning file named packages.conf that was stored with the other subpackages in the bootflash: file system:

```

Router(config)# no boot system
Router(config)# config-register 0x2102
Router(config)# boot system flash bootflash:packages.conf
Router(config)# exit
*May 11 01:31:04.815: %SYS-5-CONFIG_I: Configured from console by con
Router# copy running-config startup-config
Building configuration... [OK]
Router# reload

```

Extracting the SubPackages and the Provisioning File: Example 1

The following example shows how to extract the individual subpackages and the provisioning file from a consolidated package that has already been placed in the directory where you want to store the individual subpackages and the provisioning file. We recommend that you extract the sub packages to an empty directory to simplify the management of these files.

Output of the directory before and after the extraction is given to confirm the files were extracted.

```

Router# dir bootflash:
Directory of bootflash:/

Extracting the SubPackages, Configuring the Router to Boot Using the Provisioning File, and Reloading the Router: Example 2

In the following example, the provisioning file and the individual subpackages are extracted from a consolidated package. The router is then configured to boot using the provisioning file. This example also shows the config-register being set and the running configuration being saved because these tasks must be performed for the router to reload properly. The router is then reloaded to complete the process.

```

Router(config)# no boot system
Router(config)# config-register 0x2102
Router(config)# boot system flash bootflash:packages.conf
Router(config)# exit
```

```
Router# copy run start
Router# reload
```

Copying a Set of Individual SubPackage Files, and Booting Using a Provisioning File

To copy a set of individual subpackage files and to boot using a provisioning file, perform the following steps:

Note Although this upgrade method works, it is less efficient than other methods of upgrading the router's software.

Step 1 Copy each individual subpackage and the provisioning file into the bootflash: directory using the **copy** command. Note that this method of running the router will only work if all the individual subpackages for a release and a provisioning file are downloaded onto the router and stored in the bootflash: directory. No other file directories should be used for booting the router using individual subpackages.

The files can also be moved on the router physically using a USB Flash drive.

Step 2 Configure the router to boot using the provisioning file.

The sequence below provides an example that describes how to boot the router using the provisioning file named `packages.conf` that was stored with the other subpackages in the bootflash: file system. The router runs using individual subpackages once the reload is complete.

```
Router(config)# no boot system
Router(config)# config-register 0x2102
Router(config)# boot system flash bootflash:packages.conf
Router(config)# exit
*May 11 01:31:04.815: %SYS-5-CONFIG_I: Configured from console by con
Router# write memory Building configuration... [OK]
Router# reload
```

Installing an Optional SubPackage

To run the router using an optional subpackage, perform the following steps for each Supervisor in the chassis:

- Step 1** Verify that the Supervisor is running in individual subpackage mode and was booted from a provisioning file.
- Step 2** Verify that the version of the optional subpackage that you want to install is the same version as the software running on the active Supervisor.
- Step 3** Download the optional subpackage that you want to install. Optional subpackages must be downloaded independently from consolidated packages for the Cisco cBR Series Routers.
- Step 4** On each Supervisor, copy the optional subpackage to the directory where any other individual subpackages and the provisioning file is located.
- Step 5** Run the **request platform software package install rp file** command, as shown in the following example.

Note Do not use the optional slot or bay keywords for the initial installation.

```
Router# request platform software package install rp 0 file
bootflash: cbrsup-universal*.bin

Upgrading Individual SubPackages

Patch Installation

Individual subpackages can be upgraded in subpackage mode. Patch releases consist of one or more subpackages. After a patch has been installed, a message is displayed indicating whether the entire chassis or only the line cards must be rebooted for the updates to take effect.

Installing a Patch that Affects Both Line Card and Supervisor Card

- Step 1** The Cisco cBR router must be in subpackage mode.
 - Step 2** Copy the patch file to the same location as the active subpackages on both the active and standby supervisor cards.
 - Step 3** Install the patch using the **request platform software package install rp slot file patch file** command on the standby card.
 - Step 4** Install the patch using the **request platform software package install rp slot file patch file** command on the active card.
 - Step 5** Reload the chassis.
-

Installing a Patch that Affects Only Line Cards

- Step 1** The Cisco cBR router must be in subpackage mode.
 - Step 2** Copy the patch file to the same location as the active subpackages on both the active and standby supervisor cards.
 - Step 3** Install the patch using the **request platform software package install rp slot file patch file** command on the standby card.
 - Step 4** Install the patch using the **request platform software package install rp slot file patch file** command on the active card.
 - Step 5** Reload the line cards.
-

Installing a Patch that Affects Only Supervisor Cards

- Step 1** The Cisco cBR router must be in subpackage mode.
- Step 2** Copy the patch file to the same location as the active subpackages on both the active and standby supervisor cards.
- Step 3** Install the patch using the **request platform software package install rp slot file patch file** command on the standby card.
- Step 4** Switch over to the standby card. This will make it the active card.

- Step 5** Install the patch using the **request platform software package install rp slot file patch file** command on the standby card.

Upgrading a Line Card SubPackage

Use the **request platform software package install node file filename** command to upgrade a line card subpackage.

```
Router# request platform software package install node file
bootflash:/subpkg/cbr_patch.5.0.tar

Feature Information for Consolidated Packages and SubPackages Management

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 9: Feature Information for Consolidated Packages and SubPackages Management

Feature Name	Releases	Feature Information
Consolidated Packages and SubPackages Management	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 6

G.8275.2 Telecom Profile

This document provides information on the support for G.8275.2 telecom profile and how to configure Cisco cBR series routers to avail the support.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

G.8275.2 Telecom Profile

Information About G.8275.2 Telecom Profile

Precision Time Protocol (PTP) is a protocol for distributing precise time and frequency over packet networks. PTP is defined in the IEEE Standard 1588. It defines an exchange of timed messages.

PTP allows for separate profiles to be defined in order to adapt PTP for use in different scenarios. A profile is a specific selection of PTP configuration options that are selected to meet the requirements of a particular application.

Effective Cisco IOS XE Fuji 16.8.1, Cisco cBR Converged Broadband routers support the ITU- T G.8275.2 telecom profile (PTP telecom profile for Phase/Time-of-day synchronization with partial timing support from the network).

The G.8275.2 is a PTP profile for use in telecom networks where phase or time-of-day synchronization is required. It differs from G.8275.1 in that it is not required that each device in the network participates in the PTP protocol. Also, G.8275.2 uses PTP over IPv4 and IPv6 in unicast mode.

Why G.8275.2 Telecom Profile?

The G.8275.2 profile is based on the partial timing support from the network. Hence nodes using G.8275.2 are not required to be directly connected.

The G.8275.2 profile is used in mobile cellular systems that require accurate synchronization of time and phase. For example, the fourth generation (4G) of mobile telecommunications technology.

PTP Clocks

Two types of ordinary clocks are used in this profile:

Ordinary Clocks (OCs)

- **Telecom Grandmaster (T-GM)**—A telecom grandmaster provides timing for other devices in the network, and is usually connected to a primary reference time source, such as a GNSS receiver. It does not synchronize its local clock to other network elements. Considerations for a T-GM:
 - Only one PTP port can be configured as a primary port.
 - One T-GM primary port can have multiple subordinates associated with it.
 - The T-GM OC primary port is a fixed port; that is, it always acts as a primary clock and its role does not change by negotiating with its peer.
- **Partial-Support Telecom Time Subordinate Clocks (T-TSC-P and T-TSC-A)**—A subordinate clock synchronizes its local clock to another PTP clock (GM, T-GM or T-BC), and does not provide synchronization through PTP to any other device. Considerations for a T-TSC-P:
 - An ordinary clock with single subordinate port can be configured.
 - Only one peer clock address can be configured as clock source.

Note

- Ordinary clocks (OC) always have only one PTP port.
 - In G.8275.2 (02/2016), PTP transparent clocks are not permitted.
-

PTP Domain

A PTP domain is a logical grouping of clocks that communicate with each other using the PTP protocol.

A single computer network can have multiple PTP domains operating separately, for example, one set of clocks synchronized to one time scale and another set of clocks synchronized to another time scale. PTP can run over either Ethernet or IP, so a domain can correspond to a local area network or it can extend across a wide area network.

The allowed domain numbers of PTP domains within a G.8275.2 network are in the range of 44 and 63 (both inclusive). The default domain number is 44.

PTP Messages and Transport

The following PTP transport parameters are defined:

- In Cisco IOS XE Fuji 16.8.1, PTP over IPv4 in unicast mode must be used.
- One-step clock mode must be used.
- The G.8275.2 profile supports unicast message negotiation.

PTP Ports

A port can be configured to perform either fixed primary or subordinate role or can be configured to change its role dynamically. If no role is assigned to a port, it can dynamically assume a primary, passive, or subordinate role based on the BMCA.

In G.8275.2, PTP ports are not tied to any specific physical interfaces, but are tied to a loopback (virtual) interface. Traffic from a PTP port is routed through any physical interface based on the routing decision.

For a dynamic port, only one clock source can be configured.

Alternate BPCA

The BPCA (Best Primary Clock Algorithm, which is also known as Best Master Clock Algorithm (BMCA [RFC 7273])) implementation in G.8275.2 is different from that in the default PTP profile. The G.8275.2 implementation specifies an alternate best primary clock algorithm (ABPCA), which is used by each device to select a clock to synchronize to, and to decide the port states of its local ports.

The following considerations apply to the G.8275.2 implementation of the BPCA:

- **PrimaryOnly**—A per port attribute, PrimaryOnly defines the state of the port. If this attribute is true, the port is never placed in the subordinate state.
- **Priority 1**—Priority 1 is always static in this profile and is set to 128. Priority 1 is not used in BPCA.
- **Priority 2**—Priority 2 is a configurable value and its range is from 0 to 255.
- **Local Priority**—Local priority is configured locally on clock ports to set the priority on nominated clocks. The default value is 128 and valid range is from 1 to 255.

Benefits

With upcoming technologies like LTE-TDD, LTE-A CoMP, LTE MBSFN and Location-based services, eNodeBs (base station devices) are required to be accurately synchronized in phase and time. Having GNSS systems at each node is not only expensive, but also introduces vulnerabilities. The G.8275.2 profile meets the synchronization requirements of these new technologies.

Restrictions for Using the G.8275.2 Profile

- In G.8275.2, PTP can be used in both hybrid mode and non-hybrid mode. In hybrid mode, PTP is used to provide phase and time-of-day throughout the network synchronization along with PHY layer frequency support (SyncE). In non hybrid mode, PTP is used without PHY layer frequency support (SyncE).

- A G.8275.2 PTP clock can have redundant clock sources configured (through multiple PTP ports). However, at any given time, a G.8275.2 PTP clock synchronizes to only one clock source, which is selected by BMCA.
- The G.8275.2 does not provide any recommendations for performance analysis and network limits for the clocks.

How to Configure the G.8275.2 Profile

Creating an Ordinary Subordinate (T-TSC-P)

Cisco cBR-8 supports PTP ordinary clock subordinate mode with G8275.2 profile. In this mode, PTP ports are either on the Supervisor PIC cards or on the 10GE Ethernet ports on the DPIC cards.

To create an ordinary subordinate, run the following steps:

```
ptp clock Ordinary domain 44
    clock-port slave-port slave profile G.8275.2
    transport ipv4 unicast interface lo 0 negotiation
    clock source 10.1.1.1
```

Configuring Dual PTP Primary Clocks

Dual PTP primary clocks must connect to the same grandmaster. Both PTP primary clocks and the grandmaster must be set to Priority 2 configuration. You must set the minimum Priority 2 value for the grandmaster to keep the highest priority. The PTP primary clocks connected to the grandmaster must have a Priority 2 value.

The following example shows a grandmaster in the Dual PTP primary clocks configuration:

```
Router# show run | se ptp
license feature ptp
ptp clock ordinary domain 44
  priority2 2
  clock-port master-to-two903 master profile g8275.2
  sync interval -5
  sync one-step
  transport ipv4 unicast interface Lo1588 negotiation
```

Configuring the G.8275.2 Profiles

To configure G.8275.2 Profiles, run the following steps:

```
Router# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ptp clock ordinary domain 55
Router(config-ptp-clk)#servo tracking-type R-DTI
Router(config-ptp-clk)#clock-port slave-port slave profile g8275.2
Router(config-ptp-port)# delay-req interval -4
Router(config-ptp-port)# sync interval -4
Router(config-ptp-port)# sync one-step
Router(config-ptp-port)# transport ipv6 unicast interface Lo1588 negotiation
Router(config-ptp-port)# clock source ipv6 2001:158:158:158::158
```

Configuring an IPv4 Single Clock Source

To configure IPv4 single clock source, run the following steps:

```
ptp clock ordinary domain <domain id>
servo tracking-type R-DTI
clock-port <name> slave profile g8275.2
delay-req interval < Interval>
sync interval < Interval>
sync one-step
transport ipv4 unicast interface <loopback name> negotiation
clock source <clock ip>
```

Configuring an IPv6 Single Clock Source

To configure IPv6 single clock source, run the following steps:

```
ptp clock ordinary domain <domain id>
servo tracking-type R-DTI
clock-port <name> slave profile g8275.2
delay-req interval < Interval>
sync interval < Interval>
sync one-step
transport ipv6 unicast interface <loopback name> negotiation
clock source ipv6 <clock ip>
```

Verifying the G.8275.2 Profile

To verify the G.8275.2 profile, run the following command:

```
Router# show run | se ptp
ptp clock ordinary domain 55
servo tracking-type R-DTI
clock-port slave-port slave profile g8275.2
delay-req interval -4
sync interval -4
sync one-step
transport ipv6 unicast interface Lo1588
negotiation
clock source ipv6 2001:158:158:158::158
```

Configuration Examples

The following example shows IPv4 single clock source configuration:

```
ptp clock ordinary domain 55
servo tracking-type R-DTI
clock-port slave-from-903 slave profile g8275.2
delay-req interval -4
sync interval -5
sync one-step
transport ipv4 unicast interface Lo1588 negotiation
clock source 10.90.3.93
```

The following example shows IPv6 single clock source configuration:

```
ptp clock ordinary domain 55 profile g8275.2
servo tracking-type R-DTI
clock-port slave-from-903 slave profile g8275.2
```

```

delay-req interval -4
sync interval -5
sync one-step
transport ipv6 unicast interface Lo1588 negotiation
clock source ipv6 2001:10:90:3::93

```

Feature Information for G.8275.2 Profile

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 10: Feature Information for G.8275.2 Profile

Feature Name	Releases	Feature Information
G.8275.2 Profile	Cisco IOS XE Everest 16.8.1	This feature was introduced in Cisco IOS XE Everest 16.8.1 on Cisco cBR Series Converged Broadband Router.

Cisco IOS-XE In-Service Software Upgrade Process

Cisco cBR-8 Routers support the In-Service Software Upgrades (ISSU) for redundant platforms.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Contents

Information about In-Service Software Upgrade

Cisco cBR-8 Routers support the In-Service Software Upgrades (ISSU) for redundant platforms. The ISSU process allows software to be updated or otherwise modified while packet forwarding continues with the benefit of LCHA.

For the Cisco cBR Series Routers, ISSU-compatibility depends on the software subpackage being upgraded and the hardware configuration.

The specific procedures in this document represent supported and tested installation sequences. The Cisco IOS-XE system software allows other installation sequences for special purposes under the guidance of Cisco customer support representatives, but the steps in this document should be followed otherwise. These steps should be followed completely, as the Cisco cBR Series Routers are designed to run one version of Cisco IOS-XE on an SUP, and running subpackages from different versions of Cisco IOS-XE can cause unexpected router behavior.

How to Configure In-Service Software Upgrade

This section describes the configuration of the ISSU feature:

Configuring Subpackage Upgrade

Subpackages Upgrade

Subpackage upgrade allows a subset of the running software to be upgraded. It is intended for patching small and targeted fix instead of full image upgrade. Subpackage upgrade supports both single and dual SUP setup.

Single SUP Subpackages Upgrade

Before you begin

Be sure to complete the following prerequisites before running the ISSU process:

- Config register autoboot enabled.
- Target patch copied to active SUP in the same directory of the packages.conf file system is booted up with.
- If needed copy patch info file to SUP.
- Enough bootflash disk space on SUP.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	request platform software package install rp <i>rp-slot</i> file bootflash: Example: Router# request platform software package install rp 1 file bootflash:cbrsup-universalk9.03.17.00.S.156-1.S-std.SPA.bin	Upgrades the cBR-8 router with one SUP using subpackages ISSU procedure.

Dual SUPs Subpackages Upgrade

Before you begin

Be sure to complete the following prerequisites before running the ISSU process:

- Standby SUP must be in hot standby.
- Config register autoboot enabled.
- Both SUP in sub-package mode, running same base image and patches from same path.

- Target patch copied to active SUP in the same directory of the packages.conf file system is booted up with.
- If needed copy patch info file to both SUPs.
- Enough bootflash disk space on both SUPs.

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	request platform software package install node file bootflash: Example: <pre>Router# request platform software package install node file bootflash:cbrsup-universalk9.03.17.00.S.156-1.S-std.SPA.bin</pre>	Upgrades the cBR-8 router with dual SUPs using subpackages ISSU procedure.

Linecard Only In-Service Software Upgrade

If the upgrade fails or you manually cancel the upgrade at linecard upgrade stage, user can initiate linecard only upgrade.

Use **request platform software package install node linecard-only** command to upgrade only the linecard to the same version as the one in the current active SUP, the customer can choose to upgrade one linecard or all the linecards in the chassis.

This command can be used together with **request platform software package install node file *file-path* noreload linecard** command to upgrade SUP first, and then upgrade linecard.

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	request platform software package install node linecard-only Example: <pre>Router# request platform software package install node linecard-only all</pre>	Upgrade all the linecards to the same version as the one in the current active SUP.

ISSU Upgrade Across Major Releases

Starting from Cisco IOS XE Fuji 16.7.1 release, ISSU can upgrade cbr-8 between major releases.

Step 1 Copy the base image to active and standby SUPs. Copy the ISSU target image to active SUP.

```
copy <location>/<base_image> <location_active_sup>
copy <location>/<base_image> <location_standby_sup>
copy <location>/<target_image> <location_active_sup>
```

Step 2 Expand base image to both SUPs at the same folder.

```
request platform software package expand file <location_active_sup>/<base_image>
request platform software package expand file <location_standby_sup>/<base_image>
```

Step 3 Config register for auto boot (eg) config-reg 0x2102.

```
config-register 0x2102
boot system <location_active_sup>/packages.conf
```

Step 4 Save then reload router via subpackage mode.

```
reload
```

Step 5 After boot up, verify base image loaded using **show version running** and check more.

Step 6 Copy the target image to active SUP in the same location as before.

```
copy <location>/<target_image> <location_active_sup>
```

Step 7 Using Request command to do ISSU.

```
request platform software package install node file <location_active_sup>/<target_image>
```

Additional References

The following sections provide references related to the ISSU feature.

Technical Assistance

Description	Link
The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Feature Information for In-Service Software Upgrade

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 12: Feature Information for ISSU

Feature Name	Releases	Feature Information
ISSU	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the cisco cBR Series Converged Broadband Routers.

CHAPTER 8

Supervisor Redundancy

The Supervisor Redundancy feature reduces unplanned downtime. It enables a quicker switchover between active and standby Supervisors when a fatal error occurs on the active Supervisor. When you configure Supervisor Redundancy, the standby Supervisor is synchronized with the active Supervisor. If a fatal error occurs on the active Supervisor, the system immediately switches to the standby Supervisor.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Prerequisites for Supervisor Redundancy

- Two Supervisors (that is, two Supervisor Cards and two Supervisor PICs) must be installed in the Cisco cBR chassis.
- Both Supervisors must be running identical software releases. If there is release mismatch, when inserting the standby Supervisor, either the standby Supervisor or the active Supervisor may be impacted, even reloaded. So before inserting the new standby Supervisor, make sure it will boot with the identical software release as the active Supervisor.

Information About Supervisor Redundancy

The Supervisor redundancy feature enables the Cisco cBR router to use two Supervisors in a redundant configuration, so that if the active Supervisor fails or becomes inactive, the system automatically performs a switchover, where the standby Supervisor takes over and assumes full responsibility for systems operations.

The Supervisor redundancy feature does not require a full reboot of the system to perform a switchover. When the system boots up, the standby Supervisor performs full initialization, which includes self initialization,

running configuration synchronization from the active Supervisor, and SSO feature data synchronization from the active Supervisor, then it enters into hot standby state and monitors the active Supervisor. If the standby Supervisor detects a failure in the active Supervisor, it can quickly assume the active responsibility for systems operations.

Each Supervisor contains all the resources required to operate the router, such as bootflash memory, hard disks, Ethernet ports, and console port. In the default operation, the standby Supervisor also synchronizes the major systems files, such as the running configuration file, so that during a switchover, the standby Supervisor can duplicate the active Supervisor's configuration.

You can use Cisco IOS CLI commands to access the standby Supervisor resources, such as the bootflash and hard disk. For example, you can use the **dir** command to list the contents of a device, or use the **copy** command to transfer files between the active and standby Supervisor.

Switchover Procedure

A switchover occurs when the standby Supervisor takes over responsibilities from the active Supervisor. The switchover can occur automatically if the standby Supervisor has determined that the active Supervisor has failed, or an operator can initiate a manual switchover whenever desired.

A switchover triggers the following events:

1. If this is a manual switchover, the active Supervisor verifies that the standby Supervisor is present and has entered into SSO. If so, it instructs the standby Supervisor to begin switchover procedures, and the active Supervisor either attempts to reload its configured Cisco IOS software image or enters ROM monitor mode, depending on the setting of its configuration register.
2. The standby Supervisor assumes responsibility as the active Supervisor and brings the Cisco cBR chassis into active state, and continues the service as active Supervisor.
3. The new active Supervisor begins normal systems operations, including passing traffic.

Note The Supervisor does not begin functioning as a standby Supervisor until it is booted up with a proper Cisco IOS software.

Is Supervisor Switchover Failing?

The usual phenomenon for a Supervisor switchover to be affected is when the active Supervisor has these issues:

- Supervisor hangs
- Login to Supervisor console or Telnet to chassis fails
- Interface cards unable to connect to active Supervisor, hence crashing
- Cable modems drop offline
- Chassis reload required
- Reset of active Supervisor required to restore service

Note In case there is hardware issue with the Supervisor, do not reinsert the faulty Supervisor in the chassis. Inserting a faulty Supervisor (although a standby Supervisor) may cause the interface card to switch to the faulty Supervisor causing the interface card to crash and cable modems to go offline.

Using Redundant File Systems

Both the active and standby Supervisors have active file systems that can be accessed to store and transfer files. The table below lists the available file systems, the filenames that you can use with CLI commands to access the file systems, and a short description of each.

File System	File Name for CLI Commands	Description
<ul style="list-style-type: none"> • Bootflash • Flash • Hard disk • USB • Standby bootflash • Standby hard disk • Standby USB 	<ul style="list-style-type: none"> • bootflash: • flash: • harddisk: • usb0: • usb1: • stby-bootflash: • stby-harddisk: • stby-usb0: • stby-usb1: 	Stores image, crash file, core files, saved configuration files, and various user files.
<ul style="list-style-type: none"> • System • Temporary system • Null • Tar • Syslog • CNS • RCSF 	<ul style="list-style-type: none"> • system: • tmpsys: • null: • tar: • syslog: • cns: • revrcsf: 	Stores the running configuration and other system files.
<ul style="list-style-type: none"> • NVRAM • Standby NVRAM • Standby RCSF 	<ul style="list-style-type: none"> • nvram: • stby-nvram: • stby-rcsf: 	Typically stores the system default configuration file and startup configuration file.

File System	File Name for CLI Commands	Description
<ul style="list-style-type: none"> • TFTP • RCP • PRAM • FTP • HTTP • SCP • HTTPS 	<ul style="list-style-type: none"> • tftp: • rcp: • pram: • ftp: • http: • scp: • https: 	Protocols used to transfer files to and from remote devices.

You can use the privileged EXEC commands **dir**, **del**, and **copy** to manage the contents of the file systems. You can also use the commands **mkdir** and **rmdir** to create and remove directories on bootflash or hard disks.

Following is a sample output of the **show file systems** command on the Cisco cBRrouter:

```
Router# show file systems
```

```
File Systems:
```

```
Size (b)      Free (b)      Type  Flags  Prefixes

-            -            -    opaque rw    revrcsf:
```

Console Port Usage After Supervisor Switchover

When an active Supervisor fails, and the standby Supervisor becomes the active Supervisor, you must use the console port on the new active Supervisor to give CLI commands and display statistics for the router. The standby Supervisor console is disabled by default and cannot be used to run any CLI commands. Following is an sample output of the standby Supervisor console:

```
Router-stby>  
Standby console disabled  
Router-stby>
```

To access the console, move the PC or terminal's serial cable to the console port on the other Supervisor, which is now acting as the active Supervisor.

Benefits

- The Supervisor is not a single point of hardware failure. If a permanent hardware failure in the active Supervisor occurs, the standby Supervisor recovers the system, increasing the level of network service and reliability.
- The standby Supervisor can become the active Supervisor without the manual intervention of a system operator. This reduces the recovery time and the need for an instant response from the network administrators.
- The active Supervisor continues to dynamically synchronize the changed configuration and feature data with the standby Supervisor after the system reaches SSO. Therefore, the standby Supervisor always operates as a hot standby and ready to take over.

How to Configure Supervisor Redundancy

The Supervisor redundancy feature is automatically enabled when two Supervisor are installed in the Cisco cBR chassis. The active Supervisor automatically synchronizes the running configuration file with the standby Supervisor during the bootup of standby Supervisor.

Note The Cisco cBR router supports only the SSO mode for Supervisor redundancy. The default redundancy mode is SSO and this mode does not need any new configurations.

This section contains the following:

Forcing Switchover

To manually force a switchover, so that the standby Supervisor becomes active, use the **redundancy force-switchover** command in privileged EXEC mode on the active Supervisor. Manually forcing a switchover is useful in the following situations:

- You need to remove, replace, or upgrade the currently active Supervisor.
- A previous switchover has activated the standby Supervisor and you now want to restore the previously active Supervisor.

Tip Simply removing the active Supervisor also triggers a switchover, but using the **redundancy force-switchover** command does not generate a hardware alarm.

Before you begin

Ensure that the standby Supervisor is in the SSO state using the **show redundancy** command. For more information, see [Verifying Supervisor Redundancy](#), on page 131.

Step 1 Set the configuration register as 0x02 and the load the appropriate image on both the Supervisors

Example:

```
Router# configure terminal
Router(config)# config-register 0x02
Router(config)# boot system bootflash:cbrsup-universalk9.2015-03-08_01.38_XXXXX.SSA.bin
```

Note Do not perform this step if you want to set the previous active Supervisor to stay in ROM monitor mode or manually boot it up after the switchover.

Step 2 Use the **redundancy force-switchover** command to force the switchover.

Example:

```
Router# redundancy force-switchover

Proceed with switchover to standby RP? [confirm]
Manual Swact = enabled

Jan 1 19:23:22.483 R0/0: %PMAN-5-EXITACTION: Process manager is exiting: process exit with reload
fru code

Initializing Hardware ...

System Bootstrap, Version 12.2(20141120:061458) [153], DEVELOPMENT SOFTWARE

```

The standby Supervisor becomes the active Supervisor.

Step 3 (Optional) If you have not performed [Step 1, on page 127](#), the previous active Supervisor is put into the ROM monitor mode after the switchover. To enable the previous active Supervisor to become the new standby Supervisor, manually boot up the new standby Supervisor to enter into SSO mode.

Changing the System Boot Behavior

This section describes how to change the Cisco IOS software configuration register for modifying the system behavior when powering up or rebooting the system. The software configuration register is a 16 bit register in NVRAM that controls the following boot functions:

- Specifies the source of the Cisco IOS software image to be loaded
- Specifies whether the Cisco IOS software must ignore the contents of the saved configuration file in NVRAM memory
- Enables or disables the use of the Break function

Use the following procedure to change the software configuration register settings:

Step 1

Enter global configuration mode and use the **config-register** command to set the contents of the software configuration register to a new value.

Specify the new value as a 16 bit hexadecimal bitmask by using the values provided in the following table.

Table 14: Definition of Bits in the Software Configuration Register

Bit No.	Hex Value	Meaning/Function
00 to 03	0x0000 to 0x000F	Defines the source of the default Cisco IOS software image required to run the router: <ul style="list-style-type: none"> • 00—When powering up, the system remains at the ROM monitor prompt (rommon), awaiting a user command to boot the system manually by the rommon boot command. • 01—When powering up, the system automatically boots the first system image found in the flash memory's single in-line memory module (SIMM) on the Supervisor. • 02 to 0F—When powering up, the system automatically boots from a default Cisco IOS software image stored on a TFTP server in the network. For this setting, configure and enable the Network Management Ethernet port on the Supervisor. The port must be operational. This setting also enables boot system commands which can override the default filename.
06	0x0040	Causes system software to ignore the contents of the NVRAM configuration file.
07	0x0080	Enables the original equipment manufacturer (OEM) bit.
08	0x0100	Disables the Break function after 30 seconds.
09	0x0200	Not used.
10	0x0400	Specifies that broadcast packets are based on the 0.0.0.0 IP address.
11 and 12	0x0800 to 0x1000	Defines the console baud rate (the default value is 9600 baud).
13	0x2000	Boots an image from the boot flash memory.
14	0x4000	Specifies that the broadcast packets must use the subnet broadcast address.
15	0x8000	Enables diagnostic messages and ignores the contents of the NVRAM configuration file.

For example, to configure the router to boot to the ROM monitor prompt, set the configuration register to **0x2100** with the following commands:

Example:

```
Router# config t
Router(config)# config-register 0x2100
Router(config)#
```

Tip

The typical bitmask for normal use is 0x2102. It specifies that the router must load the Cisco IOS software from the flash memory and boot to the Cisco IOS CLI prompt. The Break key is enabled only for 30 seconds. Hence, if required, you can break to the ROM monitor prompt.

Step 2 Exit the global configuration mode.

Example:

```
Router(config)# exit
Router#
```

Step 3 View the new software configuration register setting using the **show version** command.

The last line shows the settings of the configuration register:

Example:

```
Router# show version
Cisco IOS XE Software, Version 2015-03-04_00.38_xxxxx
Cisco IOS Software, IOS-XE Software (X86_64_LINUX_IOSD-UNIVERSALK9-M), Experimental \
Version 15.5(20150302:044048) [v155_2_s_xe315_throttle-xxxxx-XE315_0301 121]

```

```
cisco cBR1013 (CBR) processor (revision CBR) with 3647635K/6147K bytes of memory.
Processor board ID CSJ13152101
16 Gigabit Ethernet interfaces
32768K bytes of non-volatile configuration memory.
50331648K bytes of physical memory.
7739391K bytes of eUSB flash at bootflash:.
```

```
97620247K bytes of SATA hard disk at harddisk:.
979258K bytes of USB flash at usb1:.
```

```
Configuration register is 0x2
```

When you modify the configuration register, the **show version** command shows both the current value of the register and the value that will be used during the next reboot or reload.

Step 4 Perform one of the following to save the new software configuration register settings in the configuration file:

- Use the **copy running-config startup-config** command.
- Use the **write** command.

Example:

```
Router# copy running-config startup-config
```

```
Router# write
Building configuration...
[OK]
```

Step 5 The changes to the software configuration register will take effect the next time the router is rebooted or restarted. To manually reboot the router, use the **reload** command:

Example:

```
Router# reload
System configuration has been modified. Save? [yes/no]: yes
Proceed with reload? [confirm]
```

Saving a Configuration File to the Bootflash or Hard Disk

This section describes how to copy a configuration file to a bootflash or hard disk and configure the Cisco cBR router.

Step 1 Copy the configuration file to the bootflash or hard disks in both Supervisors.

Example:

```
Router# copy running-config bootflash:cbr8-config
Router# copy running-config stby-bootflash:cbr8-config
Router# copy running-config harddisk:cbr8-config
Router# copy running-config stby-harddisk:cbr8-config
```

Step 2 (Optional) If the configuration file is currently on a TFTP server, copy the file from the TFTP server to the bootflash or hard disk in each Supervisor.

Example:

```
Router# copy tftp://192.168.100.10/router-config bootflash:cbr8-config
Router# copy tftp://192.168.100.10/router-config stby-bootflash:cbr8-config
Router# copy tftp://192.168.100.10/router-config harddisk:cbr8-config
Router# copy tftp://192.168.100.10/router-config stby-harddisk:cbr8-config
```

Verifying the Supervisor Redundancy Configuration

This section contains the following topics:

Verifying Supervisor Redundancy

Step 1 View the startup configuration and verify whether the lines for configuring redundancy appear:

Example:

```
Router# show startup-config
```

```
...
redundancy
mode sso
...
```

Step 2 View the current Supervisor redundancy state by running the **show redundancy** command. The active Supervisor is typically shown in slot 4 (SUP0).

```
Router# show redundancy
```

```
Redundant System Information :
-----
Available system uptime = 28 minutes
Switchovers system experienced = 0
Standby failures = 0
Last switchover reason = none

Hardware Mode = Duplex
Configured Redundancy Mode = sso
Operating Redundancy Mode = sso
Maintenance Mode = Disabled
Communications = Up

Current Processor Information :
-----
Active Location = slot 4
Current Software state = ACTIVE
Uptime in current state = 28 minutes
Image Version = Cisco IOS Software, IOS-XE Software (X86_64_LINUX_IOSD-UNIVERSALK9-M), Experimental
Version 15.5(20150302:044048) [v155_2_s_xe315_throttle-xxxxx-XE315_0301 121]
This software is an Engineering Special
Copyright (c) 1986-2015 by Cisco Systems, Inc.
Compiled Wed 04-Mar-15 00:21 by xxxxx
BOOT = bootflash:cbrsup-universalk9.2015-03-04_00.38_xxxxx.SSA.bin,12;
CONFIG_FILE = bootflash:startup_config1419513118
Configuration register = 0x2

Peer Processor Information :
-----
Standby Location = slot 5
Current Software state = STANDBY HOT
Uptime in current state = 24 minutes
Image Version = Cisco IOS Software, IOS-XE Software (X86_64_LINUX_IOSD-UNIVERSALK9-M), Experimental
Version 15.5(20150302:044048) [v155_2_s_xe315_throttle-xxxxx-XE315_0301 121]
This software is an Engineering Special
```

```

Copyright (c) 1986-2015 by Cisco Systems, Inc.
Compiled Wed 04-Mar-15 00:21 by xxxxx
BOOT = bootflash:cbrsup-universalk9.2015-03-04_00.38_xxxxx.SSA.bin,12;
CONFIG_FILE = bootflash:startup_config1419513118
Configuration register = 0x2

```

If a switchover occurs, the **show redundancy** command shows that the active Supervisor has changed slots, moving from slot 4 (SUP0) to slot 5 (SUP1). The output is similar to the one in the following example.

```
Router# show redundancy
```

```

Redundant System Information :
-----
Available system uptime = 39 minutes
Switchovers system experienced = 1
Standby failures = 0
Last switchover reason = user forced

Hardware Mode = Duplex
Configured Redundancy Mode = sso
Operating Redundancy Mode = sso
Maintenance Mode = Disabled
Communications = Up

Current Processor Information :
-----
Active Location = slot 5
Current Software state = ACTIVE
Uptime in current state = 10 minutes
Image Version = Cisco IOS Software, IOS-XE Software (X86_64_LINUX_IOSD-UNIVERSALK9-M), Experimental
  Version 15.5(20150302:044048) [v155_2_s_xe315_throttle-xxxxxx-XE315_0301 121]
This software is an Engineering Special
Copyright (c) 1986-2015 by Cisco Systems, Inc.

CONFIG_FILE = bootflash:startup_config1419513118
Configuration register = 0x2

```

If the standby Supervisor is not installed or is not operational, the **show redundancy** command gives an output similar to the following example:

```
Router# show redundancy
```

```

Redundant System Information :
-----
Available system uptime = 31 minutes
Switchovers system experienced = 1
Standby failures = 0
Last switchover reason = user forced

```

```

Hardware Mode = Simplex
Configured Redundancy Mode = sso
Operating Redundancy Mode = Non-redundant
Maintenance Mode = Disabled
Communications = Down Reason: Failure

Current Processor Information :
-----
Active Location = slot 5
Current Software state = ACTIVE
Uptime in current state = 2 minutes
Image Version = Cisco IOS Software, IOS-XE Software (X86_64_LINUX_IOSD-UNIVERSALK9-M), Experimental
Version 15.5(20150302:044048) [v155_2_s_xe315_throttle-xxxxx-XE315_0301 121]
This software is an Engineering Special
Copyright (c) 1986-2015 by Cisco Systems, Inc.
Compiled Wed 04-Mar-15 00:21 by xxxxx
BOOT = bootflash:cbrsup-universalk9.2015-03-04_00.38_xxxxx.SSA.bin,12;
CONFIG_FILE = bootflash:startup_config1419513118
Configuration register = 0x2

Peer (slot: 4) information is not available because it is in 'DISABLED' state

```

The **show redundancy** command shows details of the redundancy state, software state, system uptime, image version, boot, configuration file, and configuration register information.

After supervisor redundancy, the following messages are displayed, for example:

```

CLC 3/0: May 20 07:26:01.992: %CBR-4-RECONCL_CM_FINISH_CLC: Reconciliation (cdm->ios) for slot 3
finished: total 7, success 5, failed 2, ios-only 2, cdm-only 0, mismatch 0, offline 0,
in-transaction-reconl 0, in-transaction-recover 0.

```

Where:

total indicates the overall number of cable modems on each linecard before failover.

success indicates the number of modems, which are remained online during failover.

failed indicates the number of cable modems which have failed reconciliation check, and deleted from database.

ios-only indicates the number of cable modems which has data entry in linecard iosd only, and have been deleted from database.

cdm-only indicates the number of cable modems which has data entry in linecard cdman (us-scheduler) only, and have been deleted from database.

mismatch indicates the number of cable modems which with data mismatch in the modem instance or service-flows after failover. These modems have been deleted from database.

offline indicates the number of cable modems which are dropped offline during failover.

in-transaction-reconl indicates the number of cable modems that are deleted due to in dsx operations during failover.

in-transaction-recover indicates the number of cable modems during in dsx operations during failover.

Verifying Supervisor Switchover

Step 1 Verify the LEDs on the Supervisor Card.

When a Supervisor becomes active, the RP ACT and FP ACT LEDs on the Supervisor Card illuminate green to indicate that they have initialized and acting as the active Supervisor. The RP ACT and FP ACT on standby Supervisor Card are off. For more information, see [Monitoring the Supervisor in the Cisco cBR Chassis](#).

Step 2 Verify the Supervisor switchover by running the **show redundancy switchover history** command.

If the original Supervisor is in slot 4 (SUP0) and the standby Supervisor is in slot 5 (SUP1), the output is similar to the following sample:

Example:

```
Router# show redundancy switchover history
```

```
Index Previous Current Switchover Switchover
      active active  reason      time
-----
1     48     49     user forced 19:23:11 CST Sun Jan 1 2012
```

The value 48 indicates SUP0 and 49 indicates SUP1.

After supervisor redundancy, a messages is displayed, below is an example:

```
CLC 3/0: May 20 07:26:01.992: %CBR-4-RECONCL_CM_FINISH_CLC: Reconciliation (cdm->ios) for
slot 3 finished: total 7, success 5, failed 2, ios-only 2, cdm-only 0, mismatch 0, offline
0, in-transaction-reconl 0, in-transaction-recover 0.
```

Table 15: Message Description

Name	Description
total	Overall amount of cable modems on each linecard before failover.
success	Indicates the number of cable modems remain online during failover.
failed	Indicates the number of cable modems failed reconciliation check, and have been deleted from database.
ios-only	Indicates the number of cable modems which has data entry in linecard iosd only, and have been deleted from database.
cdm-only	Indicates the number of cable modems which has data entry in linecard cdman (us-scheduler) only, and have been deleted from database.
mismatch	Indicates the number of cable modems with data mismatch in the modem instance or service-flows after failover. These modems have been deleted from database.
offline	Indicates the number of cable modems dropped offline during failover.

Name	Description
in-transaction-reconl	Indicates the number of cable modems deleted due to in dsx operations during failover.
in-transaction-recove	Indicates the number of cable modems during in dsx operations during failover.

Configuration Example for Supervisor Redundancy

The following example shows the relevant portion of the Cisco IOS configuration file for the default configuration of the Supervisor Redundancy feature. Use this configuration for most of the applications:

```
Router# show running-config | sec redundancy

redundancy
 mode sso

Router#
```

Feature Information for Supervisor Redundancy

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 16: Feature Information for Supervisor Redundancy

Feature Name	Releases	Feature Information
Supervisor Redundancy	Cisco IOS XE Fuji 16.7.1	This feature was integrated on Cisco cBR Series Converged Broadband Routers.

CHAPTER 9

Line Card Redundancy

The line cards support high availability with redundancy schemes. Line card redundancy can help limit customer premises equipment (CPE) downtime by enabling robust automatic switchover and recovery in the event that there is a localized system failure.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Cisco cBR-8 Converged Broadband Router	<p>Cisco IOS-XE Release 16.5.1 and Later Releases</p> <p>Cisco cBR-8 Supervisor:</p> <ul style="list-style-type: none"> • PID—CBR-SUP-250G • PID—CBR-CCAP-SUP-160G • PID—CBR-CCAP-SUP-60G • PID—CBR-SUP-8X10G-PIC 	<p>Cisco IOS-XE Release 16.5.1 and Later Releases</p> <p>Cisco cBR-8 CCAP Line Cards:</p> <ul style="list-style-type: none"> • PID—CBR-LC-8D30-16U30 • PID—CBR-LC-8D31-16U30 • PID—CBR-RF-PIC • PID—CBR-RF-PROT-PIC • PID—CBR-CCAP-LC-40G • PID—CBR-CCAP-LC-40G-R <p>Cisco cBR-8 Downstream PHY Modules:</p> <ul style="list-style-type: none"> • PID—CBR-D30-DS-MOD • PID—CBR-D31-DS-MOD <p>Cisco cBR-8 Upstream PHY Modules:</p> <ul style="list-style-type: none"> • PID—CBR-D30-US-MOD • PID—CBR-D31-US-MOD

Prerequisites for Line Card Redundancy

- At least one RF Through PIC and its corresponding interface line card must be installed in the chassis to be configured as the primary card.
- An RF Protect PIC and its corresponding interface line card must be installed in the chassis to be configured as the secondary card.

Restrictions for Line Card Redundancy

- The line cards installed in slot 3 and 6 of the Cisco cBR-8 router cannot be configured as the secondary card.
- The RF Protect PIC can send RF signals only to the lower slots (with larger slot number). So, the slot number of the secondary card must be the smallest in the redundancy group.

Note We recommend that you install the RF Protect PIC in the uppermost slot (slot 0) of the chassis and configure it as the secondary card.

- The RF Through PIC can send RF signal only from upper slot to lower slot. So, do not install any RF blank PICs between the secondary card and primary cards.
- You cannot change any configuration on the primary or secondary card when the secondary card is active.
- You cannot remove the last primary card if there is a secondary card in the redundancy group. You must remove the secondary card and then remove the primary card.
- If the primary card is in the standby role, you must revert to the primary card before removing it from the redundancy group.

Information About Line Card Redundancy

Line card redundancy reduces the unplanned downtime. When you configure line card redundancy, a protect zone (redundancy group) is created on the router and the configurations on the primary cards are synchronized with the secondary card.

The following events can trigger a switchover from an active card to a standby card:

- Manual switchover using the **redundancy linecard-group switchover from slot slot** command.
- Line card reload using the **hw-module slot reload** command.
- Line card crash.
- Line card Online Insertion and Removal (OIR).

The secondary card reloads after the switchover. The router can be configured to automatically revert to the primary card when it becomes hot standby after an unplanned switchover triggered by the line card OIR or crash.

Following are the line card redundancy states:

- **Unavail**—The line card state is not available.
- **Init**—The line card did not boot up.
- **Active Cold**—The active card is downloading the configuration.
- **Active**—The active card is fully configured and working.
- **Stdb Cold**—The standby card configuration is synchronizing with the active card.
- **Stdb Warm**—(Only for the secondary card) The standby card is fully synchronized and ready for switchover. It is the stable state of a secondary standby card.
- **Stdb Hot**—The primary standby card is fully synchronized. It is the stable state of a primary standby card. The secondary standby card is chosen to switchover for a primary card, and will be active soon. It is a transient state when secondary card is becoming active.

N+1 Line Card Redundancy

The Cisco cBR-8 router supports N+1 redundancy scheme for line cards. A single RF Protect PIC can be configured as a secondary card for multiple RF Through PICs (primary cards). In this redundancy scheme, when the secondary card becomes the active card for a primary card, the redundancy scheme is changed to 1+1 redundancy.

The Cisco cBR-8 router supports a single protect zone or redundancy group (group 0).

How to Configure Line Card Redundancy

This section contains the following:

Configuring Line Card Manual Switchover

Before you begin

The line card must be in active role, and warm standby or hot standby state. Use the **show redundancy linecard all** command to verify the role and state of the card.

Restrictions

- You cannot perform a manual switchover when the standby Supervisor is booting up and not yet entered into SSO.
- You cannot auto revert the switchover triggered manually.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	redundancy linecard-group switchover from slot slot Example: Router# redundancy linecard-group switchover from slot 9	Manually switches over from the active line card.

Configuring N+1 Line Card Redundancy

Procedure

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Router> enable	
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	redundancy Example: Router(config)# redundancy	Enables redundancy and enters redundancy configuration mode.
Step 4	linecard-group group-id internal-switch Example: Router(config-red)# linecard-group 0 internal-switch	Configures the redundancy group and enters the line card redundancy configuration mode.
Step 5	description group-description Example: Router(config-red-lc)# description RedundancyGroup0	(Optional) Configures the redundancy group description.
Step 6	class 1:N Example: Router(config-red-lc)# class 1:N	Configures the N+1 redundancy class for the redundancy group.
Step 7	revertive seconds Example: Router(config-red-lc)# revertive 60	(Optional) Configures the auto revert time for the primary card, in seconds.
Step 8	member slot slot primary Example: Router(config-red-lc)# member slot 1 primary	Adds the line card as a primary card in the redundancy group. Note Repeat this step for each primary card to be added in the redundancy group.
Step 9	member slot slot secondary Example: Router(config-red-lc)# member slot 0 secondary	Adds the line card as a primary card in the redundancy group.
Step 10	end Example: Router(config-red-lc)# end	Returns to privileged EXEC mode.

Verifying the Line Card Redundancy Configuration

- **show redundancy linecard group all**—Displays the redundancy group information.

The following is a sample output of this command:

```
Router# show redundancy linecard group all

Group Identifier: 0
Revertive, Revert Timer: OFF (60000 sec)
Reserved Cardtype: 0xFFFFFFFF 4294967295
Group Redundancy Type: INTERNAL SWITCH
Group Redundancy Class: 1:N
Group Redundancy Configuration Type: LINECARD GROUP
Primary: Slot 6
Primary: Slot 7
Secondary: Slot 0
```

- **show redundancy linecard all**—Displays the role and state information for all line cards.

Following is a sample output of this command:

```
Router# show redundancy linecard all
```

Slot	Subslot	LC Group	My State	Peer State	Peer Slot	Peer Subslot	Role	Mode
9	-	0	Active	Stdby Cold	0	-	Active	Primary
8	-	0	Active	Stdby Warm	0	-	Active	Primary
7	-	0	Active	Stdby Warm	0	-	Active	Primary
6	-	0	Active	Stdby Cold	0	-	Active	Primary
3	-	0	Active	Stdby Cold	0	-	Active	Primary
2	-	0	Active	Stdby Cold	0	-	Active	Primary
1	-	0	Active	Stdby Cold	0	-	Active	Primary
0	-	0	-	-	Multiple	None	Standby	Secondary

Note The secondary card does not have a valid *My State* when it is in *Standby* role as it is the peer for *N* primary cards. The secondary card has *N* peer states. For example, it can be cold standby for some primary cards and warm standby for the other primary card.

Following is a sample output of the command when secondary card becomes active for a primary card, and the N+1 redundancy is changed to 1+1 redundancy:

```
Router# show redundancy linecard all
```

Slot	Subslot	LC Group	My State	Peer State	Peer Slot	Peer Subslot	Role	Mode
9	-	0	Stdby Hot	Active	0	-	Standby	Primary
8	-	0	Active	Unavail	0	-	Active	Primary
7	-	0	Active	Unavail	0	-	Active	Primary
6	-	0	Active	Unavail	0	-	Active	Primary
3	-	0	Active	Unavail	0	-	Active	Primary
2	-	0	Active	Unavail	0	-	Active	Primary
1	-	0	Active	Unavail	0	-	Active	Primary
0	-	0	Active	Stdby Hot	9	-	Active	Secondary

- **show redundancy linecard slot**—Displays the redundancy information for the line card.

Following is a sample output of the command:

```
Router# show redundancy linecard slot 9
```

```
LC Redundancy Is Configured:
LC Group Number: 0
LC Slot: 9 (idx=9)
LC Peer Slot: 0
LC Card Type: 0x4076 , 16502
LC Name: 9
LC Mode: Primary
LC Role: Active
LC My State: Active
LC Peer State: Stdby Warm
```

- **show redundancy linecard history**—Displays the state change history for all line cards.

Following is a sample output of the command:

```
Router# show redundancy linecard history
```

```
Jan 05 2012 12:24:27 20559 - st_mem(9): MY State Change, (Active Wait) -> (Active)
Jan 05 2012 12:24:27 20559 - st_mem(9): MY FSM execution, Active Wait:Init:State Ntfy
Jan 05 2012 12:24:27 20559 - st_mem(9): MY State Change, (Active LC Cfg Dnld) -> (Active
  Wait)
Jan 05 2012 12:24:27 20559 - st_mem(9): MY FSM execution, Active LC Cfg Dnld:Init:Cfg
  Dnld Done
Jan 05 2012 12:24:27 20559 - st_mem(9): MY State Change, (Active Cold) -> (Active LC

Jan 05 2012 12:21:39 3746 - st_mem(9): PEER FSM Execution , Init:Init:Reset
```

- **show lcha rfs**—Displays the internal RF switch PIC state information.

Following is a sample output of the command:

```
Router# show lcha rfs
```

```
Slot 0 =====
Type : Secondary PIC State: normal
Slot 1 =====
Type : Primary PIC State: normal
```

- **show lcha logging level**—Displays the cable modem line card logs.

Following is a sample output of the command:

```
Router# show lcha logging level noise
```

```
11:02:03.313 CST Tue Nov 18 2014 [error] [slot=3] [txn=229] Peer-Up Message [tag=1011]
  to slot 3 complete [36144 ms]; status=nak response

```

- When the secondary card is active, you can use the slot number of either the primary or secondary card in the **show** commands.

Following is a sample output of the **show interfaces** command after the primary card in slot 8 switches over to secondary card in slot 0:

```
Router# show interfaces c0/0/0
```

```
Cable0/0/0 is up, line protocol is up
  Hardware is CMTS MD interface, address is 0000.0000.031e (bia 0000.0000.031e)
  MTU 1500 bytes, BW 26000 Kbit/sec, DLY 1000 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation MCNS, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: weighted fair
  Output queue: 0/1000/64/0 (size/max total/threshold/drops)
    Conversations 0/0/256 (active/max active/max total)
    Reserved Conversations 0/0 (allocated/max allocated)
    Available Bandwidth 19500 kilobits/sec
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 13000 bits/sec, 17 packets/sec
    0 packets input, 0 bytes, 0 no buffer
    Received 0 broadcasts (0 multicasts)
    0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
    140520 packets output, 14052672 bytes, 0 underruns
    0 output errors, 0 collisions, 1 interface resets
    0 unknown protocol drops
    0 output buffer failures, 0 output buffers swapped out
```

```
Router# show interfaces c8/0/0
```

```
Cable0/0/0 is up, line protocol is up
  Hardware is CMTS MD interface, address is 0000.0000.031e (bia 0000.0000.031e)
  MTU 1500 bytes, BW 26000 Kbit/sec, DLY 1000 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation MCNS, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: weighted fair
  Output queue: 0/1000/64/0 (size/max total/threshold/drops)
    Conversations 0/0/256 (active/max active/max total)
    Reserved Conversations 0/0 (allocated/max allocated)
    Available Bandwidth 19500 kilobits/sec
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 14000 bits/sec, 18 packets/sec
    0 packets input, 0 bytes, 0 no buffer
    Received 0 broadcasts (0 multicasts)
    0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
    140616 packets output, 14062272 bytes, 0 underruns
    0 output errors, 0 collisions, 1 interface resets
    0 unknown protocol drops
    0 output buffer failures, 0 output buffers swapped out
```

- When the secondary card is active, the **show running-config** command displays the output for the secondary card.

Note The output of the **show running-config** command is empty for the primary card when the secondary card is active.

Following is a sample output of the **show running-config** command after the primary card in slot 8 switches over to secondary card in slot 0:

```
Router# show running-config | begin controller Upstream-Cable 0

controller Upstream-Cable 0/0/0
  us-channel 0 channel-width 1600000 1600000
  us-channel 0 docsis-mode atdma
  us-channel 0 minislots-size 4
  us-channel 0 modulation-profile 221
  no us-channel 0 shutdown
  us-channel 1 channel-width 1600000 1600000
  us-channel 1 docsis-mode atdma

Router# show running-config | begin controller Upstream-Cable 8
Router#
Router#
```

Feature Information for Line Card Redundancy

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 18: Feature Information for Line Card Redundancy

Feature Name	Releases	Feature Information
Line Card Redundancy	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

Finding Feature Information

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Hardware Compatibility Matrix for the Cisco cBR Series Routers

Note The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

Information About Downstream Interface Configuration

Overview

- Each downstream port requires port level configuration and channel level configuration. Port level configuration is optimized with a frequency profile that defines ranges of frequencies available on the port. Channel level configuration is optimized with a QAM profile and channel range configuration block that auto-increments frequency and duplicates annex, modulation, and interleaver.
- Each channel requires a set of parameters: frequency, annex, modulation, interleaver, and DOCSIS channel id.
- Configuration is done in 4 major blocks of configuration:
 - QAM Profile—Example: “cable downstream qam-profile 1”
 - Frequency Profile—Example: “cable downstream freq-profile 2”
 - Port/Controller—Example: “controller Integrated-Cable 3/0/0”
 - RF Channel block—Example: “rf-chan 0 31”

Downstream RF Port and Channel Management

The downstream RF port and channel management feature is responsible for the configuration and management of the downstream RF ports and channels. Each downstream RF channel can be provisioned either as a DOCSIS or traditional MPEG video QAM channel.

QAM Profile

A QAM profile describes the common downstream channel modulator settings, referred to as physical layer parameters. This includes QAM constellation, symbol rate, interleaver-depth, spectrum-inversion, and annex. The QAM profile is described by *CCAP DownPhyParams* object. Default QAM profiles are supported and customized for DOCSIS or MPEG Video, which are described as *DocsisPhyDefault* and *VideoPhyDefault* objects, respectively.

A maximum of 32 QAM profiles can be defined. There are four system-defined QAM profiles (0 to 3), which cannot be deleted or modified. You can define profiles 4 to 31.

The system defined profiles are:

- Profile 0 - default-annex-b-64-qam
 - interleaver-depth: I32-J4
 - symbol rate: 5057 kilo-symbol/second
 - spectrum-inversion: off
- Profile 1 - default-annex-b-256-qam
 - interleaver-depth: I32-J4
 - symbol rate: 5361 kilo-symbol/second
 - spectrum-inversion: off
- Profile 2 - default-annex-a-64-qam
 - interleaver-depth: I12-J17
 - symbol rate: 6952 kilo-symbol/second
 - spectrum-inversion: off
- Profile 3 - default-annex-a-256-qam
 - interleaver-depth: I12-J17
 - symbol rate: 6952 kilo-symbol/second
 - spectrum-inversion: off

Frequency Profile

A frequency profile defines the ranges of frequencies available on a port. A maximum of 16 frequency profiles can be defined. There are four system-defined frequency profiles (0 to 3), which cannot be deleted or modified. You can define profiles 4 to 15.

The system defined profiles are:

- Profile 0 - annex-b-low, Frequency range (Hz): 90000000 - 863999999
- Profile 1 - annex-b-high, Frequency range (Hz): 234000000 - 1002999999
- Profile 2 - annex-a-low, Frequency range (Hz): 94000000 - 867999999
- Profile 3 - annex-a-high, Frequency range (Hz): 267000000 - 1002999999

The frequency ranges are defined using lanes and blocks:

- Four lanes per port, each lane can support 216 MHz range.
- Four blocks per lane, each block can support 54 MHz range.
- Lanes and blocks may have overlapping frequency ranges.

How to Configure Downstream Interfaces

This section contains the following:

Configuring the Cisco CMTS Manually Using Configuration Mode

Connect a console terminal to the console port on the I/O controller. When asked if you want to enter the initial dialog, answer **no** to go into the normal operating mode of the router. After a few seconds the user EXEC prompt (**Router>**) appears.

Configuring the QAM Profile on the Downstream Channels

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable downstream qam-profile <i>Qam_Profile_ID</i> Example: Router(config)# cable downstream qam-profile 3	Defines or modifies a QAM profile.
Step 4	annex {A B C} Example: Router(config-qam-prof)# annex A	Defines the profile MPEG framing format. The default is Annex B.

	Command or Action	Purpose
Step 5	description <i>LINE</i> Example: Router(config-qam-prof)# description qam1	Name or description for this profile.
Step 6	interleaver-depth {I12-J17 I128-J1 I128-J2 I128-J3 I128-J4 I128-J5 I128-J6 I128-J7 I128-J8 I16-J8 I32-J4 I64-J2 I8-J16} Example: Router(config-qam-prof)# interleaver-depth I64-J2	Defines the interleaver depth. The default is I32 J4 for DOCSIS.
Step 7	modulation {256 64} Example: Router(config-qam-prof)# modulation 64	Defines the modulation. The default is 256QAM.
Step 8	spectrum-inversion {off on} Example: Router(config-qam-prof)# spectrum-inversion on	Enables or disables spectrum inversion. Default is off.
Step 9	symbol-rate <i>value</i> Example: Router(config-qam-prof)# symbol-rate 5057	Defines the symbol rate. Value is in kilo-symbol/sec.
Step 10	exit Example: Router(config-qam-prof)# exit	Exits from the QAM profile configuration mode.

Configuring the Frequency Profile on the Downstream Channels

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable downstream freq-profile <i>DS_frequency_profile_ID</i> Example: Router(config)# cable downstream freq-profile 4	Defines or modifies a frequency profile.

	Command or Action	Purpose
Step 4	lane <i>lane_id</i> start-freq <i>start_freq_value</i> Example: Router(config-freq-prof) # lane 1 start-freq 90000000	Defines the frequency lanes.
Step 5	block <i>block_id</i> start-freq <i>bl_start_freq_value</i> Example: Router(config-freq-prof-lane) # block 1 start-freq 90000000 Router(config-freq-prof-lane) #	Configures the lane frequency blocks.
Step 6	exit Example: Router(config-freq-prof-lane) # exit	Exits from the frequency lane configuration mode.

Configuring the Controller on the Downstream Channels

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	controller integrated-cable <i>slot/subslot/port</i> Example: Router(config) # controller Integrated-Cable 3/0/0	Enters the controller sub-mode.
Step 4	base-channel-power <i>value</i> Example: Router(config-controller) # base-channel-power 26	Sets the base channel power level. If not specified, the default value is calculated based on the number of carriers. Maximum limit is 34 dBmV DRFI. If you configure a value greater than the maximum specified by DRFI, the following message is displayed: Caution: RF Power above DRFI specification. May result in minor fidelity degradation.
Step 5	freq-profile <i>number</i> Example: Router(config-controller) # freq-profile 0	Specifies the frequency profile for the port.

	Command or Action	Purpose
Step 6	max-carrier <i>value</i> Example: Router(config-controller) # max-carrier 1	Specifies the maximum number of carriers.
Step 7	mute Example: Router(config-controller) # mute	Mutes the port. Use the no prefix to unmute the port. Default is "no mute".
Step 8	rf-chan <i>starting_Qam_ID ending_Qam_ID</i> Example: Router(config-controller) # rf-chan 0 1	Enters RF channel configuration sub-mode to configure an individual channel or a block of channels.
Step 9	shutdown Example: Router(config-controller) # shutdown	Changes the port administration state to down. Use the no prefix to change the port administration state to up.

Troubleshooting Tips

Shutting and No Shutting Downstream Controller Immediately

Problem Shutting down a downstream controller on a cable line card and bringing the controller back up immediately can cause a Queue ID Pending Drain event on the system. This results in traffic disruption to the modems or modems going offline.

Solution It is recommended that you wait for a few seconds (>30 secs) before issuing the no shut command on a shut downstream controller. The system also restricts the user from issuing the no shut command immediately by printing this message.

```
Config change could not be applied as a cleanup is pending following shut on
controller x/x/x. Please wait for the cleanup to complete before attempting to
no shut controller.
```

Configuring the RF Channel on a Controller

The RF channel submode is entered from the channel controller configuration submode using the **rf-chan** command as described in the previous section. If an individual channel was specified in the **rf-chan** command, only that channel configuration is changed. If a block of channels was specified in the **rf-chan** command, the configuration change is applied to all channels in the block.

Note If the user tries to add a video type RF channel to a cable interface, the following message appears to reject the configuration:

```
X/X/X rf-channel XX is video type channel, it can't be configured as primary DS
```

If a RF channel is configured under cable interface, when the user tries to change the channel type to video, the following message appears to reject the configuration:

```
X/X/X rf channel X can't be set to video type.
It is configured under Cable1/0/1.
Please remove the configuration before change the qam type
```

Step 1 **docsis-channel-id** *dcid*

Example:

```
Router(config-rf-chan)#docsis-channel-id 1
```

Changes the channel DOCSIS channel identifier. In block mode, the value is assigned to the first channel and incremented for successive channels.

Step 2 **frequency** *value*

Example:

```
Router(config-rf-chan)#frequency 93000000
```

Configures the channel's center frequency in Hz. The available frequency range is determined from the port's frequency profile, if configured. If not configured, the available range will be the full port spectrum. In block mode, the frequency will be assigned to the first channel. Successive channels will get the next center frequency for the annex specified in the QAM profile (+6 Hz for Annex B, +8 Hz for Annex A).

Step 3 **mute**

Example:

```
Router(config-rf-chan)#mute
```

Mutes the RF channel. Enter the **no** prefix to unmute the channel. Default is "no mute".

Step 4 **power-adjust** *pwr_adj_range*

Example:

```
Router(config-rf-chan)#power-adjust 8.0 - 0.0 dBmV
```

Adjusts the RF channel's power.

Step 5 **qam-profile** *qam_profile_number*

Example:

```
Router(config-rf-chan)#qam-profile 0
```

Specifies the QAM profile for this channel.

Step 6 **rf-output** *value*

Example:

```
Router(config-rf-chan)#rf-output normal
```

Changes the RF output mode to test the channel.

Step 7 **shutdown**

Example:

```
Router(config-rf-chan)#shutdown
```

Changes the channel administration state to down. Use the **no** prefix to change the channel administration state to up. The default is "no shut".

Step 8 **type value**

Example:

```
Router(config-rf-chan)#type video
```

Configures the channel QAM type. The default is DOCSIS.

Configuration Examples

Downstream Interface Configuration Example

The example below shows the configuration of:

- QAM Profile—The system defined QAM profile for Annex B and 256 QAM.
- Frequency Profile—The system defined frequency profile annex-b-low.
- Controller and RF channel—Port 0 on slot 3/0 with frequency profile 0; 96 channels with QAM profile 1 and center frequencies starting at 93 MHz.

```
cable downstream qam-profile 1
  annex B
  modulation 256
  interleaver-depth I32-J4
  symbol-rate 5361
  spectrum-inversion off
  description default-annex-b-256-qam

```

Show Command Examples for Displaying the State

Use the following commands to display the state of any QAM profile, Frequency profile, downstream controller or channel.

QAM Profile Configuration Example

```

Router#show cable qam-profile 0
QAM Profile ID 0: default-annex-b-64-qam
    annex: B
    modulation: 64
    interleaver-depth: I32-J4
    symbol rate: 5057 kilo-symbol/second
    spectrum-inversion: off
Router#

```

Frequency Profile Configuration Example

```

Router#show cable freq-profile 0
Frequency Profile ID 0 annex-b-low:
    Lane 1 start-freq 900000000hz
        Block 1 start-freq 900000000hz
        Block 2 start-freq 138000000hz
        Block 3 start-freq 186000000hz
        Block 4 start-freq 234000000hz
    Lane 2 start-freq 282000000hz
        Block 1 start-freq 282000000hz
        Block 2 start-freq 330000000hz
        Block 3 start-freq 378000000hz
        Block 4 start-freq 426000000hz
    Lane 3 start-freq 474000000hz

Feature Information for Downstream Interface Configuration on the Cisco cBR Router

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 20: Feature Information for Downstream Interface Configuration

Finding Feature Information

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Hardware Compatibility Matrix for the Cisco cBR Series Routers

Note The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

Table 21: Hardware Compatibility Matrix for the Cisco cBR Series Routers

Information About Upstream Interface Configuration

The cable interface in the Cisco cBR router supports upstream signals and serves as the radio frequency (RF) interface. This chapter provides an overview of the upstream interfaces on the Cisco cBR Series Converged Broadband Router.

Cisco IOS XE Fuji 16.9.1 and later releases support 10 Gbps of upstream throughput on the following line cards on the Cisco cBR Series Converged Broadband Router:

- CBR-CCAP-LC-40G
- CBR-CCAP-LC-40G-R

Upstream Channel Management

Upstream Channel Management (UCM) is responsible for the physical (PHY) layer configuration and resource management of upstream channels in the Cisco cBR Series Converged Broadband Router.

Upstream Controller

An upstream port represents a physical upstream RF connector on a cable line card, connected to one or more fiber nodes. An upstream RF port is a container of upstream RF channels, which imposes constraints on both topology and spectrum for the group of RF channels contained in the physical port. An upstream RF port also represents the RF front-end hardware component on a cable line card including the connector, variable gain adjustment (VGA), and A/D converter. This is directly connected to a set of upstream physical channel receivers. The number of upstream physical channels per port is thus constrained by the number of receivers accessible to the port.

Upstream Channel

An upstream RF channel represents DOCSIS physical layer operation on a single upstream center frequency with a particular channel width. It is contained by a single physical port on the CMTS line card hardware.

Upstream Resource Management

The upstream resource management (URM) feature is primarily responsible for the maintenance of the relationship between a physical upstream connector on the line card and the upstream RF channels received on that connector.

How to Configure Upstream Interfaces

This section contains the following:

Configuring the Cisco CMTS Manually Using Configuration Mode

Connect a console terminal to the console port on the I/O controller. When asked if you want to enter the initial dialog, answer **no** to go into the normal operating mode of the router. After a few seconds the user EXEC prompt (**Router>**) appears.

Configuring the Modulation Profile and Assigning to an Upstream Channel

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable modulation-profile <i>profile mode_of_oper</i> <i>qam_profile</i> Example:	Creates a preconfigured modulation profile, where the burst parameters are set to their default values for each burst type.

	Command or Action	Purpose
	<code>Router(config)# cable modulation-profile 23 tdma qam-16</code>	
Step 4	Controller Upstream-Cable <i>slot/subslot/port</i> Example: <code>Router(config)# Controller Upstream-Cable 7/0/0</code>	Enters the controller interface configuration mode.
Step 5	us-channel <i>n modulation-profile primary-profile-number [secondary-profile-number] [tertiary-profile-number]</i> Example: <code>Router(config-if)#cable upstreamus-channel 0 modulation-profile 23</code>	Assigns up to three modulation profiles to an upstream port.
Step 6	end Example: <code>Router(config-controller)# end</code>	Exits controller configuration submode and returns to privileged EXEC mode.

Configuring the Upstream Channel with PHY Layer

Procedure

	Command or Action	Purpose
Step 1	enable Example: <code>Router> enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <code>Router# configure terminal</code>	Enters global configuration mode.
Step 3	controller upstream-cable <i>slot/subslot/port</i> Example: <code>Router(config)# controller upstream-cable 1/0/0</code>	Specifies the controller interface line card and enters upstream controller config configuration submode.
Step 4	us-channel <i>rf-channel frequency freq-val</i> Example: <code>Router(config-controller)# us-channel 1 frequency 20000000</code>	Assigns frequency to an RF channel on a controller interface.
Step 5	us-channel <i>rf-channel docsis-mode mode</i> Example: <code>Router(config-controller)# us-channel 1 docsis-mode tdma</code>	Assigns DOCSIS mode to an RF channel on a controller interface.

	Command or Action	Purpose
Step 6	us-channel <i>rf-channel</i> channel-width <i>value</i> Example: Router(config-controller)# us-channel 1 channel-width 3200000	Assigns channel width in Hertz to an RF channel on a controller interface.
Step 7	us-channel <i>rf-channel</i> modulation-profile <i>profile</i> Example: Router(config-controller)# us-channel 1 modulation-profile 21	Assigns modulation profile to an RF channel on a controller interface.
Step 8	no us-channel <i>rf-channel</i> shutdown Example: Router(config-controller)# no us-channel 1 shutdown	Enables the upstream channel.
Step 9	end Example: Router(config-controller)# end	Exits upstream controller configuration submode and returns to privileged EXEC mode.

Associating Upstream Channels with a MAC Domain and Configuring Upstream Bonding

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>cable slot/subslot/cable-interface-index</i> Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	downstream integrated-cable <i>slot/subslot/port rf-channel rf-chan [upstream grouplist]</i> Example: Router(config-if)# downstream integrated-cable 7/0/0 rf-channel 3 upstream 3	Associates a set of upstream channels to the integrated downstream channels.

	Command or Action	Purpose
Step 5	upstream <i>md-us-chan-id</i> upstream-cable <i>slot/subslot/port</i> us-channel <i>rf-channel</i> Example: Router(config-if)# upstream 0 upstream-cable 7/0/0 us-channel 0	Associates a set of physical upstream channels with the Mac Domain.
Step 6	cable upstream bonding-group <i>id</i> Example: Router(config-if)# cable upstream bonding-group 200	Creates the upstream bonding group on the specified cable interface and enters upstream bonding configuration submode.
Step 7	upstream <i>number</i> Example: Router(config-upstream-bonding)# upstream 1	Adds an upstream channel to the upstream bonding group. A maximum of 16 upstream channels can be configured for each MAC Domain, which are divided into two groups: <ul style="list-style-type: none"> • Group 1: upstream channel 0-7 • Group 2: upstream channel 8-15 The upstream bonding-group should include all the upstream channels either from Group 1 or Group 2 only.
Step 8	attributes <i>value</i> Example: Router(config-upstream-bonding)# attributes eeeeeeee	Modifies the attribute value for the specified upstream bonding group.
Step 9	end Example: Router(config-upstream-bonding)# end	Exits upstream bonding configuration submode and returns to privileged EXEC mode.

Configuration Examples

Upstream Channel with PHY Layer Configuration Example

```

...
us-channel 0 frequency 20000000
us-channel 0 channel-width 3200000 3200000
us-channel 0 power-level 0
us-channel 0 docsis-mode tdma
us-channel 0 minislot-size 2
us-channel 0 modulation-profile 21
no us-channel 0 shutdown
...

Overview of DOCSIS Interfaces and Fiber Node Configurations

The Interface line card used in the Cisco cBR chassis is an integrated line card that has two downstream modules and one upstream module. The line cards support DOCSIS 3.0 features including downstream bonding groups, and upstream bonding groups.

Downstream Features

Physically, the DS (downstream) modules support eight physical connectors or ports. The DS modules support the following features:

- The DS modules support eight downstream integrated-cable controllers for these eight ports. Each downstream integrated-cable controller is associated with an RF port.
- Each downstream controller supports up to 128 downstream channels (0-127).
- Each downstream controller can be configured with 128 integrated-cable interfaces. Therefore, each line card has 1024 integrated-cable interfaces.

- Each integrated-cable interface has a static mapping to an integrated-cable controller RF channel. For example, Integrated-Cable interface 3/0/0:0 is mapped to RF Channel 0 on Integrated-Cable controller 3/0/0.
- 768 downstream DOCSIS channels may be configured on each line card.
- A total of 512 wideband-cable interfaces (downstream bonding groups) may be configured on each line card.
 - Each wideband-cable interface supports a maximum of 64 downstream channels.
 - 128 of the 512 wideband-cable interfaces (downstream bonding groups) may contain 33 or more channels.

Upstream Features

The Interface line card has one upstream module supporting 16 physical connectors or ports. The upstream features are as follows:

- The line card supports 16 upstream-cable controllers, each mapping to one upstream connector.
- 12 upstream channels can be configured per upstream controller.
- 12 upstream channels can be enabled per pair of upstream controllers.

For more details on the upstream features, see the *Downstream Upstream Guide*.

MAC Domains (Cable Interfaces)

1. 16 MAC domains (cable interfaces) may be configured per line card.
2. Maximum of 16 upstream channels can be configured in each MAC domain.
3. A maximum of 255 downstream channels may be added to a MAC domain.
4. Maximum number of primary capable downstream channels per MAC Domain is 32. Non Primary downstream channels are added automatically to the MAC domains when the fiber nodes are configured.

Fiber Nodes

512 fiber nodes may be configured for each Cisco cBR-8 chassis.

Configuring DOCSIS Interfaces and Fiber Nodes

Configuring Upstream Channels

Verifying the Controller Configuration

Use the **show controllers upstream-cable** command to verify the configuration of the upstream channels in the controllers. Use the modifier **| include upstream** to see the administrative and operational state of the controllers.

```
Router#show controllers upstream-cable 1/0/0 | include upstream
Controller 1/0/0 upstream 0 AdminState:UP OpState: UP
```

```

Controller 1/0/0 upstream 1 AdminState:UP OpState: UP
Controller 1/0/0 upstream 2 AdminState:UP OpState: UP
Controller 1/0/0 upstream 3 AdminState:UP OpState: UP
Controller 1/0/0 upstream 4 AdminState:DOWN Opstate: DOWN (Reason: Default)
Controller 1/0/0 upstream 5 AdminState:DOWN Opstate: DOWN (Reason: Default)
Controller 1/0/0 upstream 6 AdminState:DOWN Opstate: DOWN (Reason: Default)
Controller 1/0/0 upstream 7 AdminState:DOWN Opstate: DOWN (Reason: Default)
Router#

```

Binding Upstream Channels to MAC Domain

By default, a MAC domain does not contain any upstream channels. This section describes the configurations necessary to bind one or more upstream channels to a MAC domain. Each upstream channel is bound to only one MAC domain. The MAC domain and the upstream channel must reside on the same line card (same slot). If required, the upstream channels within the same upstream controller can be bound to different MAC domains.

Before you begin

Restrictions

- A maximum of 8 upstream channels may be bound to one MAC domain.

Note A maximum of 16 upstream channels may be configured in each MAC domain.

- The MAC domain and channels must share the same slot. That is, a MAC Domain may include channels from any controller on the same slot.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable Example: Router# interface cable 1/0/0	Enters MAC Domain configuration mode. Values for slot are 0-3 and 6-9, for subslot is always 0, for MD Index is 0-15.
Step 4	upstream upstream-Cable us-channel Example: Router (config-if) # upstream 4 upstream-Cable 1/0/0 us-channel 7	Binds the specified upstream channel to the MAC Domain.

	Command or Action	Purpose
Step 5	end Example: Router# end	Returns to privileged EXEC mode.

What to do next

To verify MAC Domain configurations for upstream, use the **show cable mac-domain** command with **cgd-associations** keyword.

The MD US Binding table shows the upstream channel binding.

```
Router#show cable mac-domain c1/0/0 cgd-associations

3 UP UP 399000000 DOCSIS B 256 5361 I32-J4 4 34 NORMAL
```

Configuring Integrated-cable Interface

Configure an integrated-cable interface to prepare a downstream channel for inclusion within a MAC Domain as a primary-capable downstream channel. The interface configuration provides the following advantages:

- It enables the allocation of bandwidth to the downstream channel.
- It enables the control of the administrative state (shut/no shut) of the channel interface.

The time interval required between the shut and no shut administrative states for the same controller is approximately 30 seconds. You must not change the shut and no shut states rapidly without any delay in script or copy-paste. It can generate unexpected errors.

Each integrated-cable interface is mapped statically to an integrated-cable controller RF channel. For example, IC interface 1/0/0:0 is mapped to IC controller 1/0/0 RF channel 0. Similarly, IC interface 1/0/0:1 is mapped to IC controller 1/0/0 RF channel 1.

IC controllers are numbered 0-7 and RF Channels on each controller are numbered 0-127.

Before you begin

Determine the percentage of bandwidth to allocate to a channel. The bandwidth percentage configured is converted to a committed information rate (CIR) value for the interface. The value is used to admit non-bonded service flows on this channel. For more information, see the *Dynamic Bandwidth Sharing on the Cisco CMTS Router*.

Step 1 enable

Example:

```
Router> enable
```

Enables privileged EXEC mode.

Enter your password if prompted.

Step 2 configure terminal

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 interface integrated-cable

Example:

```
Router(config)# interface integrated-cable 1/0/0:0
```

Enter the integrated-cable interface configuration mode for specified integrated-cable interface.

Step 4 cable rf-bandwidth-percent *percentage-number*

Example:

```
Router(config-if)# cable rf-bandwidth-percent 30
```

Configures the bandwidth allocation to the specified integrated-cable interface.

Step 5 **end**

Example:

```
Router# end
```

Returns to privileged EXEC mode.

What to do next

The following conditions are used to determine if an IC (Integrated-Cable) interface is up in current software.

- The IC interface is associated to a MD (MAC Domain) interface.
- The MD interface, which the IC interface associated to, is in UP state.
- The IC interface is not configured shut down.
- The IC interface is configured with bandwidth.
- The associated downstream channel within the IC controller is operationally up.

Use the **show interface Integrated-Cable controller** command to verify the status of the specified integrated-cable interface. The State info table provides information to diagnose issues affecting the operational state of the interface.

```
Router# show interface Integrated-Cable 1/0/0:0 controller
Integrated-Cable1/0/0:0 is up, line protocol is up
...
-----
State info (DSNB if and its underlying states)
-----
DSNB IF state : UP
RF Chan state : UP
RF Chan frequency : 381000000
Bandwidth configured on DSNB IF : YES
Inject Header/HW flow creation status : DSNB_IF_SM_UP
MD state (9/0/0) : UP
*DSNB i/f Line State : UP
-----
```

Binding Primary Capable Downstream Channels to a MAC Domain

After a downstream channel has a properly configured Integrated-cable interface, it may be bound to a MAC Domain as a primary capable channel. The Channel Grouping Domain (CGD) configuration allows specified downstream channels to be bound to a MAC Domain as primary capable channels. Optionally, it also allows downstream channels to be associated with a subset of upstream channels within the MAC domain.

Before you begin

Restrictions

- The downstream channel and MAC domain must reside on the same line card (same slot)
- A maximum of 32 primary capable downstream channels may be bound to a single MAC domain

Step 1 **enable****Example:**

```
Router> enable
```

Enables privileged EXEC mode.

Enter your password if prompted.

Step 2 **configure terminal****Example:**

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface cable****Example:**

```
Router#interface cable 1/0/0
```

Enters MAC domain configuration mode.

- *slot*—Specifies the chassis slot number of the interface line card. Valid values are 0-3 and 6-9
- *subslot*—Specifies the secondary slot number of the interface line card. Valid subslot is 0.
- *MD index*—Specifies the MAC Domain index number. Valid values are 0-15.

Step 4 **downstream Integrated-Cable slot/subslot/port rf-channels grouplist****Example:**

```
Router#downstream Integrated-Cable 1/0/0 rf-channels 1-6
```

Configures the downstream primary capable channels.

- *grouplist*—Specify the range of downstream rf-channels.

Step 5 **end****Example:**

```
Router# end
```

Returns to privileged EXEC mode.

What to do next

To verify the downstream primary capable channels, use the **show cable mac-domain** command with **cgd-associations** keyword.

```
Router#show cable mac-domain c1/0/0 cgd-associations
Load for five secs: 1%/0%; one minute: 2%; five minutes: 2%
Time source is NTP, *13:36:26.209 PST Fri Jan 20 2012
```

CGD Host	Resource	DS Channels	Upstreams	(ALLUS)	Active DS
Cal/0/0	1/0/0	8	0-1	Yes	8
		16	0-1	Yes	16
		24	0-1	Yes	24
		32-33	0-1	Yes	32-33
		40	0-1	Yes	40

MD US binding:

Host	MD Controller	US channel	State
Cal/0/0	U0 1/0/0	0	UP
Cal/0/0	U1 1/0/0	1	UP
Cal/0/0	U2 1/0/0	2	UP
Cal/0/0	U3 1/0/0	3	UP
Cal/0/0	U4 1/0/1	0	UP

Router#

Configuring MAC Domain Service Groups

Configuring the Fiber Nodes

A maximum of 512 fiber nodes may be configured per CMTS. A fiber node configured on the CMTS represents one or more matching physical fiber nodes in the HFC plant. The CMTS uses the fiber node configuration to identify the DOCSIS downstream service group (DS-SG) and DOCSIS upstream Service Group (US-SG) of the physical fiber nodes in the plant. The Service Group information is compared with MAC Domain channel configuration to automatically calculate the MAC Domain downstream and upstream service groups (MD-DS-SGs and MD-US-SGs respectively) within the MAC Domains.

The following is required to create a valid fiber node configuration.

- Each fiber node configuration must include at least one downstream controller and one upstream controller.
- Every MAC Domain and Wideband Interface including channels within the fiber node must use the same bundle interface.
- All downstream channels included within the fiber node must be assigned a unique frequency.
- All downstream channels associated with a particular MAC Domain must be assigned a unique DOCSIS channel ID.

If automatic DOCSIS channel ID allocation is preferred over manual DOCSIS channel ID configuration, the **cable downstream-channel-id automatic** command may be used to enable automatic DOCSIS channel ID allocation for the CMTS.

For details, see the *Cisco CMTS Cable Command Reference*.

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **cable fiber-node *id***

Example:

```
Router(config)#cable fiber-node 1
Router(config-fiber-node)#
```

Enters cable fiber-node configuration mode to configure a fiber node

- *id*— cable fiber node ID. The valid range is 1-512.

Step 4 **downstream Integrated-Cable *slot/subslot/port***

Example:

```
Router(config-fiber-node)#downstream Integrated-Cable 1/0/0
```

Adds the DOCSIS downstream channels within the controller to the fiber node.

Step 5 **upstream upstream-Cable *slot/subslot/port***

Example:

```
Router(config-fiber-node)#upstream upstream-Cable 1/0/0
```

Adds the upstream channels within the controller to the fiber node.

Step 6 **end**

Example:

```
Router# end
```

Returns to privileged EXEC mode.

What to do next

To verify the fiber-node configuration use the **show cable fiber-node** command.

```
Router# show cable fiber-node 1
-----
--
Fiber-Node 1
Description: Feed Mac Domain: Cable1/0/0
Channel(s) : downstream Integrated-Cable 1/0/0: 0-3, 32-35, 64-67,
96-99
```

```

Channel ID(s): 1 2 3 4 33 34 35 36 65 66 67 68 97 98
99 100
Upstream-Cable 1/0/0
FN Config Status: Configured (status flags = 0x01)
MDD Status: Valid
Router#

```

The output shows the downstream channel IDs configured on a fiber node. It also shows the status of the upstream-cable configured on the fiber node. Further, it shows the status of MAC Domain Descriptor (MDD) messaging.

Verify MD-DS-SG Channel Membership

Once the fiber node is valid, the MD-DS-SGs within the associated MAC domains will be automatically populated with downstream channels. The MD-DS-SGs will include the active primary downstream channels within the MAC domain as well as non-primary downstream channels automatically associated with the MAC domain through the fiber node configuration. The non-primary channels must be properly configured within the controller (that are operationally up) to be included in MD-DS-SGs

Use the **show cable mac-domain** command with the **downstream-service-group** option to display the MD-DS-SG channel membership.

```

outer#show cable mac-domain c1/0/0 downstream-service-group
Cable MD-DS-SG RF
IF Id Resource Chan Primary Chan
C1/0/0 5 1/0/0 0-3 0-3
          32-35 32-35
          64-67
          96-99

```

To verify that the primary downstream channels are transmitting MAC Management Messages (MMMs) use the **show controller Integrated-Cable counter rf-channel** command.

```

Router#sh controllers Integrated-Cable 7/0/0 counter rf-channel
Controller RF MPEG MPEG MPEG Sync MAP/UCD User QAM
           Chan Packets bps Mbps Packets Packets Tx Mbps Util
           Tx Percentage
7/0/0      0      0      0      00.00 0      0      00.00 000.00
7/0/0      1      0      0      00.00 0      0      00.00 000.00
7/0/0      2      8239954 2475952 02.47 0      0      02.39 006.60
7/0/0      3      85927382 25769779 25.76 0      0      24.94 068.71
7/0/0      4      85927608 25769027 25.76 0      0      24.94 068.71
7/0/0      5      8239088 2474599 02.47 0      0      02.39 006.59

7/0/0      7      50103 15040 00.01 0      0      00.01 000.04
7/0/0      8      50103 15040 00.01 0      0      00.01 000.04

```

Verify MD-US-SG Channel Membership

Use the **show cable mac-domain** command with the **upstream-service-group** option to display the MD-US-SG channel membership.

```

Router#show cable mac-domain c1/0/0 upstream-service-group
Cable MD 1/0/0
US-SG-ID : 5 US-Chan : U0,1,2,3
Primary-DS: 1/0/0:0 US-SG-ID: 5

```

```

MDD US-List : U0,1,2,3
MDD Ambiguity : U0,1,2,3
Primary-DS: 1/0/0:1 US-SG-ID: 5
MDD US-List : U0,1,2,3
MDD Ambiguity : U0,1,2,3
Primary-DS: 1/0/0:2 US-SG-ID: 5
MDD US-List : U0,1,2,3
MDD Ambiguity : U0,1,2,3
Primary-DS: 1/0/0:3 US-SG-ID: 5
MDD US-List : U0,1,2,3
MDD Ambiguity : U0,1,2,3

```

Downstream Bonding Group Configuration

Configuring Wideband-cable Interface (Downstream Bonding Grouping)

A Wideband-Cable interface forwards bonded traffic in the downstream direction. A set of downstream RF channels is configured under the Wideband interface. Each line card will support up to 512 Wideband interfaces.

Although there is no real relationship between these wideband interfaces and the 8 controllers (ports), there is a convention of dividing the wideband interfaces into groups per controller.

The 512 wideband interfaces are divided among the 8 controllers - 64 interfaces per controller.

You can create a wideband-cable interface to define a downstream bonding group. A downstream bonding group bonds together a set of downstream RF channels. It can only contain the RF channels from the same line card.

Associations between bonding groups and MAC Domains are automatically created. Associations occur when a bonding group channel set is found to be a subset of a MAC Domain Downstream Service Group (MD-DS-SG) within a MAC Domain. The automatic associations will trigger the creation of an RCC that contains the bonding group's channel set within the MAC Domain.

Before you begin

Restrictions:

1. Included downstream channels must be a part of the same line card slot.
2. All the downstream channels must be from the integrated-cable controllers 0-3 or 4-7.

Step 1 enable

Example:

```
Router> enable
```

Enables privileged EXEC mode.

Enter your password if prompted.

Step 2 configure terminal

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface wideband-Cable**

Example:

```
Router(config)#interface wideband-Cable 1/0/0:1  
Router(config-if)#
```

Enter the wideband-cable interface configuration mode for specified wideband-cable interface.

Step 4 **cable bundle id**

Example:

```
Router(config-if)#cable bundle 1
```

Configures the cable bundle id for this wideband-cable interface. The configured cable bundle id must match the cable bundle id configured in associated MAC domains.

- *Bundle number*— cable bundle number. The valid range is 1-255.

Step 5 **cable rf-channels channel-list grouplist bandwidth-percent percentage-bandwidth**

Example:

```
Router(config-if)#cable rf-channel channel-list 1-3 bandwidth-percent 10
```

Configures the bandwidth allocation for specified channel-list and includes the channels in the downstream bonding group. Range for channel numbers are 0-127 (<first channel num-last channel num>).

- *grouplist*—Specify the range of downstream rf-channels.

Step 6 **cable rf-channels controller controller number channel-list grouplist bandwidth-percent percentage-bandwidth**

Example:

```
Router(config-if)#cable rf-channel controller 1 channel-list 1-3 bandwidth-percent 10
```

Configures the bandwidth allocation for specified channel-list on downstream controllers and includes the channels in the downstream bonding group. Range for channel numbers are 0-127.

- *controller number*—Downstream controller number. The valid numbers are 0-7.
- *grouplist*—Specify the range of downstream rf-channels.

Step 7 **end**

Example:

```
Router# end
```

Returns to privileged EXEC mode.

What to do next

Verify the Bonding Group Interfaces.

Verifying the Bonding Group Interfaces

Use **wideband-channel** option of the **show controllers integrated-Cable** command to display bonding group interfaces:

```
Router# show controllers integrated-cable 1/0/0 wideband-channel
Load for five secs: 2%/0%; one minute: 2%; five minutes: 2%

Upstream Bonding Group Configuration

Restrictions for Upstream Bonding Groups

- Upstream bonding groups are configured within the MAC Domain interface
- Upstream bonding groups consist of a set of upstream channels that are bonded together.
- A maximum of 16 upstream channels can be configured for each MAC Domain, which are divided into two groups:
 - Group 1: upstream channel 0-7
 - Group 2: upstream channel 8-15

The **upstream bonding-group** should include all the upstream channels either from Group 1 or Group 2 only.

Configuring Upstream Bonding Groups

Before you begin

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable slot/subslot/MD index Example: Router(config)# interface cable 1/0/0	Enters MAC domain configuration mode. <ul style="list-style-type: none"> • <i>slot</i>—Specifies the chassis slot number of the interface line card. Valid values are 0-3 and 6-9 • <i>subslot</i>—Specifies the secondary slot number of the interface line card. Valid subslot is 0. • <i>MD index</i>—Specifies the MAC Domain index number. Valid values are 0-15.
Step 4	cable upstream bonding-group Example:	Creates a static upstream bonding group on a MAC Domain.

	Command or Action	Purpose
	Router(config-if)# cable upstream bonding-group 7 Router(config-upstream-bonding)#	
Step 5	upstream Example: Router(config-upstream-bonding)# upstream 7	Add upstream channels to an upstream bonding group. A maximum of 16 upstream channels can be configured for each MAC Domain, which are divided into two groups: <ul style="list-style-type: none"> • Group 1: upstream channel 0-7 • Group 2: upstream channel 8-15 The upstream bonding-group should include all the upstream channels either from Group 1 or Group 2 only.
Step 6	end Example: Router# end	Returns to privileged EXEC mode.

What to do next

Use the **show interface cable upstream bonding-group** command to display upstream bonding group information.

```
Router#show interface cable 1/0/0 upstream bonding-group
Load for five secs: 1%/0%; one minute: 2%; five minutes: 2%
Time source is NTP, *10:47:17.142 PST Thu Jan 12 2012

Feature Information for DOCSIS Interface and Fiber Node Configuration

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmg.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 24: Feature Information for DOCSIS Interface and Fiber Node Configuration

Feature Name	Releases	Feature Information
DOCSIS Interface and Fiber Node Configuration	Cisco IOS XE Everest 16.6.1	This feature was integrated into Cisco IOS XE Everest 16.6.1 on the cisco cBR Series Converged Broadband Routers.
Display QAM Utilization Percentage using the sh controllers Integrated-Cable 7/0/0 counter rf-channel	Cisco IOS XE Gibraltar 16.10.1f	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 13

Service Group Based Configuration of the Cisco cBR Router

- [Service Group Profile Based Configuration](#), on page 191
- [Service Profile Configuration for 16x8 with One MAC Domain](#), on page 193
- [Service Profile Configuration for 16x8 with Two MAC Domains](#), on page 195
- [MAC-Domain Split Configuration](#), on page 197

Service Group Profile Based Configuration

The [DOCSIS Interface and Fiber Node Configuration](#) guide describes the interface and fiber node configurations that are required to operationalize the Cisco cBR router. The steps described to accomplish the tasks involved in such configuration are complex.

To simplify and speed up the process of configuring the physical and logical interfaces required to deploy the Cisco cBR router quickly, a service group (SG) profile based approach is adopted. This document describes the simplified SG profile approach.

This approach provides the following advantages:

- Improves and simplifies the deployment of Cisco cBR router.
- Improves and simplifies the configuration of Cisco cBR Router by eliminating duplicate configurations.
- Improves and simplifies troubleshooting of Cisco cBR router.
- Supports faster Converged Cable Access Platform (CCAP) provisioning by using common and quick replication across nodes and regions.

To configure the interfaces and quickly operationalize the Cisco cBR router, a set of common profiles are created and are created and configured into global service group profiles. These global service group profiles may be applied to fiber node interfaces along with a mapping of the service group interfaces to the physical interfaces.

Common profiles are profiles which contain configurations for common service group (SG) interfaces like MAC domain, wideband-cable, and primary downstream

The common profiles and the global SG profiles may be independent of the topology of the network in which they are applied. The SG interface to physical interface mapping defines the behavior of the profiles in the topology that the SG profiles have been applied to.

Limitations:

- A common profile cannot be deleted if it is associated with the fiber nodes. It can be modified by entering the profile configuration mode using the **cable profile** command.
- A service-group profile cannot be deleted or modified if it is associated with the fiber nodes.
- To associate a new global SG profile to a fiber node, dissociate the currently associated global SG profile from the fiber node.
- To configure for a unique topology, use the full configuration approach provided in [DOCSIS Interface and Fiber Node Configuration](#) guide.
- When the secondary line card is in active mode, the following limitations apply:
 - A MAC domain, Wideband-Cable interface, downstream channel, and SG profile cannot be modified when they are associated with the fiber nodes.
 - SG profile cannot be dissociated from the fiber nodes.
 - A MAC domain, Wideband-Cable interface, downstream channel, and SG profile can be created but cannot be associated to the fiber node.
 - To enable the SG operation simplification feature, auto-reset feature must be enabled using the **cable wideband auto-reset** command.
- Do not support downgrade cBR-8 image from 16.7.x to previous image if the configuration includes mac domain split configuration.

Broadly, the following steps define and deploy the common profiles and the SG profiles:

1. Define and configure the Common profiles: The SG interface profiles or the common profiles contain configuration parameters common to a group of similar interfaces. For example, a profile may contain specific configuration parameters shared by multiple Wideband-Cable interfaces, associated across multiple line cards. A common profile is configured at the global or chassis level. All interfaces associated with a profile will inherit the configuration in the profile. Any common profile may be associated with any global SG profile. Use the **cable profile** *profile-type profile-name* command to define the following common profiles:
 - MAC Domain (MD) profile
 - Primary Downstream channel (DS) profile
 - Wideband-cable Interface (WB) profile
 - Global Service Group (SG) profile
2. Complete the following configurations to the fiber node interface using the **cable fiber-node** command:
 - Define the downstream and upstream ports. Map the appropriate interface-cable using the **downstream interface-cable** command. Map the appropriate upstream-cable interface using the **upstream upstream-cable** command.
 - Use the **downstream sg-channel** command to map the logical downstream SG channels to the physical RF channels and the **upstream sg-channel** command to map the logical upstream SG channels to the physical upstream channels.
 - Use the **service-group profile** to associate the global service group profile to the fiber node.

See the use case scenarios for configurations and examples.

Service Profile Configuration for 16x8 with One MAC Domain

This section describes the service group based configurations for a 16x8 service group with one MAC domain.

Step 1 `cable profile profile-type profile-name`

For MAC Domain profile, specify *profile-type* as **mac-domain**.

```
Router(config)#cable profile mac-domain MD1
Router(config-profile-md)#cable dynamic-secret mark
Router(config-profile-md)#cable shared-secret 0 cisco
Router(config-profile-md)#cable ip-init ipv4
Router(config-profile-md)#cable mtc-mode
Router(config-profile-md)#cable mrc-mode
Router(config-profile-md)#cable privacy mandatory
Router(config-profile-md)#cable privacy bpi-plus-policy
```

For Primary downstream profile, specify *profile-type* as **downstream**.

```
Router(config)#cable profile downstream DS1
Router(config-profile-ds)#cable rf-bandwidth-percent 20
Router(config-profile-ds)#cable attribute-mask 0x80000000
```

For wideband-cable interface profile, specify *profile-type* as **wideband-interface**.

```
Router(config)#cable profile wideband-interface BG1
Router(config-profile-wb)#cable downstream attribute-mask 0x80000000
```

For global service group profile, specify *profile-type* as **service-group**. In the service group profile, configure the cable bundle associated, mac-domain profile, and the wideband interface profile

```
Router(config)#cable profile service-group SG-16x8-1_1
Router(config-profile-sg)#cable bundle 71
Router(config-profile-sg)#mac-domain 0 profile mdl
Router(config-profile-sg-md)#downstream sg-channel 0-7 profile ds1 upstream 0-3
Router(config-profile-sg-md)#upstream 0 sg-channel 0
Router(config-profile-sg-md)#upstream 1 sg-channel 1
Router(config-profile-sg-md)#upstream 2 sg-channel 2
Router(config-profile-sg-md)#upstream 3 sg-channel 3
Router(config-profile-sg-md)#upstream 4 sg-channel 4
Router(config-profile-sg-md)#upstream 5 sg-channel 5
Router(config-profile-sg-md)#upstream 6 sg-channel 6
Router(config-profile-sg-md)#upstream 7 sg-channel 7
Router(config-profile-sg-md)#us-bonding-group 1
Router(config-profile-sg-md-usbg)#upstream 0
Router(config-profile-sg-md-usbg)#upstream 1
Router(config-profile-sg-md-usbg)#upstream 2
Router(config-profile-sg-md-usbg)#upstream 3
Router(config-profile-sg-md-usbg)#upstream 4
Router(config-profile-sg-md-usbg)#upstream 5
Router(config-profile-sg-md-usbg)#upstream 6
```

```

Router(config-profile-sg-md-usbg) #upstream 7
Router(config-profile-sg-md-usbg) #attributes 8000000
Router(config-profile-sg-md-usbg) #exit
Router(config-profile-sg-md) #exit
Router(config-profile-sg) #

Router(config-profile-sg) #wideband-interface 1 profile BG1
Router(config-profile-sg-bg) #downstream sg-channel 0 15 rf-bandwidth-percent 10
Router(config-profile-sg-bg) #end
Router#

```

Step 2 cable fiber-node

Enter fiber-node configuration mode. Configure the following in fiber-node configuration mode:

- downstream port
- upstream port
- downstream sg-channels to rf-channels mapping
- upstream sg-channels to us-channels mapping
- global service group mapping
- managed MAC domain

```

Router(config) #cable fiber-node 1
Router(config-fiber-node) #downstream integrated-cable 3/0/0
Router(config-fiber-node) #upstream upstream-cable 3/0/0
Router(config-fiber-node) #downstream sg-channel 0 15 integrated-cable 3/0/0 rf-channel 0 15
Router(config-fiber-node) #upstream sg-channel 0 7 upstream-cable 3/0/0 us-channel 0 7
Router(config-fiber-node) #service-group profile SG-16X8-1_1

```

What to do next

Use the **show cable fiber-node [id] mapping** and the **show cable fiber-node [id] derived** commands to check the configuration of the interfaces.

```

Router#show cable fiber-node 1 mapping
Fiber-node 1:
Upstream:
Sg chan      Us-chan      Op state
0            3/0/0 0      Up
1            3/0/0 1      Up
2            3/0/0 2      Up
3            3/0/0 3      Up
4            3/0/0 4      Up
5            3/0/0 5      Up
6            3/0/0 6      Up
7            3/0/0 7      Up
Downstream:
Sg chan      Ds-rf-chan   Op state
0            3/0/0:0     Up
1            3/0/0:1     Up
2            3/0/0:2     Up

```

```

3          3/0/0:3      Up
4          3/0/0:4      Up
5          3/0/0:5      Up
6          3/0/0:6      Up
7          3/0/0:7      Up
8          3/0/0:8      Up
9          3/0/0:9      Up
10         3/0/0:10     Up
11         3/0/0:11     Up
12         3/0/0:12     Up
13         3/0/0:13     Up
14         3/0/0:14     Up
15         3/0/0:15     Up

```

```

Router#show cable fiber-node 1 derived
Fiber-node 1:

```

Router#show cable mac-domain fiber-node 1 md 0 upstream-service-group
Cable MD 3/0/0
Router#

```

Service Profile Configuration for 16x8 with Two MAC Domains

This section describes the service group based configurations for a 16x8 service group with two MAC domains, split downstream and overlaid upstream channels.

Step 1 **cable profile** *profile-type profile-name*

For MAC Domain profile, specify *profile-type* as **mac-domain**.

```

Router(config)#cable profile mac-domain MD1
Router(config-profile-md)#cable dynamic-secret mark
Router(config-profile-md)#cable shared-secret 0 cisco
Router(config-profile-md)#cable ip-init ipv4
Router(config-profile-md)#cable mtc-mode
Router(config-profile-md)#cable mrc-mode
Router(config-profile-md)#cable privacy mandatory
Router(config-profile-md)#cable privacy bpi-plus-policy

```

For Primary downstream profile, specify *profile-type* as **downstream**.

```
Router(config)#cable profile downstream DS1
Router(config-profile-ds)#cable rf-bandwidth-percent 20
Router(config-profile-ds)#cable attribute-mask 0x80000000
```

For wideband-cable interface profile, specify *profile-type* as **wideband-interface**.

```
Router(config)#cable profile wideband-interface BG1
Router(config-profile-wb)#cable downstream attribute-mask 0x80000000
```

For global service group profile, specify *profile-type* as **service-group**. In the service group profile, configure the cable bundle associated, mac-domain profile, and the wideband interface profile

```
Router(config)#cable profile service-group SG-16x4-1_2
Router(config-profile-sg)#cable bundle 71
Router(config-profile-sg)#mac-domain 0 profile mdl
Router(config-profile-sg-md)#downstream sg-channel 0-15 profile dsl upstream 0-3
Router(config-profile-sg-md)#upstream 0 sg-channel 0
Router(config-profile-sg-md)#upstream 1 sg-channel 1
Router(config-profile-sg-md)#upstream 2 sg-channel 2
Router(config-profile-sg-md)#upstream 3 sg-channel 3
Router(config-profile-sg-md)#us-bonding-group 1
Router(config-profile-sg-md-usbg)#upstream 0
Router(config-profile-sg-md-usbg)#upstream 1
Router(config-profile-sg-md-usbg)#upstream 2
Router(config-profile-sg-md-usbg)#upstream 3
Router(config-profile-sg-md-usbg)#exit
Router(config-profile-sg-md)#exit
Router(config-profile-sg)#

Router(config-profile-sg)#wideband-interface 1 profile BG1
Router(config-profile-sg-bg)#downstream sg-channel 0 7 rf-bandwidth-percent 10
Router(config-profile-sg-bg)#exit
Router(config-profile-sg)#wideband-interface 2 profile BG1
Router(config-profile-sg-bg)#downstream sg-channel 8 15 rf-bandwidth-percent 10
Router#
```

Step 2 cable fiber-node

Enter fiber-node configuration mode. Configure the following in fiber-node configuration mode:

- downstream port
- upstream port
- downstream sg-channels to rf-channels mapping
- upstream sg-channels to us-channels mapping
- global service group mapping
- managed MAC domain

```
Router(config)#cable fiber-node 1
Router(config-fiber-node)#downstream integrated-cable 3/0/0
Router(config-fiber-node)#upstream upstream-cable 3/0/0
Router(config-fiber-node)#downstream sg-channel 0 7 integrated-cable 3/0/0 rf-channel 0 15
Router(config-fiber-node)#upstream sg-channel 0 3 upstream-cable 3/0/1 us-channel 0 3
```

```
Router(config-fiber-node)#service-group profile SG-16X4-1_2
Router(config-fiber-node)#exit
Router(config)#
```

```
Router(config)#cable fiber-node 2
Router(config-fiber-node)#downstream integrated-cable 3/0/0
Router(config-fiber-node)#upstream upstream-cable 3/0/1
Router(config-fiber-node)#downstream sg-channel 0 7 integrated-cable 3/0/0 rf-channel 8 15
Router(config-fiber-node)#downstream sg-channel 8 15 integrated-cable 3/0/0 rf-channel 0 7
Router(config-fiber-node)#upstream sg-channel 0 3 upstream-cable 3/0/1 us-channel 0 3
Router(config-fiber-node)#service-group profile SG-16X4-1_2
Router(config-fiber-node)#exit
Router(config)#
```

What to do next

Use the **show cable fiber-node [id] mapping** and the **show cable fiber-node [id] derived** commands to check the configuration of the interfaces.

MAC-Domain Split Configuration

This section describes the MAC-domain split configurations.

Note

- In MAC domain split scenario, we must configure upstream peer-node-us and managed MAC domain.
 - After a fiber node managed MAC domain, we will reserve cable interface by **cable managed fiber-node** command.
 - If a fiber-node has peer, we can not add managed MAC domain.
 - If a fiber-node has peer, we can not modify the configuration of channel mapping and upstream peer-node-us
 - If a fiber-node has managed MAC domain, we can not remove upstream peer-node-us.
 - Only both two fiber-nodes are associated with service group profile, mac-domains and wideband interfaces will be generated.
 - MAC domain and wideband interfaces will be removed as soon as one fiber-node is unassociated with service group profile.
-

Step 1 cable profile mac-domain

Define global common profiles for MAC-domain, bonding group, primary downstream.

```
Router(config)#cable profile mac-domain MD
```

```

Router(config-profile-md)#load-interval 30
Router(config-profile-md)#cable dynamic-secret mark
Router(config-profile-md)#cable shared-secret 0 cisco
Router(config-profile-md)#cable ip-init ipv4
Router(config-profile-md)#cable mtc-mode
Router(config-profile-md)#cable mrc-mode
Router(config-profile-md)#cable privacy mandatory
Router(config-profile-md)#cable privacy bpi-plus-policy
Router(config-profile-md)#cable privacy accept-self-signed-certificate
Router(config-profile-md)#cable privacy dsx-support
Router(config-profile-md)#cable privacy eae-policy capability-enforcement
Router(config-profile-md)#cable privacy kek life-time 300
Router(config-profile-md)#cable privacy retain-failed-certificates
Router(config-profile-md)#cable privacy skip-validity-period
Router(config-profile-md)#cable privacy tek life-time 180
Router(config-profile-md)#cable cm-status enable 3
Router(config-profile-md)#cable map-advance dynamic
Router(config-profile-md)#cable upstream 0 attribute-mask FFFFFFFF
Router(config-profile-md)#cable upstream 0 power-adjust continue 5
Router(config-profile-md)#cable upstream balance-scheduling
Router(config)#cable profile downstream DS
Router(config-profile-ds)#cable rf-bandwidth-percent 20
Router(config-profile-ds)#cable attribute-mask 0x80000000
Router(config)#cable profile wideband-interface BG
Router(config-profile-wb)#cable downstream attribute-mask 0x80000000
Router(config-profile-wb)#description BG
Router(config-profile-wb)#load-interval 30

```

Step 2 cable profile service-group

In the service group profile, configure the cable bundle associated, mac-domain profile, and the wideband interface profile.

```

Router(config)#cable profile service-group MD_SPLIT
Router(config-profile-sg)#cable bundle 1
Router(config-profile-sg)#mac-domain 0 profile MD
Router(config-profile-sg-md)#downstream sg-channel 0-15 profile DS
Router(config-profile-sg-md)#upstream 0 sg-channel 0
Router(config-profile-sg-md)#upstream 1 sg-channel 1
Router(config-profile-sg-md)#upstream 2 sg-channel 2
Router(config-profile-sg-md)#upstream 3 sg-channel 3
Router(config-profile-sg-md)#upstream 4 sg-channel 4
Router(config-profile-sg-md)#upstream 5 sg-channel 5
Router(config-profile-sg-md)#upstream 6 sg-channel 6
Router(config-profile-sg-md)#upstream 7 sg-channel 7
Router(config-profile-sg-md)#us-bonding-group 1
Router(config-profile-sg-md-usbg)#upstream 0
Router(config-profile-sg-md-usbg)#upstream 1
Router(config-profile-sg-md-usbg)#upstream 2
Router(config-profile-sg-md-usbg)#upstream 3
Router(config-profile-sg-md-usbg)#attributes 8000000
Router(config-profile-sg-md-usbg)#exit
Router(config-profile-sg-md)#us-bonding-group 2
Router(config-profile-sg-md-usbg)#upstream 4
Router(config-profile-sg-md-usbg)#upstream 5
Router(config-profile-sg-md-usbg)#upstream 6
Router(config-profile-sg-md-usbg)#upstream 7
Router(config-profile-sg-md-usbg)#attributes 8000000
Router(config-profile-sg-md-usbg)#exit
Router(config-profile-sg-md)#exit
Router(config-profile-sg)#wideband-interface 0 profile WB
Router(config-profile-sg-bg)#downstream sg-channel 0 7 rf-bandwidth-percent 1
Router(config-profile-sg-bg)#exit
Router(config-profile-sg)#wideband-interface 1 profile WB

```

```
Router(config-profile-sg-bg)#downstream sg-channel 8 15 rf-bandwidth-percent 1
```

Step 3 cable fiber-node

Enter fiber-node configuration mode. Configure the following in fiber-node configuration mode:

- downstream port
- upstream port
- downstream sg-channels to rf-channels mapping
- upstream sg-channels to us-channels mapping
- abstract upstream channel
- managed MAC domain
- global service group mapping

```
Router(config)#cable fiber-node 67
Router(config-fiber-node)#downstream integrated-cable 6/0/6
Router(config-fiber-node)#upstream upstream-cable 6/0/6
Router(config-fiber-node)#downstream sg-channel 0 15 integrated-cable 6/0/6 rf-channel 0
15
Router(config-fiber-node)#upstream sg-channel 0 3 upstream-cable 6/0/6 us-channel 0 3
Router(config-fiber-node)#upstream sg-channel 4 7 peer-node-us
Router(config-fiber-node)#service-group managed md 0 cable6/0/6
Router(config-fiber-node)#service-group profile MD_SPLIT
```

```
Router(config)#cable fiber-node 69
Router(config-fiber-node)#downstream integrated-cable 6/0/6
Router(config-fiber-node)#upstream upstream-cable 6/0/1
Router(config-fiber-node)#downstream sg-channel 0 15 integrated-cable 6/0/6 rf-channel 0
15
Router(config-fiber-node)#upstream sg-channel 4 7 upstream-cable 6/0/1 us-channel 0 3
Router(config-fiber-node)#upstream sg-channel 0 3 peer-node-us
Router(config-fiber-node)#service-group managed md 0 cable6/0/6
Router(config-fiber-node)#service-group profile MD_SPLIT
```

Prerequisites for DOCSIS Load Balancing Groups

DOCSIS Load Balancing Groups including Restricted/General Load Balancing groups with Downstream Dynamic Load Balancing feature has the following prerequisites:

- A RLBG and a DOCSIS 2.0 GLBG should have a load balancing group (LBG) ID.
- A LBG should have a default policy ID.
- During registration, a cable modem (CM) that has been assigned to a LBG must also be assigned a policy ID and priority, through Simple Network Management Protocol (SNMP), the cable modem configuration file, or Cisco Cable Modem Termination System (CMTS) configuration.
- The cable modem must send service type identifier (STID), service class name, and DOCSIS version and capability type/length/value (TLV) settings to the Cisco CMTS for registration if the fields are used by general tagging.

Restrictions for DOCSIS Load Balancing Groups

The DOCSIS Load Balancing Groups (LBG) including RLBG/GLBG Support with DLB Support feature has the following restrictions:

- A maximum of 256 DOCSIS policies and 256 rules per chassis are supported.
- Cross-line card (LC) configuration or moving of cable modems is not supported.
- When deployed with channel restriction features, if the target upstream channel attribute masks are against that of the cable modem, then the cable modem on the higher load upstream will not be load balanced, as the current load balancing moves cable modems only to the target upstream. However, cable modems that do not have an attribute mask can still be load balanced. You should consider the following while deploying the load balancing groups: the target upstream will always be the upstream that has the lowest load. If some other upstreams have the same load, the upstream with the lowest index will be chosen as the target upstream.
- We recommend all LBGs that share channels must use the same LB method.

The DOCSIS LBG with RLBG/GLBG Support and DLB Support feature have the following cross functional restrictions:

- Cable modems operating in the multiple transmit channel (MTC) mode do not register for a RLBG assignment, even if their configuration file contains relevant TLVs, such as STID and LBG ID. However, cable modems operating in the multiple receive channel (MRC) can register for a RLBG assignment.
- The Cisco CMTS can parse a specific TLV encoded in cable modem configuration file, and prohibit any DCC operation on the cable modems.
- DOCSIS MAC domain downstream service group (MD-DS-SG) channels in MDD messages are incorrect when a combination of channels from multiple line card types are placed in the same fiber node.

In a complex fiber node setup, with channels from more than one line card, or downstream channels of one MAC domain in more than one fiber node, some modems may not come w-online (wideband online). If a MAC domain has more than one MD-DS-SG, the MDD will contain more than one MD-DS-SG and cause the modem to perform downstream ambiguity resolution. When the modem analyzes the downstream channels from the other line card, it will not see MDD packets and disqualify the channel and the MD-DS-SG. The modem then sends a requested MD-DS-SG of 0 to the CMTS implying it will not participate in a bonding group.

Use the **show cable mac-domain downstream-service-group** command to see the channels in the same MD-DS-SG.

The DOCSIS LBG with RLBG/GLBG Support and DLB Support feature have the following scaling limitations:

- The total number of RLBGs and DOCSIS 2.0 GLBGs cannot exceed 256.
- The total number of tags in a Cisco CMTS cannot exceed 256.
- The total number of DOCSIS 3.0 GLBGs is bounded by free memory.
- A cable modem reset occurs if a CM moves from one cable interface to another because DCC init-tech 0 resets a cable modem during a LB move. A cable modem also resets if the two cable interfaces have been configured with a mismatched **cable ip-init** command.

Information About DOCSIS Load Balancing Groups

The DOCSIS 2.0 “Autonomous Load Balancing” specification is CM-centric, allowing a channel (US or DS) to be part of multiple RLBGs. Therefore, with the DOCSIS 2.0 specifications, you can decide on which channel the CM can be load balanced.

To configure the Restricted/General Load Balancing and Narrowband Dynamic Bandwidth Sharing with Downstream Dynamic Load Balancing feature, you should understand the following concepts:

Service-Based Load Balancing

Using the DOCSIS 3.0 modem-based load balancing specifications, you can manage the LB activity on a per-modem basis as follows:

1. Modem to RLBG association through STID
2. Modem to RLBG association through LBG ID
3. Per-modem LB policy assignment
4. Per-modem LB priority assignment
5. Per-modem channel restriction

Implementing the DOCSIS 3.0 modem-based LB specifications enables the Cisco CMTS to provide an advanced service-based LB. The service-based LB can be used to alleviate the burden for the modem-based provisioning and provide the operator an ability to selectively control LB activity based on modem service type. For example, for LB purposes modems can be classified based on:

- Device type
- DOCSIS version
- Service class

The results of the classification can then be used to selectively control the modem LB activity by mapping the modem to the following settings:

- LBG
- Policy

With the service-based LB enabled, existing service-based cable modem segregation features and channel restriction become special cases and can be handled within the same LB framework.

Functionality

The Cisco CMTS functions in the following ways for general tagging and service-based LB:

- The Cisco CMTS can classify some modems with user-defined modem classifiers using the STID, service class name, DOCSIS version and capability TLVs and MAC Organization Unique Identifier (OUI).
- Each modem classifier has a unique tag. The Cisco CMTS allows each modem to carry one tag. When multiple tags match one cable modem, the tag that has the least index gets applied on the cable modems.
- The Cisco CMTS classifies a CM and assigns a tag, and if a RLBG with that tag is configured, the CM gets assigned to that RLBG.
- The Cisco CMTS can match multiple tags to a RLBG and a DOCSIS policy.
- On the Cisco CMTS, a user can configure whether the general tagging overrides the RLBG or DOCSIS policy assignment using TLVs in the CM configuration file and SNMP when a conflict occurs.

- When doing autonomous LB, the Cisco CMTS ensures that the target channels are available to a specific CM with regard to admission control, the SF attribute masks, and CM attribute masks.
- The user can configure the number of times that a DCC fails a CM before the CM is removed from dynamic LB on the Cisco CMTS.
- The user can configure DCC initialization techniques or whether to use Upstream Channel Change (UCC) for a LBG or for a particular source and target pair on the Cisco CMTS. However, DCC is not issued to cable modems provisioned in DOCSIS 1.0 mode. By default, the UCC for a LBG is not configured and therefore, all channel changes are done through DCC.
- The Cisco CMTS supports LB on at least one logical channel on a physical US channel that has multiple logical US channels.
- As per the DOCSIS 3.0 specifications, a lower load balancing priority indicates a higher likelihood that a CM will be moved due to load balancing operations.
- You can create a policy to set the lower bandwidth for CMs. the LBG can only move cable modems with throughput that is above the threshold.

Compatibility

Both downstream and upstream autonomous load balancing is supported for single channel cable modems.

RLBG/GLBG Assignment

The user can configure one or more service type IDs for each RLBG. The user can also configure the Cisco CMTS, using CLI or SNMP, to restrict a particular cable modem to a certain STID and RLBG ID. However, if such a configuration is made, both the STID and RLBG ID in the configuration file are ignored by the Cisco CMTS.

When the STID is configured by CLI or SNMP or the STID is present in the cable modem configuration file, the Cisco CMTS selects an upstream and downstream channel, which offers the signaled service type, from a RLBG, if such channels exist. However, if an upstream and downstream channel do not exist that provide the signaled service type the Cisco CMTS assigns an upstream and downstream channel that does not offer the signaled service type.

When the LBG ID is configured by CLI or SNMP or the LBG ID is present in the cable modem configuration file, the Cisco CMTS examines the available choices for upstream and downstream channels and, if they include a channel pair associated with the signaled LBG, the Cisco CMTS assigns the cable modem to the signaled LBG. If these conditions are not met, the Cisco CMTS disregards the LBG ID.

If there are multiple upstream and downstream channels available that meet the requirements of the STID, if present, and the LBG ID, if present, the Cisco CMTS selects an upstream and/or downstream channel that meet the cable modem required and forbidden attribute masks requested in the configuration file. If upstream and downstream channels are not available that meet these criteria, the Cisco CMTS can disregard the cable modem attribute masks and select an alternative upstream and/or downstream channel.

In determining a target channel pair for a cable modem during registration time, the Cisco CMTS tries to find the target channel pair that can actually reach the cable modem by checking the current channel pair, the MD-DS-SG-ID (Media Access Control Domain Downstream Service Group Identifier) of cable modem (CM-DS-SG-ID) and the MD-US-SG-ID (Media Access Control Domain Upstream Service Group Identifier) of cable modem (CM-US-SG-ID), if present, and fiber node (FN) configurations. If the target channel pair is available to the cable modem and is different from the current channel pair, the Cisco CMTS is required to move the CM by means of DCC technique 0 or downstream frequency override (DFO).

When the Cisco CMTS identifies multiple candidate RLBGs for a CM, but cannot determine which fiber node configuration the cable modem is actually wired to, or cannot determine if the wired RLBG is unusable (when

interfaces in the load balance group are disabled or in an administratively down state), the Cisco CMTS assigns the cable modem to the RLBG with the lowest group index. This assignment causes the Cisco CMTS to attempt to move the cable modem to interfaces it is not physically connected to, resulting in service outages for the CM.

The Cisco CMTS enforces fiber node checking during RLBG assignment.

The Cisco CMTS follows the following RLBG assignment rules:

- If there is no fiber node configuration, there is no change in the candidate RLBG list. However, if the fiber node is configured, the fiber node must be configured correctly to reflect the real fiber node connection.
- If the cable modem is inside a fiber node, only those RLBGs that are inside that fiber node are selected.
- If the cable modem is not inside any fiber node, that is, the fiber node configuration does not cover all the channels, only those RLBGs that are not inside any fiber node are selected.
- If an RLBG spans across multiple fiber nodes, it is not considered to be inside any fiber node.
- If no candidate RLBG is found, cable modems are assigned to the GLBG, if the GLBG exists.

Channel Assignment

For cable modems operating in MRC mode, the registration request message can have multiple TLVs to influence the selection of upstream and downstream channels that the Cisco CMTS assigns. To avoid conflicts between the multiple TLVs, the Cisco CMTS follows the precedence order defined below:

1. TLV 56—Channel Assignment
2. TLV 43.11—Service Type Identifier
3. TLV 43.3—Load Balancing Group ID
4. TLVs 24/25.31-33—Service Flow Attribute Masks
5. TLV 43.9—CM Attribute Masks

The Cisco CMTS must follow this TLV precedence order for cable modems not operating in MRC mode:

1. TLV 43.11—Service Type Identifier
2. TLV 43.3—Load Balancing Group ID
3. TLV 43.9—CM Attribute Masks
4. TLVs 24/25.31-33—Service Flow Attribute Masks

Note When a target for the new receive channel configuration (RCC) and Transmit channel configuration (TCC) is selected, ensure that the service level for cable modems is not decreased. Target total RCCs and TCCs must not be less than the source total RCCs and TCCs so that cable modems can keep their service level unchanged. This may cause some unbalanced results when high capacity cable modems come online, later releases..

The Cisco CMTS also considers the DOCSIS 3.0 cable modem capabilities defined in the registration request message and assigns the maximum number of channels that the CM requests.

The tables below define the load balancing matrix for RLBG and GLBG assignment:

Table 27: RLBG Assignment for DOCSIS Cable Modems

Operational Mode	MAC Version				
	DOCSIS 3.0 CM	DOCSIS 2.x CM	DOCSIS 2.0 CM	DOCSIS 1.1 CM	DOCSIS 1.0 CM

Operational Mode	MAC Version				
	Assigned	Assigned	Assigned	Assigned	Assigned
Non-MRC mode (online)	Assigned	Assigned	Assigned	Assigned	Assigned
MRC mode only (w-online)	Assigned	Assigned	Assigned	NA	NA
MRC/MTC mode (UB-online)	Assigned	NA	NA	NA	NA
	DOCSIS 3.0 cable modems are assigned to the DOCSIS 3.0 RLBG	NA	NA	NA	NA

Table 28: GLBG Assignment for DOCSIS Cable Modems

Operational Mode	MAC Version				
	DOCSIS 3.0 CM	DOCSIS 2.x CM	DOCSIS 2.0 CM	DOCSIS 1.1 CM	DOCSIS 1.0 CM
Non-MRC mode (online)	Assigned to the DOCSIS 2.0 GLBG without MD-DS-SG-ID/MD-US-SG-ID				
	Assigned to the DOCSIS 3.0 GLBG with MD-DS-SG-ID/MD-US-SG-ID		NA	NA	NA
MRC mode only (w-online)	Assigned to the DOCSIS 2.0 GLBG without MD-DS-SG-ID/MD-US-SG-ID				
	Assigned to the DOCSIS 3.0 GLBG with MD-DS-SG-ID/MD-US-SG-ID		NA	NA	NA
MRC/MTC mode (UB-online)	Assigned	NA	NA	NA	NA
	DOCSIS 3.0 cable modems are assigned to the DOCSIS 3.0 GLBG	NA	NA	NA	NA

The tables below give a snapshot view of the load balancing methods and the operations used to "move" bonded and non-bonded CMs.

Table 29: Load Balancing Method to Move Bonded and Non-bonded cable modems

Modem Mode	Dynamic Service Charge (Initialization Technique)	
	Within MAC Domain	Across MAC Domains
DOCSIS 3.0 cable modems in MTC mode	NA	DCC initialization technique 0

Modem Mode	Dynamic Service Charge (Initialization Technique)	
DOCSIS 3.0/DOCSIS 2.x cable modems in MRC-only mode	DCC initialization technique 0 Note CM with primary DS outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
DOCSIS 3.0 cable modems in MRC-only mode	DCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
DOCSIS 2.x cable modems in MRC-only mode	DCC/UCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
DOCSIS 2.0 /DOCSIS 1.1 cable modems in NB mode	DCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
	UCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	UCC
DOCSIS 1.0 in NB mode	Force reinitialize CM Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	Force reinitialize CM
	UCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	UCC

Table 30: Using DCC/DBC to Load Balance Bonded and Non-bonded Cable Modems

Channel	CM in MRC, non-MTC Mode	DOCSIS 1.1/DOCSIS 2.0 cable modems with Single US/DS	DOCSIS 1.0 cable modems with Single US/DS
Upstream (US)	DCC	DCC	UCC
Downstream (DS)	NA (within the same MAC domain)	DCC (within the same MAC domain).	Force reinitialize CM
	DCC with initialization technique 0 when moving cable modems across MAC domains.	DCC with initialization technique 0 when moving cable modems across MAC domains.	Force reinitialize CM

Error Handling of Channel Assignment

This restriction is modified. As long as the interface state of the channels is not "administratively down", all channels are available for LBG assignment. For other load balancing operations, such as moving modems

using DCC, UCC, or DBC, the interface state of the channels should be in "initial", "up", "suspicious", or "testing" states.

The following conditions apply when an LBG is disabled:

- cable modems that match all load balancing criteria can be assigned to an LBG.
- cable modem moves for load balancing are disabled, but cable modem moves from outside of the LBG to inside of the LBG are allowed.

Upstream Load Balancing for DOCSIS 3.0 Cable Modems in Single Upstream Mode

The upstream load balancing functionality enables the Cisco CMTS router to effectively handle upstream traffic for wideband and narrowband cable modems that are in single upstream mode. Single upstream mode (Mx1) means that the modems cannot send upstream traffic on multiple upstream channels. In the event of traffic overload on a single upstream channel of a wideband or narrowband cable modem, the Cisco CMTS router automatically moves the cable modem to another upstream channel in the same load balancing group.

Note A cable modem operating in single upstream mode is assigned to a load balancing group based on the primary channel of the modem. A cable modem in single upstream mode can support multiple receive channel (MRC) mode or narrowband mode. However, a cable modem in single upstream mode cannot support multiple transmit channel mode (MTC).

Auto-generate DOCSIS 2.0 GLBG

Cisco CMTS does not automatically implement DOCSIS 2.0 GLBG. DOCSIS 2.0 GLBG is configured manually after a new fiber node - MAC domain (FN-MD) pair is added.

This enhancement to automatically generate DOCSIS 2.0 GLBG after adding a new FN-MD pair and resolving a new combination of MAC domain, cable modem, and service group (MD-CM-SG). This enhancement is implemented through a new command **cable load-balance d20 GLBG auto-generate**. The command has options to renew and update DOCSIS 2.0 GLBGs for a fiber node configuration.

Independent Upstream/Downstream Throughput Rules

Currently, during upstream or downstream load balancing, to move modems in load balancing operations, Cisco CMTS applies the DOCSIS policy throughput rules to both upstream and downstream throughput to upstream or downstream load balancing operations. In other words, for downstream load balancing, both upstream and downstream sets of rules are applied and similarly for upstream load balancing both set of rules are applied. This prevents movement of modems with low upstream or high downstream throughput and high upstream or low downstream throughput.

Upstream or downstream throughput rules are checked independently to corresponding upstream or downstream load balancing operations. During upstream load balancing, only upstream throughput rules are checked, and during downstream load balancing, only downstream throughput rules are checked.

The following important points are implemented for independent upstream/downstream throughput rules:

- If DOCSIS 2.0 load balancing policy configured is **us-across-ds**, it is recommended to configure a maximum of 16 downstream channels and 8 upstream channels.
- If a load balancing operation involves a change only in the downstream channel of a cable modem without any change to the upstream channel, then only the downstream lower boundary rules are checked.
- If a load balancing operation involves a change only in the upstream channel of a cable modem without any change to the downstream channel, then only the upstream lower boundary rules are checked.
- If a load balancing operation involves a change in both the upstream and downstream channels of a cable modem, then the modem rule check must pass all the rules for that (upstream or downstream) load balancing.
- If the load balancing policy configured is **pure-ds-load**, then only the downstream rules are checked.
- If the load balancing policy configured is **us-across-ds** or both **us-across-ds** and **pure-ds-load**, then two types of target interfaces occur as follows:
 - Local interface—where the cable modem shares the upstream with the source. Only downstream load balancing operation occurs.
 - Remote interface—where the cable modem does not share the upstream with the source. The upstream/downstream load balancing is triggered by upstream load.

If the load balancing policy configured is neither **us-across-ds** nor **pure-ds-load**, then the load balancing is done based on Mac domain load.

How to Configure DOCSIS Load Balancing Groups

The Restricted/General Load Balancing and Narrowband Dynamic Bandwidth Sharing with Downstream Dynamic Load Balancing feature can be configured as follows:

- A user can configure a DOCSIS 2.0 general load balancing group (GLBG) on the Cisco CMTS according to DOCSIS specification. The Cisco CMTS creates a DOCSIS 3.0 GLBG for each Media Access Control Domain Cable Modem Service Group (MD-CM-SG) automatically and checks whether the GLBG contains both upstream and downstream channels.
- A cable modem that is not provisioned to any RLBG and cannot resolve its MD-CM-SG gets assigned to a DOCSIS 2.0 GLBG. However, if the cable modem resolves its MD-CM-SG, it gets assigned to a DOCSIS 3.0 GLBG.
- A user can configure RLBGs and any upstream or downstream channel into multiple RLBGs on the Cisco CMTS. The Cisco CMTS checks whether a RLBG contains both upstream and downstream channels. A RLBG can cross multiple MDs.
- A backward compatibility with existing Cisco LB schemes is maintained. The users can switch between the old and new DOCSIS 3.0 compliant LB schemes.

Note

When the Cisco IOS system is upgraded, if the `docsis-policy` configuration of the DOCSIS load balancing groups, is missing in the output of the **show running-config** command, apply the `docsis-policy` to the DOCSIS load balancing groups using the **docsis-policy** *policy-id* command again.

The following sections describe how to create and configure DOCSIS load balancing groups to enable DOCSIS load balancing on the Cisco CMTS:

Configuring DOCSIS 3.0 and 2.0 RLBG and DOCSIS 2.0 GLBG

This section describes how to create and configure a DOCSIS load balancing group. There is a separate configuration mode for a DOCSIS load balancing group that is different from the legacy load balancing group.

Note UGS/PCMM policy and threshold do not apply on DOCSIS 3.0 LB.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance docsis-enable Example: Router(config)# cable load-balance docsis-enable	Enables DOCSIS load balancing on the Cisco CMTS.
Step 4	cable load-balance docsis-group <i>docsis-group-id</i> Example: Router(config)# cable load-balance docsis-group 1	Creates a DOCSIS load balance group on the Cisco CMTS, with the following parameter: The router enters DOCSIS load balancing group configuration mode.
Step 5	init-tech-list <i>tech-list</i> [ucc] Example: Router(config-lb-group)# init-tech-list 1 ucc	Sets the DCC initialization techniques that the Cisco CMTS can use to load balance cable modems.
Step 6	downstream { Cable { <i>slot/subslot/port</i> <i>slot/port</i> } Integrated-Cable { <i>slot/subslot/bay</i> <i>slot/port</i> } { rf-channel <i>group list</i> }} { <i>slot/port</i> } { rf-channel <i>group list</i> }}	Sets the downstream RF channels.

	Command or Action	Purpose
	<p>Example:</p> <pre>Router(config-lb-group)# downstream integrated-Cable 5/0/0 rf-channel 2</pre>	
Step 7	<p>upstream Cable {slot/subslot/port slot/port} <i>upstream-list</i></p> <p>Example:</p> <pre>Router(config-lb-group)# upstream Cable 1/0 2</pre>	Sets upstream channels with the following parameters:
Step 8	<p>docsis-policy <i>policy-id</i></p> <p>Example:</p> <pre>Router(config-lb-group)# docsis-policy 0</pre>	Assigns a policy to a group with the parameter that becomes the default policy assigned to the CM, if the CM does not choose a different policy.
Step 9	<p>restricted</p> <p>Example:</p> <pre>Router(config-lb-group)# restricted</pre>	Selects the restricted group type. By default, the general group type is selected.
Step 10	<p>init-tech-ovr Cable {slot/subslot/port slot/port} <i>upstream Cable</i> {slot/subslot/port } slot/port <i>upstream init-tech-list 0-4 [ucc]</i></p> <p>Example:</p> <pre>Router(config-lb-group)# init-tech-ovr Cable 8/1/0 0 Cable 8/1/1 1 init-tech-list 1 ucc</pre>	<p>Sets DCC initialization techniques that overrides the physical upstream channel pair. The init-tech-ovr command can also be used to determine whether the UCC can be used for modems during dynamic upstream load balancing.</p> <p>The following parameters override the physical upstream channel pair:</p> <p>Note The init-tech-list keyword accepts an upstream that is not added into the load balancing group. The upstream channel pair is invalid until the upstream is added. When the load balancing group is removed, all upstream channel pairs are also removed.</p>
Step 11	<p>service-type-id <i>string</i></p> <p>Example:</p> <pre>Router(config-lb-group)# service-type-id commercial</pre>	Adds a service type ID, with the following parameter, that is compared against the cable modem provisioned service type ID, to determine an appropriate restricted load balancing group (RLBG):
Step 12	<p>tag <i>tag name</i></p> <p>Example:</p>	Adds a tag to the RLBG.

	Command or Action	Purpose
	Router (config-lb-group) # tag t1	
Step 13	interval <1-1000> Example: Router (config-lb-group) # interval 60	Sets the time interval, the Cisco CMTS waits before checking the load on an interface.
Step 14	method {modems service-flows utilization} {us-method {modems service-flows utilization}} Example: Router (config-lb-group) # method modems us-method modems	Selects the method the Cisco CMTS use to determine the load.
Step 15	policy {pcmm ugs us-across-ds pure-ds-load} Example: Router (config-lb-group) # policy us-across-ds Router (config-lb-group) # policy ugs Router (config-lb-group) # policy pure-ds-load	Selects the modems based on the type of service flow that are balanced.
Step 16	threshold {load {minimum <1-100> <1-100>}} {pcmm <1-100> stability <0-100> ugs <1-100>} Example: Router (config-lb-group) # threshold load minimum 10 Router (config-lb-group) # threshold pcmm 70 Router (config-lb-group) # threshold load 10 Router (config-lb-group) # threshold stability 50 Router (config-lb-group) # threshold ugs 70	Selects the percentage of use beyond which load balancing occurs.
Step 17	exit Example: Router# exit	Exits DOCSIS LBG configuration.

Configuring DOCSIS 3.0 GLBG

The following sections describe how to configure a DOCSIS 3.0 GLBG and also how to configure default values of DOCSIS 3.0 certification for the DOCSIS 3.0 general group:

Note If a Cable interface on the line card is in "no shut down" state, the associated DOCSIS 3.0 GLBGs are restored in the running-configuration.

Configuring a DOCSIS 3.0 General Load Balancing Group

This section describes how to configure a DOCSIS 3.0 general load balancing group.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance docsis-enable Example: Router(config)# cable load-balance docsis-enable	Enables DOCSIS load balancing on the Cisco CMTS.
Step 4	cable load-balance docsis-group FN <i>fn-id</i> MD <i>cable {slot/subslot/port slot/port}</i> Example: Router(config)# cable load-balance docsis-group FN 1 MD c5/0/0	Enters the DOCSIS load balancing group configuration mode.
Step 5	init-tech-list <i>tech-list</i> [ucc] Example: Router(config-lb-group)# init-tech-list 1 ucc	Sets the DCC initialization technique list, with the following parameters.
Step 6	disable Example: Router(config-lb-group)# disable	Disables the load balance group.
Step 7	docsis-policy <i>policy-id</i> Example: Router(config-lb-group)# docsis-policy 0	Sets the load balance group policy.
Step 8	interval <i>1-1000</i> Example: Router(config-lb-group)# interval 10	Sets the interface polling interval.
Step 9	method {modems service-flows utilization} {us-method {modems service-flows utilization}} Example: Router(config-lb-group)# method modems us-method modems	Sets the load balancing type or method.

	Command or Action	Purpose
Step 10	policy {pcmm ugs us-across-ds pure-ds-load} Example: Router(config-lb-group)# policy us-across-ds	Sets load balancing policy.
Step 11	threshold {load {minimum 1-100 1-100} pcmm 1-100 stability 0-100 ugs 1-100} Example: Router(config-lb-group)# threshold pcmm 70	Sets the load balancing threshold in percentage.
Step 12	exit Example: Router# exit	Exits the DOCSIS load balancing group configuration mode.

Configuring Default Values of DOCSIS 3.0 Load Balancing Group

This section describes how to configure default values of DOCSIS 3.0 certification for a DOCSIS 3.0 general group on the Cisco CMTS. A DOCSIS 3.0 general group is automatically created for each MD-CM-SG derived from the fiber node (FN) configuration, and the group parameters are set as default values.

Note The configured default values of DOCSIS 3.0 certification are applicable to the new automatically created DOCSIS 3.0 GLBGs and do not affect the existing DOCSIS 3.0 GLBGs. When a DOCSIS 3.0 GLBG is removed and recreated, its group parameters do not change.

Note The default settings for interface polling interval, load balancing method, policy for modems selection, and threshold usage in percent, can be configured for DOCSIS 3.0 general group. For more information, see the [Cisco CMTS Cable Command Reference](#).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance d30-ggrp-default disable Example:	Disables the default values of the DOCSIS 3.0 general load balance group (GLBG).

	Command or Action	Purpose
	Router(config)# cable load-balance d30-ggrp-default disable	
Step 4	cable load-balance d30-ggrp-default init-tech-list <i>tech-list</i> Example: Router(config)# cable load-balance d30-ggrp-default init-tech-list 1	Sets the default DOCSIS 3.0 GLBGs DCC and dynamic bonding change (DBC) initialization techniques.
Step 5	cable load-balance d30-ggrp-default docsis-policy 0-0xfffffff Example: Router(config)# cable load-balance d30-ggrp-default docsis-policy 2	Sets the default DOCSIS 3.0 GLBGs policy ID.
Step 6	exit Example: Router# exit	Exits the global configuration mode.

Configuring Cable Modems to RLBG or a Service Type ID

This section shows how to configure a list of cable modems that are statically provisioned at the Cisco CMTS to a RLBG or a service type ID.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance restrict modem <i>index mac-addr [mac-mask] {docsis-group docsis-group-id service-type-id string}</i> Example: Router(config)# cable load-balance restrict modem 1 001a.c30c.7eee FFFF.FFFF.0000 docsis-group 100	Assigns a modem or a group of modems with a common MAC mask to a load balancing group or a service type ID.
Step 4	exit Example: Router# exit	Exits the global configuration mode.

Configuring Rules and Policies

This section shows how to create and configure rules and DOCSIS policies to restrict the movement of modems during load balancing. Rules determine whether a modem can be moved and during which time periods. The time periods are measured in seconds with the start time being an offset from midnight measured in seconds. Rules are created individually and can be combined into policies. The user is able to create DOCSIS policies that consist of one or more rules. When more than one rule is part of a DOCSIS policy, all rules apply. Each group has a default DOCSIS policy.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance rule rule-id Example: Router(config)# cable load-balance rule 1	Creates a rule to prevent the modem from being moved.
Step 4	cable load-balance rule rule-id {enabled disabled {disable-period dis-start 0-86400 dis-period <0-86400>} disable-throughput-lowerbound ds us thrupt in kbps vdoc-enabled} Example: Router(config)# cable load-balance rule 1 disable-period dis-start 40 dis-period 50	Configures the rule. Note Static multicast groups should be configured on the appropriate bundle interface as well as on the correct forwarding interfaces to enable this rule. This feature will not be supported on load balancing groups which are derived from fiber node configuration and with multicast encryption.
Step 5	cable load-balance docsis-policy policy-id rule rule-id Example: Router(config)# cable load-balance docsis-policy 2 rule 1	Associates a particular rule with the DOCSIS policy with the following parameters:
Step 6	exit Example: Router# exit	Exits the global configuration mode.

Troubleshooting Tips

Problem When you disable load balancing and enable it for the next day using the **cable load-balance rule rule-id disable-period dis-start start-time dis-period disable-period** command, the load balancing is enabled at 12.00 am instead of the configured *disable-period*.

Possible Cause Load balancing rule cannot be disabled and enabled on the next day (that is, after 24 hours) using a single load balancing rule.

Solution Configure separate load balancing rules for disabling load balancing and enabling it on the next day. Configure the rule to disable load balancing using the **cable load-balance rule *rule-id* disable-period dis-start start-time dis-period 0** command. Configure the rule to enable load balancing using the **cable load-balance rule *rule-id* disable-period dis-start 0 dis-period *disable-period*** command to enable it for the next day.

Configuring Load Balancing Parameter for a Cable Modem Movement Failure

This section describes how to configure the number of times a CM can fail before the CM is removed from the dynamic load balancing group.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance modem max-failures 0-100 Example: Router(config)# cable load-balance modem max-failures 10	Configures the number of times a CM can fail before the CM is removed from the dynamic load balancing group.
Step 4	exit Example: Router# exit	Exits the global configuration mode.

Creating and Configuring TLV type Tag

The tags for TLV type matching rule are created and configured in this section.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# configure terminal	
Step 3	cable tag <i>1-1000</i> Example: Router(config)# cable tag 1	Creates a tag. Enters the cmts-tag configuration mode.
Step 4	name <i>tag name</i> Example: Router(cmts-tag)# name CSCO	Specifies the name of the tag.
Step 5	[exclude] service-type-id <i>service-type-id</i> Example: Router(cmts-tag)# service-type-id HSD	Configures the specified service type ID for the tag.
Step 6	[exclude]service-class <i>service-class-name</i> Example: Router(cmts-tag)# service-class work	Configures the specified service class name for the tag.
Step 7	[exclude] docsis-version <i>docsis version</i> Example: Router(cmts-tag)# docsis-version docsis20	Configures the specified DOCSIS version of the cable modem for the tag.
Step 8	[exclude] oui <i>oui of CM</i> Example: Router(cmts-tag)# oui 00.1a.c3	Configures the specified OUI of the cable modem for the tag.
Step 9	[exclude] tlv <i>type value</i> Example: Router(cmts-tag)# tlv mrccs 4	Configures the specified TLV type for the tag.
Step 10	override Example: Router(cmts-tag)# override	Overrides the TLV or SNMP during load balancing an RLBG.
Step 11	exit Example: Router(cmts-tag)# exit	Exits the cmts-tag configuration mode.
Step 12	cable load-balance docsis-group <i>docsis-group-id</i> Example: Router(config)# cable load-balance docsis-group 1	Creates a DOCSIS load balancing group on the Cisco CMTS. If the DOCSIS load balancing group is already present, the router enters the specified DOCSIS load balancing group configuration mode.

	Command or Action	Purpose
Step 13	tag tag name Example: Router(config-lb-group)# tag CSCO	Adds a tag to the load balancing group.
Step 14	exit Example: Router(config-lb-group)# exit	Exits the DOCSIS load balancing group configuration mode.
Step 15	cable load-balance docsis-policy policy-id tag tag name [override] Example: Router(config)# cable load-balance docsis-policy 2 tag CSCO	Creates a DOCSIS policy and associates a new rule or an existing rule with the policy.
Step 16	exit Example: Router# exit	Exits the global configuration mode.

Configuration Examples for DOCSIS Load Balancing Groups

This section describes a sample configuration example for configuring DOCSIS Load Balancing Groups including Restricted/General Load Balancing and downstream dynamic load balancing:

Example: Configuring a Tag

The following example shows how you can configure the tag to exclude a DOCSIS version, a MAC address, a service class name or a service type ID:

```

Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# cable tag 1
Router(cmts-tag)# exclude ?
  docsis-version  set the match rule for docsis version
  oui              set the match rule for oui
  service-class   set the match rule for service class name
  service-type-id set the match rule for service type id
Router(cmts-tag)# exclude docsis-version ?
  docsis10 Match docsis 1.0 modems
  docsis11 Match docsis 1.1 modems
  docsis20 Match docsis 2.0 modems
  docsis30 Match docsis 3.0 modems
Router(cmts-tag)# exclude docsis-version docsis10
Router(cmts-tag)# exclude oui ?
  WORD OUI of the vendor in the format xx.xx.xx or xx:xx:xx
Router(cmts-tag)# exclude oui 00.1a.c3
Router(cmts-tag)# exclude service-class ?
  WORD Service class name
Router(cmts-tag)# exclude service-class work
Router(cmts-tag)# exclude service-type-id ?

```

Example: Disabling Load Balancing

```
WORD Service Type ID
Router(cmts-tag) # exclude service-type-id commercial
```

Example: Disabling Load Balancing

Use the following commands to disable DOCSIS 3.0 GLBG:

```
Router(config)# cable load-balance docsis-group FN 1 MD cable 6/0/0
Router(config-lb-group) # disable
Router(config-lb-group) #
```

Use the following commands to disable DOCSIS 3.0 RLBG:

```
Router(config)# cable load-balance docsis-group 1
Router(config-lb-group) # disable
Router(config-lb-group) #
```

How to Configure Load Balancing with Operational Simplification

To configure Load Balancing Groups with Operational Simplification, complete the following steps:

SUMMARY STEPS

1. Define the global common Load Balancing profile. Specify the Load Balancing Group configure: method, interval, threshold, policy, and so on.
2. Define the Load Balancing Group under service-group profile. Associate the Load Balancing profile with Load Balancing group. Configure the DS and US channels.
3. Define the physical mapping info for US or DS channels under fiber-mode.
4. Define the service-group profile under Fiber-node.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Define the global common Load Balancing profile. Specify the Load Balancing Group configure: method, interval, threshold, policy, and so on. Example: <pre>cable profile load-balance lb_1 disable method utilization primary-distributed us-method utilization threshold load 2 policy pcmm interval 1</pre>	

	Command or Action	Purpose
Step 2	<p>Define the Load Balancing Group under service-group profile. Associate the Load Balancing profile with Load Balancing group. Configure the DS and US channels.</p> <p>Example:</p> <pre> cable profile service-group sg load-balance docsis-group 0 profile lb_1 downstream sg-channel 0-7 upstream 0 sg-channel 0 upstream 1 sg-channel 1 </pre>	
Step 3	<p>Define the physical mapping info for US or DS channels under fiber-mode.</p> <p>Example:</p> <pre> cable fiber-node 1 downstream sg-channel 0 15 downstream-Cable 6/0/0 rf-channel 0 15 upstream sg-channel 0 3 Upstream-Cable 6/0/0 us-channel 0 3 </pre>	
Step 4	<p>Define the service-group profile under Fiber-node.</p> <p>Example:</p> <pre> cable fiber-node 1 service-group profile sg </pre>	

The Load Balancing Groups are auto-generated when the SG profile is applied.

Example

An example of the Load Balancing Groups Operational Simplification configuration, **show run** as is as follows:

```

cable profile load-balance lb
method utilization primary-distributed us-method utilization
threshold load 22
threshold load lcmm 33
policy lcmm
policy pure-ds-load
init-tech-list 1-3

cable profile service-group sg
  load-balance docs is-group 0 profile lb
  downstream sg-channel 0 15
  upstream 0 sg-channel 0
  upstream 1 sg-channel 1
  upstream 2 sg-channel 2
  upstream 3 sg-channel 3
load-balance docsis-group 2 profile RLBG_STB
  downstream sg-channel 0-3 8-11
  upstream 0 sg-channel 0

```

```

cable fiber-node 1
  downstream Downstream-Cable 6/0/0
  upstream Upstream-Cable 6/0/0
  downstream sg-channel 0 15 downstream-Cable 6/0/0 rf-channel 0 15
    upstream sg-channel 0 3 Upstream-Cable 6/0/0 us-channel 0 3
  service-group profile sg

```

An example of the Load Balancing Groups Operational Simplification configuration, **show derived** as is as follows:

```

cable profile load-balance lb
  method utilization primary-distributed us-method utilization
  threshold load 22
  threshold load lcmm 33
  policy lcmm
  policy pure-ds-load
  init-tech-list 1-3

Cable profile service-group sg
  Load-balance docsis-group 0 profile lb
  downstream sg-channel 0 15
    upstream 0 sg-channel 0
    upstream 1 sg-channel 1
    upstream 2 sg-channel 2
    upstream 3 sg-channel 3
  load-balance docsis-group 2 profile RLBG_STB
    downstream sg-channel 0-3 8-11
    upstream 0 sg-channel 0

Cable fiber-node 1
  downstream Downstream-Cable 6/0/0
  upstream Upstream-Cable 6/0/0
  downstream sg-channel 0 15 downstream-Cable 6/0/0 rf-channel 0 15
  upstream sg-channel 0 3 Upstream-Cable 6/0/0 us-channel 0 3
  service-group profile sg

Cable load-balance docsis-group 2
  restricted
  downstream Downstream-Cable 6/0/0/ rf-channel 0 15
  upstream Upstream-Cable 6/0/0 us-channel 0-3
  method utilization primary-distributed
  threshold load 22
  threshold pcmm 33
  policy lcmm
  policy pure-ds-load
  init-tech-list 1-3
  cable managed fiber-node 1
  cable load-balance-profile lb
  cable load-balance docsis-group 3
  restricted
  downstream Downstream-Cable 6/0/0 rf-channel 0-3 8-11
  Upstream Upstream-Cable 6/0/0 us-channel 0
  Threshold load 55
  Interval 5
  Cable managed fiber-node 1
  Cable load-balance-profile RLBG_STB

```

Load Balancing Groups with Operational Simplification

The Cisco IOS XE Gibraltar 16.10.1d supports simplified Load Balancing configuration in the Operational Simplification service group profile. Currently, CMTS supports auto creation of D30 GLBGs based on the existing configuration. Load Balancing would now support creation of RLBGs and D20 GLBGs.

Following are the salient features of the feature:

- For D20 GLBG created by Operational Simplification, the Group ID is in range [65024, 65535]. This follows legacy design.
- For RLBG created by Operational Simplification, the Group ID is related to the information of fiber-node id/us channel controller/docsis-group index in service group file. This also follows legacy range [1, 2147483647]. For example: RLBG ID: 12330208. Where '123' is the Fiber node ID, '302' is the Upstream-Cable 6/0/0, and '08' is the docsis-group index in service group profile.

```
cable profile service-group sg
  load-balance docsis-group 8 profile lb_1
  downstream sg-channel 0-7
  upstream 0 sg-channel 0
  upstream 1 sg-channel 1
```

- The default value of Load Balance profile are equal to the value of “cable load-balance d20-ggrp-default xxx”.
- For Load Balancing Groups that are created by Operational Simplification, the user cannot configure them with CLI.
- For one service group profile, a user is only allowed to configure one GLBG load balance.
- A user can configure a maximum of 20 tags into one load balance profile.
- A user can configure a maximum of 15 service-type-ids into one load balance profile.
- Load Balancing Groups by Operational Simplification supports fly modification.
- For Load Balancing Groups created by Operational Simplification, if a user changes the option of Load Balance profile, the OPS would update all the related LBGs automatically. However, the user cannot change the type of LBGs.

For the Load Balancing Groups created by Operational Simplification, the configuration of the groups would not be displayed for the **show run** or the **show run all** commands. The Load Balancing Groups would only be displayed using the **derived** command. This change can simplify the running configuration.

```
clab-cbr-S11K01#show derived-config | sec cable load
cable load-balance docsis-group 1
restricted
downstream Downstream-Cable 6/0/0 rf-channel 0-7
upstream Upstream-Cable 6/0/0 us-channel 0-1
method utilization primary-distributed
threshold load 2
cable managed fiber-node 1
cable load-balance-profile lb_1
```

Verifying DOCSIS Load Balancing Groups

This section describes how to use certain show commands to verify the configuration of the Restricted/General Load Balancing and Narrowband Dynamic Bandwidth Sharing with Downstream Dynamic Load Balancing feature.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show cable load-balance docsis-group <i>{docsis-group-id FN fn-id MD cable {slot/subslot/port slot/port}}</i> [all load pending statistics target modem-list primary-load] Example: Router# show cable load-balance docsis-group 1 Router# show cable load-balance docsis-group fn 1 MD c8/1/4	Displays real-time configurational, statistical, and operational information of the load balancing operations on the router.
Step 3	show cable fiber-node <i>fiber-node-id</i> [spectrum] Example: Router# show cable fiber-node 3	Displays information about a fiber node.
Step 4	show cable load-balance [group n] [all load pending statistics target fiber-node-validation] Example: Router# show cable load-balance group 1	Displays real-time statistical and operational information for load balancing operations. If given without any options, this command displays information for the load balancing groups and each cable interface's current load and load balancing status.
Step 5	show cable modem [<i>ip-address mac-address cable slot/port</i>] [upstream port] [name fqdn] [<i>verbose</i>] Example: Router# show cable modem 40.3.160.15 verbose	Displays information for the registered and unregistered CMs.

Examples

Use the **show cable load-balance docsis-group** command to see the DOCSIS group status and to see the list of modems in the group, use the **show cable fiber-node** command to see the information on fiber nodes, use the **show cable load-balance** command to see information on LBG and DOCSIS channels, and use the **show cable modem** command to see the information on all the CMs.

The following examples show the output of the **show cable load-balance docsis-group** command:

```
Router# show cable load-balance docsis-group 2
```

```

DOCSIS LB Enabled: Yes
DOCSIS      Group Status Interval DCC mask Policy      Method Threshold
Group      Index
2          82 RE 10      0xF8(0)/N 0      s/s      1/1/70/70/50
Router# show cable load-balance docsis-group 1 modem-list
US
Mo1/0/0:0/U0      Group Index Mac Address      Priority
                  81      (1)
                  0000.ca45.9898      0
Mo1/0/0:0/U1      81      (0)
Mo1/0/0:0/U2      81      (2)
                  0013.711c.0820      0
                  0016.924f.8300      0

```

The output of the **show cable load-balance docsis-group** command is modified to include an additional field MUPFXLR to display more status information on the modems in the DOCSIS groups. For more information, see the [Cisco IOS CMTS Cable Command Reference](#).

The following example shows the modified output of the **show cable load-balance docsis-group** command:

```

Router#show cable load docsis-group fn 1 md c6/0/0 modem-list
Load for five secs: 1%/0%; one minute: 2%; five minutes: 1%

               Ca5/0/0/U2 {1}
               Ca5/0/0/U3 {1}
               Ca5/0/0 {}

```

The following example shows the output of the **show cable modem** command:

```
Router# show cable modem 40.3.160.19 verbose
LB group ID assigned(index)      : 1(81)
LB group ID in config file(index) : N/A(N/A)
LB policy ID      : 0
LB policy ID in config file      : 0
LB priority      : 0
Tag      :
```

DOCSIS 3.0 GLBG is generated dynamically by the fiber node configuration, if a valid fiber node is configured.

For example, if the fiber node configuration is:

```
cable fiber-node 2
downstream Modular-Cable 1/0/0 rf-channel 0-3
downstream Cable7/0/0
upstream Cable 7/0 connector 0-3
!
```

The GLBG generated by this fiber node is similar to:

```
Router# show cable load-balance docsis-group fn 2 md cable 7/0/0
DOCSIS 3.0 General LB
MD      FN  Group S Intv DCC mask  Policy      Mtd MD-CM-SG Threshold

Feature Information for DOCSIS Load Balancing Groups

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 31: Feature Information for DOCSIS Load Balancing Groups

Feature Name	Releases	Feature Information
DOCSIS Load Balancing Groups	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the cisco cBR Series Converged Broadband Routers.
Load Balancing with Operational Simplification	Cisco IOS XE Gibraltar 16.10.1d.	This feature was integrated on the cisco cBR Series Converged Broadband Routers.

Prerequisites for DOCSIS Load Balancing Groups

DOCSIS Load Balancing Groups including Restricted/General Load Balancing groups with Downstream Dynamic Load Balancing feature has the following prerequisites:

- A RLBG and a DOCSIS 2.0 GLBG should have a load balancing group (LBG) ID.
- A LBG should have a default policy ID.
- During registration, a cable modem (CM) that has been assigned to a LBG must also be assigned a policy ID and priority, through Simple Network Management Protocol (SNMP), the cable modem configuration file, or Cisco Cable Modem Termination System (CMTS) configuration.
- The cable modem must send service type identifier (STID), service class name, and DOCSIS version and capability type/length/value (TLV) settings to the Cisco CMTS for registration if the fields are used by general tagging.

Restrictions for DOCSIS Load Balancing Groups

The DOCSIS Load Balancing Groups (LBG) including RLBG/GLBG Support with DLB Support feature has the following restrictions:

- A maximum of 256 DOCSIS policies and 256 rules per chassis are supported.
- Cross-line card (LC) configuration or moving of cable modems is not supported.
- When deployed with channel restriction features, if the target upstream channel attribute masks are against that of the cable modem, then the cable modem on the higher load upstream will not be load balanced, as the current load balancing moves cable modems only to the target upstream. However, cable modems that do not have an attribute mask can still be load balanced. You should consider the following while deploying the load balancing groups: the target upstream will always be the upstream that has the lowest load. If some other upstreams have the same load, the upstream with the lowest index will be chosen as the target upstream.
- We recommend all LBGs that share channels must use the same LB method.

The DOCSIS LBG with RLBG/GLBG Support and DLB Support feature have the following cross functional restrictions:

- Cable modems operating in the multiple transmit channel (MTC) mode do not register for a RLBG assignment, even if their configuration file contains relevant TLVs, such as STID and LBG ID. However, cable modems operating in the multiple receive channel (MRC) can register for a RLBG assignment.
- The Cisco CMTS can parse a specific TLV encoded in cable modem configuration file, and prohibit any DCC operation on the cable modems.
- DOCSIS MAC domain downstream service group (MD-DS-SG) channels in MDD messages are incorrect when a combination of channels from multiple line card types are placed in the same fiber node.

In a complex fiber node setup, with channels from more than one line card, or downstream channels of one MAC domain in more than one fiber node, some modems may not come w-online (wideband online). If a MAC domain has more than one MD-DS-SG, the MDD will contain more than one MD-DS-SG and cause the modem to perform downstream ambiguity resolution. When the modem analyzes the downstream channels from the other line card, it will not see MDD packets and disqualify the channel and the MD-DS-SG. The modem then sends a requested MD-DS-SG of 0 to the CMTS implying it will not participate in a bonding group.

Use the **show cable mac-domain downstream-service-group** command to see the channels in the same MD-DS-SG.

The DOCSIS LBG with RLBG/GLBG Support and DLB Support feature have the following scaling limitations:

- The total number of RLBGs and DOCSIS 2.0 GLBGs cannot exceed 256.
- The total number of tags in a Cisco CMTS cannot exceed 256.
- The total number of DOCSIS 3.0 GLBGs is bounded by free memory.
- A cable modem reset occurs if a CM moves from one cable interface to another because DCC init-tech 0 resets a cable modem during a LB move. A cable modem also resets if the two cable interfaces have been configured with a mismatched **cable ip-init** command.

Information About DOCSIS Load Balancing Groups

The DOCSIS 2.0 “Autonomous Load Balancing” specification is CM-centric, allowing a channel (US or DS) to be part of multiple RLBGs. Therefore, with the DOCSIS 2.0 specifications, you can decide on which channel the CM can be load balanced.

To configure the Restricted/General Load Balancing and Narrowband Dynamic Bandwidth Sharing with Downstream Dynamic Load Balancing feature, you should understand the following concepts:

Service-Based Load Balancing

Using the DOCSIS 3.0 modem-based load balancing specifications, you can manage the LB activity on a per-modem basis as follows:

1. Modem to RLBG association through STID
2. Modem to RLBG association through LBG ID
3. Per-modem LB policy assignment
4. Per-modem LB priority assignment
5. Per-modem channel restriction

Implementing the DOCSIS 3.0 modem-based LB specifications enables the Cisco CMTS to provide an advanced service-based LB. The service-based LB can be used to alleviate the burden for the modem-based provisioning and provide the operator an ability to selectively control LB activity based on modem service type. For example, for LB purposes modems can be classified based on:

- Device type
- DOCSIS version
- Service class

The results of the classification can then be used to selectively control the modem LB activity by mapping the modem to the following settings:

- LBG
- Policy

With the service-based LB enabled, existing service-based cable modem segregation features and channel restriction become special cases and can be handled within the same LB framework.

Functionality

The Cisco CMTS functions in the following ways for general tagging and service-based LB:

- The Cisco CMTS can classify some modems with user-defined modem classifiers using the STID, service class name, DOCSIS version and capability TLVs and MAC Organization Unique Identifier (OUI).
- Each modem classifier has a unique tag. The Cisco CMTS allows each modem to carry one tag. When multiple tags match one cable modem, the tag that has the least index gets applied on the cable modems.
- The Cisco CMTS classifies a CM and assigns a tag, and if a RLBG with that tag is configured, the CM gets assigned to that RLBG.
- The Cisco CMTS can match multiple tags to a RLBG and a DOCSIS policy.
- On the Cisco CMTS, a user can configure whether the general tagging overrides the RLBG or DOCSIS policy assignment using TLVs in the CM configuration file and SNMP when a conflict occurs.
- When doing autonomous LB, the Cisco CMTS ensures that the target channels are available to a specific CM with regard to admission control, the SF attribute masks, and CM attribute masks.
- The user can configure the number of times that a DCC fails a CM before the CM is removed from dynamic LB on the Cisco CMTS.
- The user can configure DCC initialization techniques or whether to use Upstream Channel Change (UCC) for a LBG or for a particular source and target pair on the Cisco CMTS. However, DCC is not issued to cable modems provisioned in DOCSIS 1.0 mode. By default, the UCC for a LBG is not configured and therefore, all channel changes are done through DCC.
- The Cisco CMTS supports LB on at least one logical channel on a physical US channel that has multiple logical US channels.
- As per the DOCSIS 3.0 specifications, a lower load balancing priority indicates a higher likelihood that a CM will be moved due to load balancing operations.
- You can create a policy to set the lower bandwidth for CMs. the LBG can only move cable modems with throughput that is above the threshold.

Compatibility

Both downstream and upstream autonomous load balancing is supported for single channel cable modems.

RLBG/GLBG Assignment

The user can configure one or more service type IDs for each RLBG. The user can also configure the Cisco CMTS, using CLI or SNMP, to restrict a particular cable modem to a certain STID and RLBG ID. However, if such a configuration is made, both the STID and RLBG ID in the configuration file are ignored by the Cisco CMTS.

When the STID is configured by CLI or SNMP or the STID is present in the cable modem configuration file, the Cisco CMTS selects an upstream and downstream channel, which offers the signaled service type, from a RLBG, if such channels exist. However, if an upstream and downstream channel do not exist that provide the signaled service type the Cisco CMTS assigns an upstream and downstream channel that does not offer the signaled service type.

When the LBG ID is configured by CLI or SNMP or the LBG ID is present in the cable modem configuration file, the Cisco CMTS examines the available choices for upstream and downstream channels and, if they include a channel pair associated with the signaled LBG, the Cisco CMTS assigns the cable modem to the signaled LBG. If these conditions are not met, the Cisco CMTS disregards the LBG ID.

If there are multiple upstream and downstream channels available that meet the requirements of the STID, if present, and the LBG ID, if present, the Cisco CMTS selects an upstream and/or downstream channel that meet the cable modem required and forbidden attribute masks requested in the configuration file. If upstream and downstream channels are not available that meet these criteria, the Cisco CMTS can disregard the cable modem attribute masks and select an alternative upstream and/or downstream channel.

In determining a target channel pair for a cable modem during registration time, the Cisco CMTS tries to find the target channel pair that can actually reach the cable modem by checking the current channel pair, the MD-DS-SG-ID (Media Access Control Domain Downstream Service Group Identifier) of cable modem (CM-DS-SG-ID) and the MD-US-SG-ID (Media Access Control Domain Upstream Service Group Identifier) of cable modem (CM-US-SG-ID), if present, and fiber node (FN) configurations. If the target channel pair is available to the cable modem and is different from the current channel pair, the Cisco CMTS is required to move the CM by means of DCC technique 0 or downstream frequency override (DFO).

When the Cisco CMTS identifies multiple candidate RLBGs for a CM, but cannot determine which fiber node configuration the cable modem is actually wired to, or cannot determine if the wired RLBG is unusable (when interfaces in the load balance group are disabled or in an administratively down state), the Cisco CMTS assigns the cable modem to the RLBG with the lowest group index. This assignment causes the Cisco CMTS to attempt to move the cable modem to interfaces it is not physically connected to, resulting in service outages for the CM.

The Cisco CMTS enforces fiber node checking during RLBG assignment.

The Cisco CMTS follows the following RLBG assignment rules:

- If there is no fiber node configuration, there is no change in the candidate RLBG list. However, if the fiber node is configured, the fiber node must be configured correctly to reflect the real fiber node connection.
- If the cable modem is inside a fiber node, only those RLBGs that are inside that fiber node are selected.
- If the cable modem is not inside any fiber node, that is, the fiber node configuration does not cover all the channels, only those RLBGs that are not inside any fiber node are selected.
- If an RLBG spans across multiple fiber nodes, it is not considered to be inside any fiber node.
- If no candidate RLBG is found, cable modems are assigned to the GLBG, if the GLBG exists.

Channel Assignment

For cable modems operating in MRC mode, the registration request message can have multiple TLVs to influence the selection of upstream and downstream channels that the Cisco CMTS assigns. To avoid conflicts between the multiple TLVs, the Cisco CMTS follows the precedence order defined below:

1. TLV 56—Channel Assignment
2. TLV 43.11—Service Type Identifier
3. TLV 43.3—Load Balancing Group ID
4. TLVs 24/25.31-33—Service Flow Attribute Masks
5. TLV 43.9—CM Attribute Masks

The Cisco CMTS must follow this TLV precedence order for cable modems not operating in MRC mode:

1. TLV 43.11—Service Type Identifier
2. TLV 43.3—Load Balancing Group ID
3. TLV 43.9—CM Attribute Masks
4. TLVs 24/25.31-33—Service Flow Attribute Masks

Note

When a target for the new receive channel configuration (RCC) and Transmit channel configuration (TCC) is selected, ensure that the service level for cable modems is not decreased. Target total RCCs and TCCs must not be less than the source total RCCs and TCCs so that cable modems can keep their service level unchanged. This may cause some unbalanced results when high capacity cable modems come online, later releases.

The Cisco CMTS also considers the DOCSIS 3.0 cable modem capabilities defined in the registration request message and assigns the maximum number of channels that the CM requests.

The tables below define the load balancing matrix for RLBG and GLBG assignment:

Table 32: RLBG Assignment for DOCSIS Cable Modems

Operational Mode	MAC Version				
	DOCSIS 3.0 CM	DOCSIS 2.x CM	DOCSIS 2.0 CM	DOCSIS 1.1 CM	DOCSIS 1.0 CM
Non-MRC mode (online)	Assigned	Assigned	Assigned	Assigned	Assigned
MRC mode only (w-online)	Assigned	Assigned	Assigned	NA	NA
MRC/MTC mode (UB-online)	Assigned	NA	NA	NA	NA
	DOCSIS 3.0 cable modems are assigned to the DOCSIS 3.0 RLBG	NA	NA	NA	NA

Table 33: GLBG Assignment for DOCSIS Cable Modems

Operational Mode	MAC Version				
	DOCSIS 3.0 CM	DOCSIS 2.x CM	DOCSIS 2.0 CM	DOCSIS 1.1 CM	DOCSIS 1.0 CM
Non-MRC mode (online)	Assigned to the DOCSIS 2.0 GLBG without MD-DS-SG-ID/MD-US-SG-ID				
	Assigned to the DOCSIS 3.0 GLBG with MD-DS-SG-ID/MD-US-SG-ID		NA	NA	NA
MRC mode only (w-online)	Assigned to the DOCSIS 2.0 GLBG without MD-DS-SG-ID/MD-US-SG-ID				
	Assigned to the DOCSIS 3.0 GLBG with MD-DS-SG-ID/MD-US-SG-ID		NA	NA	NA
MRC/MTC mode (UB-online)	Assigned	NA	NA	NA	NA
	DOCSIS 3.0 cable modems are assigned to the DOCSIS 3.0 GLBG	NA	NA	NA	NA

The tables below give a snapshot view of the load balancing methods and the operations used to "move" bonded and non-bonded CMs.

Table 34: Load Balancing Method to Move Bonded and Non-bonded cable modems

Modem Mode	Dynamic Service Charge (Initialization Technique)	
	Within MAC Domain	Across MAC Domains
DOCSIS 3.0 cable modems in MTC mode	NA	DCC initialization technique 0
DOCSIS 3.0/DOCSIS 2.x cable modems in MRC-only mode	DCC initialization technique 0 Note CM with primary DS outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
DOCSIS 3.0 cable modems in MRC-only mode	DCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
DOCSIS 2.x cable modems in MRC-only mode	DCC/UCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
DOCSIS 2.0 /DOCSIS 1.1 cable modems in NB mode	DCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	DCC initialization technique 0
	UCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	UCC
DOCSIS 1.0 in NB mode	Force reinitialize CM Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	Force reinitialize CM
	UCC Note CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.	UCC

Table 35: Using DCC/DBC to Load Balance Bonded and Non-bonded Cable Modems

Channel	CM in MRC, non-MTC Mode	DOCSIS 1.1/DOCSIS 2.0 cable modems with Single US/DS	DOCSIS 1.0 cable modems with Single US/DS
Upstream (US)	DCC	DCC	UCC
Downstream (DS)	NA (within the same MAC domain)	DCC (within the same MAC domain).	Force reinitialize CM
	DCC with initialization technique 0 when moving cable modems across MAC domains.	DCC with initialization technique 0 when moving cable modems across MAC domains.	Force reinitialize CM

Error Handling of Channel Assignment

This restriction is modified. As long as the interface state of the channels is not "administratively down", all channels are available for LBG assignment. For other load balancing operations, such as moving modems using DCC, UCC, or DBC, the interface state of the channels should be in "initial", "up", "suspicious", or "testing" states.

The following conditions apply when an LBG is disabled:

- cable modems that match all load balancing criteria can be assigned to an LBG.
- cable modem moves for load balancing are disabled, but cable modem moves from outside of the LBG to inside of the LBG are allowed.

Upstream Load Balancing for DOCSIS 3.0 Cable Modems in Single Upstream Mode

The upstream load balancing functionality enables the Cisco CMTS router to effectively handle upstream traffic for wideband and narrowband cable modems that are in single upstream mode. Single upstream mode (Mx1) means that the modems cannot send upstream traffic on multiple upstream channels. In the event of traffic overload on a single upstream channel of a wideband or narrowband cable modem, the Cisco CMTS router automatically moves the cable modem to another upstream channel in the same load balancing group.

Note A cable modem operating in single upstream mode is assigned to a load balancing group based on the primary channel of the modem. A cable modem in single upstream mode can support multiple receive channel (MRC) mode or narrowband mode. However, a cable modem in single upstream mode cannot support multiple transmit channel mode (MTC).

Auto-generate DOCSIS 2.0 GLBG

Cisco CMTS does not automatically implement DOCSIS 2.0 GLBG. DOCSIS 2.0 GLBG is configured manually after a new fiber node - MAC domain (FN-MD) pair is added.

This enhancement to automatically generate DOCSIS 2.0 GLBG after adding a new FN-MD pair and resolving a new combination of MAC domain, cable modem, and service group (MD-CM-SG). This enhancement is implemented through a new command **cable load-balance d20 GLBG auto-generate**. The command has options to renew and update DOCSIS 2.0 GLBGs for a fiber node configuration.

Independent Upstream/Downstream Throughput Rules

Currently, during upstream or downstream load balancing, to move modems in load balancing operations, Cisco CMTS applies the DOCSIS policy throughput rules to both upstream and downstream throughput to upstream or downstream load balancing operations. In other words, for downstream load balancing, both upstream and downstream sets of rules are applied and similarly for upstream load balancing both set of rules are applied. This prevents movement of modems with low upstream or high downstream throughput and high upstream or low downstream throughput.

Upstream or downstream throughput rules are checked independently to corresponding upstream or downstream load balancing operations. During upstream load balancing, only upstream throughput rules are checked, and during downstream load balancing, only downstream throughput rules are checked.

The following important points are implemented for independent upstream/downstream throughput rules:

- If DOCSIS 2.0 load balancing policy configured is **us-across-ds**, it is recommended to configure a maximum of 16 downstream channels and 8 upstream channels.
- If a load balancing operation involves a change only in the downstream channel of a cable modem without any change to the upstream channel, then only the downstream lower boundary rules are checked.
- If a load balancing operation involves a change only in the upstream channel of a cable modem without any change to the downstream channel, then only the upstream lower boundary rules are checked.
- If a load balancing operation involves a change in both the upstream and downstream channels of a cable modem, then the modem rule check must pass all the rules for that (upstream or downstream) load balancing.
- If the load balancing policy configured is **pure-ds-load**, then only the downstream rules are checked.
- If the load balancing policy configured is **us-across-ds** or both **us-across-ds** and **pure-ds-load**, then two types of target interfaces occur as follows:
 - Local interface—where the cable modem shares the upstream with the source. Only downstream load balancing operation occurs.
 - Remote interface—where the cable modem does not share the upstream with the source. The upstream/downstream load balancing is triggered by upstream load.

If the load balancing policy configured is neither **us-across-ds** nor **pure-ds-load**, then the load balancing is done based on Mac domain load.

How to Configure DOCSIS Load Balancing Groups

The Restricted/General Load Balancing and Narrowband Dynamic Bandwidth Sharing with Downstream Dynamic Load Balancing feature can be configured as follows:

- A user can configure a DOCSIS 2.0 general load balancing group (GLBG) on the Cisco CMTS according to DOCSIS specification. The Cisco CMTS creates a DOCSIS 3.0 GLBG for each Media Access Control Domain Cable Modem Service Group (MD-CM-SG) automatically and checks whether the GLBG contains both upstream and downstream channels.
- A cable modem that is not provisioned to any RLBG and cannot resolve its MD-CM-SG gets assigned to a DOCSIS 2.0 GLBG. However, if the cable modem resolves its MD-CM-SG, it gets assigned to a DOCSIS 3.0 GLBG.
- A user can configure RLBGs and any upstream or downstream channel into multiple RLBGs on the Cisco CMTS. The Cisco CMTS checks whether a RLBG contains both upstream and downstream channels. A RLBG can cross multiple MDs.
- A backward compatibility with existing Cisco LB schemes is maintained. The users can switch between the old and new DOCSIS 3.0 compliant LB schemes.

Note When the Cisco IOS system is upgraded, if the `docsis-policy` configuration of the DOCSIS load balancing groups, is missing in the output of the **show running-config** command, apply the `docsis-policy` to the DOCSIS load balancing groups using the **docsis-policy *policy-id*** command again.

The following sections describe how to create and configure DOCSIS load balancing groups to enable DOCSIS load balancing on the Cisco CMTS:

Configuring DOCSIS 3.0 and 2.0 RLBG and DOCSIS 2.0 GLBG

This section describes how to create and configure a DOCSIS load balancing group. There is a separate configuration mode for a DOCSIS load balancing group that is different from the legacy load balancing group.

Note UGS/PCMM policy and threshold do not apply on DOCSIS 3.0 LB.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance docsis-enable Example: Router(config)# cable load-balance docsis-enable	Enables DOCSIS load balancing on the Cisco CMTS.
Step 4	cable load-balance docsis-group <i>docsis-group-id</i> Example: Router(config)# cable load-balance docsis-group 1	Creates a DOCSIS load balance group on the Cisco CMTS, with the following parameter: The router enters DOCSIS load balancing group configuration mode.
Step 5	init-tech-list <i>tech-list</i> [ucc] Example: Router(config-lb-group)# init-tech-list 1 ucc	Sets the DCC initialization techniques that the Cisco CMTS can use to load balance cable modems.
Step 6	downstream { Cable { <i>slot/subslot/port</i> <i>slot/port</i> } Integrated-Cable { <i>slot/subslot/bay</i> <i>slot/port</i> } { rf-channel <i>group list</i> }} { <i>slot/port</i> } { rf-channel <i>group list</i> }}	Sets the downstream RF channels.

	Command or Action	Purpose
	<p>Example:</p> <pre>Router(config-lb-group)# downstream integrated-Cable 5/0/0 rf-channel 2</pre>	
Step 7	<p>upstream Cable {slot/subslot/port slot/port} <i>upstream-list</i></p> <p>Example:</p> <pre>Router(config-lb-group)# upstream Cable 1/0 2</pre>	Sets upstream channels with the following parameters:
Step 8	<p>docsis-policy <i>policy-id</i></p> <p>Example:</p> <pre>Router(config-lb-group)# docsis-policy 0</pre>	Assigns a policy to a group with the parameter that becomes the default policy assigned to the CM, if the CM does not choose a different policy.
Step 9	<p>restricted</p> <p>Example:</p> <pre>Router(config-lb-group)# restricted</pre>	Selects the restricted group type. By default, the general group type is selected.
Step 10	<p>init-tech-ovr Cable {slot/subslot/port slot/port} <i>upstream Cable</i> {slot/subslot/port } slot/port <i>upstream init-tech-list 0-4 [ucc]</i></p> <p>Example:</p> <pre>Router(config-lb-group)# init-tech-ovr Cable 8/1/0 0 Cable 8/1/1 1 init-tech-list 1 ucc</pre>	<p>Sets DCC initialization techniques that overrides the physical upstream channel pair. The init-tech-ovr command can also be used to determine whether the UCC can be used for modems during dynamic upstream load balancing.</p> <p>The following parameters override the physical upstream channel pair:</p> <p>Note The init-tech-list keyword accepts an upstream that is not added into the load balancing group. The upstream channel pair is invalid until the upstream is added. When the load balancing group is removed, all upstream channel pairs are also removed.</p>
Step 11	<p>service-type-id <i>string</i></p> <p>Example:</p> <pre>Router(config-lb-group)# service-type-id commercial</pre>	Adds a service type ID, with the following parameter, that is compared against the cable modem provisioned service type ID, to determine an appropriate restricted load balancing group (RLBG):
Step 12	<p>tag <i>tag name</i></p> <p>Example:</p>	Adds a tag to the RLBG.

	Command or Action	Purpose
	Router (config-lb-group) # tag t1	
Step 13	interval <1-1000> Example: Router (config-lb-group) # interval 60	Sets the time interval, the Cisco CMTS waits before checking the load on an interface.
Step 14	method {modems service-flows utilization} {us-method {modems service-flows utilization}} Example: Router (config-lb-group) # method modems us-method modems	Selects the method the Cisco CMTS use to determine the load.
Step 15	policy {pcmm ugs us-across-ds pure-ds-load} Example: Router (config-lb-group) # policy us-across-ds Router (config-lb-group) # policy ugs Router (config-lb-group) # policy pure-ds-load	Selects the modems based on the type of service flow that are balanced.
Step 16	threshold {load {minimum <1-100> <1-100>}} {pcmm <1-100> stability <0-100> ugs <1-100>} Example: Router (config-lb-group) # threshold load minimum 10 Router (config-lb-group) # threshold pcmm 70 Router (config-lb-group) # threshold load 10 Router (config-lb-group) # threshold stability 50 Router (config-lb-group) # threshold ugs 70	Selects the percentage of use beyond which load balancing occurs.
Step 17	exit Example: Router# exit	Exits DOCSIS LBG configuration.

Configuring DOCSIS 3.0 GLBG

The following sections describe how to configure a DOCSIS 3.0 GLBG and also how to configure default values of DOCSIS 3.0 certification for the DOCSIS 3.0 general group:

Note If a Cable interface on the line card is in "no shut down" state, the associated DOCSIS 3.0 GLBGs are restored in the running-configuration.

Configuring a DOCSIS 3.0 General Load Balancing Group

This section describes how to configure a DOCSIS 3.0 general load balancing group.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance docsis-enable Example: Router(config)# cable load-balance docsis-enable	Enables DOCSIS load balancing on the Cisco CMTS.
Step 4	cable load-balance docsis-group FN <i>fn-id</i> MD <i>cable {slot/subslot/port slot/port}</i> Example: Router(config)# cable load-balance docsis-group FN 1 MD c5/0/0	Enters the DOCSIS load balancing group configuration mode.
Step 5	init-tech-list <i>tech-list</i> [ucc] Example: Router(config-lb-group)# init-tech-list 1 ucc	Sets the DCC initialization technique list, with the following parameters.
Step 6	disable Example: Router(config-lb-group)# disable	Disables the load balance group.
Step 7	docsis-policy <i>policy-id</i> Example: Router(config-lb-group)# docsis-policy 0	Sets the load balance group policy.
Step 8	interval <i>1-1000</i> Example: Router(config-lb-group)# interval 10	Sets the interface polling interval.
Step 9	method {modems service-flows utilization} {us-method {modems service-flows utilization}} Example: Router(config-lb-group)# method modems us-method modems	Sets the load balancing type or method.

	Command or Action	Purpose
Step 10	policy {pcmm ugs us-across-ds pure-ds-load} Example: Router(config-lb-group)# policy us-across-ds	Sets load balancing policy.
Step 11	threshold {load {minimum 1-100 1-100} pcmm 1-100 stability 0-100 ugs 1-100} Example: Router(config-lb-group)# threshold pcmm 70	Sets the load balancing threshold in percentage.
Step 12	exit Example: Router# exit	Exits the DOCSIS load balancing group configuration mode.

Configuring Default Values of DOCSIS 3.0 Load Balancing Group

This section describes how to configure default values of DOCSIS 3.0 certification for a DOCSIS 3.0 general group on the Cisco CMTS. A DOCSIS 3.0 general group is automatically created for each MD-CM-SG derived from the fiber node (FN) configuration, and the group parameters are set as default values.

Note The configured default values of DOCSIS 3.0 certification are applicable to the new automatically created DOCSIS 3.0 GLBGs and do not affect the existing DOCSIS 3.0 GLBGs. When a DOCSIS 3.0 GLBG is removed and recreated, its group parameters do not change.

Note The default settings for interface polling interval, load balancing method, policy for modems selection, and threshold usage in percent, can be configured for DOCSIS 3.0 general group. For more information, see the [Cisco CMTS Cable Command Reference](#).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance d30-ggrp-default disable Example:	Disables the default values of the DOCSIS 3.0 general load balance group (GLBG).

	Command or Action	Purpose
	Router(config)# cable load-balance d30-ggrp-default disable	
Step 4	cable load-balance d30-ggrp-default init-tech-list <i>tech-list</i> Example: Router(config)# cable load-balance d30-ggrp-default init-tech-list 1	Sets the default DOCSIS 3.0 GLBGs DCC and dynamic bonding change (DBC) initialization techniques.
Step 5	cable load-balance d30-ggrp-default docsis-policy <i>0-0xffffffff</i> Example: Router(config)# cable load-balance d30-ggrp-default docsis-policy 2	Sets the default DOCSIS 3.0 GLBGs policy ID.
Step 6	exit Example: Router# exit	Exits the global configuration mode.

Configuring Cable Modems to RLBG or a Service Type ID

This section shows how to configure a list of cable modems that are statically provisioned at the Cisco CMTS to a RLBG or a service type ID.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance restrict modem <i>index mac-addr [mac-mask] {docsis-group docsis-group-id service-type-id string}</i> Example: Router(config)# cable load-balance restrict modem 1 001a.c30c.7eee FFFF.FFFF.0000 docsis-group 100	Assigns a modem or a group of modems with a common MAC mask to a load balancing group or a service type ID.
Step 4	exit Example: Router# exit	Exits the global configuration mode.

Configuring Rules and Policies

This section shows how to create and configure rules and DOCSIS policies to restrict the movement of modems during load balancing. Rules determine whether a modem can be moved and during which time periods. The time periods are measured in seconds with the start time being an offset from midnight measured in seconds. Rules are created individually and can be combined into policies. The user is able to create DOCSIS policies that consist of one or more rules. When more than one rule is part of a DOCSIS policy, all rules apply. Each group has a default DOCSIS policy.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance rule rule-id Example: Router(config)# cable load-balance rule 1	Creates a rule to prevent the modem from being moved.
Step 4	cable load-balance rule rule-id {enabled disabled {disable-period dis-start 0-86400 dis-period <0-86400>} disable-throughput-lowerbound ds us thrupt in kbps vdoc-enabled} Example: Router(config)# cable load-balance rule 1 disable-period dis-start 40 dis-period 50	Configures the rule. Note Static multicast groups should be configured on the appropriate bundle interface as well as on the correct forwarding interfaces to enable this rule. This feature will not be supported on load balancing groups which are derived from fiber node configuration and with multicast encryption.
Step 5	cable load-balance docsis-policy policy-id rule rule-id Example: Router(config)# cable load-balance docsis-policy 2 rule 1	Associates a particular rule with the DOCSIS policy with the following parameters:
Step 6	exit Example: Router# exit	Exits the global configuration mode.

Troubleshooting Tips

Problem When you disable load balancing and enable it for the next day using the **cable load-balance rule rule-id disable-period dis-start start-time dis-period disable-period** command, the load balancing is enabled at 12.00 am instead of the configured *disable-period*.

Possible Cause Load balancing rule cannot be disabled and enabled on the next day (that is, after 24 hours) using a single load balancing rule.

Solution Configure separate load balancing rules for disabling load balancing and enabling it on the next day. Configure the rule to disable load balancing using the **cable load-balance rule *rule-id* disable-period dis-start start-time dis-period 0** command. Configure the rule to enable load balancing using the **cable load-balance rule *rule-id* disable-period dis-start 0 dis-period *disable-period*** command to enable it for the next day.

Configuring Load Balancing Parameter for a Cable Modem Movement Failure

This section describes how to configure the number of times a CM can fail before the CM is removed from the dynamic load balancing group.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance modem max-failures 0-100 Example: Router(config)# cable load-balance modem max-failures 10	Configures the number of times a CM can fail before the CM is removed from the dynamic load balancing group.
Step 4	exit Example: Router# exit	Exits the global configuration mode.

Creating and Configuring TLV type Tag

The tags for TLV type matching rule are created and configured in this section.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# configure terminal	
Step 3	cable tag <i>1-1000</i> Example: Router(config)# cable tag 1	Creates a tag. Enters the cmts-tag configuration mode.
Step 4	name <i>tag name</i> Example: Router(cmts-tag)# name CSCO	Specifies the name of the tag.
Step 5	[exclude] service-type-id <i>service-type-id</i> Example: Router(cmts-tag)# service-type-id HSD	Configures the specified service type ID for the tag.
Step 6	[exclude]service-class <i>service-class-name</i> Example: Router(cmts-tag)# service-class work	Configures the specified service class name for the tag.
Step 7	[exclude] docsis-version <i>docsis version</i> Example: Router(cmts-tag)# docsis-version docsis20	Configures the specified DOCSIS version of the cable modem for the tag.
Step 8	[exclude] oui <i>oui of CM</i> Example: Router(cmts-tag)# oui 00.1a.c3	Configures the specified OUI of the cable modem for the tag.
Step 9	[exclude] tlv <i>type value</i> Example: Router(cmts-tag)# tlv mrccs 4	Configures the specified TLV type for the tag.
Step 10	override Example: Router(cmts-tag)# override	Overrides the TLV or SNMP during load balancing an RLBG.
Step 11	exit Example: Router(cmts-tag)# exit	Exits the cmts-tag configuration mode.
Step 12	cable load-balance docsis-group <i>docsis-group-id</i> Example: Router(config)# cable load-balance docsis-group 1	Creates a DOCSIS load balancing group on the Cisco CMTS. If the DOCSIS load balancing group is already present, the router enters the specified DOCSIS load balancing group configuration mode.

	Command or Action	Purpose
Step 13	tag tag name Example: Router(config-lb-group)# tag CSCO	Adds a tag to the load balancing group.
Step 14	exit Example: Router(config-lb-group)# exit	Exits the DOCSIS load balancing group configuration mode.
Step 15	cable load-balance docsis-policy policy-id tag tag name [override] Example: Router(config)# cable load-balance docsis-policy 2 tag CSCO	Creates a DOCSIS policy and associates a new rule or an existing rule with the policy.
Step 16	exit Example: Router# exit	Exits the global configuration mode.

Configuration Examples for DOCSIS Load Balancing Groups

This section describes a sample configuration example for configuring DOCSIS Load Balancing Groups including Restricted/General Load Balancing and downstream dynamic load balancing:

Example: Configuring a Tag

The following example shows how you can configure the tag to exclude a DOCSIS version, a MAC address, a service class name or a service type ID:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# cable tag 1
Router(cmts-tag)# exclude ?
  docsis-version  set the match rule for docsis version
  oui              set the match rule for oui
  service-class   set the match rule for service class name
  service-type-id set the match rule for service type id
Router(cmts-tag)# exclude docsis-version ?
  docsis10 Match docsis 1.0 modems
  docsis11 Match docsis 1.1 modems
  docsis20 Match docsis 2.0 modems
  docsis30 Match docsis 3.0 modems
Router(cmts-tag)# exclude docsis-version docsis10
Router(cmts-tag)# exclude oui ?
  WORD OUI of the vendor in the format xx.xx.xx or xx:xx:xx
Router(cmts-tag)# exclude oui 00.1a.c3
Router(cmts-tag)# exclude service-class ?
  WORD Service class name
Router(cmts-tag)# exclude service-class work
Router(cmts-tag)# exclude service-type-id ?
```

Example: Disabling Load Balancing

```
WORD Service Type ID
Router(cmts-tag)# exclude service-type-id commercial
```

Example: Disabling Load Balancing

Use the following commands to disable DOCSIS 3.0 GLBG:

```
Router(config)# cable load-balance docsis-group FN 1 MD cable 6/0/0
Router(config-lb-group)# disable
Router(config-lb-group)#
```

Use the following commands to disable DOCSIS 3.0 RLBG:

```
Router(config)# cable load-balance docsis-group 1
Router(config-lb-group)# disable
Router(config-lb-group)#
```

Verifying DOCSIS Load Balancing Groups

This section describes how to use certain show commands to verify the configuration of the Restricted/General Load Balancing and Narrowband Dynamic Bandwidth Sharing with Downstream Dynamic Load Balancing feature.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	show cable load-balance docsis-group { <i>docsis-group-id</i> FN <i>fn-id</i> MD cable { <i>slot/subslot/port</i> <i>slot/port</i> }} [all load pending statistics target modem-list primary-load] Example: Router# show cable load-balance docsis-group 1 Router# show cable load-balance docsis-group fn 1 MD c8/1/4	Displays real-time configurational, statistical, and operational information of the load balancing operations on the router.
Step 3	show cable fiber-node <i>fiber-node-id</i> [spectrum] Example: Router# show cable fiber-node 3	Displays information about a fiber node.
Step 4	show cable load-balance [group <i>n</i>] [all load pending statistics target fiber-node-validation] Example:	Displays real-time statistical and operational information for load balancing operations. If given without any options, this command displays information for the load balancing

	Command or Action	Purpose
	Router# show cable load-balance group 1	groups and each cable interface's current load and load balancing status.
Step 5	show cable modem [<i>ip-address</i> <i>mac-address</i> cable slot/port [<i>upstream port</i>] name fqdn] [<i>verbose</i>] Example: Router# show cable modem 40.3.160.15 verbose	Displays information for the registered and unregistered CMs.

Examples

Use the **show cable load-balance docsis-group** command to see the DOCSIS group status and to see the list of modems in the group, use the **show cable fiber-node** command to see the information on fiber nodes, use the **show cable load-balance** command to see information on LBG and DOCSIS channels, and use the **show cable modem** command to see the information on all the CMs.

The following examples show the output of the **show cable load-balance docsis-group** command:

```
Router# show cable load-balance docsis-group 2
DOCSIS LB Enabled: Yes
DOCSIS      Group Status Interval DCC mask Policy      Method Threshold
Group      Index          /UCC
2          82 RE 10          0xF8(0)/N 0          s/s      1/1/70/70/50
Router# show cable load-balance docsis-group 1 modem-list
US
Mo1/0/0:0/U0          Group Index Mac Address      Priority
                    81          (1)
                    0000.ca45.9898  0
Mo1/0/0:0/U1          81          (0)
Mo1/0/0:0/U2          81          (2)
                    0013.711c.0820  0
                    0016.924f.8300  0
```

The output of the **show cable load-balance docsis-group** command is modified to include an additional field MUPFXLR to display more status information on the modems in the DOCSIS groups. For more information, see the [Cisco IOS CMTS Cable Command Reference](#).

The following example shows the modified output of the **show cable load-balance docsis-group** command:

```
Router#show cable load docsis-group fn 1 md c6/0/0 modem-list
Load for five secs: 1%/0%; one minute: 2%; five minutes: 1%
Time source is NTP, 13:39:31.300 PDT Thu Mar 28 2013
Codes: M - Multicast, U - UGS, P - PCMM, F - Max-Failures, X - eXcluded
       L - L2vpn, R - RSVP
Primary DS   Grp Idx MAC Address      RCC-ID Bad Rfid Priority MUPFXLR
In6/0/0:0/UB 40448 (6)

LB policy ID in config file      : 0
LB priority      : 0
Tag              :

```

DOCSIS 3.0 GLBG is generated dynamically by the fiber node configuration, if a valid fiber node is configured.

For example, if the fiber node configuration is:

```

cable fiber-node 2
downstream Modular-Cable 1/0/0 rf-channel 0-3
downstream Cable7/0/0
upstream Cable 7/0 connector 0-3
!

```

The GLBG generated by this fiber node is similar to:

```

Router# show cable load-balance docsis-group fn 2 md cable 7/0/0

Feature Information for DOCSIS Load Balancing Groups

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 36: Feature Information for DOCSIS Load Balancing Groups

Feature Name	Releases	Feature Information
DOCSIS Load Balancing Groups	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the cisco cBR Series Converged Broadband Routers.
Load Balancing with Operational Simplification	Cisco IOS XE Gibraltar 16.10.1d.	This feature was integrated on the cisco cBR Series Converged Broadband Routers.

CHAPTER 15

DOCSIS Load Balancing Movements

Cisco CMTS supports static load balancing for MTC/MRC modems and dynamic load balancing for non-MTC and/or non-MRC modems. Support for configuration of load balancing groups (LBGs) that entail multiple interfaces, multiple load balancing policies, and the option to configure multiple additional load balancing parameters are also included.

The load balancing policies can be configured on the Cisco CMTS, indexed by an ID, to limit the movement of cable modems within a Load Balancing Group (LBG). The cable modem will forward TLV43.1 in its registration request (REG-REQ) message, which is then parsed and stored in the Cisco CMTS. A policy defines whether and when cable modems can be moved within their load balancing groups.

During dynamic load balancing, the specified policy of the cable modem is checked to determine whether the cable modem is allowed to move.

Load balancing supports Dynamic Channel Change (DCC). DCC in DOCSIS 1.1, dynamically changes cable modem upstream or downstream channels without forcing a cable modem to go offline, and without re-registration after the change.

Load balancing distributes downstream load balancing with upstream channel loads in the same upstream load balancing group. This improves upon the prior load balancing limitation, in which load balancing was implemented on the basis of the entire downstream channel load.

Load balancing uses rules and policies to decide on moving the cable modems within their LB groups. These policies are created on the Cisco CMTS and chosen on a per-CM basis using type-length-value (TLV) portion (43.1, Policy ID) of REG-REQ. These policies prohibit a modem from being moved or restricted.

A policy contains a set of rules. When the policy is defined by multiple rules, all rules apply in combinations. A rule can be defined as "enabled", "disabled", or "disabled during time period." Each rule can be used by more than one policy.

DOCSIS 3.0 static modem count-based load balancing uses the dynamic bonding change (DBC) to modify the following parameters of DOCSIS 3.0 cable modem with multiple transmit channel (MTC) mode or multiple receive channel(MRC) mode without primary channel change:

- Transmit channel set (TCS)
- Receive channel set (RCS)
- Downstream IDs (DSID) or DSID-associated attributes
- Security association for encrypting downstream traffic

These parameters and additional load balancing schemes are supported on the Cisco CMTS, and described in this document. This document describes all implementations of load balancing on the Cisco CMTS, dependent upon the Cisco IOS release installed and the desired parameters.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Prerequisites

Prerequisites for Load Balancing

The Load Balancing feature has the following prerequisites:

- Load balancing can be done only on upstreams and downstreams that share physical connectivity with the same group of cable modems.

Prerequisites for Dynamic Channel Change for Load Balancing

- DCC can be done only to a cable modem that is physically connected to both source and target upstream or downstream channels, or both.
- Upstreams and downstream channels that share the same physical connectivity must have different center frequencies separated by channel width.

- The difference between the physical layer parameters on the source and target DCC channels must be within the threshold required by the desired DCC initialization technique.
- DOCSIS 1.1 must be enabled for a modem to behave properly for the DCC operation. Note that not all DOCSIS 1.1 certified modems are DCC-capable, as the CableLabs DCC ATP tests need enhancement for complete coverage.

Prerequisites for Dynamic Bonding Change for DOCSIS 3.0 Static Modem Count-Based Load Balancing

- Initialization techniques 1 to 4, when used, require the Cisco CMTS to include the upstream channel descriptor (UCD) TLV (TLV46.5) in the DBC-REQ message.
- Bandwidth must be sufficient on the target bonding group to support DBC. This is determined by the admission control APIs.
- Fiber nodes must be configured before configuring DOCSIS 3.0 static modem count-based load balancing.

Restrictions

The following sections describe the restrictions applicable for the Load Balancing, Dynamic Channel Change, and Dynamic Bonding Change feature:

Restrictions for Load Balancing

The Load Balancing feature has the following restrictions:

- Load balancing can be done only on a per-line card basis—all interfaces in a load balancing group must be provided by the same line card.
- All downstreams and upstreams in a load balancing group must share physical connectivity to the same group of cable modems. All downstreams or all upstreams that have the same RF physical connectivity must be members of the same load balancing group.
- You can create a maximum of 256 load balancing groups on each line card.
- If an upstream port is operational, using the **no shutdown** command, and is not being used and not connected, load balancing attempts to use the port even though there are no cable modems registered on that port. When the upstream port is up, it is put into INIT state and load balancing includes this port as a potential target. However, if the load balancing sees multiple failures moving to this upstream, it is set to DISABLE state and the port is avoided later on in load balancing processes.
- The load balancing algorithms assume a relatively even distribution of usage among modems. In the situation where one cable modem creates the bulk of the load on an interface, the load balancing thresholds should be configured for a value above the load created by that single modem.
- You cannot select particular cable modems to be automatically moved for load balancing, although you can exclude cable modems from load balancing operations altogether on the basis of their MAC address or organization unique identifier (OUI). (You can use the **test cable load-balance** command to manually

move a particular cable modem among upstreams, but this is done typically to test the configuration of the load balancing groups.)

- If you have configured upstream shared spectrum groups while doing downstream load balancing, the downstream in each MAC domain must not use overlapping upstream groups. For example, the downstream in one MAC domain could use an upstream spectrum band of 10 to 30 MHz, while the downstream in a second MAC domain could use an upstream spectrum band of 30 to 42 MHz. Each MAC domain has its own upstream shared spectrum group, allowing the load balancing group to contain the downstreams for both MAC domains.
- All upstream ports coming from the same splitter must be using different center frequencies that are separated by the channel width. For example, if the upstreams are using a channel width of 3.2 MHz, the center frequencies for all upstreams must be separated by at least 3.2 MHz.
- You can use four initialization techniques for Dynamic Channel Change (DCC).
- If you have configured load balancing, the provisioning system must not assign specific upstream channels or downstream frequencies to individual cable modems in their DOCSIS configuration files. Any cable modems requiring specific upstream channels or downstream frequencies must be excluded from load balancing operations (using the **cable load-balance exclude** command).
- Do not use the utilization method of load balancing on cable interfaces that have a small number of cable modems and where a single modem is responsible for the majority of the interface load. In this condition, the Cisco CMTS could end up continually moving cable modems from one interface to another in an endless attempt to load balance the interfaces. To avoid this, configure the utilization threshold to a value that is higher than what can be caused by any single cable modem.
- When deployed with channel restriction features, if the target upstream channel attribute masks are against that of the cable modem, then the cable modem on the higher load upstream will not be load balanced, as the current load balancing moves cable modems only to the target upstream. However, cable modems that do not have an attribute mask can still be load balanced. You should consider the following while deploying the load balancing groups: the target upstream will always be the upstream that has the lowest load. If some other upstreams have the same load, the upstream with the lowest index will be chosen as the target upstream.
- A TLV in a cable modem configuration file restricts dynamic load balancing on per modem basis.
- If you remove the last rule of a DOCSIS policy, the policy itself will be removed.
- The Cisco CMTS load balancing feature moves a cable modem based on the load of the channels in a load balancing group, without checking if the cable modem supports the extended frequency range (5Mhz-85Mhz). This may result in moving a cable modem that supports standard frequency range (5Mhz-65Mhz) to a channel that has extended frequency configured. To overcome such scenarios, operators should not mix upstreams that have standard and extended frequencies configured into the same load balancing group, unless all modems in the group support extended frequency range.

Restrictions for Dynamic Channel Change for Load Balancing

- The source and target upstreams and downstreams must share physical connectivity with the modem desired for a DCC transaction.
- Independent downstream change is not supported, and cross-MAC domain upstream changes must occur with the associated downstream changes.

- The source and target downstream interfaces must belong to the same virtual bundle and the same load balancing group if DCC is used for load balancing.
- For DCC initialization techniques 1 to 4, all the configuration variables of the cable modem must remain constant with the exception of the configuration variables that are explicitly changed by the Dynamic Channel Change request (DCC-REQ) messages encoding.
- DCC initialization techniques 2 to 4 must not be used if the propagation delay differences between the old and new channels exceeds the ranging accuracy requirement defined in DOCSIS, for example, ± 0.25 usec plus \pm symbol time.
For example, for a symbol rate of 1.28 Msps, the timing offset difference between the source and target upstream channel is $\pm \text{floor}[(0.250 \text{ us} + 0.5 * 0.781 \text{ us}) / (1/10.24)] = \pm 6$.
- The attenuation or frequency response differences between the old and new upstream channels causes the received power at the Cisco CMTS to change by more than 6 dB.
- DCC initialization technique 3 must not be used if the conditions for using technique 2 are not met.
- DCC initialization technique 4 must not be used if the conditions for using technique 2 cannot be met.
- Micro-reflections on the new upstream channel result in an unacceptable BER (greater than $1e-8$) with pre-equalization coefficients set to the initial setting.
- DCC is used only for dynamic downstream load balancing on DOCSIS 1.1 and later CMs. Upstream Channel Change (UCC) is always used for dynamic upstream load balancing on DOCSIS 1.x CMs. For DOCSIS 2.x CMs, UCC is used when the *ucc* option is configured. For DOCSIS 3.x CMs, DCC is used irrespective of whether the *ucc* option is configured or not.
- Prolonged interruption of the multicast traffic is expected if the cable modem moved by DCC is the first one in a dynamic multicast group on the target interface. The downstream multicast service flow cannot be reestablished until the Cisco CMTS receives an Internet Group Management Protocol (IGMP) join message from the customer premises equipment (CPE) as the result of the Cisco CMTS IGMP query, where the IGMP query interval is set to one minute. This is an IGMPv2 limitation.
- Multiple statically-assigned IP addresses to a CPE can be pinged. However, this works only if all the security features, such as verification of IP addresses for cable modems and CPE devices on the upstream, and other security mechanism are disabled.
- The TCS and RCS assigned to the DOCSIS 3.0 cable modems are restricted by the upstream and downstream bonding groups configured by the Cisco CMTS.
- Load balancing and DCC are not supported for CMs that are enabled for Layer 2 VPN (L2VPN) support.
- When a DCC occurs, the cable modem US and DS counters are reset. The US and DS counters include counters such as data and throughput seen in the **show cable modem (mac-address) verbose** command output and packets and bytes seen in the **show cable modem (mac-address) counters** command output.

DCC Restrictions with N+1 Redundancy and Inter-Card Load Balancing

- Inter-card load balancing is not supported with cable interface line cards using N+1 redundancy. Refer to general DCC restrictions for additional information.
- Dynamic load balancing should not be used together with N+1 redundancy. Cable modems with outstanding DCC transactions go offline after a switchover event.

Note When cable modems go offline during a switchover event, the load balancing feature activates. Cable modems move in relation to the switchover event. When the cable modems return online, load balancing may need to initiate again.

To facilitate load balancing during a switchover, you can increase the dynamic load balance threshold, if a certain percentage of cable modems that reset during switchover is configured in the system. An alternate method is to use static load balancing with N+1 redundancy. For more information, see the [Types of Load Balancing Operations](#).

Restrictions for DOCSIS 3.0 Static Modem Count-Based Load Balancing

- Static modem count-based load balancing is supported on MTC and MRC-only cable modems. Single-channel, narrowband cable modems will continue to be supported with dynamic load balancing. MRC-only modems are supported by dynamic load balancing on upstream channels.

Note DOCSIS 3.0 static modem count-based load balancing is not supported on:

- Multiple line cards.
 - Load balancing groups and downstream channels shared across multiple line cards.
-
- DOCSIS 3.0 static modem count-based load balancing does not support service flow method of load balancing.

Restrictions for Dynamic Bonding Change for DOCSIS 3.0 Static Modem Count-Based Load Balancing

- The Cisco CMTS can use only DBC messaging to move modems within a MAC domain and applies only to cable modems operating in MTC mode or MRC-only mode without a primary downstream change.
- The Cisco CMTS moves the MRC-only cable modems with a primary channel change using DCC with initialization technique 0.
- The Cisco CMTS moves cable modems across MAC domains using only DCC with initialization technique 0.
- The Cisco CMTS must ensure minimum interruption to existing QoS services while considering an initialization technique that is suitable for the cable plant conditions.

Note DOCSIS 3.0 Static Load Balancing uses Initialization Technique 1 to move cable modems for DBC movement.

- Initialization Technique 1—(Broadcast initial ranging) may result in a lengthy interruption of service, which is mitigated by the reservation of QoS resources on the new channel(s). The service interruption can be further reduced if the Cisco CMTS supplies the UCD TLV in the DBC request in addition to providing more frequent initial ranging opportunities on the new channel.
 - Initialization Technique 2—(Unicast ranging) offers the possibility of only a slight interruption of service. To use this technique, the Cisco CMTS must include the UCD TLV in the DBC message if the upstream channel is changing.
 - Initialization Technique 3—(Broadcast or unicast ranging) offers the possibility of only a slight interruption of service. Use this technique when there is uncertainty when the CM may execute the DBC command and thus a chance that it might miss station maintenance slots. However, the Cisco CMTS should not use this technique if the conditions for using techniques 1 and 2 are not completely satisfied.
 - Initialization Technique 4—(Use the new channel directly) results in the least interruption of service.
- For a DOCSIS 3.0 cable modem that in a DOCSIS 3.0 static load balancing group, the multicast join will be dropped before REG-HOLD time elapses.

Restrictions for MRC-Only Cable Modems

- MRC-only cable modems use single channel non-bonded upstreams (similar to narrowband (NB) modems) and multi-channel bonding groups on the downstream.

Note The following restrictions apply only to DOCSIS 2.0 and DOCSIS 3.0 cable modems in MRC-only mode.

- cable modems are moved across upstream channels using DCC.
- cable modems are moved to different downstream channels through DBC, if there is a change in the upstream channel and downstream channel bonding group, but not in the primary downstream channel and the upstream channel change is ignored.

However, if there is a change in the primary downstream channel also, DCC with init tech 0 is used to balance the cable modems.

- MRC-only modems are treated similar to cable modems operating in MTC mode, to move modems across downstream channels. For change in upstream channel, MRC-only cable modems are treated similar to single-channel NB cable modems.

Information on the Load Balancing on the Cisco CMTS

This section describes the operation, concepts, and benefits of the Load Balancing on the Cisco CMTS feature:

Feature Overview

The Load Balancing on the Cisco CMTS feature allows service providers to optimally use both downstream and upstream bandwidth, enabling the deployment of new, high-speed services such as voice and video

services. This feature also can help reduce network congestion due to the uneven distribution of cable modems across the cable network and due to different usage patterns of individual customers.

By default, the Cisco CMTS platforms use a form of load balancing that attempts to equally distribute the cable modems to different upstreams when the cable modems register

This feature has been enhanced to make use of DOCSIS policies and rules to limit the movement of cable modems within a Load Balancing Group. A policy defines whether and when cable modems can be moved within their load balancing groups.

A policy consists of a set of rules. Each rule can be defined as “enabled”, “disabled”, or “disabled during time period.” Multiple policies can share a single rule. However, if you remove the last rule of a policy, that will also remove the policy.

Each rule can be used in any number of policies. When it is defined by multiple rules, all rules apply in combinations. Each rule helps to prohibit load balancing using a particular cable modem and to prohibit load balancing using a particular cable modem during certain times of the day.

Following are the general guidelines for the rules and policies:

- The policy or rule is recognized by a 32-bit ID.
- Each cable modem can have one policy only.
- Each rule can be associated to one or more policies.
- Each policy is described by at least one rule, otherwise it cannot be created.
- The zero Policy ID is reserved by Cisco CMTS indicating “Do nothing to LB prohibition.”
- If the policy ID specified by the cable modem configuration file is not configured on Cisco CMTS, no LB prohibition is applied to that CM. However, after the policy with the matched ID is configured, LB prohibition takes effect immediately.

Methods to Determine When Interfaces Are Balanced

In addition to selecting how interfaces should be balanced (using the static, passive, or dynamic types of load balancing), you can also select one of the following methods that the Cisco CMTS should use to determine when interfaces are balanced:

- Modems Method—Uses the number of active cable modems on an interface.
- Utilization Method—Uses the current percentage of utilization of an interface.

See the following sections for more information about each method.

Modems Method

The modem method of load balancing uses the number of active cable modems on an interface to determine the current load. This is a form of distribution-based load balancing, in which the absolute numbers of modems are used to determine whether interfaces are load balanced.

This method does not take into account the amount of traffic flowing through the cable modems, but the system does take into account the relative bandwidth of the channels being used, so that channels with higher bandwidths are allocated higher numbers of cable modems. This means that when interfaces are using different channel widths or modulation profiles, the system can assign different numbers of cable modems to the interfaces to achieve a balanced load. For example:

- Channel widths— If two upstreams are being load balanced, and one upstream is configured with a channel width of 1.6 MHz and the other upstream is configured for a channel width of 3.2 MHz, the Cisco CMTS allocates twice as many cable modems to the second upstream because its channel width is twice as large as the first upstream channel width.
- Modulation profiles— If one downstream is configured for 64-QAM and the other downstream is configured for 256-QAM, the Cisco CMTS allocates a proportionately larger number of cable modems to the second downstream so as to achieve a balanced load.

When both the channel width and modulation profile are set differently on two interfaces, the system calculates a “weight” value to use as a guide to determine the relative bandwidths of the interfaces.

Tip In a system with balanced loads, the interfaces will contain the same number of cable modems only when the interfaces are configured with the same channel width and modulation parameters.

Utilization Method

Note Narrowband cable modems, multiple downstream modems and upstreams of MRC-only cable modems participate in the utilization method.

The utilization method uses an interface’s current percentage of utilization to determine the current load. This method uses the amount of traffic being sent over an interface, in the form of the percentage of total bandwidth being used. The system takes into account the relative throughput and bandwidth (as determined by the modulation profiles and channel widths) of each interface when evaluating the load on those interfaces.

For example, if two upstreams are being load balanced using the utilization method, and the first upstream has twice the bandwidth of the second upstream, the two upstreams are considered balanced when they reach the same percentage of utilization. The first upstream is carrying more traffic than the second upstream because it has a larger capacity for traffic, but the percentage of utilization will be the same.

Wideband Interface Average Utilization and Throughput

The average utilization and average throughput between Wideband interfaces of the same size can be calculated by:

$$\text{Average Utilization (WB)} = \sum_{i=1}^n rfch - \text{util}(rf_i) / n$$

- n represents the size of the Wideband interface
- $\sum_{i=1}^n rfch - \text{util}(rf_i)$ represents the sum of rfch - util of QAM channels in Wideband interface.

$$\text{Average Throughput (WB)} = \text{AverageThroughput(WB)in last 30s} / \sum_{i=1}^n BW(rf_i)$$

- Average Throughput (WB) represents the KB recorded in the last 30 seconds
- $\sum_{i=1}^n BW(rf_i)$ represents the total bandwidth of Wideband interface.

Note Use the **show cable load-balance load wideband** command to view the average utilization and average throughput between Wideband interfaces.

Load Balancing Parameters

You can determine which cable interfaces should participate in load balancing operations. You can also choose which of the following methods should be used to determine the current load on a cable interface, and therefore determine whether cable modems should be moved:

- Number of active cable modems
- Channel bandwidth utilization

You can also specify the threshold values that the Cisco CMTS should use to determine how to assign new cable modems to upstreams and downstreams for both types of load balancing. You can also configure whether cable modems with active Voice-over-IP (VoIP) calls should be moved, and if so, what thresholds should be used. You can also exclude certain cable modems from one or all of the different forms of load balancing.

Configurable Minimum Threshold under Utilization Method

The utilization method does not move cable modems for load balancing until the utilization of at least one of the interfaces reaches minimum threshold. This is done to avoid the unnecessary moving of cable modems due to temporary spikes in an interface's utilization rate.

Minimum utilization threshold can be configured under Utilization Method. The minimum utilization threshold may be configured in a range of 10 to 90 percent. As a result the cable modems will be moved only when the configured minimum utilization threshold is reached on an interface.

To configure the minimum threshold under the Utilization method, use the **cable load-balance method-utilization min-threshold** command in global configuration mode. For more information, refer to **cable load-balance method-utilization min-threshold** command reference.

Single Channel Load Balancing

Error Handling of Channel Assignment

As long as the interface state of the channels is not "administratively down", all channels are available for LBG assignment. For other load balancing operations, such as moving modems using DCC, or UCC, the interface state of the channels should be in "initial", "up", "suspicious", or "testing" states.

Downstream Load Balancing Distribution with Upstream Load Balancing

Downstream load balancing provides equalized load balancing with upstream group members. This enhancement synchronizes the "pending" statistic between different cable interface line cards in the load balancing group. The result is an alternative downstream load balancing scheme that makes use of per-upstream loads rather than total downstream loads.

This enhancement performs downstream load balancing that accounts for upstream channel loads in the same upstream load balancing group, rather than on the basis of the entire downstream channel load. Prior Cisco IOS releases may not have distributed cable modems evenly over individual upstream channels, nor in a way that accounted for downstream and upstream together.

The load balancing enhancement applies when downstream load balancing occurs on a headend system with separate upstream load balancing segments; the upstream segments are spread over multiple downstream segments.

The configuration and operation of making downstream load balancing decisions is enabled as follows:

- The target downstream segment is in the same downstream load balancing group as the source downstream segment.
- The upstream load balancing group can be set for the corresponding channel on which a cable modem is balanced.
- The Cisco CMTS automatically locates the upstream segment for a load balancing group and processes the upstream group status on the source interface that has the lowest load.
- The target downstream segment must have an upstream channel set in the upstream load balancing group.
- The highest target upstream segment must carry less load than any other potential target—the highest upstream segment on other interfaces.

For example, several upstream segments can be configured across multiple downstream segments as follows:

	U0	U1	U2	U3	Downstream
3/0	LB10	LB11	LB12	LB13	LB1
4/0	LB10	LB11	LB12	LB13	LB1
5/0	LB10	LB11	LB12	LB13	LB1
6/0	LB10	LB11	LB12	LB13	LB1

In this example, a cable modem that comes online on the interface cable 5/0 Upstream 2 could potentially come online on the following interfaces:

- cable 3/0 upstream 2
- cable 4/0 upstream 2
- cable 6/0 upstream 2

The enhancement enables the following advantages and behaviors:

- This enhancement adds support for synchronizing the “pending” statistic between different cable interface line cards and the network processing engine (NPE) so that a better decision can be made about where cable modems should be moved. This function can be used as a normal downstream load balancing implementation, if desired.
- This enhancement adds the **us-groups-across-ds** keyword to **cable load-balance group** command for configuring downstream load balancing groups with upstream resources.

Note You can use the **no cable load-balance docsis20-enable** command to disable DOCSIS 2.0 dynamic downstream and upstream load balance.

Upstream Load Balancing for DOCSIS 3.0 Cable Modems in Single Upstream Mode

The upstream load balancing functionality enables the Cisco CMTS router to effectively handle upstream traffic for wideband and narrowband cable modems that are in single upstream mode. Single upstream mode (Mx1) means that the modems cannot send upstream traffic on multiple upstream channels. In the event of traffic overload on a single upstream channel of a wideband or narrowband cable modem, the Cisco CMTS router automatically moves the cable modem to another upstream channel in the same load balancing group.

Note A cable modem operating in single upstream mode is assigned to a load balancing group based on the primary channel of the modem. A cable modem in single upstream mode can support multiple receive channel (MRC) mode or narrowband mode. However, a cable modem in single upstream mode cannot support multiple transmit channel mode (MTC).

Interaction with Spectrum Management

Cisco cable interface line cards support a number of features to maximize channel bandwidth and to minimize the impact of ingress noise on cable modem traffic. These features have the following impacts upon load balancing operations:

- Frequency hopping—Frequency hopping does not affect the load balancing algorithm, because it does not change either the bandwidth of a channel nor the number of cable modems on an interface.
- Dynamic modulation changes—The dynamic modulation feature affects the load balancing algorithm because it typically switches an interface from a higher-bandwidth modulation profile to a lower-bandwidth modulation profile in response to noise conditions on the interface.

For example, if an upstream is configured for 16-QAM, sufficient noise levels could switch the upstream to a QPSK modulation profile. Depending on the load balancing configuration, this could then result in the movement of cable modems to other channels. Similarly, when the noise conditions improve, and the modulation is returned to the original, higher-bandwidth profile, the cable modems could be moved again to rebalance the upstream channels.

- Channel width changes—Cisco cable interface line cards support automatic changes to the channel width in response to noise conditions. Because changing the channel width affects the throughput of a channel, this also affects the load balancing algorithm.

For example, if noise makes the current channel width unusable, the Cisco cable interface line card reduces the channel width until it finds a usable channel width. Because this reduces the available bandwidth on the channel, the load balancing algorithm moves cable modems to rebalance the upstreams.

In addition, the Cisco cable interface line card does not automatically restore the original channel width when noise conditions improve. Instead, the card changes the channel width only when it performs a subsequent frequency hop, either in response to additional noise conditions or when an operator performs a manual frequency hop. When the hop occurs, the card then searches for the largest possible channel width, and this could result in another movement of cable modems to rebalance the channels.

Using Dynamic Channel Change

DCC in DOCSIS 1.1 dynamically changes cable modem upstream or downstream channels without forcing a cable modem to go offline, and without re-registration after the change. DCC supports five different initialization methods (0-4).

- Load balancing techniques allow for moving cable modems with DCC by using configurable initialization techniques.
- DCC allows line card channel changes across separate downstream channels in the same cable interface line card, with the DCC initialization techniques ranging from 0 to 4.
- DCC transfers cable modem state information from the originating downstream channel to the target downstream channel, and maintains synchronization of the cable modem information between the cable interface line card and the Network Processing Engine (NPE) or Route Processor (RP).

- Applications that are sensitive to delay, such as PacketCable (PC) and PacketCable Multi Media (PCMM), may use DCC initialization technique4 to retain services while the cable modem is performing DCC.
- If the channel is in mixed or ATDMA-only mode, the primary Service Identifier (SID) must be switched to ATDMA-only mode.

Note You can use the **no cable load-balance docsis20-enable** command to disable DOCSIS 2.0 dynamic downstream and upstream load balance.

Multiple Channel Load Balancing

Algorithm for Bonded Channel Cable Modem Load Balancing

During registration of the cable modem, the modem count-based method uses the number of active cable modems on the allowed RCS to determine the current load on each channel. After the modem is assigned an RCS, the Cisco CMTS does not move the cable modem even when traffic conditions change.

When a cable modem sends a registration request, modem count-based method of load balancing ranks the allowed receive channel sets (RCS) based on their modem count and assigns the set with the lowest number of CMs, to the ranging cable modem.

DOCSIS 3.0 Static Modem Count-Based Load Balancing

The static modem count-based load balancing supports the following:

- DOCSIS General and Restricted load balancing group assignment to include DOCSIS 3.0 cable modems in MTC and MRC-only modes.

Note DOCSIS 3.0 static modem count-based load balancing is not supported:

- Across multiple line cards.
 - For load balancing groups and downstream channels shared across multiple line cards. However, autonomous load balancing-based CM steering and load balancing group assignment is supported across multiple line cards
-
- Use of DCC and DBC in load balancing.
 - Use of DBC for MRC-only modems during downstream move.
 - Use of DCC with init tech 0 if the primary downstream channel is changed for MRC-only CMs.
 - Use of DBC for cable modems in MTC mode for all upstream and downstream modem move.
 - Separate counters for NB and wideband (WB)/upstream bonding (UB) CMs. For more information, see the **show cable load-balance docsis-group** command in the [Cisco IOS CMTS Cable Command Reference](#).
 - Aggregate logical channels to physical channels for load balancing. Physical channel load is calculated by using average weights among all logical channels.
 - Non-primary downstream channels load where utilization of SPA QAM is considered

Note When the CM counts across different WB interfaces are within predefined threshold levels, the load is always considered as balanced; no more CM move is initiated by the LB system. No service flow count, whether primary or secondary, is taken into consideration during this LB process.

Note The attributes considered for the forward interface for the service flow (SF) are attribute mask and available bandwidth, and *not* the number of service flows on each channel. If a channel is within the new RCS, then irrespective of the type of narrowband SF, (whether primary or secondary, or static or dynamic) the SF continues to use its current channel.

Note The US Phy Mode counters (scdma, atdma, and tdma) remain 0 for the UB interfaces.

DOCSIS 3.0 static modem count-based load balancing is based on legacy load balancing and supports any type of channel combination (upstream and downstream)—MxN, with 1x1 combination being the subset.

DOCSIS 3.0 static modem count-based load balancing controls dynamic changes to the set of downstream and upstream channels used by a registered CM. It supports the following:

- Multiple channel load balancing operation.
- Load balancing operation based on policies and priorities.
- Load balancing with multicast. DOCSIS 3.0 static modem count-based load balancing does not move any CM with active video sessions.

DOCSIS 3.0 static modem count-based load balancing supports the modem count-based load balancing in a hybrid deployment of DOCSIS 1.x, 2.0 and 3.0 cable modems.

Static modem count-based load balancing is supported only for DOCSIS 3.0 CMs. Single-channel, narrowband cable modems will continue to be supported with dynamic load balancing. MRC-only cable modems are supported by dynamic load balancing on upstream channels.

With DOCSIS 3.0 static modem count-based load balancing, when load balancing related configuration within the LBG is changed as follows, the cable modems are forced to re-register:

- Partial shut or no shut interfaces under the LBG domain
- MRC or MTC mode in cable modems is turned on or turned off
- Change in fiber node for GLBG
- Change in wideband configuration for downstream group
- Change in the upstream bonding group

Use the following commands to force cable modems to re-register:

- **clear cable modem delete**
- **clear cable load state**

- clear cable load counters

Primary Channel Load Display for Target RCS

This feature enables the bonded modems to be moved at the time of registration such that the primary channels are distributed evenly among the primary-capable channels apart from the load being balanced on the target DS channels. Modem method ranks the RCS based on their primary loads and assigns the set with the lowest primary load to the ranging cable modem.

An optional keyword **primary-load** has been added to the **show cable load-balance docsis-group** command to display the primary load of an RCS. For more information, see the [Cisco CMTS Command Reference](#).

Although the modem count-based method distributes the cable modems fairly as they register, the following conditions may cause a system imbalance:

- A channel or groups of channels fail because of a planned (administrative shutdown) or unplanned event.
- While some cable modems may continue to operate in partial mode, some may re-register because of the failure and are reassigned to the channels that are active.
- When the failed channels become operational again, the cable modems do not re-register and the system is unbalanced.

In this case, the modem count-based method sends an SNMP trap to alert the operator, and the operator can choose to manually intervene to re-balance the cable modems by resetting the MAC domain to force all cable modems to re-register.

Note For cable modems in MRC and MTC modes, the modem count based load balancing method considers the number of active modems and service flows on the primary channels in the RCS and TCS of the cable modem.

Note Use **no cable load-balance docsis30-enable static** command to disable this feature.

Dynamic Load Balancing for DOCSIS 3.0 Cable Modems

The existing Load Balancing (LB) feature is enhanced to cope with the increase in the number of downstream and upstream channels by Multi-Service Operators (MSO) and wider deployment of 16-channel, 24-channel and multiple downstream channel Cable Modems (CMs). This enhancement allows the customer to better utilize their available bandwidth. The enhancements made to the existing LB feature include:

- Utilization based Dynamic downstream LB for DOCSIS 3.0
- Support for DOCSIS 3.0 LB statistics
- Enable or Disable DOCSIS 3.0 LB feature
- Distribute the CM on all the primary channels for the target interface when performing DOCSIS 3.0 LB dynamic movement. This feature is only used on DOCSIS 3.0 LB dynamic movement. It is disabled by default. Use **method utilization primary-distributed** command in the DOCSIS load balancing group mode to enable this feature. To disable this feature, use **no** form of this command or **method utilization us-method** command.

Note Use **cable load-balance docsis-enable** command to enable this feature. In addition, use **cable load-balance docsis30-enable** and **cable load-balance docsis30-enable dynamic downstream** command to enable dynamic and utilization based dynamic downstream LB for DOCSIS 3.0 Cable Modems.

Multiple Channel Load Balancing Operation

CMs load balance in MRC and MTC modes. The following rules apply while load balancing CMs operating in these modes:

- For CMs operating in MRC and MTC modes, DBC is used to move CMs across downstreams by changing the RCS of the CM within same MAC domain.

CMs operating in MRC-only mode can be moved across upstreams only through a DCC request. However, the Cisco CMTS uses DCC with initialization technique 0 (reinitializing the MAC domain) when changing the downstream channel of a CM operating in MRC mode.

- During CM registration, the Cisco CMTS may send a multipart registration response (REG-RSP-MP) message to include a TCC TLV encoding to the CM. This CM is marked as TCC-capable.

For CMs operating in MRC, non-MTC, non-TCC-capable mode, load balancing uses:

- DBC to change RCS of the CM
- DCC to change upstream channel of the CM
- For CMs operating in narrowband mode, DCC is used to move CMs within and across MAC domains.

The tables below provide a snapshot view of the load balancing methods and the operations used to move bonded and non-bonded CMs:

Table 38: Load Balancing Method to Move Bonded and Non-bonded CMs

Modem Mode	Load Balancing Method	Load Balancing Counters	Channels	Dynamic Service Charge (Initialization Technique)	
				Within MAC Domain	Across MAC Domains

Modem Mode	Load Balancing Method	Load Balancing Counters	Channels	Dynamic Service Charge (Initialization Technique)	
DOCSIS 3.0 CM in MTC mode	DOCSIS 3.0 static modem count-based load balancing (MCBLB) DOCSIS 3.0 dynamic load balancing	WB/UB	DS	DBC Note	DCC init tech 0 When DOCSIS 3.0 LB is enabled, and the MTC CM is outside RLBG, CM is moved inside RLBG.
	DOCSIS 3.0 static modem count-based load balancing (MCBLB)	WB/UB	US	DBC Note	DCC init tech 0 When DOCSIS 3.0 LB is enabled, and the MTC CM is outside RLBG, CM is moved inside RLBG.

Modem Mode	Load Balancing Method	Load Balancing Counters	Channels	Dynamic Service Charge (Initialization Technique)	
DOCSIS 3.0/D2.x CMs in MRC-only mode	DOCSIS 3.0 static MCBLB DOCSIS 3.0 dynamic load balancing	WB/UB	No change to the primary DS channel	<p>DBC</p> <p>Note When DOCSIS 3.0 LB is enabled and CM with all DSs is outside RLBG, CM is moved inside RLBG.</p>	DCC init tech 0
			Change to the primary DS channel	<p>DCC init tech 0</p> <p>Note CM with primary DS outside RLBG moves inside RLBG with DOCSIS 2.0 LB.</p>	DCC init tech 0

DOCSIS 2.0 /DOCSIS 1.1 CMs in NB mode	DOCSIS 2.0 dynamic MCBLB, dynamic utilization	NB	DS	DCC Note	CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB. DCC init tech 0
			US	UCC Note	CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB. UCC

Modem Mode	Load Balancing Method	Load Balancing Counters	Channels	Dynamic Service Charge (Initialization Technique)	
DOCSIS 1.0 in NB mode	DOCSIS 2.0 dynamic MCBLB, dynamic utilization	NB	DS	Force reinitialize CM	Force reinitialize CM
			US	UCC	UCC
				Note	CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.
				Note	CM outside RLBG moves inside RLBG with DOCSIS 2.0 LB.

Table 39: Using DCC/DBC to Load Balance Bonded and Non-bonded Cable Modems

Channel	CM in MRC, MTC Mode	CM in MRC, non-MTC Mode	DOCSIS 1.1/2.0 CMs with Single US/DS	DOCSIS 1.0 CMs with Single US/DS
Upstream (US)	DBC	DCC	DCC	UCC
Downstream (DS)	DBC (within the same MAC domain)	DBC (within the same MAC domain)	DCC (within the same MAC domain)	Force reinitialize CM
	DCC with initialization technique 0 when moving CMs across MAC domains	DCC with initialization technique 0 when moving CMs across MAC domains	DCC with initialization technique 0 when moving CMs across MAC domains	Force reinitialize CM

Using DBC for DOCSIS 3.0 Load Balancing Movement

As part of the DOCSIS 3.0 specifications, at any time after registration, the Cisco CMTS uses the DBC command to change any of the following parameters in a DOCSIS 3.0 CM:

- Receive channel set
- Transmit channel set

- DSID(s) or DSID associated attributes
- Security association(s) for encrypting downstream traffic
- Service Flow Cluster Assignments

Note Only RCS and TCS are used by the DOCSIS 3.0 load balancing.

Use the **show cable load-balance docsis-group** command to display the current, real-time statistics for load balancing operations. For more information, see the [Cisco IOS CMTS Cable Command Reference](#).

Using DBC to Change the Receive Channel Set

The Cisco CMTS can add, delete, or change the channels in the RCS of a cable modem by including a RCC in the DBC-REQ.

If an RCS change affects the primary downstream channel of the cable modem, the cable modem is required to re-register on its upstream channels.

If channels are deleted from the RCS, the Cisco CMTS may stop sending traffic on the downstream channel to be removed, which may cause loss of traffic. The Cisco CMTS minimizes packet loss by duplicating traffic on the new and old RCS until it receives a DBC-RSP from the cable modem.

Note For cable modems in MRC-only mode, a downstream channel move is initiated by a DBC message. However, DCC initialization technique 0 is used if there is a change in the primary downstream channel.

Using DBC to Change the Transmit Channel Set

The Cisco CMTS can add, delete, or replace one or multiple channels in the TCS in a single DBC message. Whenever the TCS of the cable modem changes, the CMTS appropriately modifies the service identifiers (SIDs) associated with the affected service flows.

A change in the TCS is accompanied by a valid initialization technique.

Using DBC to Change the Downstream ID

Using DBC, the Cisco CMTS can change the following attributes of a downstream ID (DSID):

- Re-sequencing encodings:
 - Downstream re-sequencing channel list—The CMTS can add, delete, and replace channels in the DS re-sequencing channel list.
 - DSID re-sequencing wait time—The CMTS can indicate a change in skew due to network or configuration changes through DSID re-sequencing wait time.
- re-sequencing Warning Threshold
- CM-STATUS Hold-Off Timer for Out-of-range Events
- Multicast Encoding—The CMTS can initiate a DBC transaction to either add, deleted, or change attributes of an existing multicast DSID:

- Client MAC Address
- Multicast cable modem interface Mask
- Group MAC Address

Using DBC to Change the Security Association for Encrypting Downstream Traffic

- The CMTS can initiate a DBC transaction to add or delete Security Associations (SA) used to encrypt downstream traffic.
- The CMTS cannot send a DBC request to a cable modem that is not in the "Authorized" State.
- The CMTS can send a DBC request with an SA that uses a cryptographic suite unsupported by the cable modem. However, if the cable modem receives a DBC request with an SA that it is not capable of using, the cable modem rejects the DBC request.

Using DBC to Change the Service Flow SID Cluster Assignments

The Cisco CMTS uses the Service Flow SID Cluster Assignments TLV in the DBC request to assign new channels to a service flow, remove channels from a service flow, or replace one channel with another for a service flow.

Note Multiple actions can occur within a single DBC message.

Benefits of Load Balancing

The Load Balancing feature on the Cisco CMTS provides the following benefits to cable service providers and their partners and customers:

- Provides a method that service providers can use for efficient bandwidth utilization, especially when using multiple upstream channels per fiber node.
- Allows service providers to expand their networks in an efficient manner, avoiding the cost of having to install additional fiber optic equipment and further segmenting the physical plant.
- Load balancing on downstream channels enables efficient bandwidth usage when using multiple downstream channels per fiber node to enable Video over IP and other services that require high-bandwidth real-time streams.
- Load balancing of upstream and downstream channels does not require any change to the provisioning servers or to any DOCSIS configuration files.
- Load balancing of upstream and downstream channels does not require any administrator or user intervention (such as manually resetting cable interfaces or manually rebooting cable modems).
- Allows service providers to equally balance their downstreams as cable modems register, so that cable modems do not all attempt to register on the same downstream, resulting in many cable modems failing to register and having to search for a new downstream.
- Cable modems can be moved among downstream and upstream channels without having to change any network parameters in manual fashion, such as IP address.

- Allows service providers to stay ahead of customers' bandwidth demands by dynamically responding to current load-usage conditions.
- Allows service providers to optimize the load balancing parameters for critical services, such as Voice over IP (VoIP).

Exclude Cable Modems from Load Balancing Groups

Load Balancing Process

The load balancing process has two phases.

- Assignment phase.

When a modem is coming online in the assignment phase, the modem is moved to the load balance group by assigning it a load balancing group (LBG) ID. The assignment phase occurs only when a modem is coming online.

- Balancing phase.

In the balancing phase, a modem is re-assigned to an LBG to balance the load.

Excluding Cable Modems from Load Balancing

There are four options that are used to exclude cable modems from an LBG:

- The **assignment** option:

The **assignment** option is used to exclude a modem during the assignment phase. The modem is not assigned an LBG and LBG ID is not displayed in the output of the **show cable modem verbose** command. The **assignment** option cannot be used when a modem is already online.

- The **static** option:

The **static** option is used to exclude a modem during the Balancing phase. The modem is assigned to an LBG with an LBG ID. The **static** option is used to exclude a modem during static load balancing.

- The **enforce** option:

The **enforce** option is similar to the **static** option, except that the **enforce** option is used to exclude a modem during dynamic load balancing.

When a cable modem is excluded from load balancing using the **assignment** option, the cable modem is not available for load balancing using the **static** or the **enforce** options.

- The **strict** option:

The **strict** option excludes a modem in both the phases of load balancing. When a modem is online already, the **strict** option applies the **static** and the **enforce** options. It applies the **assignment** option only when the modem comes online again.

How to Configure Load Balancing

To configure load balancing groups, and to enable load balancing, refer to the configurations in the *DOCSIS Load Balancing Groups* document. Each task is marked as required or optional, as appropriate.

Enabling Single Channel Load Balancing

To configure Single Channel Load Balancing, see the *DOCSIS Load Balancing Groups guide*.

Configuring Dynamic Bonding Change for DOCSIS 3.0 Static Load Balancing

Use the **cable load-balance docsis30-enabled** command in the global configuration mode, to enable DOCSIS 3.0 Static Load Balancing.

Note DOCSIS 3.0 Static Load Balancing always uses Modem Count Method for load balancing.

Before you begin

Configure Load Balancing Groups. For more details, see the *DOCSIS Load Balancing Groups guide*.

Excluding Cable Modems from a Load Balancing Group

This configuration is optional. This section describes how to exclude a particular cable modem, or all cable modems from a particular vendor, from participating in static or dynamic load balancing operations, and optionally marking the modems for passive load balancing. This task is optional, because, by default, cable modems on an interface participate in whatever load balancing operations have been configured.

Note This step might be required for some cable modems that are not DOCSIS-compliant. Such cable modems can go offline for long periods of time when load balancing is attempted using DOCSIS MAC messages. If this is the case, use the **cable load-balance exclude** command to exclude such cable modems from load balancing operations until the modem can be upgraded to DOCSIS-compliant software.

Tip You must exclude cable modems that require specific upstream channels or downstream frequencies. Load balancing cannot be done when cable modems are assigned specific channels or frequencies in their DOCSIS configuration files.

Support for Excluding Old Devices

Load balancing for old cable devices like Set Top Boxes (STBs) which do not support load balancing, will fail. In the output for **show cable load-balance group** command, these devices will show as 'suspicious' and then as 'disabled'. This will disrupt normal operations of other modems in the load balancing group. To exclude these STBs, a **cable load-balance exclude** command is configured to exclude each STB.

Note You can configure the **cable load-balance exclude** command once to exclude all the STBs, that do not support load balancing, instead of configuring the command several times with matched MAC addresses. You can also move cable modems that were moved to a load balancing group in assignment phase.

The **cable load-balance exclude** modem command is modified to include the *mask* argument as an optional argument. The MAC address of a cable modem that belongs to the range specified by the MAC address mask, will be excluded by matching the “1” bit in mask. While configuring a new range rule using the *mask* argument, an existent rule with the same range is overwritten.

The **cable load-balance exclude** modem command is modified to include the **assignment** option. This option allows you to exclude a cable modem that was moved into a load balancing group in assignment phase.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance exclude { modem <i>mac-address</i> [<i>mac-mask</i>] oui <i>oui-value</i> } [assignment enforce static strict] Example: Router(config)# cable load-balance exclude oui 00:00:0c	Specifies that one or more cable modems should be excluded from load balancing operations. By default, the cable modems are excluded from dynamic and static load balancing, but they continue to participate in passive load balancing. Use the following options to exclude the cable modems from others combinations of load balancing:
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Distributing Downstream Load Balancing with Upstream Load Balancing

Two commands are used to configure or display the configuration and status of distributed load balancing on the Cisco CMTS:

- **cable load-balance group** *ds-lb-group-id* **policy** {**pcmm** | **ugs** | **us-groups-across-ds**}
- **show cable load all**

The optional configuration of making downstream load balancing decisions is enabled as follows:

- The target downstream segment is in the same downstream load balancing group as the source downstream segment. This feature finds the target frequency and interface based on the upstream loads within the same upstream group as the source.
- The upstream load balancing group can be set for the corresponding channel on which a cable modem is balanced on the downstream channels.
- The Cisco CMTS automatically locates the upstream segment for a load balancing group and processes the upstream group status on the source interface that has the lowest load.
- The target downstream segment must have an upstream channel set in the upstream load balancing group.
- The highest target upstream segment must carry less load than any other potential target—the highest upstream segment on other interfaces.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance group <i>ds-lb-group-id</i> policy { pcmm ugs us-groups-across-ds } Example: Router(config)# cable load-balance group 1 policy us-groups-across-ds	Sets the type of service flow policy for use with Load Balancing. This command synchronizes the pending statistic between different cable interface line cards in the load balancing group. The result is an alternative downstream load balancing scheme that makes use of per-upstream loads rather than total downstream loads when making load balancing decisions.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.
Step 5	show cable load all Example: Router# show cable load all	Displays load balancing statistics and status of load balancing configurations on the Cisco CMTS, to include distributed upstream-to-downstream load balancing when configured.

How to Configure Dynamic Channel Change for Load Balancing

DCC in DOCSIS 1.1 dynamically changes cable modem upstream or downstream channels without forcing a cable modem to go offline, and without reregistration after the change. DCC supports five different initialization methods (0-4), instead of one, as in earlier DOCSIS support.

Dynamic Channel Change (DCC) and DCC for Load Balancing on the Cisco CMTS supports the following:

- Load balancing techniques allow for moving cable modems with DCC by using configurable initialization techniques.
- DCC allows line card channel changes across separate downstream channels in the same cable interface line card, with the DCC initialization techniques ranging from 0 to 4.
- DCC transfers cable modem state information from the originating downstream channel to the target downstream channel, and maintains synchronization of the cable modem information between the cable interface line card and the Network Processing Engine (NPE) or Route Processor (RP).
- Applications that are sensitive to delay, such as PacketCable (PC) and PacketCable MultiMedia (PCMM), may use DCC initialization technique 4 to retain services while the cable modem is performing DCC.
- If the channel is in mixed or ATDMA-only mode, the primary Service Identifier (SID) must be switched to ATDMA-only mode.

Configuring Dynamic Channel Change for Load Balancing

To configure the DCC feature for load balancing, use the following steps. Values indicated are sample values that may differ from your own.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cable load-balance docsis-enable**
4. **cable load-balance docsis-group** *docsis-group-id*
5. **init-tech-list** *tech-list* [**ucc**]
6. **policy** {**pcmm** | **ugs** | **us-across-ds** | **pure-ds-load**}
7. **threshold** {**load** {**minimum** <1-100> | <1-100>} | **pcmm** <1-100> | **stability** <0-100> | **ugs** <1-100>} }
8. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable load-balance docsis-enable Example: Router(config)# cable load-balance docsis-enable	Enables DOCSIS load balancing on the Cisco CMTS.

	Command or Action	Purpose
Step 4	cable load-balance docsis-group <i>docsis-group-id</i> Example: <pre>Router(config)# cable load-balance docsis-group 1</pre>	Creates a DOCSIS load balance group on the Cisco CMTS, with the following parameter: The router enters DOCSIS load balancing group configuration mode.
Step 5	init-tech-list <i>tech-list</i> [ucc] Example: <pre>Router(config-lb-group)# init-tech-list 1 ucc</pre>	Sets the DCC initialization techniques that the Cisco CMTS can use to load balance cable modems.
Step 6	policy { pcmm ugs us-across-ds pure-ds-load } Example: <pre>Router(config-lb-group)# policy us-across-ds Router(config-lb-group)# policy ugs Router(config-lb-group)# policy pure-ds-load</pre>	Selects the modems based on the type of service flow that are balanced.
Step 7	threshold { load { minimum <I-100> <I-100>} pcmm <I-100> stability <0-100> ugs <I-100>} Example: <pre>Router(config-lb-group)# threshold load minimum 10 Router(config-lb-group)# threshold pcmm 70 Router(config-lb-group)# threshold load 10 Router(config-lb-group)# threshold stability 50 Router(config-lb-group)# threshold ugs 70</pre>	Selects the percentage of use beyond which load balancing occurs.
Step 8	end Example: <pre>Router# end</pre>	Returns to privileged EXEC mode.

What to do next

To test and verify DCC for load balancing, use the following two commands:

- **test cable dcc**
- **show controllers cable**

These commands are described in the *Cisco CMTS Cable Command Reference* .

Verifying Load Balancing Operations

This section describes how to use certain test and show commands to verify the configuration and operation of the Load Balancing feature or Dynamic Channel Change feature on the Cisco CMTS.

Example

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	show cable load-balance [group n] [all load pending statistics target] Example: Router# show cable load-balance group 1	Displays real-time statistical and operational information for load balancing operations. If given without any options, this command displays information for the load balancing groups and each cable interface's current load and load balancing status. You can also specify the following options:
Step 3	test cable dcc [mac-addr ip-addr cable-if-src sid cable-if-target uschan {ranging-tech}] Example: Router# test cable dcc 0000.394e.4e59	Tests Dynamic Channel Change (DCC) by moving a target cable modem, as specified by MAC address, IP address, or the primary service ID (SID) value. Applies to a cable modem on the source interface to an upstream channel on a target downstream interface using the initialization technique specified.

Example

This example shows the result of load balancing operations.

Troubleshooting Tips

Problem Packets are dropped when a cable modem moves from one channel to another.

Possible Cause When the **test cable dcc** command is used to move a cable modem from one channel to another with DCC initialization technique 3:

- If the pre-equalization coefficient is enabled, the cable modem moves and packet drop occurs for 5 seconds.
- If the pre-equalization coefficient is disabled, the cable modem moves and packet drop occurs for less than 1 second.

Possible Cause When the **test cable dcc** command is used to move a cable modem from one channel to another with DCC initialization technique 4:

- If the pre-equalization coefficient is enabled, the cable modem moves and packet drop occurs for less than 1 second.
- If the pre-equalization coefficient is disabled, the cable modem moves without any packet drop.

Solution No action is required.

Examples

Use the **show cable load-balance target** command to display the interfaces being used for load balancing, use the **test cable load-balance** command to test whether a cable modem can move between interfaces, and use the **show cable load-balance statistics** command to display the results of the test.

The following example shows how to test whether a specific cable modem responds to both a UCC request and to an upstream channel override to move from one upstream to another in its load balancing group:

```
Router# show cable load-balance target

Target assignments:
Interface           State      Group  Target
Cable1/0/0 (669 MHz) up         1
Cable1/0/0/U0       up         1      Cable1/0/0/U1 [enforce]
Cable1/0/0/U1       up         1
```

```
Router# show cable load-balance statistics

Statistics:

Target interface    State      Transfers
                   Complete  Pending  Retries  Failures
Cable1/0/0 (669 MHz) up         15         0         1         0
Cable1/0/0/U0       up         33         0         1         0
Cable1/0/0/U1       up         22         0         2         0
```

```
Router# test cable load-balance 0000.394e.4e59

Sending UCC request: Cable1/0/0/U0 --> U1
Waiting for test completion .....
Test results:
  UCC Response: 0.0s
  Initial Ranging: 8.5s
  Ranging Complete: failed.
  Modem replied to DOCSIS ping.
Test summary:
  UCC Response: success rate 100% min 0.0s max 0.0s avg 0.0s
  Initial Ranging: success rate 100% min 8.5s max 8.5s avg 8.5s
Testing US Channel Override: Cable1/0/0/U1 --> U0
Waiting for test completion .....
Test results:
  Initial Ranging: 8.5s
  Ranging Complete: failed.
  Modem replied to DOCSIS ping.
Test summary:
  UCC Response: success rate 100% min 0.0s max 0.0s avg 0.0s
  Initial Ranging: success rate 100% min 8.5s max 8.5s avg 8.5s
```

```
Router# show cable load-balance statistics

Statistics:

Target interface    State      Transfers
                   Complete  Pending  Retries  Failures
Cable1/0/0 (669 MHz) up         15         0         1         0
Cable1/0/0/U0       up         34         0         1         0
Cable1/0/0/U1       up         23         0         2         0
```

The following example shows how to test whether a specific modem responds to a UCC request to move from one upstream to another in its load balancing group:

```

Router# show cable load-balance statistics

Statistics:

Target interface      State      Transfers
                   Complete Pending  Retries  Failures
Cable1/0/0 (669 MHz) up          15         0         1         0
Cable1/0/0/U0        up          34         0         1         0
Cable1/0/0/U1        up          23         0         2         0

Router# test cable load-balance 0007.0e01.4129 ucc 1

Sending UCC request: Cable1/0/0/U0 --> U1
Waiting for test completion .....
Test results:
  UCC Response: 0.0s
  Initial Ranging: 10.3s
  Ranging Complete: 11.2s
  Modem replied to DOCSIS ping.
Test summary:
  UCC Response: success rate 100% min 0.0s max 0.0s avg 0.0s
  Initial Ranging: success rate 100% min 10.3s max 10.3s avg 10.3s
  Ranging Complete: success rate 100% min 11.2s max 11.2s avg 11.2s

```

```

Router# show cable load-balance statistics

Statistics:

Target interface      State      Transfers
                   Complete Pending  Retries  Failures
Cable1/0/0 (669 MHz) up          15         0         1         0
Cable1/0/0/U0        up          35         0         1         0
Cable1/0/0/U1        up          24         0         2         0

```

The following example shows information when moving a cable modem to a different upstream channel using DCC initialization technique 1. This example moves the cable modem 0012.17ea.f563 from interface c7/1/0 upstream 1 to interface c7/1/1 upstream 0 using DCC initialization technique 1:

```

Router# show cable modem

MAC Address      IP Address      I/F      MAC      Prim RxPwr  Timing  Num BPI

Configuration Examples for Load Balancing

This section provides the following configuration examples:

Example: Configuring Dynamic Channel Change for Load Balancing

The following examples illustrate the working of dynamic load balancing working process in DOCSIS 3.0 cable modems.

Verify configuration:

```
Router# show cable load-balance docsis-group 1
DOCSIS LB Enabled: Yes
DOCSIS 2.0 LB Enabled: No
DOCSIS 3.0 LB Enabled: Yes
DOCSIS 3.0 Static LB Enabled: No
DOCSIS 3.0 Dynamic Downstream LB Enabled: Yes
DOCSIS Status Interval DCC mask Policy Method Threshold
Group /UCC DS/US M/E/U/P/S
1 RE 60 0x38(2)/N 0 u/u 1/10/70/70/50
```

Verify channel current load:

```
Router# show cable load-balance docsis-group 1 load wideband
DOCSIS load-balancing wide band load
Interface Size Group Throughput(Kbps) /bw(Mbps) Avg-Util
Wi9/0/0:1 8 1 93324/300 36%
Wi9/0/0:2 8 1 37329/300 39%
Wi9/0/0:3 8 1 74659/300 31%
Wi9/0/0:4 8 1 0/300 13%
Wi9/0/0:5 8 1 9332/300 2%
```

Verify channel overload and target:

```
Router# show cable load-balance docsis-group 1 target wideband
Interface Bg-Id State Group Target
Wi9/0/0:1 28674 up 1 Wi9/0/0:5 ...
Wi9/0/0:2 28675 up 1 Wi9/0/0:5 ...
Wi9/0/0:3 28676 up 1 Wi9/0/0:5 ...
Wi9/0/0:4 28677 up 1 Wi9/0/0:5
Wi9/0/0:5 28678 up 1
```

Verify channel modem-list:

```
Router# show cable load-balance docsis-group 1 modem-list wideband
Codes: M - Multicast, U - UGS, P - PCMM, F - Max-Failures, X - eXcluded
L - L2vpn, R - RSVP
Primary WB MAC Address Primary DS RCC-ID Priority MUPFLXR State
Wi9/0/0:1 (10)
c8fb.26a6.c02c In9/0/0:4 1 0 ----- LB_CM_READY
c8fb.26a6.c62c In9/0/0:4 1 0 ----- LB_CM_READY
c8fb.26a6.c706 In9/0/0:4 1 0 ----- LB_CM_READY
c8fb.26a6.c0dc In9/0/0:4 1 0 ----- LB_CM_READY
c8fb.26a6.c53a In9/0/0:4 1 0 ----- LB_CM_READY
```

Verify QAM channel utilization:

```
Router# show cable load-balance docsis-group 1 rfch-util
Interface Pstate Pending-In Pending-Out Throughput(Kbps) Util
In9/0/0:4 up No No 6517 17
In9/0/0:5 NA No No 6574 17
In9/0/0:6 NA No No 6520 17
In9/0/0:7 NA No No 6738 17
In9/0/0:8 up No No 8624 22
In9/0/0:9 NA No No 8482 22
In9/0/0:10 NA No No 8353 22
```

Verify channel statistic movement:

```

Router# show cable load-balance docsis-group 1 statistics wideband
Target interface State Transfers
Complete Pending Total Failures Disabled
Wi9/0/0:1 up 0 0 0 0 0
Wi9/0/0:2 up 0 0 0 0 0
Wi9/0/0:3 up 3 0 3 0 0
Wi9/0/0:4 up 0 0 0 0 0
Wi9/0/0:5 up 9 0 9 0 0

```

The following example of the running configuration illustrates DCC for load balancing.

```
Router# show cable load all
```

```

*Nov 11 15:42:18.955: %SYS-5-CONFIG_I: Configured from console by conscable load all
Group Interval Method DCC Init Threshold
Technique Minimum Static Enforce Ugs PCMM
1 10 modems 0 5 10% --- --- ---

```

Current load:

Interface	State	Group	Utilization	Reserved	Modems	Flows	Weight
Cable3/0 (0 MHz)	initial	1	0%(0%/0%)	0%	0	0	26

Target assignments:

Interface	State	Group	Target
Cable3/0 (0 MHz)	initial	1	

Statistics:

Target interface	State	Transfers			
		Complete	Pending	Retries	Failures
Cable3/0 (0 MHz)	initial	0	0	0	0

Pending:

Modem	Group	Source interface	Target interface	Retries

The following example of the running configuration illustrates DCC for load balancing.

```
Router# show running configuration
```

```

```

The following example of the show cable load all command illustrates DCC for load balancing.

```
Router# show cable load all
```

```

*Nov 11 15:43:39.979: %SYS-5-CONFIG_I: Configured fromconf t
Group Interval Method DCC Init Threshold
Technique Minimum Static Enforce Ugs PCMM
1 10 modems 0 5 75% 75% 75% 75%

Current load:

Interface State Group Utilization Reserved Modems Flows Weight
Cable3/0 (0 MHz) initial 1 0%(0%/0%) 0% 0 0 26

Target assignments:

Interface State Group Target
Cable3/0 (0 MHz) initial 1

Statistics:

Target interface State Transfers
Complete Pending Retries Failures
Cable3/0 (0 MHz) initial 0 0 0 0

Pending:

Modem Group Source interface Target interface Retries

```

The following example illustrates a DCC load balancing group with the default DCC initialization technique. This command configures load balancing group 1:

```
Router(config)# cable load-balance group 1 threshold load 10 enforce
```

This configuration creates a dynamic load balancing group with the following default settings:

```

cable load-balance group 1 method modem
cable load-balance group 1 threshold load 10 enforce
cable load-balance group 1 interval 10
cable load-balance group 1 dcc-init-technique 0

```

The following example changes this DCC load balancing configuration to initialization technique 4:

```
Router# cable load-balance group 1 dcc-init-technique 4
```

Note By default, UGS and PCMM policies are not turned on, so that CMs with active voice calls or PCMM calls participate in load balancing.

Feature Information for DOCSIS Load Balancing Movements

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 40: Feature Information for DOCSIS Load Balancing Groups

Feature Name	Releases	Feature Information
DOCSIS Load Balancing Movements	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 16

DOCSIS 3.0 Downstream Bonding

The DOCSIS 3.0 Downstream Bonding feature helps cable operators offer new, more bandwidth-intensive services by adding one or more additional downstream quadrature amplitude modulation (QAM) channels to the standard broadband DOCSIS system.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Information About DOCSIS 3.0 Downstream Bonding

DOCSIS 3.0 Downstream Bonding enables high-speed broadband access and helps cable operators offer more bandwidth-intensive services by adding one or more additional downstream quadrature amplitude modulation (QAM) channels to the standard broadband DOCSIS system. This new set of downstream channels is grouped into one larger channel, known as a bonded channel.

Channel bonding combines several RF channels into one virtual channel. Data rates in this virtual channel range from hundreds of megabits to potentially gigabits per second, creating more available bandwidth in the network.

Receive Channel Profile

An RCP is an encoding that represents the receive channels and receive modules of a cable modem. A cable modem communicates to the CMTS one or more RCP encodings within its registration request using either verbose description, which contains complete subtype encoding defined in DOCSIS 3.0, or simple description, which only contains RCP identifiers.

The cable modem reporting method is configurable within the MAC domain and communicated to cable modems via the MDD.

You must define an RCP-ID to describe the cable modem's capabilities for that RCP-ID and to input information about cable modems which are not defined on the system. Once configured the RCP-ID is available to the entire system since it is not meant to be card specific or mac-domain specific. The path selection module ensures that the RCP ID is accurately transmitted as part of the RCC profile.

The CableLabs MULPI specification defines standard RCPs which are automatically created by the CMTS.

Receive Channel Configuration

A cable modem reports its ability to receive multiple channels with one or more RCP encodings in a REG-REQ or REG-REQ-MP message. Each receive channel profile describes a logical representation of the cable modem's downstream physical layer in terms of receive channels (RCs) and receive modules (RMs). The CMTS initially configures the cable modem's receive channels and receive modules with an RCC encoding in the registration response.

This feature supports any arbitrary RCP ID configuration and receive channel configuration on a Cisco cBR Series Converged Broadband Router.

RCC Template

You can configure one or more RCC templates for an RCP. An RCC template configures the physical layer components described by an RCP, including receive modules and receive channels to specific downstream frequencies. The template also specifies the interconnections among receive modules, or between a receive module and a receive channel. An RCC template can be associated only to the cable interface (MAC domain).

A cable modem's RCP ID is matched with an RCC, when RCC templates are configured. A cable modem's RCP ID may be matched with an RCC generated by an RCC template when RCC templates are configured. The path selection module ensures that the RCP ID that is transmitted as part of the RCC profile is accurate.

At time of registration, if there are multiple valid RCCs that can be assigned to the CM after going through the sequence of checks outlined in the CableLabs MULPI specifications then the RCC with the most channels will be the one selected. If there are multiple valid RCCs of equal size then the RCC with the least amount of cable modems will be selected.

Channel Assignment

The CMTS assigns a receive channel configuration encoding to a DOCSIS 3.0-certified cable modem operating in a Multiple Receive Channel (MRC) mode during cable modem registration.

With the implementation of this feature, the DOCSIS 3.0-certified cable modem reports its receiving capabilities and characteristics using the receive channel profile type, length, value (TLV) list in the registration request message. Based on this report, the CMTS assigns an RCC encoding that is compatible with the reported RCP.

Cable modems operating in MRC mode are assigned an RCC encoding associated with an RCP. RCC encodings may be derived from RCC templates or from a wideband-cable interface configuration.

Downstream Traffic Forwarding

DOCSIS 3.0 introduces the concept of assigning downstream service flows of cable modems, which are operating in an MRC mode, to downstream (DS) channels or bonding groups. Forwarding interfaces assigned to service flows (SFs) can be either DS channel interfaces (integrated cable interfaces) or downstream bonding groups (wideband interfaces).

Note Valid interfaces that are available for SF assignment must be a subset of the cable modem's assigned RCC encoding.

Service Flow Priority in Downstream Extended Header

The purpose of the feature is to be able to reflect the traffic priority of downstream packets into the DOCSIS extended header. The priority is derived from the service flow that the packet is mapped to. Priority refers to the service flow priority specified in the CM configuration file, or the Cisco CMTS service class configuration.

The service flow priority can be set using cable modem configuration file, or dynamic configuration.

By default, this feature is disabled on Cisco cBR-8 router, user can use **cable service flow priority** command to enable this feature.

How to Configure RCP and RCC Encoding

The following tasks describe how to configure a receive channel profile and configuration encoding for a receive channel profile:

Configuring the RCP ID

You must configure the RCP IDs with the cable modem capabilities that are not defined in the CMTS. This is done to supplement the standard MULPI RCP IDs already created by the CMTS.

Before you begin

Restrictions

The configurations are subject to RCC Templates and RCP Interactions as follows:

- RCC templates can only be created for an RCP that is already defined on the system. By default the system will contain the RCPs that are specified in the MULPI spec.
- When defining RCC templates for a particular RCP, error checking will be done to ensure that the information being configured in the RCC template does not violate the corresponding RCP information. For example, if the RCP information indicates that there are 2 receive modules then the RCC template configuration will not allow the user to configure more than 2 modules.
- Once an RCP is included in an RCC template users will not be allowed to modify the RCP. Only an RCP which is not being used by any RCC template can be modified
- A valid RCP that can be applied to an rcc-template must contain the following;
 - center-frequency-spacing

- At least one module which defines the minimum and maximum center frequency range.
- Rules of inheritance.
- rcc-template inherit definition from the associated user-defined RCP, such as center-frequency-spacing.
- rcc-template channel frequencies must fall within the range of the minimum and maximum center frequency per the corresponding RCP module.
- common-module definition is applicable to the rcc-template module referenced with the same index.
- rcc-template module channel frequencies overrides the same channel from the corresponding common-module.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable rcp-id <i>rcp-id</i> Example: Router(config)# cable rcp-id 00 10 00 01 08 Router(config-rcp)#	Defines the RCC template. <ul style="list-style-type: none"> • <i>rcp-id</i> - Specifies an RCP ID in Hex. This command changes the input mode to the RCC configuration mode.
Step 4	name <i>word</i> Example: Router(config-rcp)# name rcp-id_1	name —Assigns a name to the RCP ID <ul style="list-style-type: none"> • <i>word</i>—Use a string to name the RCP ID. Note Do not include space between words in the name
Step 5	center-frequency-spacing <i>frequency</i> Example: Router(config-rcp)# center-frequency-spacing 6	Assigns a center frequency space to the RCP ID. The valid values are 6 and 8.
Step 6	module <i>module index</i> minimum-center-frequency <i>Hz</i> maximum-center-frequency <i>Hz</i> Example: Router(config-rcp)# module 1 minimum-center-frequency 120000000 maximum-center-frequency 800000000	Configures a receive module configuration for the selected RCP. <ul style="list-style-type: none"> • <i>module index</i> - Specifies the module number for the receive module. The valid range is 1 to 12. • minimum-center-frequency - Specifies the minimum center frequency for the channels of the receive module channel. • <i>Hz</i>- Specifies the center frequency value in Hz. The valid range is from 111000000 to 999000000.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • maximum-center-frequency - Specifies the maximum center frequency for the channels of the receive module channel.
Step 7	module <i>module index</i> number-of-adjacent-channels <i>Integer</i> Example: <pre>Router(config-rcp)#module 2 number-of-adjacent-channels 10 Router(config-rcp)#</pre>	Specifies the frequency band for the receive module. The valid values are 1-255.
Step 8	module <i>module index</i> connected-module <i>module index</i> Example: <pre>Router(config-rcp)# module 1 connected-module 0</pre>	Specifies a receive channel configuration for the selected RCP. <ul style="list-style-type: none"> • connected-receive-module— (Optional) Specifies a nested receive module in the RCC template. Generally, only one receive module is configured for an RCC template. • module index—Specifies the module number for the receive module. The valid range is 1 to 12.
Step 9	number-of-channels <i>Number of channel</i> Example: <pre>Router (config-rcp)#number-of-channels 8</pre>	Specifies the number of receive channels in the RCP ID.
Step 10	primary-capable-channels <i>Number of channel</i> Example: <pre>Router(config-rcp)# primary-capable-channels 1</pre>	Specifies the number of receive channels that are defined as primary capable channels.

What to do next

Verify RCP ID configurations using the **show cable rcps** command.

```
Router# show cable rcps
RCP ID   : 00 10 00 01 08
Name     : rcp-id 1
Center Frequency Spacing   : 6
Max number of Channels     : 8
Primary Capable Channel    : 1
Number of Modules          : 2
Module[1]:
  Number of Adjacent Channels: 10
  Minimum Center Frequency-Hz: 111000000
  Maximum Center Frequency-Hz: 999000000
Module[2]:
  Number of Adjacent Channels: 10
  Minimum Center Frequency-Hz: 120000000
  Maximum Center Frequency-Hz: 800000000
```

```

RCP ID : 00 10 00 00 02
Name : rcp-id 2
Center Frequency Spacing : 6
Max number of Channels : 2
Primary Capable Channel : 1
Number of Modules : 1
Module[1]:
  Number of Adjacent Channels: 10
Minimum Center Frequency-Hz: 111000000
Maximum Center Frequency-Hz: 867000000
Connected Module : 64

```

Configuring the RCC Templates

You must configure an RCC template with a unique RCP ID for a particular CMTS. A valid RCC template consists of a configured RCP ID, RMs, and RCs. There is dependency between the RCC templates and the RCP since information present in the RCP configuration is also present in RCC templates.

Each RCC encoding contains all operational DS channels with their channel parameters, including the frequency match RC attribute specified in the RCC template. An RCC template specifies the intended receive channel assignment in the available DS spectrum.

Note If an RCC template is removed from a MAC domain through configuration, the CMTS removes all RCC encodings derived from the RCC template, and all cable modems assigned to the RCC encoding are marked offline.

Before you begin

At least one RC must be configured as a primary Receive Channel (RC).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable rcc-templates frequency-based <i>id</i> Example: Router (config) # cable rcc-templates frequency-based 1 Router (config-rcc-freq-based) #	<i>id</i> —Specifies an RCC template. The valid range is 1-64.

	Command or Action	Purpose
Step 4	rcp-id <i>id</i> Example: <pre>Router(config-rcc-freq-based)#rcp-id 00 10 00 01 08</pre>	<i>id</i> —Specifies an RCP ID for the RCC template. The valid range is 00 00 00 00 00 to FF FF FF FF. By default, the RCP ID is set to 00 00 00 00 00.
Step 5	common-module <i>module-index</i> channel <i>grouplist</i> start-frequency <i>Hz</i> Example: <pre>Router(config-rcc-freq-based)# common-module 1 channels 0-6 start-frequency 555000000</pre>	Specifies module configurations that are common for a selected set of channels assigned to the selected RCP ID. <ul style="list-style-type: none"> • <i>Module-index</i>—Specifies the index value for the receive module. The valid range is 1 to 12. • channels—Specifies the list of channels to which the common configurations apply. • <i>grouplist</i>—Specifies the list of channels to which a specific list of configurations apply. The range of values are 1-64. • start-frequency —Specifies the start frequency value in Hz. • <i>Hz</i>—Specifies the frequency value for the start frequency for the common module. The valid range is from 111000000 to 999000000.
Step 6	rcc-template <i>Id</i> Example: <pre>Router(config-rcc-freq-based)# rcc-template 1</pre>	Specifies an RCC template ID to configure the selected RCC template. <ul style="list-style-type: none"> • <i>Id</i>—Specifies the ID of the RCC template. The valid range is from 1-8.
Step 7	cm-attribute-mask <i>value</i> Example: <pre>Router (config-rcc-freq-based-tmpl)# cm-attribute-mask 1</pre>	(Optional) Configured to be used to match against the cm attribute mask define in CM 's configuration file. <ul style="list-style-type: none"> • <i>value</i>—The valid range is 00 00 00 00 00 to FF FF FF FF.
Step 8	module <i>module-index</i> channel <i>grouplist</i> start-frequency <i>Hz</i> . Example: <pre>Router(config-rcc-freq-based)# common-module 1 channels 0-6 start-frequency 555000000</pre>	Specifies module configurations that are common for a selected set of channels assigned to the selected RCP ID. <ul style="list-style-type: none"> • <i>Module-index</i>—Specifies the index value for the receive module. The valid range is 1 to 12. • channels—Specifies the list of channels to which the common configurations apply. • <i>grouplist</i>—Specifies the list of channels to which a specific list of configurations apply. The range of values are 1-64. • start-frequency —Specifies the start frequency value in Hz.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • H_z—Specifies the frequency value for the start frequency for the common module. The valid range is from 111000000 to 999000000. <p>Repeat Step 3 and Step 7 to configure other frequency based RCC templates.</p>

What to do next

The following configuration examples show the cable rcc-template configuration:

```

cable rcc-templates frequency-based 2
  rcp-id 00 10 00 01 08
  common-module 1 channels 1-4 start-frequency 381000000
  rcc-template 1
  module 1 channels 5-8 start-frequency 501000000
  rcc-template 2
  module 1 channels 5-8 start-frequency 669000000
  rcc-template 3

cable rcc-templates frequency-based 1
  rcp-id 00 10 00 01 08
  rcc-template 1
  cm-attribute-mask 2
  module 1 channels 1-4 start-frequency 381000000
  module 2 channels 5-8 start-frequency 501000000
  rcc-template 2
  module 1 channels 1-4 start-frequency 381000000
  module 2 channels 5-8 start-frequency 669000000
  rcc-template 3
  module 1 channels 1-4 start-frequency 381000000

```

After defining an RCC template, you must assign the template to a cable interface.

Assigning an RCC Template to a MAC Domain (Cable Interface)

The CMTS derives an RCC or RCCs from the RCC template for each MAC Domain Downstream Service Group (MD-DS-SG).

The following information is required for RCC assignment to cable modems:

- RCC templates assigned to the MAC domain.
- DS channel physical parameters including frequency and connected-receive-module index .
- DS channel primary capable indicator.
- DS channel membership to the MD-DS-SG.
- Cable modem membership to the MD-DS-SG.

This section describes how to assign an RCC template to a MAC Domain.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable slot / subslot / port Example: Router(config)# interface cable 1/0/0	Enters MAC domain configuration mode. <ul style="list-style-type: none"> • <i>slot</i>—Specifies the chassis slot number of the interface line card. • <i>subslot</i>—Specifies the secondary slot number of the interface line card. Valid subslot is 0. • <i>MD index</i>—Specifies the MAC Domain index number. Valid values are 0-15.
Step 4	cable rcc-template frequency-based Id Example: Router(config-if)# cable rcc-template frequency-based 1	Assigns the RCC template to the specified cable interface. <ul style="list-style-type: none"> • <i>Id</i>—Specifies the template you want to assign to the cable interface. The valid range is from 1 to 64.

What to do next

Verify RCC template binding to MD.

The following example shows the RCC template binding using the **show cable mac-domain rcc**

```
Router#show cable mac-domain c1/0/0 rcc
```

RCC-ID	RCP	RCs	MD-DS-SG	CMs	WB/RCC-TMPL
1	00 00 00 00 00	4	0	2	WB (Wi1/0/0:0)
2	00 00 00 00 00	4	0	2	WB (Wi1/0/0:1)
3	00 00 00 00 00	4	0	0	WB (Wi1/0/1:2)
4	00 00 00 00 00	4	0	0	WB (Wi1/0/2:3)
8	00 10 00 01 08	8	5	0	RCC-TMPL (1:1)
9	00 10 00 01 08	8	5	0	RCC-TMPL (1:2)
10	00 10 00 01 08	4	5	0	RCC-TMPL (1:3)
14	00 10 00 01 08	8	5	0	RCC-TMPL (2:1)
15	00 10 00 01 08	8	5	0	RCC-TMPL (2:2)
16	00 10 00 01 08	4	5	0	RCC-TMPL (2:3)

The following example shows the RCC template binding using the **show cable mac-domain rcc id** command.

```
Router#show cable mac-domain c1/0/0 rcc 8
```

```

```

Verifying the RCC Configuration

To verify the runtime RCCs on a cable interface, use the **show cable mac-domain rcc** command.

```

Router#show cable mac-domain c1/0/0 rcc

RCC-ID  RCP                RCs MD-DS-SG CMs  WB/RCC-TMPL
1       00 00 00 00 00   4  0      2   WB (Wi1/0/0:0)

```

2	00 00 00 00 00	4	0	2	WB (Wi1/0/0:1)
3	00 00 00 00 00	4	0	0	WB (Wi1/0/1:2)
4	00 00 00 00 00	4	0	0	WB (Wi1/0/2:3)
8	00 10 00 01 08	8	5	0	RCC-TMPL (1:1)
9	00 10 00 01 08	8	5	0	RCC-TMPL (1:2)
10	00 10 00 01 08	4	5	0	RCC-TMPL (1:3)
14	00 10 00 01 08	8	5	0	RCC-TMPL (2:1)
15	00 10 00 01 08	8	5	0	RCC-TMPL (2:2)
16	00 10 00 01 08	4	5	0	RCC-TMPL (2:3)

Note A zero (0) value in the RCP or MD-DS-SG field indicates that the RCC encoding is configured directly through a wideband interface configuration and not through any RCC template.

How to Configure Attribute Masks

DOCSIS 3.0 introduces the concept of assigning service flows to channels or bonding groups based on binary attributes. The attribute masks configured on a cable, modular, integrated or wideband interface are called provisioned attribute masks.

The two types of attributes are as follows:

- Specification-defined attributes—Contain default values based on the characteristics of the channel or bonding group.
- Operator-defined attributes—Default to zero.

The operator can configure a provisioned attribute mask for each channel and provisioned bonding group to assign values to the operator-defined binary attributes. The operator can also assign new values to override the default values of the specification-defined attributes.

The operator can configure a required attribute mask and a forbidden attribute mask for a service flow in the cable modem configuration file. These required and forbidden attribute masks are optionally provided on the DOCSIS 3.0 service flows and are matched with the provisioned attribute masks of the interfaces.

Each service flow is optionally configured with the following TLV parameters:

- Service flow required attribute mask—To configure this, assign a service flow to a channel that has a 1-bit in all positions of its provisioned attribute mask corresponding to the 1-bit in the service flow required attribute mask.
- Service flow forbidden attribute mask—To configure this, assign a service flow to a channel that has a 0-bit in all positions of its provisioned attribute mask corresponding to the 1-bit in the service flow forbidden attribute mask.

Additionally, in a cable modem-initiated dynamic service request, the cable modem can include a required attribute mask and a forbidden attribute mask for a service flow. The CMTS assigns service flows to channels or bonding groups so that all required attributes are present and no forbidden attributes are present in the cable modem configuration file.

The table below lists the supported binary attributes for channels and bonding groups.

Table 42: Binary Attributes

Bit Position	Definition
Bit 0	Bonded—This bit is zero for all individual channel interfaces and one for all bonding groups.
Bit 1	Low latency—This bit is set when the interface can provide relatively low latency service. This bit is set to zero for all channels, and left up to the operator to define.
Bit 2	High availability—This bit is set to zero for all channels, and left up to the operator to define.
Bit 3:15	Reserved—Set to zero.
Bit 16:31	Operator defined—Set to zero by default.

You can configure provisioned attribute masks for cable, integrated cable, wideband cable, and modular cable interfaces.

Prerequisites

- To assign an interface to a wideband cable modem's service flow, the interface must be a subset of the cable modem's RCC.
- To assign a service flow to an integrated cable (IC) channel, the corresponding integrated cable interface must be configured and operational.

Restrictions

- The service flow from a narrowband cable modem is always assigned to the primary interface of the cable modem. No attribute checking is performed in this case.

This section describes the following:

Configuring Provisioned Attributes for an Integrated Cable Interface

The default provisioned attribute is zero for an integrated cable interface.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface integrated-cable {slot/port slot/subslot/port}:rf-channel Example:	Specifies the cable interface line card on a Cisco CMTS router: • <i>slot</i> —Chassis slot number of the cable interface line card.

	Command or Action	Purpose
	Router(config)# interface integrated-cable 1/0/0:0	<ul style="list-style-type: none"> • <i>subslot</i>—subslot number of the cable interface line card. Valid subslot is always 0. • <i>port</i>—Downstream port number. • <i>rf-channel</i>—RF channel number with a range of 0 to 3.
Step 4	cable attribute-mask mask Example: Router(config-if)# cable attribute-mask 800000ff	Specifies the mask for the interface.

Configuring Provisioned Attributes for a Wideband Cable Interface

The default provisioned attribute is 0x80000000 for a wideband cable interface, and the zero bit is automatically added to the wideband cable interface whenever an attribute is configured for that interface.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface wideband-cable {slot/port slot/subslot/port}:wideband-channel Example: Router(config)# interface wideband-cable 1/0/1:4	Specifies the wideband cable interface and enters interface configuration mode:
Step 4	cable downstream attribute-mask mask Example: Router(config-if)# cable downstream attribute-mask 800000ff	Specifies the mask for the interface.

Verifying the Attribute-Based Service Flow Assignments

To verify the attribute-based assignment of service flows on a cable interface, use the **show interface cable service-flow** or **show interface wideband-cable service-flow** command as shown in the following example:

```
Router# show interface cable 3/0 service-flow
```

```

Sfid  Sid   Mac Address      QoS  Param Index Type  Dir  Curr  Active  DS-ForwIf/
      Sid   Address          Prov Adm  Act   Type  Dir  State Time  US-BG/CH

```

The table below shows descriptions for the fields displayed by this command:

Table 43: show interface cable service-flow Field Descriptions

Field	Description
Sfid	Identifies the service flow identification number. Note Primary service flow IDs are displayed even for offline cable modems because they are needed for modem re-registration.
Sid	Identifies the service identification number (upstream service flows only).
Mac Address	Identifies the MAC address for the cable modem.
QoS Parameter Index Prov	Identifies the QoS parameter index for the provisioned state of this flow.
QoS Parameter Index Adm	Identifies the QoS parameter index for the Admitted state of this flow.
QoS Parameter Index Act	Identifies the QoS parameter index for the Active state of this flow.
Type	Indicates if the service flow is the primary flow or a secondary service flow. Secondary service flows are identified by an “S” (created statically at the time of registration, using the DOCSIS configuration file) or “D” (created dynamically by the exchange of dynamic service messages between the cable modem and CMTS).
Dir	Indicates if this service flow is DS or US.
Curr State	Indicates the current run-time state of the service flow.
Active Time	Indicates the length of time this service flow has been active.
DS-ForwIf/US-BG/CH BG/DS	Indicates the bonding group ID or the downstream RFID of the forwarding interface assigned to the downstream service flow.

How to Enable Service Flow Priority in Downstream Extender Header

The following tasks describe how to enable service flow priority in downstream extender header:

Enabling Service Flow Priority in Downstream Extender Header

This section describes how to enable service flow priority in downstream extender header on the Cisco cBR-8 routers:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable service flow priority Example: Router(config)# cable service flow priority	Enables the service flow priority in downstream extender header.

Verifying the Enablement of the Service Flow Priority in Downstream Extended Header

To verify the enablement of the service flow priority in downstream extended header, use the **show running-config | in service flow cable service flow priority** or **show cable modem [ip-address | mac-address] verbose** command as shown in the following example:

```
Router# show running-config | in service flow
cable service flow priority

Router# show cable modem 100.1.2.110 verbose

MAC Address           : 0025.2e2d.74f8
IP Address            : 100.1.2.110
IPv6 Address          : 2001:420:3800:909:7964:98F3:7760:ED2
Dual IP               : Y

Enabling Verbose Reporting for Receive Channel Profiles

A receive channel profile is an encoding that represents the receive channels and receive modules of a cable modem. A cable modem communicates to the CMTS one or more RCP encodings within its registration request using either verbose description, which contains complete subtype encodings defined in DOCSIS 3.0, or simple description, which only contains RCP identifiers.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable <i>{slot/port slot/subslot/port}</i> Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router: <ul style="list-style-type: none"> • <i>slot</i>—Chassis slot number of the cable interface line card. • <i>subslot</i>—subslot number of the cable interface line card. Valid subslot is 0. • <i>port</i>—Downstream port number.
Step 4	cable rcp-control verbose Example: Router(config-if)# cable rcp-control verbose	Enables RCP reporting with verbose description.

Configuration Example for an RCC Template

The following sample shows an RCP ID configuration:

```
...
!
cable rcp-id 00 10 00 01 08
  center-frequency-spacing 6
  module 1 minimum-center-frequency 120000000 maximum-center-frequency 800000000 module 1
  number-of-adjacent-channels 10
  module 2 minimum-center-frequency 120000000 maximum-center-frequency 800000000 module 2
  number-of-adjacent-channels 10
  number-of-channels 8
  primary-capable-channels 1
!
```

The following sample shows an RCC template configuration:

```
...
!
cable rcc-templates frequency-based 1
  rcp-id 00 10 00 01 08
  rcc-template 1
  cm-attribute-mask 2
  module 1 channels 1-4 start-frequency 381000000
  module 2 channels 5-8 start-frequency 501000000
  rcc-template 2
  module 1 channels 1-4 start-frequency 381000000
  module 2 channels 5-8 start-frequency 669000000
  rcc-template 3
  module 1 channels 1-4 start-frequency 381000000
!
```

The following sample shows an RCC template configuration using the **common-module** option:

```
...
!
cable rcc-templates frequency-based 2
  rcp-id 00 10 00 01 08
  common-module 1 channels 1-4 start-frequency 381000000
  rcc-template 1
  module 1 channels 5-8 start-frequency 501000000
  rcc-template 2
  module 1 channels 5-8 start-frequency 669000000
  rcc-template 3
!
```

The following sample shows the assignment of an RCC template to MAC Domain:

```
...
!
configure terminal
interface c1/0/0
  cable rcc-templates frequency-based 1
end
...
```

Feature Information for DOCSIS 3.0 Downstream Bonding

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 44: Feature Information for Downstream Interface Configuration

Feature Name	Releases	Feature Information
DOCSIS 3.0 Downstream Bonding	Cisco IOS XE Everest 16.6.1	This feature was integrated on the Cisco cBR Series Converged Broadband Router.
Service Flow Priority in Downstream Extended Header	Cisco IOS XE Everest 16.6.1	This feature was integrated on the Cisco cBR Series Converged Broadband Router.

CHAPTER 17

DOCSIS 2.0 A-TDMA Modulation Profiles

This document describes the DOCSIS 2.0 A-TDMA services feature, which provides support for DOCSIS 2.1 Advanced Time Division Multiple Access (A-TDMA) upstream modulation profiles on the router. This feature supplements the existing support for DOCSIS 1.0 and DOCSIS 1.1 Time Division Multiple Access (TDMA) modulation profiles.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Prerequisites for DOCSIS 2.0 A-TDMA Modulation Profiles

- The cable physical plant must be capable of supporting the higher-bandwidth DOCSIS 2.0 A-TDMA modulation profiles.
- Cable modems must be DOCSIS-compliant. If cable modems go offline, or appear to be online but do not pass traffic when in the mixed TDMA/A-TDMA mode, upgrade the modem software to a DOCSIS-compliant version.
- The following are required to support the DOCSIS 2.0 A-TDMA features:
 - Cable modems must be DOCSIS 2.0 capable.
 - The DOCSIS configuration file for a DOCSIS 2.0 cable modem must either omit the DOCSIS 2.0 Enable field (TLV 39), or it must set TLV 39 to 1 (enable). If you set TLV 39 to 0 (disable), a DOCSIS 2.0 CM uses the TDMA mode.
 - The upstream must be configured for either A-TDMA-only or mixed TDMA/A-TDMA mode. To use the 6.4 MHz channel width, the upstream must be configured for A-TDMA-only mode.
- Complete a basic configuration of the router; this includes, at a minimum, the following tasks:
 - Configure a host name and password for the router.

- Configure the router to support Internet Protocol (IP) operations.
- Install and configure at least one WAN adapter to provide backbone connectivity.
- Determine a channel plan for the router and all of its cable interfaces.
- Verify that your headend site includes all necessary servers to support DOCSIS and Internet connectivity, including DHCP, ToD, and TFTP servers.
- The system clock on the router should be set to a current date and time to ensure that system logs have the proper timestamp and to ensure that the BPI+ subsystem uses the correct timestamp for verifying cable modem digital certificates.

Restrictions for DOCSIS 2.0 A-TDMA Services

- Does not support virtual channels, as described in DOCSIS 2.0 specification.
- Does not support Synchronous Code Division Multiple Access (S-CDMA) channels.
- Changing the DOCSIS mode of an upstream takes all cable modems on that upstream offline, which forces the cable modems to reregister, so that the CMTS can determine the capabilities of the cable modems on the new channels.

Information About DOCSIS 2.0 A-TDMA Services

DOCSIS 2.0 A-TDMA services improve the maximum upstream bandwidth on existing DOCSIS 1.0 and DOCSIS 1.1 cable networks by providing a number of advanced PHY capabilities that have been specified by the new DOCSIS 2.0 specifications.

DOCSIS 2.0 A-TDMA services incorporate the following advantages and improvements of DOCSIS 2.0 networks:

- Builds on existing DOCSIS cable networks by providing full compatibility with existing DOCSIS 1.0 and DOCSIS 1.1 cable modems. (The registration response (REG-RSP) message contains the DOCSIS version number to identify each cable modem's capabilities.)
- Upstreams can be configured for three different modes to support different mixes of cable modems:
 - An upstream can be configured for TDMA mode to support only DOCSIS 1.0 and DOCSIS 1.1 cable modems.
 - An upstream can be configured for A-TDMA mode to support only DOCSIS 2.0 cable modems.
 - An upstream can be configured for a mixed, TDMA/A-TDMA mode, to support both DOCSIS 1.0/DOCSIS 1.1 and DOCSIS 2.0 cable modems on the same upstream.

Note DOCSIS 2.0 A-TDMA cable modems will not register on a TDMA upstream if an A-TDMA or mixed upstream exists in the same MAC domain, unless the CMTS explicitly switches the cable modem to another upstream using an Upstream Channel Change (UCC) message. DOCSIS 1.0 and DOCSIS 1.1 cable modems cannot register on an A-TDMA-only upstream.

- A-TDMA mode defines new interval usage codes (IUC) of A-TDMA short data grants, long data grants, and Unsolicited Grant Service (UGS) grants (IUC 9, 10, and 11) to supplement the existing DOCSIS 1.1 IUC types.

- Increases the maximum channel capacity for A-TDMA upstreams to 30 Mbps per 6 MHz channel.
- A-TDMA and mixed modes of operation provide higher bandwidth on the upstream using new 32-QAM and 64-QAM modulation profiles, while retaining support for existing 16-QAM and QPSK modulation profiles. In addition, an 8-QAM modulation profile is supported for special applications.
- Supports a minislot size of 1 tick for A-TDMA operations.
- Increases channel widths to 6.4 MHz (5.12 Msymbol rate) for A-TDMA operations.
- A-TDMA and mixed modes of operation provide a more robust operating environment with increased protection against ingress noise and other signal impairments, using a number of new features:
 - Uses a symbol (T)-spaced adaptive equalizer structure to increase the equalizer tap size to 24 taps, compared to 8 taps in DOCSIS 1.x mode. This allows operation in the presence of more severe multipath and microreflections, and can accommodate operation near band edges where group delay could be a problem.
 - Supports new QPSK0 and QPSK1 preambles, which provide improved burst acquisition by performing simultaneous acquisition of carrier and timing lock, power estimates, equalizer training, and constellation phase lock. This allows shorter preambles, reducing implementation loss.
 - Increases the forward error correction (FEC) T-byte size to 16 bytes per Reed Solomon block (T=16) with programmable interleaving.

Modes of Operation

Depending on the configuration, the DOCSIS 2.0 A-TDMA Service feature supports either DOCSIS or Euro-DOCSIS operation:

- DOCSIS cable networks are based on the ITU J.83 Annex B physical layer standard and Data-over-Cable Service Interface Specifications (DOCSIS, Annex B) specification, which use 6 MHz National Television Systems Committee (NTSC) channel plans. In this mode, the downstream uses a 6 MHz channel width in the 85 to 860 MHz frequency range, and the upstream supports multiple channel widths in the 5 to 42 MHz frequency range.
- EuroDOCSIS cable networks are based on the ITU J.112 Annex A physical layer standard and European DOCSIS (EuroDOCSIS, Annex A) specification, which use 8 MHz Phase Alternating Line (PAL) and Systeme Electronique Couleur Avec Memoire (SECAM) channel plans. In this mode, the downstream uses an 8 MHz channel width in the 85 to 860 MHz frequency range, and the upstream supports multiple channel widths in the 5 to 65 MHz frequency range.

Note The difference between DOCSIS and EuroDOCSIS is at the physical layer. To support a DOCSIS or EuroDOCSIS network requires the correct configuration of the DOCSIS 2.0 A-TDMA Service card, as well as upconverters, duplex filters, and other equipment that supports the network type.

The table below shows the maximum supported DOCSIS 1.1 data rates.

Table 46: Maximum DOCSIS 1.1 Data Rates

Upstream Channel Width	Modulation Scheme	Baud Rate Sym/sec	Maximum Raw Bit Rate Mbit/sec
3.2 MHz	16-QAM QPSK	2.56 M	10.24 5.12
1.6 MHz	16-QAM QPSK	1.28 M	5.12 2.56

The table below shows the maximum supported DOCSIS 2.0 (A-TDMA-mode) data rates.

Table 47: Maximum DOCSIS 2.0 (A-TDMA-mode) Data Rates

Upstream Channel Width	Modulation Scheme	Baud Rate Sym/sec	Maximum Raw Bit Rate Mbit/sec
6.4 MHz	64-QAM	5.12 M	30.72
	32-QAM		25.60
	16-QAM		20.48
	8-QAM		15.36
	QPSK		10.24
3.2 MHz	64-QAM	2.56 M	15.36
	32-QAM		12.80
	16-QAM		10.24
	8-QAM		7.68
	QPSK		5.12
1.6 MHz	64-QAM	1.28 M	7.68
	32-QAM		6.40
	16-QAM		5.12
	8-QAM		3.84
	QPSK		2.56

Modulation Profiles

To simplify the administration of A-TDMA and mixed TDMA/A-TDMA modulation profiles, the DOCSIS 2.0 A-TDMA Service feature provides a number of preconfigured modulation profiles that are optimized for different modulation schemes. We recommend using these preconfigured profiles.

Each mode of operation also defines a default modulation profile that is automatically used when a profile is not specifically assigned to an upstream. The default modulation profiles cannot be deleted. The table below lists the valid ranges according to cable interface and modulation type:

Table 48: Allowable Ranges for Modulation Profiles

Cable Interface	DOCSIS 1.X (TDMA)	Mixed DOCSIS 1.X/2.0	DOCSIS 2.0 (A-TDMA)
Cisco cBR-8 CCAP Line Cards	1 to 400 (default is 21)	1 to 400 (default 121)	1 to 400 (default 221)

Benefits

The DOCSIS 2.0 A-TDMA Service feature provides the following benefits to cable service providers and their partners and customers:

- Full compatibility with DOCSIS 1.0 and DOCSIS 1.1 cable modems (CMs) and cable modem termination systems (CMTS).
- Additional channel capacity in the form of more digital bits of throughput capacity in the upstream path.
- Increased protection against electronic impairments that occur in cable systems, allowing for a more robust operating environment.

How to Configure DOCSIS 2.0 A-TDMA Services

This section contains the following:

Creating Modulation Profiles

Cisco cable modem termination systems (CMTSs) can handle modulation profiles for the RF configuration of a voice and data cable modem plant. Cisco IOS® Software is designed with a default modulation profile that is optimal in most conditions. Therefore, do not change the default configuration. However, if the modulation needs are different for the customer plant, Cisco IOS Software has the ability to customize and to configure the modulation profiles to suit the customer needs.

Caution

Only an expert, who understands modulation changes and Data-over-Cable Service Interface Specifications (DOCSIS), should modify these parameters. Otherwise, changes can cause disruption or the degradation of services because the commands affect the physical layer.

This section describes how to create modulation profiles for the different modes of DOCSIS operations, using the preconfigured modulation profile options.

Creating a TDMA Modulation Profile

This section describes how to create a modulation profile for the DOCSIS 1.0/DOCSIS 1.1 TDMA mode of operation, using one of the preconfigured modulation profiles.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable modulation-profile <i>profile</i> tdma {mix qam-16 qpsk robust-mix} Example:	Creates a preconfigured modulation profile, where the burst parameters are set to their default values for each burst type:

	Command or Action	Purpose
	<pre>Router(config)# cable modulation-profile 3 tdma mix Router(config)# cable modulation-profile 4 tdma qpsk</pre>	<p>Note You can also create custom modulation profiles with the cable modulation-profile command by configuring the values for the individual burst parameters. These parameters, however, should not be modified unless you are thoroughly familiar with how changing each parameter affects the DOCSIS MAC layer. We recommend using the preconfigured default modulation profiles for most cable plants.</p>
Step 4	<p>exit</p> <p>Example:</p> <pre>Router(config)# exit</pre>	Exits global configuration mode.

Creating a Mixed Mode Modulation Profile

This section describes how to create a modulation profile for the mixed TDMA/A-TDMA mode of operation, using one of the preconfigured modulation profiles.

Procedure

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <p>Enter your password if prompted.</p>
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>cable modulation-profile <i>profile</i> mixed {mix-high mix-low mix-mid mix-qam qam-16 qpsk robust-mix-high robust-mix-mid robust-mix-qam}</p> <p>Example:</p> <pre>Router(config)# cable modulation-profile 143 mixed mix-medium Router(config)# cable modulation-profile 144 mixed mix-high</pre>	<p>Creates a preconfigured modulation profile, where the burst parameters are set to their default values for each burst type:</p> <p>Note The robust-mix profiles are similar to but more robust than the mix profiles, so that they are more able to deal with noise on the upstream.</p>

	Command or Action	Purpose
		<p>Note You can also create custom modulation profiles with the cable modulation-profile command by configuring the values for the individual burst parameters. These parameters, however, should not be modified unless you are thoroughly familiar with how changing each parameter affects the DOCSIS MAC layer. We recommend using the preconfigured default modulation profiles for most cable plants.</p>
Step 4	<p>exit</p> <p>Example:</p> <pre>Router(config)# exit</pre>	Exits global configuration mode.

Creating an A-TDMA Modulation Profile

This section describes how to create a modulation profile for the DOCSIS 2.0 A-TDMA mode of operation, using one of the preconfigured modulation profiles.

Procedure

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>cable modulation-profile <i>profile</i> atdma {mix-high mix-low mix-mid mix-qam qam-8 qam-16 qam-32 qam-64 qpsk robust-mix-high robust-mix-low robust-mix-mid}</p> <p>Example:</p> <pre>Router(config)# cable modulation-profile 242 atdma qam-32 Router(config)# cable modulation-profile 243 atdma qam-64</pre> <p>Example:</p> <pre>cable modulation-profile 45 tdma request 0 16 0 22 qpsk scrambler 152 no-diff 64 fixed</pre>	<p>Note For Cisco Remote PHY 220, preamble with QPSK modulation must have values—32×2^n (0, 1, 2, 3) bits.</p> <p>Preamble with 16-QAM modulation must have values—64×2^n (0, 1, 2,) bits.</p> <p>Note The robust-mix profiles are similar to but more robust than the mix profiles, so that they are more able to deal with noise on the upstream.</p>

	Command or Action	Purpose
	<pre>cable modulation-profile 45 tdma initial 5 34 0 48 16qam scrambler 152 no-diff 256 fixed cable modulation-profile 45 tdma station 5 34 0 48 16qam scrambler 152 no-diff 256 fixed cable modulation-profile 45 tdma short 3 76 12 22 16qam scrambler 152 no-diff 128 shortened cable modulation-profile 45 tdma long 9 232 0 22 16qam scrambler 152 no-diff 128 shortened cable modulation-profile 45 tdma initial 5 34 0 48 16qam scrambler 152 no-diff 256 fixed</pre>	<p>Note You can also create custom modulation profiles with the cable modulation-profile command by configuring the values for the individual burst parameters. These parameters, however, should not be modified unless you are thoroughly familiar with how changing each parameter affects the DOCSIS MAC layer. We recommend using the preconfigured default modulation profiles for most cable plants.</p> <p>Note For Cisco Remote PHY 220, preamble with QPSK modulation must have values—32×2^n (0, 1, 2, 3) bits.</p> <p>Preamble with 16-QAM modulation must have values—64×2^n (0, 1, 2,) bits.</p>
Step 4	<p>exit</p> <p>Example:</p> <pre>Router(config)# exit</pre>	Exits global configuration mode.

Configuring the DOCSIS Mode and Profile on an Upstream

This section describes how to configure an upstream for a DOCSIS mode of operation, and then to assign a particular modulation profile to that upstream.

Note By default, all upstreams are configured for ATDMA-only mode, using the default modulation profile.

Procedure

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>controller upstream-Cable slot/subslot/port</p> <p>Example:</p> <pre>Router(config)# controller upstream-Cable 2/0/1</pre>	Enters controller configuration mode for the interface.

	Command or Action	Purpose
Step 4	us-channel <i>n</i> docsis-mode { <i>atdma</i> <i>tdma</i> <i>tdma-atdma</i> } Example: <pre>Router(config-controller)# us-channel 0 docsis-mode atdma</pre>	Configures the upstream for the desired DOCSIS mode of operation.
Step 5	us-channel <i>n</i> modulation-profile <i>primary-profile-number</i> [<i>secondary-profile-number</i>] [<i>tertiary-profile-number</i>] Example: <pre>Router(config-controller)# us-channel 0 modulation-profile 241</pre>	Assigns up to three modulation profiles to the upstream port. Note The type of modulation profiles must match the DOCSIS mode configured for the upstream, using the us-channel docsis-mode command.
Step 6	us-channel <i>n</i> equalization-coefficient Example: <pre>Router(config-controller)# us-channel 0 equalization-coefficient</pre>	(Optional) Enables the use of a DOCSIS pre-equalization coefficient on the upstream port.
Step 7	us-channel <i>n</i> ingress-noise-cancellation <i>interval</i> Example: <pre>Router(config-controller)# us-channel 0 ingress-noise-cancellation 400</pre>	(Optional) Configures the interval, in milliseconds, for which the interface card should sample the signal on an upstream to correct any ingress noise that has appeared on that upstream.
Step 8	us-channel <i>n</i> maintain-psd Example: <pre>Router(config-controller)# us-channel 0 maintain-psd</pre>	(Optional) Requires DOCSIS 2.0 cable modems that are operating on an ATDMA-only upstream to maintain a constant power spectral density (PSD) after a modulation rate change. Note Repeat Step 3, on page 325 through Step 8, on page 326 for each upstream to be configured.
Step 9	end Example: <pre>Router(config-controller)# end</pre>	Exits controller configuration mode and returns to privileged EXEC mode.

Monitoring the DOCSIS 2.0 A-TDMA Services

This section contains the following:

Displaying Modulation Profiles

To display the modulation profiles that are currently defined on the CMTS, use the **show cable modulation-profile** command without any options:

```
Router# show cable modulation-profile
```

```
Mod Docsis IUC Type Pre Diff FEC FEC Scrmb Max Guard Last Scrmb Pre Pre RS
```

	-Mode		len	enco	T	k	seed	B	time	CW	offst	Type

Configuration Examples for DOCSIS 2.0 A-TDMA services

This section contains the following:

Creating Modulation Profiles Examples

This section contains the following:

Example: DOCSIS 1.0/DOCSIS 1.1 TDMA Modulation Profiles

The following sample configurations show typical modulation profiles for the DOCSIS 1.0/DOCSIS 1.1 TDMA mode of operation:

- Profile 21 is the default profile for TDMA operations.
- Profiles 24 and 25 use the preconfigured 16-QAM and QPSK modulation profiles.
- Profile 26 is a typical QPSK modulation profile using some customized burst parameters.

```
cable modulation-profile 24 tdma qam-16
cable modulation-profile 25 tdma qpsk
cable modulation-profile 26 tdma request 0 16 0 8 qpsk scrambler 152 no-diff 68 fixed
cable modulation-profile 26 tdma initial 5 34 0 48 qpsk scrambler 152 no-diff 128 fixed
cable modulation-profile 26 tdma station 5 34 0 48 qpsk scrambler 152 no-diff 128 fixed
cable modulation-profile 26 tdma short 4 76 12 8 qpsk scrambler 152 no-diff 80 shortened
cable modulation-profile 26 tdma long 8 236 0 8 qpsk scrambler 152 no-diff 80 shortened
```

Example: Mixed TDMA/A-TDMA Modulation Profiles

The following sample configurations show typical modulation profiles for the DOCSIS 1.X/DOCSIS 2.0 mixed TDMA/A-TDMA mode of operation:

- Profile 121 is the default profile for mixed mode operations.
- Profiles 122 through 126 use the preconfigured mixed mode modulation profiles.
- Profile 127 is a typical mixed mode modulation profile some customized burst parameters.

```
cable modulation-profile 121 mixed request 0 16 0 8 qpsk scrambler 152 no-diff 64 fixed
cable modulation-profile 121 mixed initial 5 34 0 48 qpsk scrambler 152 no-diff 32 fixed
cable modulation-profile 121 mixed station 5 34 0 48 qpsk scrambler 152 no-diff 32 fixed
cable modulation-profile 121 mixed short 5 75 6 8 qpsk scrambler 152 no-diff 72 shortened
cable modulation-profile 121 mixed long 8 220 0 8 qpsk scrambler 152 no-diff 80 shortened
cable modulation-profile 121 mixed a-short 0 16 15 99 64qam scrambler 152 no-diff 128
shortened qpsk0 0 18
cable modulation-profile 121 mixed a-long 0 16 15 200 64qam scrambler 152 no-diff 128
shortened qpsk0 0 18

cable modulation-profile 122 mixed mix-high
cable modulation-profile 123 mixed mix-low
cable modulation-profile 124 mixed mix-medium
cable modulation-profile 125 mixed qam-16
cable modulation-profile 126 mixed qpsk

cable modulation-profile 127 mixed request 0 16 0 8 qpsk scrambler 152 no-diff 68 fixed
cable modulation-profile 127 mixed initial 5 34 0 48 qpsk scrambler 152 no-diff 128 fixed
cable modulation-profile 127 mixed station 5 34 0 48 qpsk scrambler 152 no-diff 128 fixed
cable modulation-profile 127 mixed short 6 76 7 8 16qam scrambler 152 no-diff 160 shortened

cable modulation-profile 127 mixed long 8 231 0 8 16qam scrambler 152 no-diff 160 shortened

cable modulation-profile 127 mixed a-short 9 76 6 8 32qam scrambler 152 no-diff 160 shortened
qpsk1 1 2048
cable modulation-profile 127 mixed a-long 12 231 0 8 64qam scrambler 152 no-diff 132 shortened
qpsk1 1 2048
```

Example: DOCSIS 2.0 A-TDMA Modulation Profiles

The following sample configurations show typical modulation profiles for the DOCSIS 2.0 A-TDMA mode of operation:

- Profile 221 is the default profile for A-TDMA mode operations.
- Profiles 222 through 226 use the preconfigured A-TDMA mode modulation profiles.
- Profile 227 is a typical A-TDMA mode modulation profile customized burst parameters.

```

Assigning Modulation Profiles to Upstreams Examples

This section contains the following:

Example: Assigning DOCSIS 1.0/DOCSIS 1.1 TDMA Modulation Profiles

The following sample configuration shows DOCSIS 1.0/DOCSIS 1.1 TDMA modulation profiles being assigned to the upstreams. The TDMA modulation profile (profile 21) is assigned to the upstream controller 2/0/0.

```

controller Upstream-Cable 2/0/0
us-channel 0 channel-width 1600000 1600000
us-channel 0 docsis-mode tdma
us-channel 0 minislot-size 4
us-channel 0 modulation-profile 21
no us-channel 0 shutdown

```

```

us-channel 1 channel-width 1600000 1600000
us-channel 1 docsis-mode tdma
us-channel 1 minislot-size 4
us-channel 1 modulation-profile 21
no us-channel 1 shutdown
us-channel 2 channel-width 1600000 1600000
us-channel 2 docsis-mode tdma
us-channel 2 minislot-size 4
us-channel 2 modulation-profile 21
no us-channel 2 shutdown
us-channel 3 channel-width 1600000 1600000
us-channel 3 docsis-mode tdma
us-channel 3 minislot-size 4
us-channel 3 modulation-profile 21
no us-channel 3 shutdown
!
```

Example: Assigning Mixed TDMA/A-TDMA Modulation Profiles

The following sample configuration shows mixed mode TDMA/A-TDMA modulation profiles being assigned to the upstreams. The mixed modulation profile (profile 121) is assigned to the upstream controller 2/0/15.

```

controller Upstream-Cable 2/0/15
us-channel 0 channel-width 1600000 1600000
us-channel 0 docsis-mode tdma-atdma
us-channel 0 minislot-size 4
us-channel 0 modulation-profile 121
no us-channel 0 shutdown
us-channel 1 channel-width 1600000 1600000
us-channel 1 docsis-mode tdma-atdma
us-channel 1 minislot-size 4
us-channel 1 modulation-profile 121
no us-channel 1 shutdown
us-channel 2 channel-width 1600000 1600000
us-channel 2 docsis-mode tdma-atdma
us-channel 2 minislot-size 4
us-channel 2 modulation-profile 121
no us-channel 2 shutdown
us-channel 3 channel-width 1600000 1600000
us-channel 3 docsis-mode tdma-atdma
us-channel 3 minislot-size 4
us-channel 3 modulation-profile 121
no us-channel 3 shutdown
!
```

Example: Assigning DOCSIS 2.0 A-TDMA Modulation Profiles

The following sample configuration shows DOCSIS 2.0 A-TDMA modulation profiles being assigned to the upstreams. The A-TDMA modulation profile (profile 221) is assigned to the upstream controller 2/0/10.

```

controller Upstream-Cable 2/0/10
us-channel 0 channel-width 1600000 1600000
us-channel 0 docsis-mode atdma
us-channel 0 minislot-size 4
us-channel 0 modulation-profile 221
no us-channel 0 shutdown
us-channel 1 channel-width 1600000 1600000
us-channel 1 docsis-mode atdma
us-channel 1 minislot-size 4
us-channel 1 modulation-profile 221
no us-channel 1 shutdown
us-channel 2 channel-width 1600000 1600000
```

```

us-channel 2 docsis-mode atdma
us-channel 2 minislots-size 4
us-channel 2 modulation-profile 221
no us-channel 2 shutdown
us-channel 3 channel-width 1600000 1600000
us-channel 3 docsis-mode atdma
us-channel 3 minislots-size 4
us-channel 3 modulation-profile 221
no us-channel 3 shutdown
us-channel 4 channel-width 1600000 1600000
us-channel 4 docsis-mode atdma
us-channel 4 minislots-size 4
us-channel 4 modulation-profile 221
us-channel 4 shutdown
us-channel 5 channel-width 1600000 1600000
us-channel 5 docsis-mode atdma
us-channel 5 minislots-size 4
us-channel 5 modulation-profile 221
us-channel 5 shutdown
!

```

Feature Information for DOCSIS 2.0 A-TDMA Modulation Profile

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmg.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 49: Feature Information for DOCSIS 2.0 A-TDMA Modulation Profile

Feature Name	Releases	Feature Information
DOCSIS 2.0 A-TDMA Modulation Profile	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the cisco cBR Series Converged Broadband Routers.

CHAPTER 18

Downstream Resiliency Bonding Group

With more wideband (WB) modems being deployed in cable plants, WB modem resiliency is an important feature. When a comparatively smaller number of cable modems (CMs) observe an impairment on an RF channel, that RF channel stops working. It impacts all the CM using that RF channel, irrespective of whether they reported the impairment on that RF channel. Instead, the solution should be to communicate with the affected cable modems using the good RF channel, without affecting the other cable modems.

The Downstream Resiliency Bonding Group feature allows cable modems with multiple impaired RF channels to be allocated to a dynamically-created wideband interface, which ensures that the performance of the wideband cable modems is not drastically affected.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Prerequisites for Downstream Resiliency Bonding Group

- Set aside WB interfaces so that new WB interfaces can be dynamically created from the reserved list of WB interfaces.
- Free up RF bandwidth so that those RF channels can be added to a resiliency bonding group (RBG).
- Remove all existing RBG configuration from the WB interface.

Restrictions for the Downstream Resiliency Bonding Group

- If an existing wideband interface is reserved as a Resiliency Bonding Group (RBG) and later the RBG is removed (through the **no cable ds-resiliency** command), the modems using this RBG go offline and the RBG configuration itself is deleted. Therefore, it is highly recommended that users should not configure an existing BG as an RBG.

- This feature is enabled only when the number of cable modems observing an RF channel impairment is *below* the resiliency threshold. If the number of cable modems on an impaired RF channel is above the resiliency threshold, the impaired RF channel is temporarily removed from the bonding group.
- A cable modem is assigned to an RBG on a first-come-first-served basis. To handle this feature optimally, it is recommended to set aside more WB interfaces and RF channel bandwidth.
- The Cisco CMTS controls the freeing of unused RBGs, when there is no modem using the RBG. The freeing of the unused RBG may take some time and the RBG, which is not completely free cannot be used by the modems. Irrespective of the number of configured RBGs, if all the old RBGs are not completely set free and if the Cisco CMTS tries to move the cable modem to a new RBG, the Cisco CMTS moves the cable modem to the primary DS channel instead of RBG.
- Only SFs on the WB interface associated with the primary SF are moved to an RBG. SFs on other interfaces will not be moved.
- Static SFs are assigned to an RBG on a best effort quality of service (QoS).
- If the **resiliency rf-change-trigger** setting does not have the **secondary** keyword set, only the primary SF is moved to the RBG or a NB interface.
- If the Downstream Resiliency Bonding Group feature is not enabled to use an RBG, only cable modems with impairments on the primary WB interface are moved to the NB interface.
- SFs carrying multicast traffic are not moved.

There may not be enough reserved bonding groups to support all modems facing an impairment at any given time thus the following restrictions must be considered:

- Each RBG has at least two RF channels.
- RBG RF assignments are always a subset of the RF channel assignment of the parent WB interface.
- If an RBG is unavailable for a cable modem, the SF of the CM is moved to a NB interface.
- If a high percentage of cable modems experience an RF impairment and there are no more available bonding group IDs, the impaired RF itself may be removed from the bonding group. Removal of an impaired RF from a parent bonding group is also reflected in the RBG. If an RBG drops to a single RF, all SFs are moved to the NB interface.

The Downstream Resiliency Bonding Group feature has the following cross-functional restrictions:

- All Dynamic service flows, whether they require a committed information rate (CIR) or not, typically voice flows, are created on the NB interface when an RF channel is impaired. Because all SFs assigned to an RBG are best effort only, voice calls may report a quality issue.
- Cable modems participating in the resiliency mode do not take part in load balancing.
- The Downstream Resiliency Bonding Group feature is only supported in the Dynamic Bandwidth Sharing (DBS) mode.

Information About Downstream Resiliency Bonding Group

You can set aside unused bonding groups as RBGs. Ensure that each RF channel is assigned at least 1% of the available bandwidth. Use the **cable rf-channel bandwidth-percent** command to configure the RF channel bandwidth.

Note If the bandwidth-percent is set to 100, the Cisco CMTS does not add any RFs to the RBG. In other words, this feature will not be enabled.

The Cisco CMTS controls the assignment and freeing of unused RBGs. If an RF channel is removed from a WB interface, it is also removed from any associated RBGs.

Note If the wideband interface is in standby mode, the Cisco CMTS does not assign or free up the unused downstream bonding group.

A suspended RF channel is restored for all affected wideband interfaces when a specified number of cable modems report (via CM-STATUS) that the channel connectivity is restored. The Wideband Modem Resiliency feature defines the specified number of cable modems as half of the configured count or percentage of rf-change-trigger, or both. For example, if the count is 20 and the percent is 10, then the number of cable modems reporting recovery should reduce the count to 10 and the percent to 5 for the suspended RF channel to be restored.

Finding a Best-Fit RBG for the Cable Modem

A bonding group is a list of channels that provide a means to identify the channels that are bonded together. The Cisco CMTS assigns a service flow (SF) to an RBG based on the attributes of the SF and the attributes of the individual channels of the bonding group.

In the Downstream Resiliency Bonding Group feature, when a line card receives a CM-STATUS message from the cable modem informing the line card that there is an RF channel impairment, the line card checks for the number of good RF channels and:

- Moves the cable modem to narrowband mode if there is only one available RF channel.
- Moves the cable modem to wideband mode if the cable modem reports all RF channels are in good state.
- Moves the cable modem to an RBG if there are two or more good RF channels, with at least one RF channel impaired, and if the Downstream Resiliency Bonding Group feature is enabled.

When the Cisco CMTS receives a message from the line card to move a cable modem to an RBG, the Cisco CMTS attempts to find an existing RBG or creates an RBG that satisfies the impairment.

Note If two or more RBGs are reserved for the same wideband controller, the Cisco CMTS creates one RBG for each cable modem.

Note The Cisco CMTS creates more than one RBG from a parent WB interface if the user has set aside more than one WB interface as the RBG and the RF bandwidth does not exceed 100%.

If a matching RBG is not found or cannot be created, the Cisco CMTS looks for an RBG with a subset of the required RF channels and if available, the cable modem is assigned to such an RBG.

However, if no such RBG exists, the Cisco CMTS instructs the line card to move the cable modem to NB mode.

How to Configure Downstream Resiliency Bonding Group

This section contains the following:

Enabling Downstream Resiliency Bonding Group

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable rf-change-trigger {percent value count number} [secondary] Example: Router(config)# cable rf-change-trigger percent 50 count 1 secondary	Specifies the amount of time an event must persist before it triggers an action for the reporting CM.
Step 4	cable resiliency ds-bonding Example: Router(config)# cable resiliency ds-bonding	Enables the downstream resiliency bonding group.
Step 5	exit Example: Router(config)# exit	Returns to the global configuration mode.

What to do next

Note The result of using the **cable rf-change-trigger** command with the **cable resiliency ds-bonding** command is different from using only the **cable rf-change-trigger** command. For more information, see [Downstream Resiliency Narrowband Mode Versus Resiliency Bonding Group, on page 341](#).

Reserving a Resiliency Bonding Group for a Line Card

This section describes reserving a bonding group or a wideband interface for a line card per controller.

Restriction When you reserve a resiliency bonding group using the **cable ds-resiliency** command, the existing bundle and RF channel configurations on the wideband interface will be removed automatically. Other configurations like admission control, should be removed manually.

After downstream resiliency bonding group is configured, avoid other manual configurations.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface wideband-cable <i>slot/subslot/port:wideband-channel</i> Example: Router(config)# interface wideband-cable 1/0/0:7	Configures a wideband cable interface.
Step 4	cable ds-resiliency Example: Router(config-if)# cable ds-resiliency	Reserves an individual bonding group or WB interface for usage on a line card, on a per controller basis.
Step 5	exit Example: Router(config-if)# exit	Returns to the global configuration mode.

Verifying Downstream Resiliency Bonding Group Configuration

This section contains the following:

Verifying the Downstream Resiliency Bonding Group

To verify if the Downstream Resiliency Bonding Group feature is enabled, use the **show cable modem resiliency** command as shown in the following example:

```
Router# show cable modem resiliency
              Orig BG
I/F      MAC Address  ID  I/F      RFs ID  Curr BG  RFs
-----
C7/0/0   0025.2eaf.843e 897 Wi7/0/0:0 4 898 Wi7/0/0:1 3
C7/0/0   0025.2eaf.8356 897 Wi7/0/0:0 4 899 Wi7/0/0:2 3
C7/0/0   0015.d176.5199 897 Wi7/0/0:0 4 720 In7/0/0:0
```

The **Current BG I/F** field indicates whether Downstream Resiliency Bonding Group feature is enabled and if the cable modems are assigned to a WB interface.

Verifying a Reserved Resiliency Bonding Group

To verify if a BG is reserved for a line card, use the **show cable resiliency** command as shown in the following example:

```
Router# show cable resiliency
              BG  Resil BG
Resil BG I/F  ID  State      Count Time      RF
-----
Wi1/0/0:10   10  Free
Wi1/0/0:20   20  Free
Wi7/0/0:1    1   Assigned   3   Nov 3 09:55:49 0   0
                                                    1
                                                    2
Wi7/0/0:2    2   Assigned   3   Nov 3 09:57:09 0   0
                                                    1
                                                    3
```

Downstream Resiliency Narrowband Mode Versus Resiliency Bonding Group

This section provides the sample outputs when using the **cable rf-change-trigger** command with the **cable resiliency ds-bonding** command and using only the **cable rf-change-trigger** command.

Table 51: Downstream Resiliency Narrowband Mode Versus Resiliency Bonding Group - Scenario 1

Effect on	Using only cable rf-change-trigger command (Downstream Resiliency NB Mode)		Using cable rf-change-trigger command with cable resiliency ds-bonding (Downstream Resiliency Bonding Group)	
	Below Threshold	Above Threshold	Below Threshold	Above Threshold

Effect on	Using only cable rf-change-trigger command (Downstream Resiliency NB Mode)		Using cable rf-change-trigger command with cable resiliency ds-bonding (Downstream Resiliency Bonding Group)	
	Primary Service Flow	Moves to the primary channel.	Remains on the original bonding group while the impaired downstream channels are not used and are reported as DOWN.	Moves to dynamic bonding group.
Secondary Service Flows	Remain on the original WB interface.	Remains on the original bonding group while the impaired downstream channels are not used and are reported as DOWN.	Remains on the original bonding group.	Remains on the original bonding group while the impaired downstream channels are not used and are reported as DOWN.

The following is a sample output for a cable modem when the **cable rf-change-trigger** command is used with the **cable resiliency ds-bonding** command and the number of cable modems observing an RF channel impairment is *below* the resiliency threshold:

```
Router# show cable modem
```

```

MAC Address      IP Address      I/F           MAC           Prim RxFwr  Timing Num I

Troubleshooting the Downstream Resiliency Bonding Group Configuration

Use the following commands to get information on the WB interface, number of CMs in an impaired state, resiliency bonding groups, their associated bonding groups, available RF channels, and the number of CMS and service flows assigned to them:

- **debug cable wbcmts resiliency**
- **debug cable wbcmts resiliency report**
- **show cable resiliency**
- **show cable modem resiliency**
- **show cable modem wideband rcs-status**
- **show cable modem service-flow verbose**
- **show cable resil-rf-status**
- **show cable modem summary wb-rfs**

Configuration Examples for the Downstream Resiliency Bonding Group

The following is an example of the configuration of the Downstream Resiliency Bonding Group feature:

```

Feature Information for Downstream Resiliency Bonding Group

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 53: Feature Information for Downstream Resiliency Bonding Group

Feature Name	Releases	Feature Information
Downstream Resiliency Bonding Group	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 19

Downstream Channel ID Assignment

First Published: April 17, 2015

The DOCSIS downstream channel ID (DCID) is defined as an 8-bit identifier for recognizing a Downstream Channel within a MAC Domain. All CMTS downstream channels are assigned a DCID by default that may be subsequently changed by configuration. It is used in most DOCSIS downstream packet headers and its valid range is from 1 to 255 (0 is reserved for network management purposes).

Note All downstream channels in a MAC domain must have a unique DCID within the MAC domain.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Information About Downstream Channel ID Assignment on the Cisco CMTS Routers

These are the downstream channel ID assignment features:

- Unique DCIDs are provided for all channels within a single controller by default.

Note DCID values for downstream channels in the same MAC Domain must be unique. If a MAC Domain only contains channels from a single controller, the default DCID values will be sufficient. If a MAC Domain contains channels from multiple controllers, DCID conflicts may be encountered within the MAC Domain. DCID conflicts may be resolved by changing the DCID value of the conflicting channels within the controller configuration or by enabling the automatic channel ID assignment feature.

- The default DCID value for each downstream channel within a controller is equivalent to rf-chan number plus one. For example, the default value for rf-chan 0 is 1, for rf-chan 1 is 2.

Manual Downstream Channel ID Assignment

When using the manual DCID provisioning feature, every downstream channel in the system is assigned a default DCID value equivalent to (controller QAM id + 1). The table below shows the default DCID ranges per downstream controller.

Table 55: Default Downstream Channel IDs Per Slot/Subslot/Controller

	0/0	1/0	2/0	3/0	6/0	7/0	8/0	9/0
DS Controller 0	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 1	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 2	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 3	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 4	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 5	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 6	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128
DS Controller 7	1-128	1-128	1-128	1-128	1-128	1-128	1-128	1-128

The default DCID value can be replaced with a user configurable value. The configuration is available in the downstream controller per channel. The current DCID values for the channels within a downstream controller can be viewed in the dcid column of the **show controller Integrated-Cable rf-chan** command output. The example shows channels with default DCID values. When a DCID value is changed in the configuration, the new value appears in the output below.

```
Router#show controllers integrated-Cable 3/0/0 rf-channel 1-127
```

Chan	State	Admin	Frequency	Type	Annex	Mod	srates	Interleaver	dcid	power	output

Router#

Automatic Downstream Channel ID Assignment on the Cisco CMTS Routers

It is possible to automatically assign a unique set of downstream channel IDs to meet all DOCSIS requirements by enabling the Automatic DCID Assignment feature. When enabled, Downstream channel DCIDs will be automatically assigned when the channels are added to a fiber node and associated with a MAC Domain. Therefore, the use of fiber node configuration is a prerequisite for this feature.

Service Impact

Changing the DOCSIS downstream channel ID causes cable modems to re-register. Cable modems receive MAC Domain Descriptor (MDD) and Upstream Channel Descriptor (UCD) messages with a changed DCID in their headers.

- Enabling the automatic DCID assignment displays the following message:

```
WARNING: Enabling automatic DCID assignment will cause modems to flap and will apply
to all fiber nodes on this CMTS.
```

- Disabling the automatic DCID assignment displays the following message:

```
WARNING: Disabling automatic DCID assignment will no longer enforce channel-id uniqueness
at fiber nodes. Channel ID changes may require manual verification to prevent conflicts.
```

- If there is a DCID conflict with another channel in the MAC Domain, the following error message is displayed:

```
ERROR: <slot>/<subslot>/<controller> rf-channel <channel>: The downstream channel id
conflicts with interface In<slot>/<subslot>/<controller>:channel. Downstream channel
id must be unique in a CGD.
```

- After automatic DCID assignment is configured, if there is a DCID conflict when a downstream channel that belongs to a fiber node is added to a MAC Domain, the automatic DCID feature tries to resolve the conflict by assigning another automatic DCID and the following message is displayed:

```
WARNING: The downstream channel id conflict for <slot>/<subslot>/<controller> rf-channel
<channel> was resolved by Automatic DCID Assignment.
Please run "interface <md-slot>/<md-subslot>/<md-index>" followed by
```

"<slot>/<subslot>/<controller> rf-channel <channel>" again in order to add the channel.

To add the channel, use this channel grouping domain (CGD) command again:

cable downstream *x/y/z* **rf-channel** *channel*

- If automatic DCID is configured and the channel does not belong to a fiber node, or if automatic DCID cannot resolve the conflict, the following message is displayed:

WARNING: The downstream channel id conflict for <slot>/<subslot>/<controller> rf-channel <channel> could not be resolved by Automatic DCID Assignment.

To resolve this issue, add the channel to a fiber node.

How to Configure Downstream Channel ID Assignment on the Cisco CMTS Routers

The following sections describe how to configure downstream channel ID assignment.

Configuring Manual Downstream Channel ID Assignment

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface controller integrated-Cable <i>slot/subslot/port</i> Example: Router(config)# interface controller integrated-Cable 1/0/1	Enters controller configuration mode for the Channel Grouping Domain host line card.
Step 4	rf-chan <i>downstream QAM ID</i> <ul style="list-style-type: none"> • Alternatively, use the rf-chan <i>starting downstream QAM ID ending downstream QAM ID</i> command to set the range of downstream channel IDs. Example: Router(config-controller)# rf-chan 0	Enters the rf-channel configuration mode.

	Command or Action	Purpose
Step 5	docsis-channel-id <i>DCID</i> Example: <pre>Router(config-rf-chan)#docsis-channel-id 1</pre>	Configures the downstream channel's DCID to the specified value, for the RF channel. For the rf-channel range that was configured using the rf-chan <i>starting downstream QAM ID ending downstream QAM ID</i> command, the docsis-channel-id <i>DCID</i> command configures the DCIDs for the rf-channels in that range.

Configuring Automatic Downstream Channel ID Assignment

Automatic DCID assignment should be permanently configured. However, if you need to remove the feature, use the **no** or **default** commands.

Note The **no** or **default** form of the command is not written to startup-config file.

In this case, the DCIDs are retained as computed for all channels, and are not set to the defaults of the channels. Save the configuration containing the newly-assigned DCIDs to the startup-config file by using the **write memory** command.

When you enable automatic DCID assignment, any DCID conflict arising due to adding a channel to a MAC Domain is resolved automatically.

Restriction

- After running the **cable downstream-channel-id automatic** command in the configuration, manually editing the configuration file in an editor to add RF channels to the fiber nodes could cause DCID conflicts. The feature assumes all channels in fiber nodes have unique automatic DCIDs in global configuration mode. If the configuration is manually edited and the feature does not verify the unique DCIDs, the DCIDs of the newly-added channels may conflict with those of the existing channels. To fix any DCID conflicts, undo and re-apply the global automatic DCID configuration.

Note Re-applying global automatic DCID configuration is a disruptive operation.

To avoid DCID conflicts, edit the configuration to configure the fiber nodes, then run the **cable downstream-channel-id automatic** command so all channels have unique automatic DCIDs.

Make additions to the fiber nodes on the Cisco uBR10012 router command line interface with the automatic DCID configured.

- The **cable downstream-channel-id automatic** command should not be manually edited in to the startup-config file, since it does not guarantee unique DCIDs for channels in the fiber node.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: Router> enable	<ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable downstream-channel-id automatic Example: Router(config)# cable downstream-channel-id automatic	Specifies automatic assignment of the DCIDs by the Cisco CMTS.

Example

This example displays the restriction on manually editing configurations:

```
Router# show run | include automatic
cable downstream-channel-id automatic

router# show cable fiber-node 3
-----
Fiber-Node 3
Channel(s) : downstream Integrated-Cable 1/0/2: 0-3, 32-35, 64-67, 96-99
Channel ID(s): 1 2 3 4 33 34 35 36 65 66 67 68 97 98 99 100
Upstream-Cable 1/0/2
FN Config Status: Configured (status flags = 0x01)
MDD Status: Valid
Router#
```

If you manually edit the startup-config file in an editor to add a downstream controller, for example, 1/0/3, it causes a conflict.

```
Router> configure terminal
Router# cable fiber-node 3
Router# downstream integrated-Cable 1/0/3
```

If this downstream controller is added, the automatic DCID assignment feature automatically resolves it. However, since the startup-config file was manually edited to add the downstream controller, the automatic DCID assignment feature is unable to resolve it. This causes a DCID conflict when the edited startup-config file is loaded and invalidates the fiber node.

```
down Modular-Cable 5/0/0 rf-channel 0
DS frequency is not unique.
DS channel id is not unique.
Warning: D3.0 CMs cannot get w-online with an invalid fiber-node.
router#
```

What to do next

Run the **show cable fibernode** command to view DCIDs assigned to all the channels in the fiber node.

```

Router# show cable fiber-node 3
Fiber-Node 3
Channel(s) : downstream Integrated-Cable 1/0/2: 0-3, 32-35, 64-67,
96-99
Channel ID(s): 1 2 3 4 33 34 35 36 65 66 67 68 97 98
99 100
Upstream-Cable 1/0/2
FN Config Status: Configured (status flags = 0x01)
MDD Status: Valid

```

Feature Information for Downstream Channel ID Assignment

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 56: Feature Information for Downstream Channel ID Assignment

Feature Name	Releases	Feature Information
Downstream Channel ID Assignment	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Router.

CHAPTER 20

Upstream Channel Bonding

The Upstream Channel Bonding (USCB) feature helps cable operators offer higher upstream (US) bandwidth per cable modem (CM) user by combining multiple radio frequency (RF) channels to form a larger bonding group at the MAC layer.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Prerequisites for Upstream Channel Bonding

- Enable downstream channel bonding before configuring the Upstream Channel Bonding feature on a Cisco cable modem termination system (CMTS) router.
- Ensure that the CM is registered in Multiple Receive Channel (MRC) mode before configuring upstream channel bonding on a Cisco CMTS router.
- Ensure that the CM is DOCSIS 3.0 certified.

Restrictions for Upstream Channel Bonding

The following are the general restrictions for the Upstream Channel Bonding feature:

- Only the static bonding groups are supported.
- Only the upstream channels belonging to the same MAC domain can be added to an upstream bonding group.

Note A maximum of 16 upstream channels can be configured for each MAC Domain, which are divided into two groups:

- Group 1: upstream channel 0-7
- Group 2: upstream channel 8-15

The **upstream bonding-group** should include all the upstream channels either from Group 1 or Group 2 only.

- Committed information rate (CIR) oversubscription is not supported on USCB groups.

Cisco CMTS allows oversubscription of the available bandwidth for individual upstream channels. However, oversubscription of bandwidth is not supported for USCB groups.

An individual upstream may get oversubscribed due to static CIR service flows created for voice traffic. This may cause the DOCSIS 3.0 CMs with USCB to come online on single channel US bonding group (also known as default bonding group).

This problem is mainly encountered in the voice deployments using static service flows. It is, therefore, recommended to choose from the following voice deployments such that the CIR is allocated (or released) when a voice call is attempted (or dropped):

1. Dynamic Quality of Service (DQoS) Lite
2. Packet Cable (PC) DQoS
3. Packet Cable Multimedia (PCMM)

These deployments avoid the individual upstream oversubscription and CMs come online on expected bonding groups.

Information About Upstream Channel Bonding

DOCSIS 3.0-based upstream channel bonding is a method for increasing upstream bandwidth up to a maximum of 120 Mbps raw throughput per CM user in a cable communications system that includes a Cisco CMTS router and multiple CMs. The upstream channel bonding method enables a CM to transmit data to a Cisco CMTS router on multiple upstream channels simultaneously.

Channel bonding is a method by which smaller bandwidth upstream channels are bonded together to create a larger upstream bonding group in the MAC domain. A MAC domain is a logical sub-component of a Cisco CMTS router and is responsible for implementing all DOCSIS functions on a set of downstream and upstream channels.

The Upstream Channel Bonding feature supports upstream traffic in Multiple Transmit Channel (MTC) mode for data and video services as these services require more bandwidth than voice-based services. Voice-based services either use the traditional single upstream channel or a single upstream channel bonding group configuration. Any traffic contract that exceeds 30 Mbps requires upstream channel bonding as the physical capacity of a single RF channel in DOCSIS cannot exceed 30 Mbps.

The Upstream Channel Bonding feature is supported on the Cisco cBR-8 router. Upstream data from the subscriber comes through the upstream ports (US0-US19) that are automatically configured on the cable interface line card. The cable interface line card processes the data and sends it across the backplane to the WAN card and out to the Internet.

The table below lists the downstream and upstream frequency supported on the cable interface line card.

Table 58: Downstream and Upstream Frequency

Line Card	Downstream Frequency	Upstream Frequency
Cisco cBR-8 CCAP	55-999 MHz ¹	The upstream frequency range for the Cisco cBR-8 CCAP line card is from 5 to 85 MHz irrespective of the region and Annexure configuration.

¹ This frequency range is subjected to the frequency restriction of the attached EQAM device.

Multiple Transmit Channel Mode

Multiple Transmit Channel mode is a CM capability that enables CMs to send upstream traffic on multiple upstream channels. You can enable the MTC mode on a cable interface line card:

- MTC mode for all CMs in a MAC domain—The MTC mode for all CMs in a MAC domain is enabled by default on an upstream bonding capable cable interface line card.

Multiple Receive Channel Mode

MRC mode is a CM capability that enables CMs to receive downstream traffic on multiple downstream channels. The MRC mode is enabled by default on an upstream bonding capable cable interface line card. You can enable or disable the MRC mode in the MAC domain during or after the CM registration using the `cable mrc-mode` command.

Dynamic Range Window and Transmit Power Levels for Upstream Channel Bonding

The dynamic range window functionality is based on the CableLabs DOCSIS 3.0 MAC and Upper Layer Protocols Interface Specification and DOCSIS 3.0 Specification. This requires a DOCSIS 3.0 CM to have upstream transmit channel power level within a 12 dB range for all channels in its transmit channel set (TCS).

DOCSIS 1.x or 2.0 CMs operating with a single upstream channel, in non-MTC mode, have a higher maximum transmit power level than DOCSIS 3.0 CMs operating in the MTC mode with two or more upstream channels. That is, the maximum transmit power level per channel is reduced in the MTC mode.

When the upstream attenuation exceeds the maximum transmit power level, a DOCSIS 3.0 CM attempting to register in the MTC mode may fail to come online, or register in partial mode. The CM fails to register when the transmit power level of all upstream channels in its TCS exceeds the maximum transmit power level. If the CM has some upstream channels that are within the maximum transmit power level, the CM may come online in partial mode. However, the upstream channels that exceed the maximum transmit power level are marked as down and cannot be used for upstream traffic.

To verify the transmit power levels on a CM, use the `show cable modem` command with the verbose keyword. This command displays the following transmit power values for each assigned upstream channel:

- Reported Transmit Power—This is the reported transmit power level by the CM for each upstream channel.
- Minimum Transmit Power—This is the minimum transmit power level that the CM in the MTC mode could transmit at for the upstream channel.

- **Peak Transmit Power**—This is the maximum transmit power level that the CM in the MTC mode could transmit at for the upstream channel.

To support upstream channel bonding, the minimum transmit power must be less than or equal to the reported transmit power, and the reported transmit power must be less than or equal to the peak transmit power. The peak transmit power and minimum transmit power levels are derived from the CM TCS assignment and each individual upstream channel configuration.

If the minimum transmit power is higher than the reported transmit power, or the reported transmit power is higher than the peak transmit power, the CM may not come online or may register in partial mode.

You can troubleshoot this transmit power problem in the following two ways:

- Insert an additional amplifier to reduce the upstream attenuation so that the upstream transmit power falls within the allowed transmit power range (12 dB).
- Disable the MTC mode. To switch the CM from the MTC mode to non-MTC mode, disable the bonded-bit (bit-0) in type, length, value (TLV) 43.9.3 using the CM configuration file.

Extended Transmit Power

During the early deployment of DOCSIS 3.0 CMs, additional power is required from the CMs in order to compensate for the attenuation in the upstream path. CMs should transmit at extended power level than that defined in DOCSIS. This scenario is generally observed when USCB is enabled at the Cisco CMTS and the DOCSIS 3.0 CMs are operating in MTC mode.

Additional upstream power provides the operator with a power margin that helps overcome the upstream signal loss, reduces the cable plant operational cost, and enables rapid deployment of DOCSIS 3.0 CMs.

The Cisco CMTS supports the following features with which the CMs can transmit data at an extended power:

- Cisco Extended Transmit Power Feature
- DOCSIS Extended Transmit Power Feature

Cisco Extended Transmit Power Feature

The Cisco Extended Transmit Power feature supports DOCSIS 3.0 CMs operating in MTC mode to transmit at a higher power level than the power level specified in the *DOCSIS 3.0 Specification*. This feature is supported only with Cisco DPC3000 CMs.

The Cisco Extended Transmit Power feature enables cable operators to have better control on the cable modems that register in 4-channel or 2-channel MTC mode or in non-MTC mode to transmit at a higher power level than the DOCSIS-defined maximum power level. The cable operator can configure extended transmit power using the **cable tx-power-headroom** command in global configuration mode.

DOCSIS Extended Transmit Power Feature

The DOCSIS Extended Transmit Power feature supports extended upstream transmit power capability as defined in the DOCSIS3.0 Specification. This feature allows the CMs to transmit at a high extended power level to counter the attenuation in the US channel.

The table below lists the new TLVs supported by the DOCSIS Extended Transmit Power feature.

Table 59: TLVs for DOCSIS Extended Power Feature

TLV Name	Type	Length	Value
Extended Upstream Transmit Power Support	16	1	0—Extended Upstream Transmit Power Support Off 1—Extended Upstream Transmit Power Support On 2-255—Reserved
Extended Upstream Transmit Power CM Capability	5.40	1	0, 205-244 (units of one-quarter dB)

The Cisco CMTS sends TLV16 to inform the CM if the DOCSIS Extended Transmit Power feature is enabled. The CM in turn, sends TLV5.40 to the Cisco CMTS to communicate its extended power capability. After the negotiations are complete, the CM can transmit at an extended power.

DOCSIS Extended Transmit Power feature is enabled by default. Use the cable upstream ext-power command to enable or disable this feature. For more information on how to enable or disable DOCSIS Extended Power feature, see [Configuring DOCSIS Extended Transmit Power Feature, on page 385](#).

Note DOCSIS Extended Transmit Power feature takes precedence, if both Cisco Extended Transmit Power feature and DOCSIS Extended Transmit Power feature are configured.

Reduced Transmit Channel Set

The Reduced Transmit Channel Set feature enables the Cisco CMTS router to reduce upstream channel set assignment based on the total power budget of the CM. For example, a reduction from four to two upstream channels gains 3 dB headroom. Further reduction from two channels to a single channel gains another 3 dB headroom, and the CM starts operating in non-MTC mode.

In order to take advantage of the reduced upstream channel set, the corresponding static bonding groups must be configured. For example, a MAC domain is configured with a bonding group having four channels. A CM with the reduced channel set of two is unable to match to the 4-channel bonding group, and can only be matched to a bonding group with two channels or less.

The Reduced Transmit Channel Set feature is helpful when a DOCSIS 3.0 CM is required to increase its total transmit power by 3 dB. For example, a DOCSIS 1.0 or 2.0 CM supports a maximum transmit power of 58 dBmV for Quadrature Phase Shift Keying (QPSK) modulation, while a DOCSIS 3.0 CM supports a maximum transmit power of 61 dBmV. In this case, the DOCSIS 3.0 CM operating in 4-channel MTC mode has a reduction in the maximum transmit power per upstream channel. This feature enables the Cisco CMTS router to support reduced input power level by 6 dB to prevent upstream path attenuation.

T4 Multiplier

T4 multiplier is the T4 timeout multiplier value of the default T4 timeout values as defined in for cable modems that are in the MTC mode. The default value is derived from the number of channels in the modem transmit channel set. You can change the default T4 multiplier value using the cable upstream ranging-poll command in cable interface configuration mode.

The T4 timeout multiplier values range is from 1 to 10. If the T4 multiplier value is equal to 1, the cable modem will T4 time out in 30 seconds (that is, $1 \times 30 = 30$). If you change the T4 multiplier to 4, then the new T4 timeout value will be 120 seconds (that is, $4 \times 30 = 120$).

Note If the T4 timeout multiplier is not configured from the range (1 - 10), then the CMTS uses the T4 timeout value of modem as T4 timeout value. For example, if the T4 timeout of the modem is 90 seconds, then the CMTS applies 3 as the T4 multiplier.

In the MTC mode, you can increase the T4 timeout value in order to reduce the router overhead associated with processing of ranging request (RNG-REQ) slots and ranging response messages. If an RNG-RSP message does not contain a T4 timeout multiplier value, then the CM uses the default T4 timeout value.

Fiber Node Configuration for Upstream Channel Bonding

The fiber node configuration on a Cisco CMTS router is used to define MAC domain downstream service groups (MD-DS-SGs) and MAC domain upstream service groups (MD-US-SGs) as defined in DOCSIS 3.0. Only the DOCSIS 3.0 certified modems use this information.

In hybrid fiber coaxial (HFC) networks, all CMs connected to the same coaxial segment of a fiber node reach the same set of downstream and upstream channels on one or more Cisco CMTS routers located at the headend.

A CM is physically connected to only one fiber node. The fiber node must include at least one primary-capable controller for the CM connected to the fiber node to be operational.

New TLVs for Upstream Channel Bonding

The table below lists the new CableLabs defined type, length, values (TLVs) for the Upstream Channel Bonding feature.

Table 60: New TLVs for Upstream Channel Bonding

TLV Name	Type	Length	Value
CM vendor ID	43.8	3	Per vendor definition
Cable modem attribute mask	43.9	n	Cable modem attribute mask subtype encodings

A Cisco CMTS can have multiple upstream channel bonding groups (USBG) configured. Each of these bonding groups can include upstream channels with different upstream frequencies. Some bonding groups can include channels with frequencies within the extended frequency range (see [Table 58: Downstream and Upstream Frequency, on page 362](#)). An HFC network consists of several types of CMs, each supporting standard or extended upstream frequencies.

When you register a CM, the Cisco CMTS does not assign bonding groups based on the upstream frequency range supported by that CM. The assignment of the bonding groups is done to balance the CM count on each of the bonding groups. This may lead to assignment of a bonding group, in the extended frequency range, to a CM that lacks the extended frequency support. As a result, the CM will not be able to register. This scenario is generally observed in the Cisco cBR-8 CCAP line card deployment (containing a mix of CMs), which supports frequency as high as 85MHz (see [Table 58: Downstream and Upstream Frequency, on page 362](#)).

If the Cisco CMTS assigns a USBG with a channel within the extended frequency range to a CM limited to the standard frequency range, that CM may not be able to register on that upstream bonding group. Use the TLV 43.9.3 (CM US Required Attribute Mask) or TLV 43.9.4 (CM US Forbidden Attribute Mask) as a workaround. These TLVs enable the Cisco CMTS to assign CM to a USBG, which is in the upstream frequency range supported by that CM.

The default attributes (in hexadecimal) on a CM Attribute Mask (TLV 43.9) are "80 00 00 00", which means by default the mask is all zeroes with the bonding bit enabled. The first four bytes are pre-defined while the last four bytes are user defined. In order to enable Cisco CMTS to assign bonding groups based on the frequency range supported by CMs, complete these steps:

1. Configure a mask, using TLV 43.9.3 or TLV 43.9.4, by modifying the last four bytes. The mask should be configured such that a unique attribute is assigned to each of the bonding groups.
2. Apply this mask to the CM configuration file. CMs supporting extended frequency, can register with any USBGs, irrespective of the configured frequency range of the USBG. CMs supporting standard frequency, can only register with USBGs that are configured with standard frequency range.

Apply the mask you have configured above, to the CMs that support standard or extended frequency ranges. However, the ONLY CMs that need to employ the attribute mask are the ones with the standard frequency range, since they will not be able to register with the USBG configured with extended upstream frequency range. No attribute mask on the extended frequency supporting CMs means that these modems will be assigned any USBG.

The Cisco CMTS uses this mask, received in the CM configuration file during registration, to decide which USBG should be assigned to the CM.

Upstream Weighted Fair Queuing

The upstream weighted fair queuing (WFQ) is a quality of service (QoS) feature that enables the Cisco CMTS router to allocate optimum bandwidth to upstream service flows based on the WFQ parameter configurations. To enable upstream WFQ, you must configure either the class-based or activity-based WFQ on a cable interface.

The following WFQ parameter configurations are supported:

Class-Based Weighted Fair Queuing

In the class-based weighted fair queuing configuration, allocation of available bandwidth is dependent on the service flows that are active in a service class. A service class is a group of queuing attributes configured on the Cisco CMTS router. The class must have at least one active service flow. The class receives its portion of the available bandwidth based on the weight of the class. By default, each class (0 to 7) has a weight of "class + 1." For example, the class 0 has a weight of 1, and class 1 has a weight of 2.

Activity-Based Weighted Fair Queuing

In the activity-based weighted fair queuing configuration, allocation of available bandwidth is based on the service class and the total number of service flows that are active in a map for the service class. A service class with higher number of service flows receives the larger percentage of bandwidth.

Custom Weight for Service Flow Priorities

The weighted fair queuing functionality helps the Cisco CMTS router share the available bandwidth based on the weight of the service flow priorities specified for outstanding requests from an upstream service flow. Priority refers to the service flow priority specified in the CM configuration file, or the Cisco CMTS service

class configuration. By default, the weight of a priority is equal to “priority+1.” For example, priority 0 has a weight of 1, and priority 1 has a weight of 2. A higher priority provides more weight to the outstanding request. The custom weight can be specified for a total of eight priorities (0 to 7) in a service class.

The priority parameter refers to the priority of traffic in a service flow ranging from 0 (the lowest) to 7 (the highest). In the upstream traffic, all of the pending high priority service flows are scheduled for transmission before low priority service flows. You can configure the weight for priorities based on how much weight is appropriate per priority.

The table below lists the default weight for each service flow priority.

Table 61: Default Weight of Service Flow Priorities

Service Flow Priority	Default Weight
0	1
1	2
2	3
3	4
4	5
5	6
6	7
7	8

Upstream Scheduler and Service Flows

A DOCSIS-qualified Cisco CMTS router can provide varied upstream scheduling modes for different packet streams or applications using upstream service flows. A service flow represents either an upstream or a downstream flow of data. A unique service flow ID (SFID) identifies each service flow. Each service flow can have its own quality of service (QoS) parameters, such as maximum throughput, minimum guaranteed throughput, and priority. In the case of upstream service flows, you can also specify a scheduling mode.

Scheduling is a process that enables the Cisco CMTS router to receive bandwidth requests and grant timeslots to CMs for the upstream traffic. The Cisco CMTS router periodically creates a grant map for each enabled upstream channel. The map grants individual timeslots to enable CMs to place packets on the upstream channels.

DOCSIS 3.0 describes a method by which a CM creates an upstream service flow. The following scheduling types enable the Cisco CMTS router to allocate bandwidth for upstream service flows:

- Unsolicited grant service (UGS)
- Solicited grant service

The unsolicited grant service is primarily used for voice. In the case of UGS, the CM does not have to explicitly request grants from the Cisco CMTS router whereas in the solicited grant service the CM has to explicitly request grants from the Cisco CMTS router. The solicited grant service is primarily used for best effort (BE) services.

Unlike DOCSIS 2.0, DOCSIS 3.0 allows multiple outstanding requests per service flow. For more information about the upstream scheduler, see the *Upstream Scheduler Mode for the Cisco CMTS Routers* feature guide at the following URL:

http://www.cisco.com/en/US/docs/ios/cable/configuration/guide/cmts_upstm_sch_md_ps2209_TSD_Products_Configuration_Guide_Chapter.html

Upstream Service Flow Fairness

The service flows in the same class receive approximately the same amount of bandwidth. Fairness resolves the bandwidth distribution disparity among various service flows including:

- non-bonded service flow vs bonded service flows
- Service flows on modems of different vendors, i.e Intel/TI vs Broadcom
- Service flows associated with different sized bonding groups, i.e. 1,2 4 channels

The upstream scheduler supports flow based queuing. When Upstream Service Flow Fairness is configured, the upstream scheduler determines the order and amount of BW a service flow should receive based on its current consumption relative to other flows in the flows in the same class.

Use the **cable upstream qos fairness** command to configure the Upstream Service Flow Fairness feature. Use this command in interface configuration mode (or MAC Domain configuration mode).

Distribution of Traffic across all Channels in a USBG

When upstream channel bonding (USCB) is enabled, the Distribution of Traffic across all Channels in a USBG feature can be used to balance the bandwidth utilization across upstream channels on one upstream bonding group.

This feature balances the utilization only if there is one upstream channel bonding group configured per MAC domain.

Restrictions:

- This feature is supported only on one upstream bonding group under a MAC domain. When multiple upstream bonding groups are configured under a MAC domain, the utilization is unfair.
- All the channels must be configured in one upstream bonding group under the same MAC domain.
- This feature is used only for UB-online cable modems.

The USCB Balancing Scheduler may be enabled or disabled using the **cable upstream balance-scheduler** command in the interface (config-if) configuration mode.

DOCSIS 3.0 Load Balancing with USBG Smaller than Cable Modem Capabilities

When using USCB in a service group with USBGs containing fewer upstream channels than the total upstream channel set with DOCSIS 3.0 load balancing enabled, the CMTS can assign a Transmit Channel Set (TCS) to DOCSIS 3.0 cable modems for potential use which falls outside of the configured USBG. The CMTS will try to bind smaller USBGs and default single channel bonding groups into a bigger channel set in order to increase the cable modem services. For example, a DOCSIS 3.0 cable modem receiving the larger TCS can use these additional channels for dynamic service flow addition. The DOCSIS 3.0 Load Balancing feature can also move cable modems to upstream channels that are not explicitly configured with USBGs as a result of the larger TCS.

If you activate DOCSIS 3.0 Load Balancing while using upstream bonding, ensure that the upstream bonding group configuration is embedded and aligned by performing the following:

- Configure USBGs, which is matched to cable modem capabilities within the service group, such as a 4 channel USBG, 2 channel USBG, and 3 channel USBG as applicable.
- Ensure that configured USBGs are optimal for the upstream channel set based on modem capabilities within the service group. For example, if four upstream channels are available, channels 0+1 and 2+3 should each be an USBG to avoid dynamic TCS creating sub optimal bonding scenarios.
- Alternatively, you can choose to shut down any upstream channels that is not configured in USBGs which is not be used for bonding.

Cisco cBR-8 CCAP Line Card Rate Limiting

The rate limiting functionality enables you control the aggregated rate and CPU consumption of upstream traffic for DOCSIS 3.0 bonded service flows on the Cisco cBR-8 CCAP line card. The rate limiting functionality is configured by default on the Cisco cBR-8 CCAP line card. However, the default configuration can be modified using the **cable upstream rate-limit-ccf** command.

The rate limiting functionality uses the following two rate limiting methods:

- Aggregated rate limiting—This is based on Peripheral Component Interconnect (PCI) bus aggregated throughput. The throughput is per line card for all bonded service flows. You can modify the default throughput and burst rate configuration. The maximum allowed throughput is 115 Mbps.
- CPU-based rate limiting—This method controls the CPU consumed by Continuous Concatenation and Fragmentation (CCF) and ensures that the line card functions properly when traffic is overloaded with bonded service flows. The default configuration allocates 50 per cent of CPU to CCF. You can modify the default CPU threshold value and burst rate as required.

SID Tracking

The service ID (SID) tracking functionality enables you to track events related to upstream bandwidth requests and processing of grants. The SID tracker module can track events for a maximum of two service flows per MAC domain. The SID tracker module tracks up to 40,000 events per service flow on a cable interface line card.

You can enable SID tracking for the following types of events:

- DOCSIS 2.0 bandwidth request
- DOCSIS 3.0 bandwidth request
- Grant
- Pending grant (due to traffic congestion)
- Pending grant (due to shaping)

You can enable SID tracking using the **track keyword** along with the **debug cable interface sid** command. To verify SID tracking, use the **show interface cable upstream debug** command in privileged EXEC mode.

Service ID Clusters

A Cisco CMTS router can assign one or more service ID clusters to the upstream bonded service flows (upstream service flows assigned to an upstream bonding group) at the time of service flow creation. A SID

cluster contains one SID per upstream in a bonding group. A CM uses one of the SIDs defined in the SID cluster for the upstream interface when the CM sends a bandwidth request. The CM chooses a SID or a SID cluster based on the SID cluster switching criteria.

For example, assume that a CM has ranged on upstream channels from 1 to 4. The Cisco CMTS router creates a bonded service flow and assigns a single SID cluster to each upstream channel. That is SID1 for UP1, SID2 for UP2, SID3 for UP3, and SID4 for UP4. Now, the CM can send a bandwidth request using any of the four upstream channels. That is, the CM can request bandwidth on any of the upstream interfaces in the SID cluster using the SID defined for the particular upstream. The Cisco CMTS router grants bandwidth to the CM using any combination of upstream channels.

How to Configure Upstream Channel Bonding

Note Before configuring the Upstream Channel Bonding feature, ensure that the fiber node is configured. The fiber node must be configured in accordance with the physical plant topology.

The following tasks describe how to configure Upstream Channel Bonding on the Cisco cBR-8 router:

Enabling MTC Mode on a Cisco CMTS Router

This section explains how to enable the MTC mode on a Cisco CMTS router.

Default MTC Mode Configuration on a Cisco CMTS Router

By default, the MTC mode is configured on a cable interface line card. With this default configuration, the Cisco CMTS router enables the MTC mode on a per MAC domain basis depending on the configuration file of each CM. When the CM configuration file has the bonded-bit (bit-0) enabled in TLV 43.9.3 (cable modem upstream required attribute mask), the Cisco CMTS router enables the CM to come online in the MTC mode. If the CM configuration file does not have the bonded-bit on, the CM comes online in non-MTC mode.

For more information on how to add the required attribute in the CM configuration file, see [Example: Enabling MTC Mode for a Single CM Using the CM Configuration File, on page 387](#).

Enabling MTC Mode for All CMs

Note

- For DOCSIS 3.1 cable modems, the CMTS router must be configured to use MTC mode.
- This MTC mode configuration supersedes the default MTC mode configuration (per CM basis) with the required attribute. To disable the MTC mode for all CMs in a MAC domain, use the **no** form of the **cable mtc-mode** command. If the MTC mode is enabled and the forbidden mask of the upstream bonding in TLV 43.9.4 is disabled, the CM does not support the Upstream Channel Bonding feature.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable mtc-mode Example: Router(config-if)# cable mtc-mode	Enables MTC mode at the MAC interface for all CMs.
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring UCSB Required Attribute

If the CM configuration file has TLV 43.9.3 (CM upstream required attribute mask) configured and bonded bit is set to 1, then the modem comes UB-online on a MAC domain basis. If the CM configuration file has no TLV 43.9.3 or the bonded bit is not set to 1, then the modem comes online with a single upstream channel on a MAC domain basis.

Note Without this configuration, the modem comes UB-online on the MAC domain regardless of whether the TLV 43.9.3 is configured in the modem configuration file.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# configure terminal	
Step 3	interface cable { <i>slot/subslot/port</i> <i>slot/subslot/cable-interface-index</i> <i>slot/port</i> <i>slot/cable-interface-index</i> } Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable mtc-mode required-attribute Example: Router(config-if)# cable mtc-mode required-attribute	Enable enforcement of required CM attribute on UCSB.
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Creating a Bonding Group

An upstream bonding group is created by combining multiple upstream channels together on a cable interface line card.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable { <i>slot/subslot/port</i> <i>slot/subslot/cable-interface-index</i> <i>slot/port</i> <i>slot/cable-interface-index</i> } Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream bonding-group id Example: Router(config-if)# cable upstream bonding-group 200	Creates the bonding group on the specified cable interface.

	Command or Action	Purpose
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

What to do next

After creating an upstream bonding group, you must add upstream channels to the bonding group.

Adding Upstream Channels to a Bonding Group

Restriction DOCSIS 3.0-certified CMs support only four upstream channels on an upstream bonding group. These CMs do not accept additional upstream channels that are added to a bonding group.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream bonding-group <i>id</i> Example: Router(config-if)# cable upstream bonding-group 200	Creates the bonding group on the specified interface.
Step 5	upstream <i>number</i> Example:	Enters upstream bonding configuration submode and adds an upstream channel to the upstream bonding group.

	Command or Action	Purpose
	Router(config-upstream-bonding)# upstream 1	<p>Note Upstream channel needs to be bonded to mac-domain first before adding it to the bounding group. For detailed configuration steps of the upstream channel bonding, please refer to Configuration Example for Upstream Channel Bonding</p> <p>A maximum of 16 upstream channels can be configured for each MAC Domain, which are divided into two groups:</p> <ul style="list-style-type: none"> • Group 1: upstream channel 0-7 • Group 2: upstream channel 8-15 <p>The upstream bonding-group should include all the upstream channels either from Group 1 or Group 2 only.</p>
Step 6	<p>end</p> <p>Example:</p> <pre>Router(config-upstream-bonding)# end</pre>	Exits upstream bonding configuration submode and returns to privileged EXEC mode.

Adding Upstream Channel Ports to a Fiber Node

You must add upstream channel controllers to a fiber node in order to complete the basic upstream channel bonding configuration on a cable interface line card. The fiber node must contain all upstream and downstream controllers reached by the CMs.

Restriction

- Configuration of a fiber node is valid only if all upstream channels inside the fiber node have different upstream frequencies.
- For any two upstream channels mapped to the upstream cable controllers in the same fiber node where a spectrum group is assigned to one upstream channel, and a frequency is assigned to the other upstream channel, any overlap between any bands associated with the spectrum group of the upstream channel and the frequency of the upstream channel will result in an invalid fiber node configuration. That is a fixed frequency cannot overlap with another upstream channel's available spectrum group bands.

Note The fiber node configuration must be done in accordance with the physical plant topology.

Procedure

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	cable fiber-node <i>fiber-node-id</i> Example: Router(config)# <code>cable fiber-node 2</code>	Enters fiber node configuration mode.
Step 4	upstream Upstream-Cable <i>slot/subslot/port</i> Example: Router(config-fiber-node)# <code>upstream Upstream-Cable 7/0/1</code>	Specifies the upstream channel ports for a fiber node.
Step 5	end Example: Router(config-fiber-node)# <code>end</code>	Exits fiber node configuration mode and returns to privileged EXEC mode.

Configuring the Class-Based Weighted Fair Queuing

In the case of a class-based configuration, allocation of available bandwidth is dependent on the service flows that are active in a service class.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	interface cable { <i>slot/subslot/port</i> <i>slot/subslot/cable-interface-index</i> <i>slot/port</i> <i>slot/cable-interface-index</i> } Example: Router(config)# <code>interface cable 7/0/0</code>	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream qos wfq class Example: Router(config-if)# <code>cable upstream qos wfq class</code>	Enables class-based weighted fair queuing.

	Command or Action	Purpose
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring the Activity-Based Weighted Fair Queuing

In the activity-based configuration, allocation of available bandwidth is based on the service class and the total number of service flows that are active in a map for the service class.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream qos wfq activity Example: Router(config-if)# cable upstream qos wfq activity	Enables activity-based weighted fair queuing.
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring Custom Weights for Service Flow Priorities

The WFQ functionality helps the Cisco CMTS router share the available bandwidth based on the weight of the service flow priorities specified for outstanding requests from an upstream service flow.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: Router> <code>enable</code>	Enter your password if prompted.
Step 2	configure terminal Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	interface cable { <i>slot/subslot/port</i> <i>slot/subslot/cable-interface-index</i> <i>slot/port</i> <i>slot/cable-interface-index</i> } Example: Router(config)# <code>interface cable 7/0/0</code>	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream qos wfq weights <i>priority0-priority7</i> Example: Router(config-if)# <code>cable upstream qos wfq weights 10 20 30 40 50 60 70 80.</code>	Enables custom weight configuration for all the service flow priorities in a service class. Note You must specify custom weight values for all the eight service flow priorities (0 to 7) when you modify the default weights of priorities. The valid range is from 1 to 255.
Step 5	end Example: Router(config-if)# <code>end</code>	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring the SID Cluster

This section explains how to configure and assign a SID cluster to an upstream bonded service flow.

Note Configure the **cable sid-cluster-group num-of-cluster 2** command to achieve desired upstream bonded speeds. Alternatively, use a large upstream Max Traffic burst value in the cable modem file (such as 30 kB). The Max Concat burst value in the cable modem file need not be changed because DOCSIS 3.0 uses continuous concatenations and fragmentation (CCF) and can therefore use the default value of 3044 in the Max Concat field.

Note If the **cable sid-cluster-group** command is not used, the router accepts the default SID cluster configuration. By default, only one SID cluster is configured. Similarly, if the **cable sid-cluster-switching** command is not used, the router accepts the default SID cluster switchover criterion. That is, only one request can be made using the SID cluster.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable { <i>slot/subslot/port</i> <i>slot/subslot/cable-interface-index</i> <i>slot/port</i> <i>slot/cable-interface-index</i> } Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable sid-cluster-group [dynamic req-multiplier <i>value</i> num-of-cluster <i>number</i>] Example: Router(config-if)# cable sid-cluster-group dynamic Router(config-if)# cable sid-cluster-group req-multiplier 12 Router(config-if)# cable sid-cluster-group num-of-cluster 2	Creates a SID cluster group.
Step 5	cable sid-cluster-switching [max-outstanding-byte <i>value</i> max-request <i>value</i> max-time <i>seconds</i> max-total-byte <i>value</i>] Example: Router(config-if)# cable sid-cluster-switching max-outstanding-byte 4444 Router(config-if)# cable sid-cluster-switching max-request 222 Router(config-if)# cable sid-cluster-switching max-time 444 Router(config-if)# cable sid-cluster-switching max-total-byte 67890	Specifies SID cluster switchover criteria.
Step 6	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

What to do next

Use the **show running-config all** command to verify the SID cluster configuration. Following is a sample output of the command:

```
Router# show running-config all
.
.
.
cable sid-cluster-group num-of-cluster 1
cable sid-cluster-group dynamic
cable sid-cluster-group req-multiplier 4
```

Configuring the Channel Timeout for a Cable Modem

The channel timeout configuration allows you to specify the maximum time that a CM can spend performing initial ranging on the upstream channels described in the Registration Response (REG-RSP) and REG-RSP-MP messages. The default channel timeout value (60 seconds) is automatically configured.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable init-channel-timeout value Example: Router(config-if)# cable init-channel-timeout 160	Specifies the maximum time that a CM can spend performing initial ranging on the upstream channels.
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring Cable Upstream Resiliency

The cable upstream resiliency module ensures that a CM remains operational if one or more non-primary upstream service flows of the CM enter temporary or persistent error states. This module enables a Cisco CMTS router to handle various events and maintain the transmit channel set of each CM.

In the event of the primary upstream service flow failure, the upstream resiliency module forces the CM to go offline.

For a Multiple Transmit Channel (MTC) modem, the (NRTPS), Real-time Polling Service (RTPS), (UGS), and (UGS-AD) upstream service flows on an impaired upstream channel is moved to another good upstream channel in the cable modem without resetting the cable modem.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable upstream resiliency data-burst polling-interval number Example: Router(config)# cable upstream resiliency data-burst polling-interval 60	Configures the polling interval for data-burst resiliency in seconds. The range is from 5 to 3600. The default configuration for polling-interval is 60.
Step 4	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 5	cable upstream resiliency {channel-down-detect number data-burst snr number ufec number cfec number hysteresis number modem-offline-detect number on-failure {disable-channel extended-ranging reset-modem} sf-move {NRTPS RTPS UGS UGS-AD} } Example: Router(config-if)# cable upstream resiliency channel-down-detect 68 Router(config-if)# cable upstream resiliency modem-offline-detect 16 Router(config-if)# cable upstream resiliency on-failure disable-channel Router(config-if)# cable upstream resiliency sf-move NRTPS Router(config-if)# cable upstream resiliency sf-move RTPS	Configures upstream resiliency for bonded upstream service flows.

	Command or Action	Purpose
	<pre>Router(config-if)# cable upstream resiliency sf-move UGS Router(config-if)# cable upstream resiliency sf-move UGS-AD Router(config-if)# cable upstream resiliency data-burst snr 24 ufec 1 cfec 0 hysteresis 3</pre>	
Step 6	<p>end</p> <p>Example:</p> <pre>Router(config-if)# end</pre>	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring Rate Limiting on the Cisco cBR-8 CCAP Line Card

The rate limiting functionality is configured by default on the Cisco cBR-8 CCAP line card. However, the default configuration can be modified using the cable upstream rate-limit-ccf command.

Procedure

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>cable upstream rate-limit-ccf [aggregated-burst <i>value</i> aggregated-throughput <i>value</i> cpu-burst <i>value</i> cpu-threshold <i>value</i>]</p> <p>Example:</p> <pre>Router(config)# cable upstream rate-limit-ccf aggregated-burst 25000 Router(config)# cable upstream rate-limit-ccf aggregated-throughput 540000 Router(config)# cable upstream rate-limit-ccf cpu-burst 30 Router(config)# cable upstream rate-limit-ccf cpu-threshold 60</pre>	Configures rate limiting parameters for upstream bonded service flows on a cable interface line card.
Step 4	<p>end</p> <p>Example:</p> <pre>Router(config)# end</pre>	Exits global configuration mode and returns to privileged EXEC mode.

Enabling Upstream Related Events for CM Status Reports

You can enable upstream related CM status events only on a cable interface line card. You can enable the following upstream related CM status events per interface using the `cable cm-status enable` command:

- T4 time-out
- T3 re-tries exceeded
- Successful ranging after T3 re-tries exceeded

For details on how to enable upstream and downstream related CM status events, see the Wideband Modem Resiliency feature guide at the following URL:

http://www.cisco.com/en/US/docs/ios/cable/configuration/guide/ubr_wm_resiliency.html

Modifying the Bonding Group Attributes

Bonding group attributes are automatically configured for each upstream bonding group. You can modify them using the `attributes` command in upstream bonding configuration mode.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable { <i>slot/subslot/port</i> <i>slot/subslot/cable-interface-index</i> <i>slot/port</i> <i>slot/cable-interface-index</i> } Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream bonding-group id Example: Router(config-if)# cable upstream bonding-group 200	Creates the bonding group on the specified cable interface and enters the upstream bonding configuration mode.
Step 5	attributes value Example: Router(config-upstream-bonding)# attributes eeeeeeee	Modifies the attribute value for the specified bonding group.
Step 6	end Example:	Exits upstream bonding configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
	Router(config-upstream-bonding)# end	

Modifying the Ranging Poll Interval on Upstream Channels

You can change the default ranging poll interval (20 seconds) on upstream channels using the cable upstream ranging-poll command in cable interface configuration mode. You can also specify the T4 timeout multiplier value using this command.

For information on T4 Multiplier, see [T4 Multiplier, on page 364](#).

Note We recommend that you do not modify the default ranging poll interval unless required. With the default configuration, a DOCSIS 2.0 CM in non-MTC mode performs ranging on one upstream channel every 20 seconds.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream ranging-poll [interval value t4-multiplier timeout_value] Example: Router(config-if)# cable upstream ranging-poll interval 24000 t4-multiplier 4	Specifies the ranging poll interval for upstream channels. Note If t4-multiplier timeout_value is not configured, then the CMTS uses the the T4 timeout of the modem. For example, if the T4 timeout of the modem is 90 seconds, then the CMTS will apply 3 as T4 multiplier for the modem.
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring the Reduced Channel Set Assignment

You need to configure the transmit power offset budget to enable the Cisco CMTS router to reduce upstream channel set assignment based on the total power budget of the CM.

Note The threshold value specified for the power budget offset (`max-channel-power-offset`) must be less than the power threshold value (`power-adjust continue`) that determines the value of the Ranging Status field in the Ranging Response (RNG-RSP) messages that the Cisco CMTS router sends to the CM. You can specify the power threshold value using the **cable upstream power-adjust** command.

Before you begin

- Configure extended transmit power using the **cable tx-power-headroom** command in global configuration mode.
- Ensure that corresponding static bonding groups are configured.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream max-channel-power-offset <i>dB-value</i> Example: Router(config-if)# cable upstream max-channel-power-offset 2	Specifies the power offset value for upstream channels.
Step 5	end Example: Router(config-if)# end	Exits cable interface configuration mode and returns to privileged EXEC mode.

Configuring DOCSIS Extended Transmit Power Feature

The DOCSIS Extended Transmit Power feature is enabled by default on the Cisco CMTS. However, the default configuration can be modified using the cable upstream ext-power command.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface cable {slot/subslot/port slot/subslot/cable-interface-index slot/port slot/cable-interface-index} Example: Router(config)# interface cable 7/0/0	Specifies the cable interface line card on a Cisco CMTS router.
Step 4	cable upstream ext-power Example: Router(config-if)# cable upstream ext-power	Enables the DOCSIS Extended Transmit Power feature on the Cisco CMTS. Using the no form of this command disables the DOCSIS Extended Transmit Power feature.
Step 5	end Example: Router(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Troubleshooting Tips

The following debug commands help you troubleshoot an improper upstream channel bonding configuration and its related features:

- **debug cable cm-status**—Provide debugging information about CM status messages on the Cisco CMTS routers.
- **debug cable mdd**—Provides debugging information about MAC domain descriptor (MDD).
- **debug cable md-sg**—Provides information about service group debugging messages.
- **debug cable ubg**—Provides debugging information about upstream bonding groups.

Configuration Example for Upstream Channel Bonding

The following example shows how to configure the basic upstream channel bonding on the Cisco cBR-8 CCAP line card interface 7/0/0 on the Cisco cBR-8 router:

Configuration Example for Upstream Channel Bonding

```

controller Upstream-Cable 7/0/0
us-channel 0 frequency 10000000
us-channel 0 channel-width 3200000 3200000
us-channel 0 ingress-noise-cancellation 50
us-channel 0 docsis-mode atdma
us-channel 0 minislots-size 2
us-channel 0 modulation-profile 221
us-channel 0 equalization-coefficient
no us-channel 0 shutdown
us-channel 1 frequency 16400000
us-channel 1 channel-width 6400000 6400000
us-channel 1 ingress-noise-cancellation 50
us-channel 1 docsis-mode atdma
us-channel 1 minislots-size 1
us-channel 1 modulation-profile 221
us-channel 1 equalization-coefficient
no us-channel 1 shutdown
us-channel 2 frequency 22800000
us-channel 2 channel-width 6400000 6400000
us-channel 2 docsis-mode atdma
us-channel 2 minislots-size 1
us-channel 2 modulation-profile 221
us-channel 2 equalization-coefficient
no us-channel 2 shutdown
us-channel 3 frequency 29200000
us-channel 3 channel-width 6400000 6400000
us-channel 3 docsis-mode atdma
us-channel 3 minislots-size 1
us-channel 3 modulation-profile 221
us-channel 3 equalization-coefficient
no us-channel 3 shutdown
us-channel 4 channel-width 1600000 1600000
us-channel 4 docsis-mode tdma
us-channel 4 minislots-size 4
us-channel 4 modulation-profile 21
us-channel 4 shutdown
us-channel 5 channel-width 1600000 1600000
us-channel 5 docsis-mode atdma
us-channel 5 minislots-size 4
us-channel 5 modulation-profile 221
us-channel 5 shutdown
!

interface Cable7/0/0
load-interval 30
downstream Integrated-Cable 7/0/0 rf-channel 0
downstream Integrated-Cable 7/0/0 rf-channel 8
downstream Integrated-Cable 7/0/0 rf-channel 16
upstream 0 Upstream-Cable 7/0/0 us-channel 0
upstream 1 Upstream-Cable 7/0/0 us-channel 1
upstream 2 Upstream-Cable 7/0/0 us-channel 2
upstream 3 Upstream-Cable 7/0/0 us-channel 3
no cable upstream 0 equalization-error-recovery
no cable upstream 1 equalization-error-recovery
no cable upstream 2 equalization-error-recovery
no cable upstream 3 equalization-error-recovery
cable upstream 7 attribute-mask 1FF
cable upstream bonding-group 1
upstream 0
upstream 1
upstream 2
attributes 80000000
cable bundle 1

```

```

cable map-advance static 2000
cable sync-interval 121
cable reduction-mode mta-battery enable
cable privacy accept-self-signed-certificate
end

cable fiber-node 1
description Feed Mac Domain: Cable7/0/0
downstream Integrated-Cable 7/0/0
upstream Upstream-Cable 7/0/0

```

Note Bonded channels are typically from the same connector; however, channels from different connectors in the same MAC domain can also be bonded together. A single MAC domain can support multiple channel bonding groups.

Note Up to 8 frequencies can be stacked to one upstream-cable controller. Once the upstream-cable controller has 8 frequencies stacked, no more frequency left for the adjacent upstream-cable controller.

Example: Enabling MTC Mode for a Single CM Using the CM Configuration File

The following example shows how to enable the MTC required attribute using the CM configuration file:

```

03 (Net Access Control) = 1
Unknown Type 005 = 01 01 01
18 (Maximum Number of CPE) = 4
24 (Upstream Service Flow Encodings)
  S01 (Service Flow Reference) = 1
  S06 (QoS Parameter Set Type) = 7
  S10 (Min Reserved Traffic Rate)= 500000
25 (Downstream Service Flow Encodings)
  S01 (Service Flow Reference) = 2
  S06 (QoS Parameter Set Type) = 7
  S10 (Min Reserved Traffic Rate) = 1000000
29 (Privacy Enable) = 0
43 (Vendor Specific Options)
  S08 (Vendor ID) = ff ff ff
  S009 (Unknown sub-type) = 03 04 80 00 00 00

```

Verifying the Upstream Channel Bonding Configuration

Use the following **show** commands to verify the upstream channel bonding configuration:

- **show cable mac-domain upstream-service-group**
- **show cable fiber-node**
- **show interface cable upstream**
- **show interface cable service-flow**
- **show cable modem**

To verify the runtime statistics of the upstream service group on a cable interface line card, use the **show cable mac-domain upstream-service-group** command.

To verify the configuration of a fiber node, use the **show cable fiber-node** command.

To verify the bonding groups configured on a cable interface line card, use the **show interface cable upstream** command.

To verify upstream bonding information on a cable interface line card, use the **show interface cable service-flow** command.

To verify the transmit power levels on a CM, use the **show cable modem** command.

Verifying Weighted Fair Queuing for Upstream Service Flows

To verify WFQ parameters configured for upstream service flows on a cable interface line card, use the **show interface cable mac-scheduler** command.

Verifying Rate Limiting for Upstream Bonded Service Flows

To verify the rate limiting criteria configured on the Cisco cBR8 CCAP line card for upstream bonded service flows, use the **show cable rate-limit-ccf** command.

Note The **show cable rate-limit-ccf** command is applicable only to the Cisco cBR8 CCAP cable interface line card.

Verifying Extended Power Transmission

To verify that a CM is transmitting at a higher power level, use the **show cable modem** command.

To list all the CMs that are transmitting at higher power level, use the **show cable modem extended-power** command.

Feature Information for Upstream Channel Bonding

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmg.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 62: Feature Information for Upstream Channel Bonding

Feature Name	Releases	Feature Information
Upstream Channel Bonding	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Router.

CHAPTER 21

Dynamic Bonding Group

This document describes how to configure Dynamic Bonding Group that helps manage resource of all downstream bonding groups by automatically creating bonding groups.

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Information About Dynamic Bonding Group

Dynamic Bonding Group (DBG) helps manage the resource of all downstream bonding groups, including automatically creating and reclaiming the downstream bonding groups.

Overview of Dynamic Bonding Group

To reduce the effort required in configuring and managing RCC, the DBG feature implements the automatic creating and reclaiming of the downstream bonding groups. DBG creates the bonding group automatically depending on the channel's load usage. With DBG, the modem is assigned the downstream bonding group without any static RCC configuration. The load balancing feature leverages DBG to balance traffic among all channels. DBG also accommodates primary channel and CM capacity distributions automatically.

DBG also accommodates primary channel and CM capacity distributions automatically.

Dynamic Bonding Group supports the following:

- Support 896 bonding groups per CLC for CYLONS card.

- Support creating DBGs and reclaiming DBG.
- Support DOCSIS 3.0 and DOCSIS 3.1 channel types.
- Support DOCSIS 3.0 and DOCSIS 3.1 load balance.
- Supports DBG interoperation — Modem registration and load balancing.
- Enhance dynamic load balance — Fixed primary channel movement.
- Enhance raider FPGA SQF — Fairness in channel utilization.

How to configure Dynamic Bonding Group

Enable Dynamic Bonding Group

To enable DBG, run the following commands:

```
ROUTER# config t
Enter configuration commands, one per line. End with CNTL/Z.
ROUTER(config)# cable dynamic-bonding-group
ROUTER(config)# end
ROUTER#
ROUTER#
ROUTER# show run
ROUTER# show running-config | in dynamic-bonding
cable dynamic-bonding-group
```

Enable DS-Resiliency and Configure Resiliency Bonding Group

To make sure that the modem remains w-online with maximum downstream capability when several rf channels are impaired, enable ds-resiliency feature by running the following commands:

```
Router# config t
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# cable resiliency ds-bonding
Router(config)# end
Router#
Router# show running-config | in resiliency
cable resiliency ds-bonding
Router#
Router# config t
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# interface wideband-Cable 3/0/1:30
Router(config-if)# cable ds-resiliency
Wideband-Cable3/0/1:30 is set to WB resiliency bonding group.
Remove any existing bundle and rf-channel configuration.
Router(config-if)#end
Router#
Router#show running-config interface wideband-Cable 3/0/1:30
Building configuration...
Current configuration : 61 bytes
!
interface Wideband-Cable3/0/1:30
cable ds-resiliency
end
```

Enable ACFE

Enable ACFE feature to make sure that modem registration is not blocked because of QoS failures:

```
Router# config t
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# cable acfe enable
Router(config)# end
Router# show running-config | in acfe
cable acfe enable
```

Configure Interface Mac-Domain and Fiber-Node

Note The recommended size of service group is 32 or 48. The recommended primary channel distribution is one primary channel for contiguous four channels, such as 0, 4, 8, 12, 16, 20, 24, 28 and so on.

To set up interface mac-domain and fiber-node, run the following commands:

```
Router# show running-config interface c3/0/1
Building configuration...
Current configuration : 963 bytes
!
interface Cable3/0/1

Enable Load Balancing for DOCSIS 3.0 and DOCSIS 3.1

To enable DOCSIS load balancing, run the `cable load-balance docsis-enable` command. When DOCSIS load balancing is enabled, run the `cable load-balance docsis30-enable` command to enable load balancing for DOCSIS 3.0 and DOCSIS 3.1.

Note The `cable load-balance docsis30-enable` command enables load balancing for DOCSIS 3.0 and DOCSIS 3.1.

Enable DOCSIS 3.0 and DOCSIS 3.1 Static Load Balance

To balance the load of primary channels, enable static load balance by running the following commands:

```
ROUTER# config t
Enter configuration commands, one per line. End with CNTL/Z.
ROUTER(config)# cable load-balance docsis30-enable static
ROUTER(config)# end
ROUTER# show cable load-balance
DOCSIS LB Enabled: Yes
DOCSIS 2.0 LB Enabled: Yes
DOCSIS 3.0 LB Enabled: Yes
DOCSIS 3.0 Static LB Enabled: Yes
DOCSIS 3.0 Dynamic Downstream LB Enabled: No
```

Enable DOCSIS 3.0 and DOCSIS 3.1 General Load Balance Group

To enable general load balance group, run the following commands:

```
Router# config t
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# cable load-balance docsis-group fn 1 md c3/0/1
Router(config-lb-group)# no disable
Router(config-lb-group)# end
Router# show cable load-balance

```

Enable Dynamic Load Balance and Fixed-Primary Channel Movement

Note To reduce service outage while enabling dynamic load balancing, enable fixed primary channel movement.

To balance the load of all of downstream channels based on utilization, enable dynamic load balance by running the following commands:

```
Router# config t
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# cable load-balance docsis30-enable dynamic downstream
Router(config)# end
Router#
Router# show cable load-balance
DOCSIS LB Enabled: Yes
```

```

```

Verifying Dynamic Bonding Group Configuration

To verify that the DBGs are created:

Check the modem's primary wideband interface by using the **show cable modem wideband channel** command:

```

Router# show cable modem 4800.33ee.ebee wideband channel
MAC Address      IP Address      I/F      MAC      DSxUS      Primary
                State          WB
4800.33ee.ebee   30.132.15.246  C3/0/1/UB  w-online  32x2      Wi3/0/1:3
Router# scm 4800.33ee.ebee ver

```

Check the modem's downstream tuner capability by using the **show cable modem verbose | in DS Tuner** command.

```

Router# show cable modem 4800.33ee.ebee verbose | in DS Tuner
DS Tuner Capability : 32

```

Check the related RCC by using the **show cable mac-domain rcc** command:

```

Router# show cable mac-domain c3/0/1 rcc
RCC-ID  RCP      RCs  MD-DS-SG  CMs  WB/RCC-TMPL      D3.0  D3.1
32 00 00 00 00 00 8 0      11  WB (Wi3/0/1:1)  Y      Y
33 00 00 00 00 00 32 0      6   WB (Wi3/0/1:3)  Y      Y
34 00 00 00 00 00 8 0      7   WB (Wi3/0/1:2)  Y Y
35 00 00 00 00 00 8 0      7   WB (Wi3/0/1:4)  Y Y
36 00 00 00 00 00 8 0      7   WB (Wi3/0/1:5)  Y Y

```

Check the dynamically created bonding groups, use the **show cable dynamic-bonding-group summary** command as shown in the example below:

```

Router# show cable dynamic-bonding-group summary
Dynamic bonding group: Enable
BG ID BG Name      BG Size CMs ServFlows Create Time      Create Client      BG State
Rfid list
24834 Wi3/0/1:1 8      11 11      Sep 14 14:36:35.194 MODEM_ONLINE      OPERATIONAL
24832-24839
24836 Wi3/0/1:3 32     6   6       Sep 14 14:43:24.144 MODEM_ONLINE      OPERATIONAL

```

```

24848-24855

```

Table 64: Dynamic Bonding Group States

CREATE_WAITING_SUP	Line card sends request to create DBG and waits for SUP to create the bonding group.
HOLD	DBG is created from SUP, or bonding group reverts from reclaim to ready for use.
OPERATIONAL	If modem is used on the bonding group after the HOLD state times out, the DBG state changes to OPERATIONAL.
RECLAIM_HOLD	Ready for reclaim. If no modem is used on the bonding group or match the reclaim in two minutes, the bonding group is reclaimed. The DBG state changes to RECLAIM_HOLD.
RECLAIM_MODEM_MOVING	Ready for reclaim. The modem is moved out of the bonding group.
RECLAIM_WAITING_SUP	Line card sends DBG reclaim request and waits for SUP to reclaim the BG.

To show the detailed channel list information of dynamic bonding group, use the **show derived-config interface wideband** command.

```

Router# show derived-config interface wideband-Cable 3/0/1:1
Building configuration...
Derived configuration: 113 bytes
!
interface Wideband-Cable3/0/1:1
  cable bundle 255
  cable rf-channels channel-list 0-7 bandwidth-percent 1
end

```

Check the usage of bonding group resource by using the **show cable dynamic-bonding-group quota summary | slot | controller** command.

```

Router# show cable dynamic-bonding-group quota controller 3/0/1
slot/subslot/ctrlr: 3/0/1
Total BG number: 128
Used BG number (static/dynamic): 6(1/5) Available BG number: 122
Available BG list port: 0, 6-29, 31-127

```

Note 128 BGs can be configured on one controller, but only 896 BGs are supported per CLC. All controllers share the 896 BG resources.

Check the reclaimed bonding group by using the **show cable dynamic-bonding-group reclaim-history summary** command:

```
Router# show cable dynamic-bonding-group reclaim-history summary
BG ID BG Name      BG Size Create Time      Create Client Reclaim Time      Reclaim Client RFid
list
24835 Wi3/0/1:2 16      Sep 14 14:40:27 MODEM_ONLINE  Sep 14 14:44:27 DBG_INTERNAL
24832-2484
```

Verifying Static Load Balancing Configuration

To verify if static load balancing is configured:

Check the load of all primary channels by using the **show cable load-balance docsis-group fn 1 md cable load | in In** command.

```
Router# show cable load-balance docsis-group fn 1 md c3/0/1 load | in In
Interface          State      Group          Utilization Rsvd  NBCM  WB/UB  Weight
In3/0/1:0 (573 MHz) initial  2147557888  0%(0%/0%)  0%  0    17    37
In3/0/1:4 (597 MHz) initial  2147557888  0%(0%/0%)  0%  0    17    37
In3/0/1:8 (621 MHz) initial  2147557888  0%(0%/0%)  0%  0    13    37

```

This command output lists all primary channels and shows the number of cable modems used with these channels. NBCM is the number of narrow band modems used with a channel while WBCM (WB/UB) is the number of wideband modems used with a channel. The total number of WBCMs should be balanced among all the channels.

The difference between the total number of WBCMs used with any two channels is smaller or equal to the threshold load minimum. The default value of the threshold load minimum is 5.

Check the load of all rf channels by using the **show cable load-balance docsis-group fn 1 md rfch-util** command.

```
Router# show cable load-balance docsis-group fn 1 md c3/0/1 rfch-util
Interface  Pstate Pending-In Pending-Out Throughput(Kbps) Util NBCM WBCM
In3/0/1:0 up      No         No         0              0%  0    17

```

This command lists the load information about the primary and secondary channels. WBCM is the number of wideband modems used with a channel.

Check the cable modem's internal state in load balancing using the **show cable load-balance docsis-group fn 1 md modem-list wideband** command.

```

Router# show cable load-balance docsis-group fn 1 md c3/0/1 modem-list wideband

Table 65: Cable Modem States

CM state	Description
LB_CM_STATIC_READY	Modem is ready for static load balance movement.
LB_CM_STATIC_MOVING	Modem is in movement triggered via static LB.
LB_CM_HOLD_EXPIRE_IN	Modem is in hold for the next movement. The default hold time is 600 seconds.
LB_CM_DYANMIC_READY	Modem is ready for dynamic load balance movement.
LB_CM_DYANMIC_MOVING	Modem is in movement triggered via dynamic LB.
LB_CM_DISABLED	Modem is not ready for movement. If the modem failure movement count reaches max-failure threshold, then set the modem in LB_CM_DISABLED to avoid further movement.

Verifying Dynamic Load Balancing Configuration

Check the utilization of all rf channels by using **show cable load-balance docsis-group fn 320 md rfch-util** command.

```
Router# show cable load-balance docsis-group fn 320 md c3/0/0 rfch-util
Interface Pstate Pending-In Pending-Out Throughput (Kbps) Util NBCM WBCM

Wi1/0/4:4    9221       up         2147510276

```

If no target bonding groups are displayed, no bonding groups are created to balance traffic among rf channels.

A sample output with DOCSIS 3.1 modems with configured threshold of 14% is shown below. For utilization based load balancing to start on DOCSIS 3.1 modems, the OFDM channel must be 100% utilized and traffic must flow on SC-QAM. The utilization based load balancing balances the traffic flowing on the SC-QAM channels in a D31 modem.

```

Feature Information for Dynamic Bonding Group

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 66: Feature Information for for Dynamic Bonding Group

Feature Name	Releases	Feature Information
Dynamic Bonding Group	Cisco IOS XE Fuji 16.7.1	This feature was introduced on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 22

Spectrum Management and Advanced Spectrum Management

This chapter describes the spectrum management features supported for the Cisco Cable Modem Termination System (CMTS) routers. Spectrum management support is divided into two main groups:

- Guided and scheduled spectrum management features (supported in software)
- Intelligent and advanced spectrum management features (supported in hardware only on specific cable interfaces)
- [Finding Feature Information, on page 405](#)
- [Hardware Compatibility Matrix for the Cisco cBR Series Routers, on page 406](#)
- [Prerequisites for Spectrum Management, on page 406](#)
- [Restrictions for Spectrum Management, on page 407](#)
- [Information About Spectrum Management, on page 409](#)
- [How to Configure Spectrum Management, on page 424](#)
- [Monitoring Spectrum Management, on page 442](#)
- [Configuration Examples, on page 447](#)
- [Additional References, on page 454](#)
- [Feature Information for Spectrum Management and Advanced Spectrum Management, on page 455](#)

Finding Feature Information

Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

Hardware Compatibility Matrix for the Cisco cBR Series Routers

Note The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

Table 67: Hardware Compatibility Matrix for the Cisco cBR Series Routers

Prerequisites for Spectrum Management

Ensure that your network is designed to support reliable broadband data transmission. At minimum, your network must include:

- A Dynamic Host Configuration Protocol (DHCP) server to assign IP addresses to cable modems or set-top boxes on the hybrid fiber-coaxial (HFC) network. This can be a Cisco CMTS router that has been configured to act as the DHCP server.

- If you are not using cable interface line cards with integrated upconverters, you must install the appropriate IF-to-RF external upconverter between the Cisco CMTS router and the combiner.

Note The term “combiner” refers to all cables, amplifiers, and taps at the headend or cable distribution center that connect the Cisco CMTS router to the HFC network.

- Diplex filters installed in the downstream RF path between the cable modems and the cable interface cards in the router. RG-59 headend coaxial cable with the maximum braid available (60 percent + 40 percent braid), double foil, and the correct connector for this cable.
- Avoid frequencies with known ingress problems such as amateur radio bands or short-wave bands.
- Avoid hostile spectrums below 20 MHz.
- When designing your channel plan, allow extra bands for frequency hopping.
- Use the receive power level setting to perform slight equalization adjustments.
- Due to the nature of CATV technology, upstream noise management is a significant issue. We recommend that you follow the rigorous North American plant maintenance procedures documented in the NCTA Supplement on Upstream Transport Issues (available from the National Cable and Telecommunications Association, <https://www.ncta.com>) to adjust return amplifiers and lasers.

Restrictions for Spectrum Management

This section describes the restrictions for the following spectrum management features:

Shared Spectrum Groups

- Advance spectrum management does not support inter-line-card shared spectrum groups.
- Guided spectrum management does support inter-line-card shared spectrum groups.

Dynamic Upstream Modulation

- The Cisco CMTS router has one preconfigured (primary) modulation profile that defines a typical profile for quadrature phase-shift keying (QPSK) modulation. To use the Dynamic Upstream Modulation feature, you must create a secondary modulation profile that has a higher modulation scheme than the preconfigured profile. The Three Step Dynamic Modulation feature allows you to create and use a third modulation profile. However, the third modulation profile is optional.
- Upstream modulation profiles are assigned to upstream ports and affect all cable modems on those upstream ports.
- Modulation profiles affect the physical layer of the cable network, so only trained technicians who are familiar with the Data-over-Cable Service Interface Specifications (DOCSIS) specifications should create modulation profiles.

- When using the Dynamic Upstream Modulation feature with Voice over IP (VoIP) services, frequent changes to the upstream modulation or channel width could briefly impact the quality of voice calls.

Fixed-Frequency Spectrum Groups with Advanced Spectrum Management

Do the following to configure fixed-frequency spectrum groups:

```
Router(config)#controller upstream-cable 9/0/15
Router(config-controller)#us-channel 0 spectrum-group n
Router(config-controller)#us-channel 0 channel-width 1600000
```

Limitations on Upstream Modulation Parameters for PacketCable VoIP Calls

We recommend the use of a channel width that is 1.6Mhz, 3.2Mhz, or 6.4Mhz while configuring upstreams for PacketCable operations and VoIP calls. (All DOCSIS channel widths and upstream parameter combinations are supported, but not optimum when offering VoIP.)

N+1 Redundancy Support

N+1 redundancy requires the working and protect cable interface line cards to be identical. This ensures that the protect interface supports the same exact configuration as the working interface.

When protecting cards that support intelligent and advanced spectrum management, a switchover preserves the spectrum management configuration, and the protect interface initially uses the same upstream frequency as the working interface. The protect interface does not begin using the advanced spectrum management features until the system stabilizes to avoid any unnecessary frequency hops or channel width changes.

Intelligent and Advanced Spectrum Management Support

- Cable interfaces use standard DOCSIS, EuroDOCSIS, and the extended Japanese frequency ranges (5 to 85 MHz for upstream interfaces) to support the intelligent and advanced spectrum management features.
- Intelligent and advanced spectrum management features are supported only in the DOCSIS 1.0 and DOCSIS 1.1 Time Division Multiple Access (TDMA) mode of operation. These features cannot be used when a cable interface is operating in the DOCSIS 2.0 mixed, Advanced TDMA (A-TDMA), and Synchronous Code Division Multiple Access (S-CDMA) modes of operation. Similarly, these features are also not available when the cable interface is configured to use multiple logical channels. However, these restrictions do not apply for guided spectrum management.
- Upstream channels must meet the carrier-to-noise plus interference ratio (CNiR [CNR]), and carrier-to-ingress power ratio values given in the DOCSIS specifications. The minimum value for both parameters is 25 dB in the 5 to 65 MHz frequency range.
- The intelligent and advanced spectrum management features do not support inter-line card shared spectrum groups. Spectrum management features require that upstream ports on different line cards have their own RF domain (a unique set of non-overlapping frequencies).
- N+1 redundancy is not supported on any cable interface line card that has defined spectrum groups, which typically is the normal configuration for advanced spectrum management.

- The intelligent and advanced spectrum management feature is activated by assigning spectrum groups on cards with built-in spectrum analyzer.

Information About Spectrum Management

Spectrum management allows a Cisco Cable Modem Termination System (CMTS) to sense upstream plant impairments, report them to a management entity, and automatically correct them where possible. The spectrum management feature performs these functions without reducing throughput or latency and without creating additional packet overhead on the radio frequency (RF) plant.

In particular, because the cable interfaces on the router receive upstream packets, it can directly detect upstream transmission errors. The router can also indirectly monitor the condition of the plant by keeping a record of modem state changes, such as the number and frequency of cable modems that are “flapping” (modems that either miss a station maintenance message or that go offline and then come back online).

Note For more information about the cable modem flapping and how to monitor the cable modem flap list, see the [Flap List Troubleshooting for the Cisco CMTS Routers](#).

Spectrum management can prevent long-term service interruptions caused by upstream noise events in the cable plant. It is also used for fault management and troubleshooting the cable network. When cable modems are detected to go online and offline by flap detectors, the cable operators can look at the flap list and spectrum tables to determine the possible causes.

Because of the nature of cable television (CATV) technology, upstream noise management is a significant issue. Frequency bands must have a sufficient CNR (CNiR) and carrier-to-ingress power ratio to support the transmission of QPSK and quadrature amplitude modulation (QAM) data. The DOCSIS sets the minimum value for both of these ratios to 25 dB in the 5 to 65 MHz frequency range. If the CNR (CNiR) drops below 25 dB on a particular channel due to noise, the cable modem on that channel degrades and can drop off the hybrid fiber-coaxial (HFC) network.

This overview contains the following subsections:

- [Spectrum Management Measurements, on page 410](#)—Provides an overview of fundamental concepts and terms that are used in spectrum management.
- [Upstream Signal Channel Overview, on page 413](#)—Describes how signals are sent and how changes occur in upstream channels.
- [Upstream Segments and Combiner Groups, on page 414](#)—Describes sparse and dense segments and combiner groups.
- [Frequency Management Policy, on page 415](#)—Describes the types of noise impairments and how to counteract ingress noise with spectrum groups and frequency hopping.
- [Guided and Scheduled Spectrum Management, on page 417](#)—Describes the following guided and scheduled spectrum management features: frequency hopping capabilities, dynamic upstream modulation (signal-to-noise ratio-based), and input power levels.
- [Intelligent and Advanced Hardware-Based Spectrum Management, on page 422](#)—Describes spectrum management features that are supported by a number of cable interface line cards that have onboard

spectrum management hardware. These features include a real-time spectrum analyzer, CNR-based, proactive frequency hopping, and a more robust dynamic upstream modulation.

- [Benefits, on page 422](#)—Describes the spectrum management features provided on the Cisco CMTS router platforms.

Spectrum Management Measurements

Measuring the signal-to-noise ratio (SNR [MER]) and carrier-to-noise ratio (CNR [CNiR]) are the major ways of determining the quality of a downstream or upstream signal. The following sections provide an overview of these two ratios, as well as explaining the differences between them, and some additional values that might be useful:

Signal and Carrier Noise Ratios

Measuring the Modulation Error Ratio (MER [SNR]) and CNR (CNiR) of a downstream or upstream is the first step in determining the quality of the signal, and whether spectrum management needs to be performed to correct any errors. The following are brief descriptions of these two values:

- **Modulation Error Ratio (MER [SNR])**—This is an estimate of the signal strength on the upstream after ingress noise cancellation is performed. This means that the MER (SNR) takes into account a variety of modulation impairments, including frequency response distortions (such as in-channel amplitude tilt and ripple), group delay, microreflections, and phase noise. The MER (SNR) is a good gauge of the overall end-to-end quality of the cable network, because it includes the impact that the transmitter circuitry, receiver circuitry, and transmission media have on the upstream signal.
- **Carrier-to-Noise Ratio (CNR)**—This is an ratio of the measured modulated power, in dB, on the upstream (before ingress noise cancellation is done) that compares the channel power to the noise power.

The term CNiR is part of the CableLabs nomenclature for the CNR measurement. Therefore these two terms, CNR and CNiR, can be used interchangeably.

The CNR (CNiR) measurement is usually provided only by an external spectrum analyzer, but the cable interface line cards that support intelligent and advanced hardware spectrum management features also provide CNR (CNiR) measurement.

The following two types of CNR (CNiR) measurements are supported on the Cisco CMTS:

- **CNR (CNiR) measured for a particular upstream**—This is the overall CNR (CNiR) for all of the cable modems on an upstream, which is determined by measuring the RF power of the upstream receiver at the cable interface. This value is always just a snapshot in time for a particular upstream. The cable interface measures the RF power at a time when no bursts are expected from the cable modems, but it can be skewed by a small number of cable modems that are experiencing or creating signal problems.
- **Per-modem CNR (CNiR)**—This is the CNR (CNiR) for a particular cable modem, which is signal strength of the burst transmissions of the modem at the upstream receiver of the cable interface. The per-modem CNR (CNiR) measurement is a very accurate measure of a particular cable modem's signal, but you should not use a single modem's CNR (CNiR) to make assumptions about other cable modems on that upstream or about the upstream itself. However, you can get a good picture of the upstream's signal quality by polling the CNR (CNiR) for a number of cable modems over a representative time period.

Tip Changing the channel width has a direct impact on the CNR (CNiR). Doubling the channel width (for example, from 400 KHz to 800 KHz) decreases the CNR (CNiR) for an upstream by approximately 3 dB. Cutting the channel width in half (for example, from 3.2 MHz to 1.6 MHz) increases the CNR (CNiR) for an upstream by approximately 3 dB.

Differences Between the MER (SNR) and CNR (CNiR) Values

In a perfect network, such as a test lab where the only impairment is additive white Gaussian noise (AWGN), you can expect the CNR (CNiR) and MER (SNR) values to be comparable throughout all of the allowable power levels and frequency ranges. In a live network, however, it is expected that the MER (SNR) value should be a few dB lower than the CNR (CNiR) value, given that the MER (SNR) value takes into account noise impairments and distortions that are not accounted for by the CNR (CNiR) power measurements.

In general, when the CNR (CNiR) value is in the 15 to 25 dB range, you can expect the MER (SNR) value to have a comparable value. The difference between the MER (SNR) and CNR (CNiR) values is expected to be larger when the CNR (CNiR) value falls outside of the 15 to 25 dB range.

The table below provides a comparison between the MER (SNR) and CNR (CNiR) values, listing the major reasons for why the MER (SNR) and CNR (CNiR) values might diverge on an active network that is passing live traffic:

Table 68: Comparison of MER (SNR) and CNR (CNiR) in a DOCSIS Cable Network

Signal-to-Noise (SNR)	Carrier-to-Noise (CNR)
Post-detection measurement of the RF signal.	Pre-detection measurement of the RF signal.
Measurement of the baseband domain.	Measurement of the RF frequency domain.

Signal-to-Noise (SNR)	Carrier-to-Noise (CNR)
<p>Includes the effect of signal distortions and impairments on the signal. These include:</p> <ul style="list-style-type: none"> • Group delay in the channel such as occurs during operation near the diplexer band edge. • Channel amplitude variation and echoes. • Data collisions. • Microreflections. • Narrow band ingress in the channel. • Non-linearities in the cable plant. • Phase noise. • Poor selection of the preamble. • Poor symbol fidelity in the transmission of a cable modem, despite a good MER (SNR) value. • Unrecoverable carrier offsets. • Unrecoverable symbol timing offsets. 	<p>Measures only the RF modulated carrier power versus noise power.</p>
<p>Provides an indication of overall, end-to-end network quality (what the transmitter, receiver, and transmission media are doing to the signal).</p>	<p>Provides an indication of network performance (what the transmission media or network is doing to the signal).</p>
<p>Average over time with current data traffic patterns, useful for tracking long-term trends in signal quality.</p>	<p>Real-time spectrum analysis.</p>
<p>Reflects the CNR (CNiR) value as part of its value.</p>	<p>Does not reflect the MER (SNR) value as part of its value.</p>
<p>Averaged over 10,000 symbols, and an accurate reading requires that short and long grants are being transferred.</p>	<p>Unaffected by the type of traffic being transmitted.</p>
<p>Does not use packets with uncorrectable FEC errors to determine its value. Bursts of uncorrectable errors, therefore, could result in a deceptively high MER (SNR) value.</p>	<p>Unaffected by uncorrectable FEC packet bursts.</p>
<p>DOCSIS specifications do not define any required MER (SNR) values for upstreams and downstreams.</p>	<p>Minimum downstream CNR of 35 dB in a 6-MHz band (44 dB in DOCSIS 2.0 for 8-MHz band)</p> <p>Minimum upstream CNR (CNiR) of 25 dB.</p>

Additional Measurements

In addition to MER (SNR) and CNR (CNiR) values, you should be aware of and monitor the following indicators of signal quality:

- **MER**—This is the measure of RF signal quality, in dB, which is equivalent to SNR and similar to CNR (CNiR) under additive white Gaussian noise (AWGN) impairments. However, MER is preferred for data networks, because it also includes additional factors that affect the signal, such as analog-to-digital and digital-to-analog conversions, rounding errors, distortions, and signal impairments such as phase noise, group delay, and jitter. For this reason, the DOCSIS 2.0 RF specification adds a requirement for the minimum MER value for a signal, supplementing the existing CNR (CNiR) minimum requirements.

A simple formula for calculating the MER value for an upstream is:

$$\text{MER} = 20 \times \log (\text{RMS error magnitude} / \text{Average symbol magnitude})$$

You can also calculate the Error Vector Modulation (EVM) to find the equivalent value expressed as a percentage of noise on an upstream:

$$\text{EVM} = \text{Average error magnitude} / \text{Max symbol magnitude} * 100$$

See the DOCSIS 2.0 specification for more complete information on calculating and using the MER value.

- **FEC Counters**—These are counters that keep track of how many correctable and uncorrectable FEC errors occur on the upstream. The FEC error counters are useful for tracking fast transient errors such as impulse noise that are not usually reflected in MER (SNR) or CNR (CNiR) values.

A correctable error count of more than 1 percent can be used as a warning sign of possible physical plant or cable modem problems that might be developed. An uncorrectable error count of more than 1 percent can indicate an existing problem that is blocking traffic on the upstream. Cable interface line cards that support the intelligent and advanced spectrum management features can use the FEC counters as one of the indicators to be monitored to determine whether an upstream must change frequencies so as to correct noise problems.

- **Microreflections**—Additional copies of a signal that arrive at the receiver, usually at different times and attenuated by different amounts, causing the receiver to misidentify the incoming signal's true phase and amplitude. Microreflections typically are caused by impedance mismatches in the physical cable plant, and can indicate either equipment that has been degraded by weather or other causes, or equipment that has not been installed correctly.

Upstream Signal Channel Overview

The upstream channel is characterized by many cable modems transmitting to the CMTS. These signals operate in a burst mode of transmission. Time in the upstream channel is slotted. The CMTS provides time slots and controls the usage for each upstream interval. The CMTS periodically broadcasts Upstream Channel Descriptor (UCD) messages to all cable modems. The UCD message contains the upstream frequency and transmission parameters associated with an upstream channel. These messages define upstream channel characteristics including the upstream frequencies, symbol rates and modulation schemes, forward error correction (FEC) parameters, and other physical layer values.

Cisco supports all DOCSIS error-correction encoding and modulation types and formats. Upstream signals are demodulated using QPSK or QAM. QPSK carries information in the phase of the signal carrier, whereas QAM uses both phase and amplitude to carry information.

Sending data reliably in the upstream direction is an issue. Because upstream spectrum varies greatly between cable plants, select upstream parameters based on your cable plant's return paths. Select or customize upstream

profiles for the maximum trade-off between bandwidth efficiency and upstream channel robustness. For example, QAM-16 requires approximately 7 dB higher CNR (CNI_R) to achieve the same bit error rate as QPSK, but it transfers information at twice the rate of QPSK.

Note The above specifications are based on predetermined sets of frequencies that may or may not have an adequate CNR (CNI_R) at any given time.

Upstream frequencies can be assigned as follows:

- Fixed—Configuring a spectrum group disables the fixed upstream frequency setting.
- Single subband—The CMTS administrator can define a center frequency and symbol rate such that the boundaries of the upstream carrier stay within the subband. The frequency and symbol rate can change within the boundary in response to noisy line conditions, based on the defined upstream parameters.
- Multiple subbands—The data carrier can remain in a particular subband for a duration of time and then hop to another subband based on the defined upstream parameters.

Tip Measurement of noise power levels with a spectrum analyzer should be part of the procedure in initially selecting and setting up frequency allocations. We recommend having fixed frequency settings during early deployment, at least until amplifier cascade adjustments or plant repair have become infrequent enough that they no longer significantly affect the nodes connected to the upstream port.

Upstream Frequency Changes

As stated in the DOCSIS radio frequency interface (RFI) specification, RF channel migration or upstream frequency change occurs when a change in the UCD message is broadcast to all cable interfaces.

The speed of channel migration via the UCD message is typically less than 20 milliseconds (ms). During this time, upstream transmission is interrupted until the cable interface transmitter adjusts to its new frequency. Data is stored in the cable interface buffers during this time and is sent when the frequency hop is complete.

Station maintenance intervals are used to perform per modem keepalive polling. The CMTS polls each cable modem at least once every 30 seconds, with the default being once every 20 seconds. When ingress noise causes loss of keepalive messages from a configurable percentage of all cable interfaces, resulting in missed polls, a new frequency is selected from the allocation table and a UCD update is performed. The migration time is 2 msec for any upstream UCD update. After the UCD is updated, the hop occurs. The system must wait until a hop threshold time interval has elapsed before it can change the UCD a second time.

Upstream Segments and Combiner Groups

The Cisco routers divide a cable plant into downstream channels. Downstream channels contain upstream segments. Each upstream segment typically serves more than one fiber node. Upstream segments can be defined as one of the following:

- Sparse segment—Containing one upstream channel per upstream segment.
- Dense segment—Containing multiple upstream channels per upstream segment; frequencies must be different.

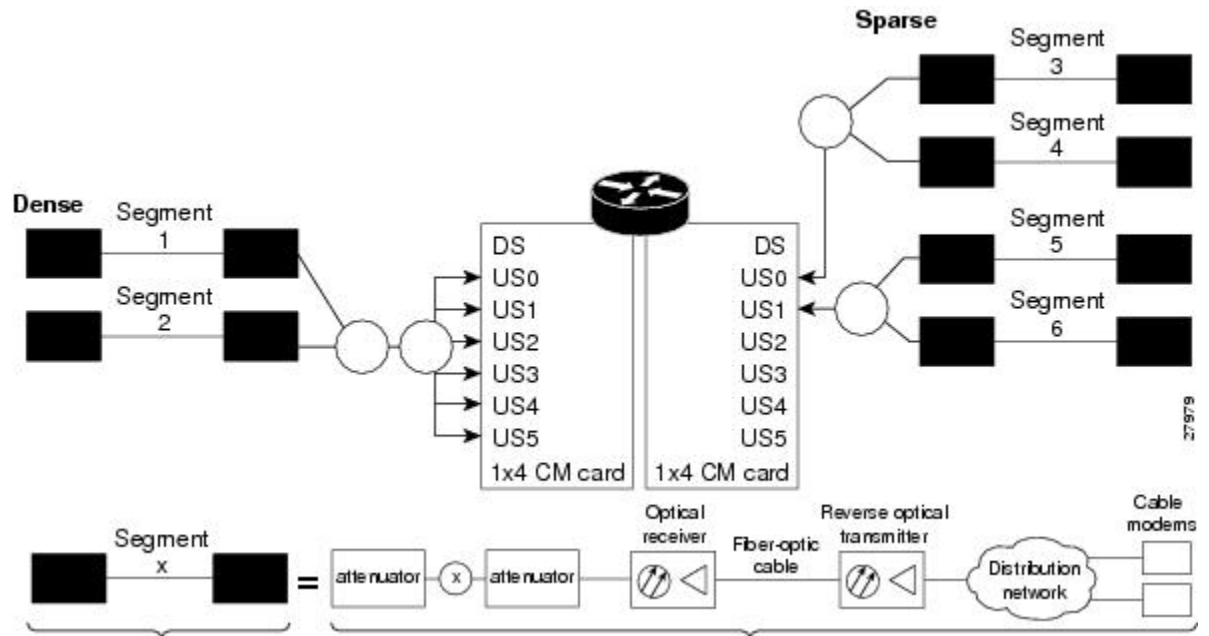

Note A cable interface line card can support sparse or dense segments, or both.

Defining sparse segments allows the cable operator to share upstream bandwidth among fiber nodes with fewer subscribers. Defining dense segments allows the cable operator to provide larger upstream bandwidth to fiber nodes with many subscribers.

The figure below illustrates sparse versus dense segments.

Figure 18: Sparse Versus Dense Segment Illustrations

As shown in the figure above, the downstream segment can contain multiple upstream segments. Two fiber nodes can be in one downstream segment but in different upstream segments.

The return path of several fiber nodes can be combined at a single point to form a single RF frequency domain called a combiner group. The CMTS software allows a frequency hop table called a spectrum group to be associated with a combiner group.

Note A combiner group refers to an RF topology point. A spectrum group refers to the frequency hop table associated with a combiner group.

Frequency Management Policy

Spectrum management applies a common frequency-management policy to a set of upstream ports to ensure that data is delivered reliably over the cable plant. Cable plant operators must make noise measurements and determine the cable plant's spectrum management policy. Different modulation schemes, upstream frequency techniques, and symbol rates are used based on the cable plant characteristics and the cable interface line card in the chassis.

See the following sections for more information about these topics:

Noise Impairments

Upstream noise impairments such as signal degradation on cable networks can negatively affect service to subscribers. Two-way digital data signals are more susceptible than one-way signals to stresses in the condition of the HFC network. Degradation in video signal quality might not be noticeable in one-way cable TV service, but when two-way digital signals share the network with video signals, digital signals can be hampered by:

- **Impulse and electrical signal ingress**—Noise can enter the network from electrical sources within a residence or from high-voltage lines that run near cable television cabling. Two types of ingress noise include broadband and narrowband. Broadband noise is generally of lower frequency (below 10 MHz) and results in harmonic rolloff. Narrowband noise is a more significant interference source. Cable equipment and infrastructure often pick up noise from amateur radio transmissions, citizen band radios, or high-power shortwave broadcast signals. Implement a signal leakage maintenance program to locate and repair areas of signal ingress.
- **Amplifier noise**—Amplifiers add noise to the HFC network that typically goes unnoticed in video signals, but degrades digital data signals if amplifiers are improperly configured. The larger the network, the higher the probability of amplifier noise affecting signals.
- **Noise funneling**—The upstream data path to the headend is susceptible to interference from the entire network. All upstream noise ultimately ends up at the headend because the cumulative nature of noise becomes concentrated at the headend. As a network serviced by a single RF receiver increases in size, the probability of noise funneling also increases.
- **Variable transmit levels**—Temperature affects signal loss over coaxial cable. This can cause variations of 6 to 10 dB per year.
- **Clipping**—The lasers in fiber-optic transmitters can stop transmitting light when input levels are excessive. Excessive input levels introduce bit errors in both the upstream and downstream transmissions. If a laser is overdriven as briefly as a fraction of a second, clipping can occur.

To adjust your return amplifiers and lasers, follow rigorous plant maintenance procedures documented in the NTSC Supplement on Upstream Transport Issues or appropriate cable plant standard.

Spectrum Groups and Frequency Hopping

We recommend that CMTS administrators configure upstream frequency hopping to counteract long-term, narrowband noise. Cisco CMTS routers support a combination of guided frequency hopping and time-scheduled frequency hopping.

The frequency hop to proactively avoid noise ingress is sometimes called frequency agility. Frequency agility is configured and activated using spectrum groups. Spectrum management supports the creation of a number of cable spectrum groups, allowing multiple upstream ports in a single spectrum group. Each spectrum group defines the table of frequencies to be used in a specific frequency plan. Upstream frequencies can be a fixed single frequency, a single continuous range of frequencies (band), or multiple ranges (or bands) of frequencies.

The cable interface does not operate until you assign a frequency to the upstream, which can be done either by configuring and assigning a spectrum group or assigning a fixed frequency. The spectrum group takes precedence, so if you configure both a spectrum group and a fixed frequency on an upstream, the spectrum group overrides the fixed upstream frequency setting.

From the interface point of view, a spectrum group also represents the set of upstreams connected to the same group of fiber nodes. The spectrum manager software in Cisco routers examines all the RF parameters that

have been configured on an upstream to determine whether the upstream frequencies need to be managed together. For example, if you configure a spectrum group with several fixed frequencies, but those frequencies are all within the configured channel width, the spectrum manager software combines the frequencies into a single band.

The upstream ports use the spectrum group to determine which frequencies are available if frequency hopping is needed to deal with noise or other path impairments. The types of frequency hopping techniques are guided, time-scheduled, and combined guided and time-scheduled. See the [Frequency Hopping Capabilities, on page 417](#) for more information on the types of frequency hopping techniques.

Note When each upstream port has its own RF domain, the group is called a nonshared spectrum group. When multiple upstream ports share the same RF domain, the group is called a shared spectrum group.

Guidelines for Spectrum Management

In general, when defining your spectrum, use the following guidelines:

- Avoid frequencies with known ingress problems, such as amateur radio bands or short-wave bands.
- Avoid a hostile spectrum below 20 MHz.
- Allow extra bands for frequency hopping.
- Take the possible channel widths into account when creating frequency bands. The range of frequencies being used must be able to hop between at least two different frequencies when using the channel width that is configured on the upstream.
- Place upstream ports in the same combiner group in a shared spectrum group.
- Use the receive power level setting to perform slight equalization adjustments.
- If you combine multiple upstream ports to provide increased bandwidth, you must avoid overlapping frequency bands. Each port should be using a discrete band of frequencies that does not overlap the bands being used by other ports in the group. We recommend adding at least 20 KHz between the ending frequency of one band and the starting frequency of the next band, to ensure that the bands do not overlap.

Guided and Scheduled Spectrum Management

Guided and scheduled spectrum management constitutes a set of basic features for all currently supported cable interface line cards. These features are considered basic because they are available for all cable interfaces, and constitute the elementary, cornerstone features upon which the intelligent and advanced spectrum management features are built.

See the following sections for more information about each feature:

Frequency Hopping Capabilities

Noise in the upstream transmission line, that is from the consumer to the service provider, can degrade data transmission from the subscriber's home. If the noise impairment is of substantial duration, it may cause the cable modem to temporarily lose communication with the headend facility. As a contingency plan, the multiple service operators (MSOs) can reserve multiple channels or upstream frequencies for their subscribers. If one channel suffers too much interference, the CMTS requests that the cable modems "hop" to another channel.

To provide frequency hopping capability, Cisco CMTS routers contain a spectrum manager that continuously monitors the noise in unused upstream channels. If the CNR (CNI_R) reaches an unacceptable level on a particular channel, the spectrum manager automatically assigns a new upstream channel to the cable modem using that channel.

Cisco CMTS routers support the following techniques for upstream frequency hopping when the frequency band in use is not clean:

- Guided frequency hopping—In guided frequency hopping (also known as blind hopping), the spectrum manager automatically assigns a new upstream channel frequency when a configurable threshold of station maintenance (keepalive) messages fails. Failed station maintenance messages represent an impairment of the upstream channel due to noise, plant, or equipment failure. Explicit frequency subbands and associated input power levels are assigned in a spectrum group in guided frequency hopping.
- Time-scheduled frequency hopping—Frequency reassignment is scheduled by the time of day or by a specific day of the week.
- Combined guided and time-scheduled frequency hopping.

Note Frequency hopping is not effective against broadband noise phenomena such as impulse noise.

Time-scheduled and guided hopping techniques are independent concepts:

- The spectrum is controlled by a script, not a frequency table.
- The available spectrum is time-scheduled as an option.
- A guided hopping frequency is selected from the available spectrum at the current time.

You can configure and activate frequency hopping by using spectrum groups. You can create up to 40 cable spectrum groups, each containing multiple upstream ports. The configured channel width is used for each upstream frequency.

After you have created one or more spectrum groups for your cable network, you can add characteristics to them, providing you with more definitive control over frequency usage and frequency hopping.

You can configure hopping thresholds. For example, the frequency hop threshold percentage method prevents a single failing cable modem from affecting service to other working cable modems. As long as a high enough threshold is configured, the system does not hop endlessly due to a single cable modem failing to respond to 90 percent of its station maintenance (keepalive) messages.

You can also configure the minimum period between frequency hops, with a default setting of 30 seconds. If the destination channel is expected to be impaired, you can reduce the minimum period between frequency hops to a small value, such as 10 seconds. This allows the frequency hop to continue more rapidly until a clear channel is found. If excessive frequency hop is an issue, you can increase the minimum period between hops.

To configure different techniques of frequency hopping, see the [Creating and Configuring Spectrum Groups, on page 425](#).

Note Spectrum management is not supported for one-way (telco return) cable modems, because spectrum management capabilities focus on the upstream path over an HFC network.

Note After the spectrum-band is changed, the spectrum management does not rearrange the frequency for each US channel if the previous frequency belongs to the range of new spectrum-band, which means that the US frequency will not be changed; if the previous frequency is out of range of new spectrum-band, those US channels will not get frequencies.

Time-Scheduled Frequency Hopping

You can specify upstream channel frequency reassignment based on a configured time of every day or of a specific day of the week. If your cable plant has an upstream noise characteristic on a weekly cycle, use time-scheduled spectrum allocation. With a time-scheduled policy, a single frequency becomes valid at any given time.

Dynamic Upstream Modulation (MER [SNR]-Based)

This section describes the operation of this feature, which is based on evaluating the MER (SNR) of an upstream.

Note A more advanced version of dynamic upstream modulation, which uses the carrier-to-noise ratio (CNR [CNiR]), is supported on the cards that support intelligent and advanced spectrum management.

Feature Overview

Cisco cable interface line cards monitor the MER (SNR) values and the forward error correction (FEC) counters in the active return path of each upstream port. The Dynamic Upstream Modulation feature determines whether upstream channel signal quality can support the modulation scheme configured, and adjusts to the most robust modulation scheme when necessary. When return path conditions improve, this feature returns the upstream channel to the higher modulation scheme that includes the modulation profile.

A modulation profile is a collection of burst profiles that are sent out in a UCD message to configure modem transmit parameters for the upstream. The Dynamic Upstream Modulation feature adjusts the modulation profiles of an upstream channel based on upstream signal quality.

The Dynamic Upstream Modulation feature is configured on interfaces with fixed upstream frequencies or on interfaces with assigned spectrum groups.

The following examples show two different configurations of the Dynamic Upstream Modulation feature, using two and three modulation profiles.

Example Showing Dynamic Upstream Modulation Using Two Modulation Profiles

You can configure the Dynamic Upstream Modulation feature on the Cisco CMTS router using the following primary and secondary modulation profiles:

- The primary modulation profile uses 64-QAM or 16-QAM, which is a more bandwidth-efficient modulation scheme and has a higher throughput than a QPSK profile.
- The secondary modulation profile uses QPSK, which uses a more robust modulation scheme, but is not bandwidth-efficient.

We recommend that the primary profile use 64-QAM or 16-QAM modulation and the secondary use QPSK. However, this is optional as both modulation profiles can either be QPSK or QAM. It is not mandatory for one profile to be QAM and the other QPSK, but modulation profile switchover is tied to the QAM and QPSK thresholds.

Example Showing Dynamic Upstream Modulation Using Three Modulation Profiles

You can configure the Dynamic Upstream Modulation feature on the Cisco CMTS router using the following primary, secondary, and tertiary modulation profiles:

- The primary modulation profile uses 64-QAM, which is a more bandwidth-efficient modulation scheme and has a higher throughput than a 16-QAM profile.
- The secondary modulation profile uses 16-QAM, which is a more bandwidth-efficient modulation scheme and has a higher throughput than a QPSK profile.
- The tertiary modulation profile uses QPSK, which uses a more robust modulation scheme, but is not bandwidth-efficient.

We recommend that the primary profile use 64-QAM modulation, the secondary profile use 16-QAM, and the tertiary profile uses QPSK. However, this is optional as the modulation profiles can either be QPSK or QAM. It is not mandatory that one is QPSK and the other two are QAM, but modulation profile switchover is tied to the QAM and QPSK thresholds.

Criteria for Switching Modulation Profiles

The Dynamic Upstream Modulation feature uses the following criteria to determine whether it should switch from the primary modulation profile (the more bandwidth-efficient, but less robust profile) to the secondary modulation profile (more robust, but less bandwidth-efficient profile) or to the (optional) tertiary modulation profile (most robust, but less bandwidth-efficient profile):

The modulation switch from the primary profile (high performance) to the secondary profile (mid-level performance) uses the following criteria:

- The upstream MER (SNR) is less than or equal to MER (SNR) threshold one and the percentage of correctable FEC (cFEC) errors is greater than or equal to the correctable FEC error threshold or the percentage of uncorrectable FEC (uFEC) errors is greater than or equal to the uncorrectable FEC error threshold.

Before switching back to the primary profile from the secondary profile, the following criteria must be satisfied:

- The upstream MER (SNR) is greater than or equal to the sum of MER (SNR) threshold one and the hysteresis value and the percentage of correctable FEC errors is less than or equal to the correctable FEC error threshold and the percentage of uncorrectable FEC errors is less than or equal to the uncorrectable FEC error threshold and the hop period equals to the default value of 15 seconds.

The modulation switch from the secondary profile (mid-level performance) to the tertiary profile (most robust) uses the following criteria:

- The upstream MER (SNR) is less than or equal to MER (SNR) threshold two and the percentage of correctable FEC (cFEC) errors is greater than or equal to the correctable FEC error threshold or the percentage of uncorrectable FEC (uFEC) errors is greater than or equal to the uncorrectable FEC error threshold.

Before switching back to the secondary profile from the tertiary profile, the following criteria must be satisfied:

- The upstream MER (SNR) is greater than or equal to the sum of MER (SNR) threshold two and the hysteresis value and the percentage of correctable FEC errors is less than or equal to the correctable FEC error threshold and the percentage of uncorrectable FEC errors is less than or equal to the uncorrectable FEC error threshold.

The modulation switch from the primary profile to the tertiary profile uses the following criteria:

- The upstream MER (SNR) is less than or equal to MER (SNR) threshold two and the percentage of correctable FEC (cFEC) errors is greater than or equal to the correctable FEC error threshold or the percentage of uncorrectable FEC (uFEC) errors is greater than or equal to the uncorrectable FEC error threshold.

Before switching back to the primary profile from the tertiary profile, the following criteria must be satisfied:

- The modulation switch from the tertiary profile to the primary profile is a two-step process:
 1. The modulation switch happens from tertiary profile to the primary profile, when the upstream MER (SNR) is greater than or equal to the sum of MER (SNR) threshold one and the hysteresis value.
 2. After a 15-second (non-configurable) delay, the modulation switch occurs from secondary profile to the primary profile, when the upstream MER (SNR) remains greater than or equal to the sum of MER (SNR) threshold one and the hysteresis value.

If the only problem is that the upstream is experiencing a large number of uncorrectable errors, then a situation could occur where the router continues to switch back and forth between profiles. The uncorrectable errors occur with the primary profile, so the router switches to the secondary profile. The secondary profile does not experience any problems, so the router switches back to the primary profile. But the uncorrectable errors reoccur and the router switches back to the secondary profile, and this cycle continues indefinitely.

To avoid this problem, make sure that the cable plant is capable of supporting the modulation scheme being used in the primary profile (for example, 64-QAM). If you cannot guarantee successful operation on an upstream using this modulation scheme, then you should select a primary profile that uses a more bandwidth-efficient set of burst parameters (such as QPSK). The Cisco IOS software includes predefined modulation profiles that can be used for the primary, secondary, and tertiary profiles.

Input Power Levels

The input power level, *power-level-dBmV*, is an option in the **cable spectrum-group** command. The option allows you to specify the expected upstream input power levels on the upstream receivers on the CMTS when the cable modems are hopping from one fixed frequency to another or from one band to another. Each upstream channel width has an associated upstream input power level in dBmV. The power level is the modem transmit power that each spectrum group can use when an upstream frequency change is necessary. The input power level may be set at the time of the frequency hop.

Specifying an input power level is done so that the cable modems do not have to increase or decrease their transmit power with every hop. The cable operator can perform minor power equalizations as a function of frequency. The valid range is -10 to 10dBmV. The power level value should be changed only if you want to change the power level as part of spectrum management. Some cable plants may want to change only the input power level, and not the frequency, on a daily time schedule.

Intelligent and Advanced Hardware-Based Spectrum Management

Several cable interface line cards include hardware-based spectrum management features that provide enhancements to the basic features supported by the other Cisco cable interface line cards.

Intelligent Spectrum Management Enhancements

The following features are part of the intelligent spectrum management feature set:

- Integrates a DOCSIS cable interface line card with an onboard spectrum analyzer that continuously analyzes the upstream spectrum quality in the DOCSIS frequency range of 5 to 42 MHz.
- Includes hardware-assisted frequency hopping, providing for more intelligent and faster frequency selection than software-only solutions.
- Reduces the response time to ingress noise that could cause modems to drop offline.
- Eliminates blind frequency hopping by initiating frequency hops to known clean channels.
- Improves frequency agility to help eliminate dropped packets and thereby maintain full upstream data rates.
- Supports frequency agility in dense-mode combining environments across a shared spectrum.
- Restricts frequency hopping to a set of discrete fixed frequencies or to a range of frequencies, as desired.
- Allows frequency hop conditions to be customized for specific plant environments and requirements.
- Optionally schedules frequency hops to take advantage of known usage patterns or plant conditions.
- Optionally dynamically reduces channel width to allow cable modems to remain online, even in noisy upstream conditions.

Benefits

The spectrum management features provided on the Cisco CMTS router platforms provide several key system benefits:

- Improves response time to ingress noise impairments that appear in the upstream return path.
- Boosts the percentage of modems online.
- Mitigates the impact of ingress to subscriber services.
- Saves time and effort by MSO staff when troubleshooting minor plant outages.
- Increases cable plant reliability.
- Maximizes spectrum utilization.

Guided and Scheduled Spectrum Management Benefits

The following summarizes the specific benefits of the guided and scheduled spectrum management features that are supported for all Cisco CMTS router platforms.

Input Power Levels

Allows the cable plant operator to perform minor power level equalization as a function of frequency.

Frequency Hopping Capabilities

Proactively countermeasures upstream noise impairments by assigning a new upstream channel to the cable modem. MSOs can take advantage of this feature especially when they have less than an optimal carrier-to-noise ratio in the upstream frequencies or when their cable plants exhibit random bursts of ingress noise that affect reliability.

Dynamic Upstream Modulation

- Reduces the risk associated with transitioning to QAM-16 modulation in the return path and provides assurance that subscribers remain online and connected during return path impairments.
- Checks that the active upstream signal quality can support the configured modulation scheme and proactively adjusts to the more robust modulation scheme when necessary.
- Eliminates the necessity to hop channels for cable modems to stay online by automatically switching from the primary modulation profile to the secondary modulation profile.

Intelligent and Advanced Spectrum Management Benefits

The following summarizes the specific benefits of the advanced spectrum management features that are supported on Cisco CMTS routers using supported cable interface line cards.

Dynamic Channel Width Change

- Improves the DOCSIS upstream channel availability by finding the maximum possible channel width for an upstream when noise conditions make the current channel width unusable.
- Provides the maximum RF spectrum utilization efficiency for current plant conditions.
- Customizable range of channel widths that can be used to respond to noise problems.

Intelligent Frequency Hopping

- Proactively changes upstream frequency for an interface before noise conditions become severe enough to force cable modems offline.
- Dedicated hardware intelligent frequency hopping performs “look-ahead” to choose new upstream frequency to find a stable channel.
- Flexible priority configuration allows hopping decision criteria to be tailored to the individual cable plant environment.
- Improves responsiveness to ingress impairments, by matching the hopping decision criteria to the fluctuating plant conditions.
- Pinpoints CNR (CNiR) variations with per-modem accuracy to isolate problematic cable modems.
- Sustains or even improves subscriber online percentages through user-programmable proactive channel management techniques.

Dynamic Upstream Modulation

- Reduces the risk associated with switching between QPSK and QAM-16 modulation in the upstream to respond to ingress noise, so that subscribers remain online and connected.
- Checks the current upstream signal to ensure that it can support the configured modulation scheme, and proactively adjusts to the secondary more robust modulation scheme when necessary.
- Improves DOCSIS upstream channel availability and provides maximum RF spectrum utilization efficiency.
- Eliminates unnecessary frequency hopping by switching modulation profiles to one that allows cable modems to remain online while using the currently assigned upstream.
- Provides assurance that subscribers remain online and connected during periods of return path impairments.

SNMP Interface

- Provides a way to remotely obtain the current status of noise on an upstream. This information can then be inserted into third-party or custom reporting and graphing applications.
- Provides visibility to ingress and impulse noise under the carrier frequency on a per-port basis.
- Provides an easy-to-use, distributed method to remotely gather real-time display of the DOCSIS upstream spectrum for individual cable modems and set-top boxes (STBs).
- Reduces the reliance on costly spectrum analyzers at every headend or hub.
- Quickly provides spectrum views through an intuitive interface, without the complicated setup time of a spectrum analyzer.
- Allows the technician to troubleshoot the network remotely, as opposed to having to be physically present to connect and use a spectrum analyzer.

Default Hop Priority

For Intelligent and Advanced Spectrum Management feature, the default hop priority is as given below:

- Frequency, modulation, and channel width (when using spectrum groups on spectrum cards).
- Modulation, guided frequency hop, and channel width (when using analyzer cards with spectrum groups).
- Modulation only (when not using spectrum groups [fixed frequency]).

How to Configure Spectrum Management

This section describes the configuration tasks that are most commonly performed when using the spectrum management features on the Cisco CMTS platforms. See the following sections for the configuration tasks that are appropriate for your platform and cable interface line cards.

Guided and Scheduled Spectrum Management Configuration Tasks

The following tasks configure the guided and scheduled spectrum management features that are supported on all Cisco CMTS platforms:

Creating and Configuring Spectrum Groups

A spectrum group defines the frequencies that an upstream is allowed to use when frequency hopping is done, as well as other parameters that control the frequency hops. When creating and configuring spectrum groups, you can specify the following parameters:

- Frequencies that are assigned to the group. The cable interface uses these frequencies to determine what frequencies are available to use when frequency hopping is needed. You can specify either a list of fixed frequencies or a band of frequencies, or both. The Cisco CMTS uses the following rules when adding frequencies to a spectrum group:
 - When specifying a fixed frequency, the Cisco CMTS assumes it is a center frequency with a 6.4-MHz channel width to allow that frequency to operate at all possible channel widths. For example, specifying a frequency of 17,700,000 Hz is equivalent to specifying a frequency band from 14,500,000 Hz to 20,900,000 Hz (a band that is 6.4 MHz wide).
 - If you configure multiple fixed frequencies or bands of frequencies that overlap, the spectrum group combines them into one band. For example, if you specify a fixed frequency of 17,700,000 Hz and a band from 15,800,000 Hz to 25,200,000 Hz, the spectrum group is configured with one band from 14,500,000 Hz to 25,200,00 Hz.
 - If you want more control over a spectrum group's frequencies, configure bands of frequencies with the same width as the desired channel width. For example, if you want to use a center frequency of 17,700,000 Hz with a 3.2-MHz channel width, specify a band that ranges from 16,100,000 Hz to 19,300,000 Hz. To ensure you configure non-overlapping bands, separate the bands by a minimum of 20 KHz.
- Upstream input power level—(Optional) Power level, in dBmV, that the upstream should use when hopping to a new frequency. (Some cable plants might want to change only the input power level, and not the frequency, on a daily time schedule.)
- Hop threshold—(Optional) Percentage of cable modems that start missing station maintenance messages before a frequency hop can occur. Configure the hop threshold percentage as needed to prevent a single failing cable interface from affecting service to other good cable interfaces. This ensures that the system does not hop endlessly because one cable modem is generating 90 percent of the errors and 90 percent of the traffic.
- Hop period—(Optional) Minimum time period that must elapse between frequency hops. This allows you to specify a time period long enough to allow an upstream to stabilize before another frequency hop can be performed.
- Scheduled hop time—(Optional) Time of day at which a frequency hop should be scheduled.

Tip Before adding a list of upstream frequencies (or frequency hop tables), start by determining which upstream ports are assigned to a combiner group. Refer to the [Example: Determining the Upstream Ports Assigned to a Combiner Group, on page 448](#) for an example.

To create and configure a spectrum group, use the following procedure.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable spectrum-group <i>group-number</i> time [<i>day hh:mm:ss</i>] frequency <i>up-freq-Hz</i> [<i>power-level-dBmV</i>] Example: Router(config)# cable spectrum-group 4 time Monday 12:00:00 frequency 40000000	Creates the spectrum group (if it does not already exist), and adds the specified fixed frequency to the group.
Step 4	cable spectrum-group <i>group-number</i> time [<i>day hh:mm:ss</i>] band <i>up-freq-Hz up-freq2-Hz</i> [<i>power-level-dBmV</i>] Example: Router(config)# cable spectrum-group 4 band 20000000 24000000 13	Creates the spectrum group (if it does not already exist), and adds the specified band of frequencies to the group. Note Repeat Step 4 and Step 6 as needed for each fixed frequency and frequency band that should be a member of this spectrum group. You must assign at least two fixed frequencies, or a frequency band that contains at least two center frequencies, to a spectrum group before frequency hopping can occur.
Step 5	cable spectrum-group <i>group-number</i> hop period <i>seconds</i> Example: Router(config)# cable spectrum-group 4 hop period 60	Specifies the minimum time, in seconds, between frequency hops. Note We recommend a configuration of 30 seconds when using a Cisco uBR-MC5X20S/U/H BPE.
Step 6	cable spectrum-group <i>group-number</i> hop threshold [<i>percent</i>] Example: Router(config)# cable spectrum-group 4 hop threshold 25	Specifies the frequency hop threshold for a spectrum group. • percent —(Optional) Frequency hop threshold as a percentage of station maintenance messages that are lost. Valid range is from 1 to 100 percent, with a default of 50 percent.
Step 7	cable spectrum-group <i>group-number</i> Example: Router(config)# cable spectrum-group 4	(Optional) Specifies that the upstream ports in a spectrum group should use a unique upstream frequency.

	Command or Action	Purpose
Step 8	end Example: Router(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Assigning a Spectrum Group to One or More Upstream Ports

After a spectrum group has been created and configured, you must assign it to one or more upstream ports before the group's frequency spectrum is used for frequency hopping.

To assign a spectrum group to one or all upstream ports on a controller interface, use the following procedure.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	controller upstream-cable <i>slot/subslot/port</i> Example: Router(config)# controller upstream-cable 9/0/15	Enters controller configuration mode.
Step 4	us-channel <i>us -channel_num</i> spectrum-group <i>spectrum-group-num</i> Example: Router(config-controller)# us-channel 0 spectrum-group 1	Assigns the specified spectrum group as the default group for all upstream on this controller interface.
Step 5	us-channel <i>us -channel_num</i> channel-width <i>value</i> Example: Router(config-controller)# us-channel 0 channel-width 1600000	Configures the channel-width for the specified upstream channel spectrum group.
Step 6	end Example: Router(config-controller)# end	Exits controller interface configuration mode and returns to privileged EXEC mode.

What to do next

Tip To verify the spectrum group configuration, use the **show cable spectrum-group** command in privileged EXEC mode.

Configuring Shared Spectrum Groups (Fiber Node Groups) for DOCSIS 3.0

This feature supports shared spectrum groups that cross multiple cable interface line cards on the Cisco CMTS router, and shared spectrum groups within a single cable interface line card.

For additional information about configuring fiber node groups on the Cisco CMTS, see:

- http://www.cisco.com/c/en/us/td/docs/cable/cbr/configuration/guide/b_cbr_layer2_docsis/spectrum_management.html#task_1044164
- http://www.cisco.com/c/en/us/td/docs/cable/cbr/configuration/guide/b_cbr_layer2_docsis/spectrum_management.html#task_4BF4590BA65D4CF1851A4DA0C8A9ADB2

Configuring Dynamic Upstream Modulation (MER [SNR]-Based)

To use the Dynamic Upstream Modulation feature on cable interface line cards that support only the MER (SNR) version of this feature, you must do the following:

1. Create a primary modulation profile. This typically is a more bandwidth-efficient but a less robust profile.
2. Optionally create a secondary modulation profile. This typically is a less bandwidth-efficient but a moderately robust profile.
3. Optionally create a tertiary modulation profile. This typically is a less bandwidth-efficient but a more robust profile.
4. Assign the profiles to the desired cable interfaces and upstreams.

Tip When creating the modulation profiles, we recommend that you use the predefined modulation profiles, as opposed to manually specifying each burst parameter for each modulation profile.

**Restriction**

- The Dynamic Upstream Modulation feature is supported only for DOCSIS 1.0 or DOCSIS 1.1 TDMA-only modulation profiles for advanced spectrum management.
- The DOCSIS 2.0 mixed-mode or ATDMA-only mode modulation profiles are supported only for basic spectrum management (MER [SNR]-based) and not for advanced spectrum management.
- The Three Step Dynamic Modulation feature supports only basic spectrum management features. It does not support modulation profile changes based on CNR (CNiR) thresholds and CNR (CNiR) measurements.
- The Dynamic Upstream Modulation feature is not enabled for single modulation profile configurations.
- You can configure only two modulation profiles when an upstream is already assigned to a spectrum group for frequency hopping. The spectrum group here implies advanced spectrum management and/or the use of CNR (CNiR).
- A single profile is automatically removed from the configuration if three modulation profiles are assigned to an upstream interface before assigning spectrum group, based on the following conditions:
 - The robust profile is dropped if the upstream port is using a high performance profile.
 - The high performance profile is dropped if the upstream port is using a mid-level or robust profile.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable modulation-profile profile {mixed tdma atdma} Example: Router(config)# cable modulation-profile 3 mixed	Creates the primary modulation profile for use on a DOCSIS 1.0 or DOCSIS 1.1 TDMA or A-TDMA upstream. Note Repeat this command to create the secondary and tertiary profile for use on a DOCSIS 1.0 or DOCSIS 1.1 TDMA or A-TDMA upstream.

	Command or Action	Purpose
		<p>Note You can also create custom modulation profiles with the cable modulation-profile command by configuring the values for the individual burst parameters. These parameters, however, should not be modified unless you are thoroughly familiar with how changing each parameter affects the DOCSIS MAC layer. We recommend using the preconfigured default modulation profiles for most cable plants.</p>
Step 4	<p>controller upstream-cable <i>slot/subslot/port</i></p> <p>Example:</p> <pre>Router(config)# controller upstream-cable 9/0/15</pre>	Enters controller configuration mode.
Step 5	<p>us-channel <i>n modulation-profile primary-profile-number [secondary-profile-number] [tertiary-profile-number]</i></p> <p>Example:</p> <pre>Router(config-controller)# us-channel 0 modulation-profile 21 121 221</pre>	Assigns a primary modulation profile, and the optional secondary and tertiary modulation profiles, to the specified upstream port.
Step 6	<p>Use one of the following commands:</p> <ul style="list-style-type: none"> • us-channel <i>n threshold snr-profiles threshold1-in-db threshold2-in-db</i> • us-channel <i>n m threshold snr-profiles threshold1-in-db threshold2-in-db</i> <p>Example:</p> <pre>Router(config-controller)# us-channel 0 threshold snr-profiles 25 15</pre>	(Optional) Specifies the MER (SNR) threshold in dB.
Step 7	<p>Use one of the following commands:</p> <ul style="list-style-type: none"> • us-channel <i>n threshold corr-fec corr-fec</i> • us-channel <i>n m threshold corr-fec corr-fec</i> <p>Example:</p> <pre>Router(config-controller)# us-channel 0 threshold corr-fec 20</pre>	(Optional) Specifies the allowable number of correctable FEC errors for the upstream.
Step 8	<p>Use one of the following commands:</p> <ul style="list-style-type: none"> • us-channel <i>n threshold uncorr-fec uncorr-fec</i> • us-channel <i>n m threshold uncorr-fec uncorr-fec</i> <p>Example:</p> <pre>Router(config-controller)# us-channel 0 threshold uncorr-fec 10</pre>	(Optional) Specifies the allowable number of uncorrectable FEC errors for the upstream.

	Command or Action	Purpose
Step 9	us-channel <i>n</i> threshold hysteresis <i>hysteresis-in-db</i> Example: <pre>Router(config-controller)# us-channel 0 threshold hysteresis 10</pre>	(Optional) Specifies the hysteresis value to be used in conjunction with the dynamic modulation upgrade thresholds.
Step 10	end Example: <pre>Router(config-controller)# end</pre>	Exits controller interface configuration mode and returns to privileged EXEC mode.

What to do next

Tip See the [Dynamic Upstream Modulation \(MER \[SNR\]-Based\), on page 419](#) for a complete description of the Dynamic Upstream Modulation feature.

Verifying Frequency Hopping

You can verify frequency hopping on the CMTS by using the command-line interface (CLI).

Verifying Frequency Hopping Using CLI Commands

To verify frequency hopping using CLI commands, use the following procedure:

Step 1 Verify that the interface being tested is up, using the **show interfaces cable** command in privileged EXEC mode. The first line of the output shows whether both the interface and line protocol are up.

Example:

```
Router# show interfaces cable 9/0/0

Hardware is CMTS MD interface, address is c414.3c16.cf8f (bia c414.3c16.cf8f)
MTU 1500 bytes, BW 26000 Kbit/sec, DLY 1000 usec,
reliability 255/255, txload 1/255, rxload 1/255
Encapsulation MCNS, loopback not set
```

Step 2 Verify that the upstream being tested is up, using the **show interfaces cable upstream** command. The first line shows whether the upstream is up.

Example:

```
Router# show interfaces cable 9/0/0 upstream 0

MAC domain upstream impairment report: 0x0
Cable9/0/0: Upstream 0 is up
Description: UC9/0/0:U0
Received 5 broadcasts, 0 multicasts, 26 unicasts
0 discards, 0 errors, 0 unknown protocol
31 packets input
Codewords: 348 good 0 corrected 0 uncorrectable
```

Step 3 Use the **show cable hop upstream-cable** command to display the frequency that the upstream is currently using:

Example:

```
Router# show cable hop upstream-cable 9/0/0

Upstream   Port      Poll Missed Min      Missed Hop   Hop   Corr   Uncorr
Port       Status    Rate Poll  Poll    Poll   Thres Period FEC    FEC
          (ms) Count  Sample Pcnt   Pcnt   (sec) Errors Errors
Cable6/0/U5 16.816 Mhz 1000 0      10      0%    20%   25    0      0
```

Step 4 Use the **show cable hop upstream-cable history** command to display the frequency change, modulation change, and channel width change action history of the upstreams:

Example:

```
Router# show cable hop upstream-cable 9/0/0 history

F = Frequency Hop, M = Modulation Change, C = Channel Width Change
Upstream   Action          Chg   Chg   Action
Port       Time           Code From  To    Reason
Ca7/0/0/U0 Sep 17 17:00:24 C  1.6   3.2   Configuration changed
Sep 14 19:38:55 F  41.117 26.358 Interface state changed
Sep 14 19:38:55 F  0.000 41.117 Interface state changed
Sep 14 19:38:24 M  21     221   Configuration changed
```

Step 5 Use the **show cable hop upstream-cable threshold** command to display the user-defined thresholds and current CNR, MER (SNR), correctable FEC percentage, uncorrectable FEC percentage, and missed station maintenance percentage values of the upstreams:

Example:

```
Router# show cable hop upstream-cable 6/0/0 threshold

Upstream   SNR(dB)          CNR(dB)          CorrFEC%  UncorrFEC%      MissedSM%
Port       Val Thre1 Thre2 Val Thre1 Thre2 Pcnt Thre Pcnt Thre Pcnt Thre
Ca6/0/0/U0 27  25  15  39  35  25  0  3  0  1  75  75
Ca6/0/0/U1 31  25  15  51  35  25  0  3  0  1  90  75
Ca6/0/0/U2 --  35  25  --  35  25  0  3  0  1  0  75
Ca6/0/0/U3 --  35  25  --  35  25  0  3  0  1  0  75
```

Step 6 Use the **test cable hop** command to force the desired upstream to perform a frequency hop. A few seconds after giving the command, a console message should appear informing you of the hop. Repeat the command as needed to verify that the upstream hops through all the frequencies that have been assigned to the upstream's spectrum group.

Example:

```
Router# test cable hop cable 6/0 upstream 5

2w0d: %UBR7200-5-USFREQCHG: Interface Cable6/0 Port U5, frequency changed to 15.760 MHz

Router# test cable hop cable 6/0 upstream 5

2w0d: %UBR7200-5-USFREQCHG: Interface Cable6/0 Port U5, frequency changed to 26.832 MHz
```

- Step 7** Use the **test cable channel-width** command to force the desired upstream to perform a channel-width change. A few seconds after giving the test command, use the **show cable hop** command to verify the channel-width change.

Example:

```
Router# test cable channel-width cable 7/0/0 upstream 0

Channel width changed to 1600000 Hz for Cable7/0/0 U0

Router# *Sep 17 17:06:46.882: %UBR10000-5-USCWCHG: Interface Cable7/0/0 U0, channel width changed to
1600 kHz SLOT 7/0: Sep 17 17:06:46.898: %UBR10000-5-USCWCHG: Interface Cable7/0/0 U0, channel width
changed to 1600 kHz

Router# Sep 17 17:06:46.898: %Interface Cable7/0/0 U0 With channel width 1600 kHz, the minislots size
is now changed to 4 ticks.

Router# show cable hop cable 7/0/0 upstream 0 history

F = Frequency Hop, M = Modulation Change, C = Channel Width Change
Upstream      Action          Chg   Chg   Action
Port          Time           Code From To     Reason
Ca7/0/0/U0    Sep 17 17:06:46 C   3.2   1.6   Test command enforced
              Sep 17 17:06:02 M   222   221   SNR 36>=28 CFEC 0<=3 UnCFEC 0<=1
              Sep 17 17:06:00 M   221   222   Test command enforced
              Sep 17 17:03:21 M   222   221   SNR 36>=28 CFEC 0<=3 UnCFEC 0<=1
              Sep 17 17:03:19 M   221   222   Test command enforced
              Sep 17 17:01:44 F   26.358 19.742 Test command enforced
              Sep 17 17:01:17 F   21.528 26.358 Test command enforced
              Sep 17 17:00:24 C   1.6     3.2   Configuration changed
              Sep 14 19:38:55 F   41.117 21.528 Interface state changed
              Sep 14 19:38:55 F   0.000 41.117 Interface state changed
              Sep 14 19:38:24 M   21     221   Configuration changed

Router#
```

- Step 8** Use the **test cable freq-hop** command to force the desired upstream to perform a dynamic frequency change. A few seconds after giving the test command, use the **show cable hop** command to verify the frequency change.

Example:

```
Router# test cable freq-hop cable 7/0/0 upstream 0

SLOT 7/0: Sep 17 17:01:44.650: %UBR10000-5-USFREQCHG: Interface Cable7/0/0 U0, changed to Freq 19.742
MHz

Router# show cable hop cable 7/0/0 upstream 0 history

F = Frequency Hop, M = Modulation Change, C = Channel Width Change
Upstream      Action          Chg   Chg   Action
Port          Time           Code From To     Reason
Ca7/0/0/U0    Sep 17 17:01:44 F   26.358 19.742 Test command enforced
              Sep 17 17:00:24 C   1.6     3.2   Configuration changed
              Sep 14 19:38:55 F   41.117 26.358 Interface state changed
              Sep 14 19:38:55 F   0.000 41.117 Interface state changed
              Sep 14 19:38:24 M   21     221   Configuration changed
```

- Step 9** Use the **test cable modulation-change** command to force the desired upstream to perform a dynamic modulation change. A few seconds after giving the test command, use the **show cable hop** command to verify the modulation change.

Example:

```
Router# test cable modulation-change cable 7/0/0 upstream 0

SLOT 7/0: Sep 17 17:03:19.038: %UBR10000-5-USMODCHANGE: Interface Cable7/0/0 U0, dynamic modulation
  changed to QPSK
SLOT 7/0: Sep 17 17:03:19.038: %UBR10000-6-PREAMLENADJUST: request burst's preamble length in mod
  profile 222 is adjusted to 38 bits.
SLOT 7/0: Sep 17 17:03:19.038: %UBR10000-6-PREAMLENADJUST: initial burst's preamble length in mod
  profile 222 is adjusted to 100 bits.
SLOT 7/0: Sep 17 17:03:19.038: %UBR10000-6-PREAMLENADJUST: station burst's preamble length in mod
  profile 222 is adjusted to 100 bits.
```

```
Router# show cable hop cable 7/0/0 upstream 0 history
```

```
F = Frequency Hop, M = Modulation Change, C = Channel Width Change
Upstream      Action          Chg   Chg   Action
Port          Time           Code  From  To    Reason
Ca7/0/0/U0   Sep 17 17:03:19 M   221   222   Test command enforced
              Sep 17 17:01:44 F   26.358 19.742 Test command enforced
              Sep 17 17:01:17 F   21.528 26.358 Test command enforced
              Sep 17 17:00:24 C    1.6    3.2   Configuration changed
              Sep 14 19:38:55 F   41.117 21.528 Interface state changed
              Sep 14 19:38:55 F    0.000 41.117 Interface state changed
              Sep 14 19:38:24 M    21     221   Configuration changed
```

Troubleshooting Spectrum Group Characteristics

To troubleshoot the configuration, make sure that you entered a valid spectrum group number, time, frequency, and input power level. Also, when defining your spectrum, use the following guidelines:

- Avoid frequencies with known ingress problems, such as amateur radio bands or short-wave bands.
- Avoid a hostile spectrum below 20 MHz.
- Allow extra bands for frequency hopping.
- Place upstream ports in the same combiner group in a shared spectrum group.
- Use the receive power level setting to perform slight equalization adjustments.

Intelligent and Advanced Spectrum Management Configuration Tasks

The following sections describe the configuration tasks that are needed to configure a Cisco uBR7200 series or Cisco uBR10012 universal broadband router for the intelligent and advanced spectrum management features that are available with the Cisco cable interface line cards.

Configuring and Assigning Spectrum Groups

You must create and configure a spectrum group before you can use the intelligent and advanced spectrum management features. These procedures are the same as those used for guided and scheduled spectrum management, which are given in the following sections:

- http://www.cisco.com/c/en/us/td/docs/cable/cbr/configuration/guide/b_cbr_layer2_docsis/spectrum_management.html#task_1044164

- http://www.cisco.com/c/en/us/td/docs/cable/cbr/configuration/guide/b_cbr_layer2_docsis/spectrum_management.html#task_4BF4590BA65D4CF1851A4DA0C8A9ADB2

After the spectrum groups have been configured and assigned to upstreams, the Cisco IOS software automatically uses the advanced frequency hopping algorithms on the cable interface line cards that support it.

Note For efficient use of the intelligent and advanced spectrum management features, we recommend configuring only frequency bands, and not fixed frequencies, when creating spectrum groups. A spectrum group must contain a frequency band that is wide enough for the cable interface to find at least two center frequencies at the configured channel width, before frequency hopping can occur.

Configuring Dynamic Upstream Modulation (CNR-Based)

Configuring the CNR-based version of the Dynamic Upstream Modulation feature is similar to configuring the MER (SNR)-version of this feature:

1. Create a primary modulation profile. This typically is a more bandwidth-efficient but a less robust profile.
2. Create a secondary modulation profile. This typically is a less bandwidth-efficient but a more robust profile.

Tip When creating the modulation profiles, we recommend that you use the predefined modulation profiles, as opposed to manually specifying each burst parameter for each modulation profile.

3. Assign the profiles to the desired cable interfaces and upstreams.

After the modulation profiles have been created and assigned to upstreams, the Cisco IOS software automatically uses the advanced CNR-based version of the Dynamic Upstream Modulation feature on the cable interface line cards that support it.

Restriction

- The Dynamic Upstream Modulation feature is supported only for DOCSIS 1.0 or DOCSIS 1.1 TDMA-only modulation profiles. It is not supported for DOCSIS 2.0 mixed-mode or A-TDMA-only mode modulation profiles.
- Three Step Dynamic Modulation is not supported on the CNR-based version of dynamic upstream modulation.
- The CNR-based Dynamic Upstream Modulation feature does not support A-TDMA modulation profiles. However, A-TDMA is supported in the MER (SNR)-based Dynamic Upstream Modulation feature.

To assign the primary and secondary profiles to an upstream, use the following procedure.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	cable modulation-profile <i>profile</i> { mix qam-16 qpsk robust-mix } Example: Router(config)# cable modulation-profile 3 mix	Creates the primary modulation profile for use on a DOCSIS 1.0 or DOCSIS 1.1 TDMA upstream. Typically, the primary profile is either qam-16 or mix . Note Repeat this command to create the secondary profile for use on a DOCSIS 1.0 or DOCSIS 1.1 TDMA upstream. Typically, the secondary profile is either robust-mix or qpsk . Note You can also create custom modulation profiles with the cable modulation-profile command by configuring the values for the individual burst parameters. These parameters, however, should not be modified unless you are thoroughly familiar with how changing each parameter affects the DOCSIS MAC layer. We recommend using the preconfigured default modulation profiles for most cable plants.
Step 4	controller upstream-cable <i>slot/subslot/port</i> Example: Router(config)# controller upstream-cable 9/0/15	Enters controller configuration mode.
Step 5	cable upstream <i>n</i> modulation-profile <i>primary-profile-number secondary-profile-number</i> Example: Router(config-controller)# cable upstream 0 modulation-profile 3 4	Assigns a primary modulation profile, and an optional secondary modulation profile, to the specified upstream port.
Step 6	end Example: Router(config-controller)# end	Exits controller interface configuration mode and returns to privileged EXEC mode.

Configuring Proactive Channel Management

The cable interface line cards that support the advanced spectrum management features can be configured with the following parameters to fine-tune the operation of proactive channel management on the upstreams of the cards:

- Priority of the corrective actions to be taken when noise on an upstream exceeds the threshold for its modulation profile.
- CNR (CNI_R) and MER (SNR) threshold and FEC values for the upstream and its two modulation profiles.
- Allowable range of channel widths that can be used if frequency hopping or modulation switching cannot avoid the upstream problems.

These parameters all have default settings, so you do not need to perform this procedure unless you want to change these parameters to better match the characteristics of your physical plant.

To configure the parameters, use the following procedure.

Configuring Proactive Channel Management

You can configure two logical channels on a single physical port of the Cisco CMTS router. When you configure logical channels, the upstream related commands are categorized into two groups: physical port level and logical channel level.

Physical Port Level

Physical port level commands use the format of **cable upstream *n***, where *n* denotes the physical port number.

Logical Channel Level

Logical channel level commands use the format of **cable upstream *n m***, where *n* denotes the physical port number, and *m* denotes the logical channel index number of 0 or 1.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	controller upstream-cable <i>slot/subslot/port</i> Example: Router(config)# controller upstream-cable 9/0/0	Enters controller configuration mode.
Step 4	us-channel <i>n</i> hop modulation frequency channel-width Example: Router(config-controller)# us-channel 0 hop modulation frequency channel-width	Specifies the priority of the three types of corrective actions (modulation , frequency , and channel-width) to be taken when the noise for the upstream exceeds the threshold specified for the current modulation profile. The default priority is frequency , modulation , and channel-width .

	Command or Action	Purpose
		<p>Note The channel-width option must always appear after the frequency option.</p>
Step 5	<p>cable upstream n threshold cnr-profiles threshold1-in-db threshold2-in-db</p> <p>Example:</p> <pre>Router(config-controller)# cable upstream 2 threshold cnr-profiles 23 14</pre>	<p>(Optional) Specifies the CNR (CNIr) threshold and FEC values for the upstream and its two modulation profiles.</p> <p>Note To bypass both the primary and secondary CNR (CNIr) thresholds, set the first parameter (<i>threshold1-in-db</i>) to 0. This disallows the second parameter (<i>threshold2-in-db</i>), enabling you to bypass both the CNR (CNIr) thresholds.</p>
Step 6	<p>Use one of the following commands:</p> <ul style="list-style-type: none"> • cable upstream n upstream threshold snr-profiles threshold1-in-db threshold2-in-db • • cable upstream n m upstream threshold snr-profiles threshold1-in-db threshold2-in-db • <p>Example:</p> <pre>Router(config-controller)# cable upstream 2 threshold snr-profiles 23 14</pre>	<p>(Optional) Specifies the MER (SNR) threshold and FEC values for the upstream and its two modulation profiles.</p> <p>Note You can bypass the primary MER (SNR) threshold (<i>threshold1-in-db</i>) by setting it to 0. However, you must enter the second parameter (<i>threshold2-in-db</i>).</p>
Step 7	<p>cable upstream n threshold hysteresis hysteresis-in-db</p> <p>Example:</p> <pre>Router(config-controller)# cable upstream 2 threshold hysteresis 3</pre>	<p>(Optional) Specifies the hysteresis value to be used in conjunction with the dynamic modulation upgrade thresholds.</p> <p>Note You can bypass the hysteresis threshold by setting the value to 0.</p>
Step 8	<p>Use one of the following commands:</p> <ul style="list-style-type: none"> • cable upstream n threshold corr-fec corr-fec-threshold • cable upstream n m threshold corr-fec corr-fec-threshold <p>Example:</p> <pre>Router(config-controller)# cable upstream 5 threshold corr-fec 5</pre>	<p>(Optional) Specifies the CNR (CNIr) threshold and FEC values for the upstream and its two modulation profiles.</p> <p>Note You can bypass the corr-fec threshold by setting the value to 0.</p>
Step 9	<p>Use one of the following commands:</p> <ul style="list-style-type: none"> • cable upstream n threshold uncorr-fec uncorr-fec-threshold • cable upstream n m threshold uncorr-fec uncorr-fec-threshold 	<p>(Optional) Specifies the CNR (CNIr) threshold and FEC values for the upstream and its two modulation profiles.</p> <p>Note You can bypass the uncorr-fec threshold by setting the value to 0.</p>

	Command or Action	Purpose
	Example: <pre>Router(config-controller)# cable upstream 5 threshold uncorr-fec 1</pre>	Note For normal plant use, we recommend that the uncorrectable FEC threshold remain at its default of 1 percent to avoid an unacceptable number of errors on the channel.
Step 10	cable upstream <i>n</i> channel-width <i>first-choice-width</i> [<i>last-choice-width</i>] Example: <pre>Router(config-controller)# cable upstream 0 channel-width 800000 800000</pre>	
Step 11	end Example: <pre>Router(config-controller)# end</pre>	Exits controller interface configuration mode and returns to privileged EXEC mode.

Verifying the Spectrum Management Configuration

Follow the steps given below to verify the spectrum management configuration.

Step 1 To check the value of the settings you have entered, use the **show running-config** command in privileged EXEC mode:

Example:

```
Router# show running-config
```

Step 2 To display the configuration for each modulation profile, use the **show cable modulation-profile** command in privileged EXEC mode:

Example:

```
Router# show cable modulation-profile
```

To display the configuration for a specific modulation profile, add the profile number to the **show cable modulation-profile** command in privileged EXEC mode:

Example:

```
Router# show cable modulation-profile 6
```

Step 3 To display the status and configuration of each upstream, use the **show controllers cable upstream** command in privileged EXEC mode. The following example displays information for upstreams 0 on a cable line card:

Example:

```
Router# show controller cable 8/1/14 upstream 0

Cable8/1/14 Upstream 0 is up
Frequency 19.504 MHz, Channel Width 3.200 MHz, Symbol Rate 2.560 Msps
Modulations (64-QAM) - A-short 64-QAM, A-long 64-QAM, A-ugs 64-QAM
Mapped to shared connector 18 and receiver 56
Spectrum Group 8
MC3Gx60 CNR measurement : 30 dB
US phy MER(SNR)_estimate for good packets - 32.5530 dB
```

```

Nominal Input Power Level 0 dBmV, Tx Timing Offset 1547
Ranging Backoff Start 3, Ranging Backoff End 6
US timing offset adjustment type 0, value 0
Ranging Insertion Interval automatic (60 ms)
US throttling off
Tx Backoff Start 3, Tx Backoff End 5
Modulation Profile Group 221
Concatenation is enabled
Fragmentation is enabled

Dropped MAC messages: (none)

```

Step 4 To display the hop period and hop threshold values for each upstream, use the **show cable hop** command in privileged EXEC mode:

Example:

```
Router# show cable hop
```

Upstream Port	Port Status	Poll Rate	Missed Poll	Min Poll	Missed Hop Poll	Hop Thres	Hop Period	Corr FEC	Uncorr FEC

	(ms)	Count	Sample	Pcnt	Pcnt	(sec)	Errors	Errors
Cable3/0/U0	20.800	Mhz 105 0	20	0%	25%	45	1	4
Cable3/0/U1	20.800	Mhz 105 0	48	0%	25%	45	2	19
Cable3/0/U2	23.120	Mhz 105 0	45	0%	25%	45	0	5
Cable3/0/U3	22.832	Mhz 105 0	26	0%	25%	45	0	6
Cable3/0/U4	22.896	Mhz 105 0	43	0%	25%	45	0	7
Cable3/0/U5	23.040	Mhz 105 0	54	0%	25%	45	1	3
Cable4/0/U0	22.896	Mhz 117 0	26	0%	25%	45	0	2
Cable4/0/U1	23.168	Mhz 117 0	87	0%	25%	45	4	2
Cable4/0/U2	22.896	Mhz 117 0	23	0%	25%	45	1	0
Cable4/0/U3	20.800	Mhz 117 0	54	0%	25%	45	0	0
Cable4/0/U4	22.928	Mhz 117 0	22	0%	25%	45	0	1
Cable4/0/U5	22.960	Mhz 117 0	0	-----	25%	45	0	0

Step 5 To display changes from one state to another, at any time and for any reason, for frequency, modulation, and channel width, use the **history** option of the **show cable hop** command.

Example:

```
Router# show cable hop c8/1/1 u0 history
```

```
F = Frequency Hop, M = Modulation Change, C = Channel Width Change
Upstream Action Chg Chg Action
Port Time Code From To Reason
C8/1/1 U0 Feb 20 12:21:29 M 142 141 SNR 28>=28 CFEC 0<=3 UnCFEC 0<=1
Feb 20 12:09:08 F 0.000 24.000 Configuration changed
```

Step 6 To display thresholds for MER (SNR), CNR (CNiR), and FEC, use the **threshold** option of the **show cable hop** command.

Example:

```
Router# show cable hop c8/1/1 u0 threshold
```

Upstream Port	SNR (dB) Val	Thre1	Thre2	CNR (dB) Val	Thre1	Thre2	CorrFEC% Pcnt	UncorrFEC% Pcnt	Thre	MissedSM% Pcnt	Thre	
C8/1/1 u0	33	23	14	60	25	15	0	1	0	2	0	50

Step 7 To display the assignment of each spectrum group, use the **show cable spectrum-group** command in privileged EXEC mode:

Example:

```
Router# show cable spectrum-group
```

Group No.	Frequency Band (MHz)	Upstream Port	Weekly Scheduled Availability	Power Level (dBmV)	Shared Spectrum
1	42.967 [3.20]	UC2/0/4:U0	From Time: To Time:	-1	No
1	83.400 [3.20]	UC2/0/4:U1		-1	No
1	80.200 [3.20]	UC2/0/4:U2		-1	No
1	42.922 [3.20]	UC2/0/4:U3		-1	No
1	17.677 [3.20]	UC2/0/5:U0		-1	54
1	10.603 [3.20]	UC2/0/5:U1		-1	54

In the above example,

- No—Fiber node is not configured
- 54—ID of the fiber node

Step 8 To display the current CNR (CNiR) value for a particular cable modem, use the **show cable modem cnr** command in privileged EXEC mode:

Example:

```
Router# show cable modem 5.100.1.94 cnr

MAC Address      IP Address      I/F           MAC           Prim  snr/cnr
                State           Sid           (dB)
0018.689c.17b8  5.100.1.94     C7/0/0/U1    online        428   36.12
```

Monitoring Spectrum Management

You can either use Cisco CLI commands or SNMP to monitor spectrum management activity on the Cisco CMTS.

See the following sections for more information:

Using CLI Commands

The following commands provide information on the spectrum condition of an upstream:

Command	Purpose
Router# show cable hop [cable x/y] [upstream usport]	Displays the hop period and hop threshold values, as well as the FEC error counters, for all upstreams in the router, all upstreams on one cable interface line card, or a single upstream.
Router# show cable hop [cable x/y[z]] [upstream n] [thresholds]	Displays the configured and current value of MER (SNR) in dB, CNR (CNiR) in dB, CorrFEC in percentage, UncorrFEC in percentage, and missed station maintenance in percentage for a specified upstream.
Router# show cable hop history	<ol style="list-style-type: none"> 1. With the show cable hop history command for entire CMTS, the most recent change of each action is displayed. 2. With the show cable hop history command for a MAC domain, the most recent three changes of each action are displayed. 3. With the show cable hop history command for a specific upstream, the last ten changes of each action are displayed. Changes are sorted by time with the most recent at the top.
Router# show cable hop [cable x/y[z]] [upstream n] [summary]	Displays hourly, daily, weekly, 30 days running average, and average since the system was brought up for each specified upstream.
Router# show cable hop [cable x/y[z]] [upstream n] [history]	Displays changes from one state to another, at any time and for any reason, for frequency, modulation, and channel width.

Command	Purpose
Router# show cable modem [ip-address interface mac-address] [options]	Displays information, including MER (SNR) values, for the registered and unregistered cable modems.
Router# show cable modulation-profile [num] [initial long reqdata request short station]	Displays the configuration for all modulation profiles, for a particular modulation profile, or for a specific burst type for a particular modulation profile.
Router# show cable spectrum-group [groupnum] [detail]	Displays information about the spectrum groups that have been configured.
Router# show controllers cable x/y upstream n [ip-address mac-address] start-freq end-freq res-freq	Displays the upstream status, including the current frequency, channel width, modulation rate, and spectrum groups.
Router# show controllers cable x/y upstream n spectrum [ip-address mac-address] start-freq end-freq res-freq	Displays the noise levels for a particular cable modem or displays the background noise for an entire upstream.

Note The **show cable flap-list** command displays the flap list of the CMTS router, which provides additional information about whether cable modems on an upstream are experiencing problems, and if so, what type of problems are occurring. For more information about the cable modem flapping and how to monitor the cable modem flap list, see the [Flap List Troubleshooting for the Cisco CMTS Routers](#).

Using SNMP

You can use SNMP to monitor the spectrum management activity. The SNMP manager can be a graphically-based SNMP manager such as CiscoView or the Cable Broadband Troubleshooter (Release 3.0 or later).

The CISCO-CABLE-SPECTRUM-MIB has been enhanced to provide this SNMP support using the following MIB attributes:

ccsSNRRRequestTable

The table below lists the attributes in the ccsSNRRRequestTable table, which contains the CNR (CNiR) measurements that are made for individual cable modems on an upstream.

Table 69: ccsSNRRRequestTable Attributes

Attribute	Type	Description
ccsSNRRRequestIndex	Integer32	Arbitrary index to uniquely identify each table entry.
ccsSNRRRequestMacAddr	MacAddress	MAC address of the remote online cable modem being reported on.

Attribute	Type	Description
ccsSNRRRequestSNR	Integer32	MER (SNR) value, in dB, that has been measured. This value is 0 when the Operation State is “running.”
ccsSNRRRequestOperation	CCSRequestOperation	Sets the current operation: start, pending, running, or cancel.
ccsSNRRRequestOperState	CCSRequestOperState	Reports on the current operation state: idle, pending, running, noError, canceled, notOnLine, invalidMac, timeOut, fftBusy, fftFailed, others.
ccsSNRRRequestStartTime	TimeStamp	Contains the time when the MER (SNR) measurement operation starts.
ccsSNRRRequestStoppedTime	TimeStamp	Contains the time when the MER (SNR) measurement stops.
ccsSNRRRequestStatus	RowStatus	Controls the modification, creation, and deletion of table entries.

ccsSpectrumRequestTable

The table below lists the attributes for each entry in the ccsSpectrumRequestTable table, which is used to obtain the spectrum profile for a particular cable modem or to obtain the background MER (SNR) for an entire upstream.

Table 70: ccsSpectrumRequestTable Attributes

Attribute	Type	Description
ccsSpectrumRequestIndex	Integer32	Arbitrary index to uniquely identify each table entry.
ccsSpectrumRequestIfIndex	InterfaceIndexOrZero	Interface identifying the upstream.
ccsSpectrumRequestMacAddr	MacAddress	MAC address to specify an MER (SNR) value for a particular cable modem, or 0000.0000.0000 to indicate background noise for the entire spectrum.
ccsSpectrumRequestUpperFreq	CCSFrequency	Upper frequency for the frequency range to be monitored (5000 to 42000 KHz, with a default of 42000 KHz).
ccsSpectrumRequestLowFreq	CCSFrequency	Lower frequency (in KHz) for the frequency range to be monitored (5000 to 42000 KHz, with a default of 5000 KHz).
ccsSpectrumRequestResolution	Integer32	Requested resolution to determine how the frequency range should be sampled (12 to 37000 KHz, with a default of 60 KHz).
ccsSpectrumRequestStartTime	TimeStamp	Time when the spectrum measurement began.

Attribute	Type	Description
ccsSpectrumRequestStoppedTime	TimeStamp	Time when the spectrum measurement finished.
ccsSpectrumRequestOperation	CCSRequestOperation	Starts a new spectrum management request or cancels the current one.
ccsSpectrumRequestOperState	CCSRequestOperState	Provides the operational state of the current spectrum management request.
ccsSpectrumRequestStatus	RowStatus	Controls the modification, creation, and deletion of table entries.

ccsSpectrumDataTable

The table below lists the attributes in each entry of the ccsSpectrumDataTable table, which contains the results for a spectrum request.

Table 71: ccsSpectrumDataTable Attributes

Attribute	Type	Description
ccsSpectrumDataFreq	CCSMeasuredFrequency	Frequency in KHz for which this power measurement was made.
ccsSpectrumDataPower	INTEGER	Measured received power for the given frequency (–50 to 50 dBmV).

Note The ccsSpectrumRequestTable and ccsSpectrumDataTable tables provide the same information as that provided by the **show controllers cable upstream spectrum** command.

ccsUpSpecMgmtTable

The table below lists the attributes in the ccsUpSpecMgmtTable table, which provides an entry describing each frequency hop.

Table 72: ccsUpSpecMgmtEntry Attributes

Attribute	Type	Description
ccsUpSpecMgmtHopPriority	INTEGER	Specifies the priority of frequency, modulation profile, and channel width in determining corrective action for excessive noise on the upstream (default is frequency, modulation profile, and channel width).
ccsUpSpecMgmtSnrThres1	Integer32	Specifies the upper MER (SNR) threshold for modulation profile 1 (5 to 35 dB, default of 25).

Attribute	Type	Description
ccsUpSpecMgmtSnrThres2	Integer32	Specifies the upper MER (SNR) threshold for modulation profile 2 (5 to 35 dB, default of 13, and must be lower than that specified for ccsUpSpecMgmtSnrThres1).
ccsUpSpecMgmtFecCorrectThres1	Integer32	Specifies the FEC correctable error threshold for modulation profile 1 (1 to 20 percent)
ccsUpSpecMgmtFecCorrectThres2	Integer32	Deprecated and no longer used.
ccsUpSpecMgmtFecUnCorrectThres1	Integer32	Specifies the FEC uncorrectable error threshold for modulation profile 1 (1 to 20 percent).
ccsUpSpecMgmtFecUnCorrectThres2	Integer32	Deprecated and no longer used.
ccsUpSpecMgmtSnrPollPeriod	Integer32	Deprecated and no longer used.
ccsUpSpecMgmtHopCondition	INTEGER	Reports the condition that triggers a frequency hop (MER [SNR] value or percentage of modems going offline).
ccsUpSpecMgmtFromCenterFreq	CCSFrequency	Provides the center frequency (in KHz) before the latest frequency hop.
ccsUpSpecMgmtToCenterFreq	CCSFrequency	Provides the current center frequency (in KHz) after the latest frequency hop.
ccsUpSpecMgmtFromBandWidth	CCSFrequency	Provides the channel width (in KHz) before the latest frequency hop.
ccsUpSpecMgmtToBandWidth	CCSFrequency	Provides the current channel width (in KHz) after the latest frequency hop.
ccsUpSpecMgmtFromModProfile	Integer32	Provides the modulation profile number before the latest frequency hop.
ccsUpSpecMgmtToModProfile	Integer32	Provides the current modulation profile number after the latest frequency hop.
ccsUpSpecMgmtSNR	Integer32	Provides the current MER (SNR) value (in dB) for the upstream.
ccsUpSpecMgmtCnrThres1	Integer32	Specifies the upper CNR (CNIr) threshold for modulation profile 1 (5 to 35 dB, default of 25).

Attribute	Type	Description
ccsUpSpecMgmtCnrThres2	Integer32	Specifies the upper CNR (CNiR) threshold for modulation profile 2 (5 to 35 dB, default of 13, and must be lower than that specified for ccsUpSpecMgmtCnrThres1).
ccsUpSpecMgmtCNR	Integer32	Provides the current CNR (CNiR) value (in dB) for the upstream.
ccsUpSpecMgmtMissdMaintMsgThres	Integer32	Provides the frequency hop threshold, as a percentage of station maintenance messages that are lost for a spectrum group.
ccsUpSpecMgmtHopPeriod	Integer32	Provide the minimum time, in seconds, between frequency hops.

ccsHoppingNotification

The table below describes the attributes contained in the notification that is sent after each frequency hop.

Table 73: ccsHoppingNotification Attributes

Attribute	Type	Description
ccsUpSpecMgmtHopCondition	INTEGER	Reports the condition that triggers a frequency hop (MER [SNR] value or percentage of modems going offline).
ccsUpSpecMgmtFromCenterFreq	CCSFrequency	Provides the center frequency (in KHz) before the latest frequency hop.
ccsUpSpecMgmtToCenterFreq	CCSFrequency	Provides the current center frequency (in KHz) after the latest frequency hop.
ccsUpSpecMgmtFromBandWidth	CCSFrequency	Provides the channel width (in KHz) before the latest frequency hop.
ccsUpSpecMgmtToBandWidth	CCSFrequency	Provides the current channel width (in KHz) after the latest frequency hop.
ccsUpSpecMgmtFromModProfile	Integer32	Provides the modulation profile number before the latest frequency hop.
ccsUpSpecMgmtToModProfile	Integer32	Provides the current modulation profile number after the latest frequency hop.

Configuration Examples

This section provides the following configuration examples:

Spectrum Group and Combiner Group Examples

The following examples help you to determine whether spectrum group and combiner groups are configured and activated.

Example: Verifying Spectrum Group Creation

To verify that a spectrum group has been created, enter the **show cable spectrum-group** command:

```
Router# show cable spectrum-group
spectrum-group 1
spectrum-group 2
spectrum-group 3
```

Example: Time-Scheduled Spectrum Group

If your cable plant has an upstream noise characteristic on a weekly cycle, use time-scheduled spectrum allocation.

```
Router(config)# cable spectrum-group 1 time Mon 08:00:00 frequency 21600000
```

Deletion is performed using the **delete** keyword:

```
Router(config)# cable spectrum-group 1 time Mon 18:00:00 delete frequency 21600000
```

Example: Verifying Spectrum Group Configuration

To verify if spectrum groups have been configured and activated, enter the **show cable spectrum-group** command. This command displays each spectrum group, the frequencies assigned to it, the upstream port to which it has been assigned, whether a schedule exists for it, the currently measured power level, and whether it is a shared spectrum group.

```
Router# show cable spectrum-group

22:07:46: %SYS-5-CONFIG_I: Configured from console by console
Group  Frequency      Upstream      Weekly Scheduled      Power  Shared
No.    Band                Port           Availability           Level  Spectrum
      (Mhz)
1      5.000-15.000
1      12.000
1      22.000             Cable6/0 U5         From Time:             To Time:              7      Yes
2      29.000             Cable6/0 U4         6      No
2      26.000
3      35.000-41.000
3      16.000-19.000     Cable6/0 U3         5      No
5*     5.000-10.000     Thu 21:50:00 Thu 21:45:00 0      Yes
```

Example: Determining the Upstream Ports Assigned to a Combiner Group

Following is a sample topology for a CMTS with combiner groups designated A through J. Combiner groups C and E have multiple upstream ports that should be configured in a shared spectrum group. The other upstreams should be configured in a nonshared spectrum group.

In this example, ten combiner groups are served with frequency hop tables from three spectrum groups:

```
Cable3/0
DS +-----+ Upconverter +----- laser group 1
U0 +----- combiner group A
U1 +----- combiner group B
```

```

U2 +-----combiner group C
U3 +-----combiner group C
U4 +----- combiner group D
U5 +-----combiner group E
Cable4/0
DS +-----+ Upconverter +----- laser group 2
U0 +-----combiner group E
U1 +----- combiner group F
U2 +----- combiner group G
U3 +----- combiner group H
U4 +----- combiner group I
U5 +----- combiner group J

```

The *laser group* term refers to the set of fiber nodes that share the same downstream signal. An optical splitter is often used to create individual feeds per node.

In the downstream direction, two 6-MHz channel slots are assigned. All fiber nodes in combiner groups A through E should have a channel slot containing the downstream signal from Cable3/0. Combiner groups A through E are said to belong to laser group 1.

All fiber nodes in combiner groups E through J should have a channel slot containing the downstream signal from Cable4/0. Combiner groups E through J are said to belong to laser group 2.

Because combiner group E belongs to two laser groups, there should be two different downstream channel slots for Cable3/0 and Cable4/0.

Example: Combiner Group

The following example enables spectrum management for all upstream ports, where all combiner groups use the frequency band from 20 to 26 MHz:

```

CMTS01(config)# cable spectrum-group 1 band 20000000 26000000
CMTS01(config)# cable spectrum-group 2 shared
CMTS01(config)# cable spectrum-group 2 band 20000000 26000000
CMTS01(config)# cable spectrum-group 3 shared
CMTS01(config)# cable spectrum-group 3 band 20000000 26000000
CMTS01(config)# controller upstream-Cable 9/0/0
CMTS01(config-controller)# cable spectrum-group 1
CMTS01(config-controller)# cable upstream 2 spectrum-group 2
CMTS01(config-controller)# cable upstream 3 spectrum-group 2
CMTS01(config-controller)# cable upstream 5 spectrum-group 3
CMTS01(config-controller)# exit
CMTS01(config)# controller upstream-Cable 9/0/1
CMTS01(config-controller)# cable spectrum-group 1
CMTS01(config-controller)# cable upstream 0 spectrum-group 3

```

A description of the spectrum groups 1 through 3 follows:

- Spectrum group 1—This group is nonshared. Upstream RF domains exist for each member upstream port.

Upstream Port	RF Domain
Cable3/0 U0	combiner group A
Cable3/0 U1	combiner group B
Cable3/0 U4	combiner group D
Cable4/0 U1	combiner group F
Cable4/0 U2	combiner group G
Cable4/0 U3	combiner group H
Cable4/0 U4	combiner group I
Cable4/0 U5	combiner group J

- Spectrum group 2—This group is shared. A single upstream RF domain exists.

```
Upstream Port  RF Domain
Cable3/0 U2    combiner group C
Cable3/0 U3    combiner group C
```

- Spectrum group 3—This group is shared. A single upstream RF domain exists.

```
Upstream Port  RF Domain
Cable3/0 U5    combiner group E
Cable4/0 U0    combiner group E
```

For the 20- to 26-MHz band of each RF domain, the spectrum is channelized according to the channel width settings of each member port. For example, if the ports U2 and U3 of Cable3/0 are set to 3.2 MHz and 1.6 MHz channel widths, respectively, then spectrum group 2 uses the following channelization:

```
> Channel Width Start Stop Center
>          (Mhz) (Mhz) (Mhz) (Mhz)
> 1         3.2   20.0 23.2 21.6
> 2*        1.6   20.0 21.6 20.8
> 3*        1.6   21.6 23.2 22.4
> 4         1.6   23.2 24.8 24.0
```

Note Channels 2 and 3 are not available when channel 1 is in use.

Because the group is shared, ports U2 and U3 will be assigned channels 1 and 4, respectively, to prevent overlap.

Note There are no alternate frequency assignments for either port, and bandwidth is wasted from 24.8 to 26.0 MHz. To create alternate channels, increase the upper boundary from 26.0 to 28.0 MHz.

```
> Channel Width Start Stop Center
>          (Mhz) (Mhz) (Mhz) (Mhz)
> 1         3.2   20.0 23.2 21.6
> 2         3.2   23.2 26.4 24.8
> 3         1.6   20.0 21.6 20.8
> 4         1.6   21.6 23.2 22.4
> 5         1.6   23.2 24.8 24.0
> 6         1.6   24.8 26.4 25.6
> 7         1.6   26.4 28.0 27.4
```

Try to reduce the spectrum allocation when it is used with small channel widths. Otherwise, there will be a large number of upstream channel slots, and the frequency hopping may require several minutes to find a clean slot.

Example: Other Spectrum Management Configurations

To configure differing spectrum groups, refer to the following examples:

- Use the following example to configure spectrum group 3 with an upstream band of 12,000,000 to 18,000,000 Hz and default power level of 0 dBmV:

```
Router(config)# cable spectrum-group 3 band 12000000 18000000
```

- Use the following example to add the upstream band 20,000,000 to 24,000,000 Hz to the list of valid bands with a change in the power level of 13 dBmV for spectrum group 3:

```
Router(config)# cable spectrum-group 3 band 20000000 24000000 13
```

- Use the following example to configure a continuous band between 5,000,004 and 40,000,000 Hz for scheduled spectrum group 4 with a default power level of 0 dBmV. The band is available to the spectrum group starting at 12:00 p.m. local time each Monday:

```
Router(config)# cable spectrum-group 4 time Monday 12:00:00 band 5000004 40000000
```

- Use the following example to add the upstream frequency 9,500,000 Hz to the list of valid frequencies and change the nominal power level to 5 dBmV. The spectrum manager adjusts frequencies and power levels on this group at 2:00 a.m. local time each day:

```
Router(config)# cable spectrum-group 3 time 02:00:00 frequency 9500000 5
```

- Use the following example to configure the minimum period before which a frequency hop can occur in seconds:

```
Router(config)# cable spectrum-group 3 hop period 800
```

- Use the following example to configure the threshold value (expressed as a percentage) of the number of “offline” modems identified before the router initiates an automatic frequency hop:

```
Router(config)# cable spectrum-group 3 hop threshold 40
```

- Use the following example to configure a particular spectrum group as a shared RF spectrum group. Specifying a given spectrum group as “shared” tells the router that you want to be sure that upstream frequencies assigned to upstream ports are not assigned to additional upstream ports:

```
Router(config)# cable spectrum-group 3 shared
```

- Use the following example to remove a specified spectrum group from your configuration:

```
Router(config)# no cable spectrum-group 3
```

Dynamic Upstream Modulation Examples

The following examples describe how to display modulation profile information with the **show cable modulation-profile** command and to define a modulation profile with the **cable modulation-profile** command.

Verifying Your Settings

Step 1 To check the value of the settings you have entered, enter the **show running-config** command in privileged EXEC mode:

Example:

```
Router# show running-config
```

To review changes you make to the configuration, use the **show startup-config** command in privileged EXEC mode to display the information stored in NVRAM.

Step 2 To display modulation profile group information, use the **show cable modulation-profile** command in privileged EXEC mode:

Example:

```
Router# show cable modulation-profile [profile] [iuc-code]
```

This command uses the following syntax:

- *profile*—(Optional) Profile number. Valid values are from 1 to 8.
- *iuc-code*—(Optional) Internal usage code.

Valid options are:

- **initial**—Initial ranging burst
- **long**—Long grant burst
- **request**—Request burst
- **short**—Short grant burst
- **station**—Station ranging burst

Example: Modulation Profiles

The Cisco CMTS has one preconfigured modulation profile resident in memory, which defines a typical profile for QPSK modulation. To use the Dynamic Upstream Modulation feature, a second profile must be created that is unique from the first profile, and typically provides a higher, more robust modulation scheme.

The following example is a modulation profile for QAM-16, in which the initial, request, and station maintenance messages are sent as QPSK, and the short and long data packets are sent as QAM-16. The QAM-16 modulation is more bandwidth-efficient than QPSK, but QPSK is more robust than QAM-16.

Note The upstream request and station maintenance messages use less time on the cable network when configured in QPSK for symbol rates of 640K, 1280K, and 2560K symbols/sec. Thus, these messages are actually more efficient when used in QPSK mode and they ensure a more reliable modem connection. The upstream initial maintenance message takes exactly the same amount of time on the cable network, no matter how it is configured. Modems connect more quickly and experience fewer cycles of power adjustment during initial maintenance if the system is set for QPSK.

```
Router# configure terminal
Router(config)# cable modulation-profile 2 request 0 16 1 8 qpsk scrambler 152 no-diff 64
fixed uw16
Router(config)# cable modulation-profile 2 initial 5 34 0 48 qpsk scrambler 152 no-diff 128
fixed uw16
Router(config)# cable modulation-profile 2 station 5 34 0 48 qpsk scrambler 152 no-diff 128
fixed uw16
Router(config)# cable modulation-profile 2 short 6 75 6 8 16qam scrambler 152 no-diff 72
```

```

fixed uw16
Router(config)# cable modulation-profile 2 long 8 220 0 8 16qam scrambler 152 no-diff 160
fixed uw16

```

In the following example, all message types are carried with QAM-16 modulation. Although QAM-16 modulation offers a consistent modulation scheme for all five types of messages, the added length of the QAM-16 preamble offsets the increased bandwidth efficiency of the MAC data message for the station maintenance messages and bandwidth request messages.

```

Router# configure terminal
Router(config)# cable modulation-profile 2 request 0 16 1 8 16qam scrambler 152 no-diff 128
fixed uw16
Router(config)# cable modulation-profile 2 initial 5 34 0 48 16qam scrambler 152 no-diff
256 fixed uw16
Router(config)# cable modulation-profile 2 station 5 34 0 48 16qam scrambler 152 no-diff
256 fixed uw16
Router(config)# cable modulation-profile 2 short 5 75 6 8 16qam scrambler 152 no-diff 144
fixed uw16
Router(config)# cable modulation-profile 2 long 8 220 0 8 16qam scrambler 152 no-diff 160
fixed uw16

```

Note When using DOCSIS concatenation with a 16-QAM or mixed symbol rate, configure the CMTS for Unique Word 16 (“uw16”) in the preamble for both short and long data burst profiles.

Add the **cable upstream *port-number* modulation-profile *primary profile-number* *secondary profile-number*** command to the appropriate interfaces. In this example, modulation profile 2 is for QAM-16 modulation and profile 1 is for QPSK modulation.

```

Router# configure terminal
Router(config)# controller upstream-Cable 6/0/0
Router(config-controller)# cable upstream 0 modulation-profile 2 1

```

Example: Input Power Level

In the following example, the modem transmit power at 24.8 MHz is adjusted upstream by 1 dBmV and the modem transmit power at 28.0 MHz is adjusted upstream by 2 dBmV.

```

CMTS01(config)# cable spectrum-group 1 frequency 21600000
CMTS01(config)# cable spectrum-group 1 frequency 24800000 1
CMTS01(config)# cable spectrum-group 1 frequency 28000000 2

```

Advanced Spectrum Management Configuration Examples

This section provides the following typical configurations:

Example: Advanced Spectrum Management for the Cisco cBR Series Routers

This section provides an excerpt from a typical configuration example for a Cisco cBR Series router using a cable interface line card. This configuration does the following:

- Configures four spectrum groups with a hop period of 30 seconds.

- Creates a QPSK modulation profile and assigns it to four upstreams on the Cisco cable interface line card in slot 6/1/0.
- Assigns a spectrum group to each of the four upstreams.
- Configures each upstream for the default CNR (CNiR) and FEC thresholds.

```

cable modulation-profile 21 qpsk
interface Cable6/1/0
cable bundle 1
cable downstream annex B
cable downstream modulation 256qam
cable downstream interleave-depth 32
! upstream 0
cable upstream 0 spectrum-group 1
cable upstream 0 modulation-profile 21

Feature Information for Spectrum Management and Advanced Spectrum Management

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmng.cisco.com/> link. An account on the Cisco.com page is not required.

Note The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Feature Name	Releases	Feature Information
Spectrum Management and Advanced Spectrum Management	Cisco IOS XE Fuji 16.7.1	This feature was integrated on the Cisco cBR Series Converged Broadband Routers.

CHAPTER 23

Upstream Scheduler Mode

This document describes how to configure optional upstream (US) scheduler modes.

With this feature, you can select Unsolicited Grant Services (UGS), Real Time Polling Service (rtPS) or Non-Real Time Polling Service (nrtPS) scheduling types, as well as packet-based or Time Division Multiplex (TDM) based scheduling. Low latency queuing (LLQ) emulates a packet-mode-like operation over the TDM infrastructure of DOCSIS. As such, the feature provides the typical trade-off between packets and TDM. With LLQ, you have more flexibility in defining service parameters for UGS, rtPS or nrtPS, but with no guarantee (other than statistical distribution) regarding parameters such as delay and jitter.

Restrictions for Upstream Scheduler Mode

- To ensure proper operation, Interface-based Admission Control must be enabled. When the LLQ option is enabled, it is possible for the upstream path to be filled with so many calls that it becomes unusable, making voice quality unacceptable. Interface-based admission control must be used to limit the number of calls to ensure acceptable voice quality, as well as to ensure traffic other than voice traffic.
- Even if Interface-based admission control is not enabled, the default (DOCSIS)scheduling mode blocks traffic after a certain number of calls.
- UGS with Activity Detection (UGS-AD) is not supported by the LLQ scheduler mode but remains supported by the default DOCSIS scheduler mode.

Information About Upstream Scheduler Mode for the Cisco CMTS Routers

With UGS, a service flow is created that enables a cable modem to transmit fixed-size bursts of data at a guaranteed rate and with a guaranteed level of jitter by providing periodic transmission opportunities to the cable modem for fixed-sized frames. This kind of service flow is particularly suitable for VoIP applications.

With rtPS, a service flow is created that provides a periodic opportunity for a cable modem to request permission to transmit data by polling a single cable modem for a bandwidth request, rather than all the cable modems. This satisfies applications that have a requirement for real-time data transmission, and enables the cable modem to transmit data bursts of varying length. This kind of service flow is particularly suitable for MPEG VoIP.

The rtPS requests, by default, are internally treated as priority 7—the highest priority for all Best Effort traffic. This high priority reduces the latency of rtPS traffic under congestion.

With nrtPS, a service flow is created that provides a periodic opportunity for a cable modem to request permission to transmit data by polling a single cable modem for a bandwidth request, rather than all the cable modems. The data bursts may be of varying length. This kind of service flow is particularly suitable for non-interactive services such as file transfers.

How to Configure Upstream Scheduler Modes

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Use one the following commands: <ul style="list-style-type: none"> • interface cable <i>slot/subslot/port</i> • interface cable <i>slot/port</i> Example: Router(config)# interface cable 7/0/1	Enters interface configuration mode for the specified cable interface.
Step 4	cable upstream <i>n</i> scheduling type ugs mode [llq docsis] Example:	Enables LLQ-type (packet-based) scheduling for UGS services.

	Command or Action	Purpose
	Router(config-if)# cable upstream 4 scheduling type ugs mode llq	Note Any combination of ugs , rtps , nrtps , llq , and docsis is allowed. The only default value is docsis .
Step 5	cable upstream n scheduling type rtps mode [llq docsis] Example: Router(config-if)# cable upstream 4 scheduling type rtps mode docsis	Enables standard DOCSIS (TDM-based) scheduling for rtPS services. Note Any combination of ugs , rtps , nrtps , llq , and docsis is allowed. The only default value is docsis .
Step 6	end Example: Router(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

What to do next

To confirm whether the scheduler is operating in DOCSIS mode, use the **show interface cable mac-scheduler** command.

```
Router# show interface cable 7/0/1 mac-scheduler 0
DOCSIS 1.1 MAC scheduler for Cable7/0/1/U0 : rate 30720000

Restrictions for Implementing Tunnels

- It is important to allow the tunnel protocol to pass through a firewall and access control list (ACL) check.
- Multiple point-to-point tunnels can saturate the physical link with routing information if the bandwidth is not configured correctly on a tunnel interface.
- A tunnel looks like a single hop link, and routing protocols may prefer a tunnel over a multihop physical path. The tunnel, despite looking like a single hop link, may traverse a slower path than a multihop link. A tunnel is as robust and fast, or as unreliable and slow, as the links that it actually traverses. Routing

protocols that make their decisions based only on hop counts will often prefer a tunnel over a set of physical links. A tunnel might appear to be a one-hop, point-to-point link and have the lowest-cost path, but the tunnel may actually cost more in terms of latency when compared to an alternative physical topology. For example, in the topology shown in the figure below, packets from Host 1 will appear to travel across networks w, t, and z to get to Host 2 instead of taking the path w, x, y, and z because the tunnel hop count appears shorter. In fact, the packets going through the tunnel will still be traveling across Router A, B, and C, but they must also travel to Router D before coming back to Router C.

Figure 19: Tunnel Precautions: Hop Counts

- A tunnel may have a recursive routing problem if routing is not configured accurately. The best path to a tunnel destination is via the tunnel itself; therefore recursive routing causes the tunnel interface to flap. To avoid recursive routing problems, keep the control-plane routing separate from the tunnel routing by using the following methods:
 - Use a different autonomous system number or tag.
 - Use a different routing protocol.
 - Ensure that static routes are used to override the first hop (watch for routing loops).

The following error is displayed when there is recursive routing to a tunnel destination:

```
%TUN-RECURDOWN Interface Tunnel 0
temporarily disabled due to recursive routing
```

Restrictions for GRE IPv6 Tunnels

- GRE tunnel keepalive packets are not supported.
- Multipoint GRE (mGRE) IPv6 tunneling is not supported.
- There is limited support for tunnel transport in virtual routing and forwarding (VRF). The limited support in VRF is applicable to IPv6 point-to-point GRE without tunnel protection.

Information About Implementing Tunnels

Tunneling Versus Encapsulation

To understand how tunnels work, you must be able to distinguish between concepts of encapsulation and tunneling. Encapsulation is the process of adding headers to data at each layer of a particular protocol stack. The Open Systems Interconnection (OSI) reference model describes the functions of a network. To send a data packet from one host (for example, a PC) to another on a network, encapsulation is used to add a header in front of the data packet at each layer of the protocol stack in descending order. The header must contain a data field that indicates the type of data encapsulated at the layer immediately above the current layer. As the packet ascends the protocol stack on the receiving side of the network, each encapsulation header is removed in reverse order.

Tunneling encapsulates data packets from one protocol within a different protocol and transports the packets on a foreign network. Unlike encapsulation, tunneling allows a lower-layer protocol and a same-layer protocol to be carried through the tunnel. A tunnel interface is a virtual (or logical) interface. Tunneling consists of three main components:

- Passenger protocol—The protocol that you are encapsulating. For example, IPv4 and IPv6 protocols.
- Carrier protocol—The protocol that encapsulates. For example, generic routing encapsulation (GRE) and Multiprotocol Label Switching (MPLS).
- Transport protocol--The protocol that carries the encapsulated protocol. The main transport protocol is IP.

Tunnel ToS

Tunnel type of service (ToS) allows you to tunnel network traffic and group all packets in the same ToS byte value. The ToS byte values and Time-to-Live (TTL) hop-count value can be set in the encapsulating IP header of tunnel packets for an IP tunnel interface on a router. Tunnel ToS feature is supported for Cisco Express Forwarding (formerly known as CEF), fast switching, and process switching.

The ToS and TTL byte values are defined in RFC 791. RFC 2474, and RFC 2780 obsolete the use of the ToS byte as defined in RFC 791. RFC 791 specifies that bits 6 and 7 of the ToS byte (the first two least significant bits) are reserved for future use and should be set to 0.

Path MTU Discovery

Path MTU Discovery (PMTUD) can be enabled on a GRE or IP-in-IP tunnel interface. When PMTUD (RFC 1191) is enabled on a tunnel interface, the router performs PMTUD processing for the GRE (or IP-in-IP) tunnel IP packets. The router always performs PMTUD processing on the original data IP packets that enter the tunnel. When PMTUD is enabled, packet fragmentation is not permitted for packets that traverse the tunnel because the Don't Fragment (DF) bit is set on all the packets. If a packet that enters the tunnel encounters a link with a smaller MTU, the packet is dropped and an Internet Control Message Protocol (ICMP) message is sent back to the sender of the packet. This message indicates that fragmentation was required (but not permitted) and provides the MTU of the link that caused the packet to be dropped.

Note PMTUD on a tunnel interface requires that the tunnel endpoint be able to receive ICMP messages generated by routers in the path of the tunnel. Ensure that ICMP messages can be received before using PMTUD over firewall connections.

Use the **tunnel path-mtu-discovery** command to enable PMTUD for the tunnel packets and use the **show interfaces tunnel** command to verify the tunnel PMTUD parameters. PMTUD works only on GRE and IP-in-IP tunnel interfaces.

QoS Options for Tunnels

A tunnel interface supports various quality of service (QoS) features as a physical interface. QoS provides a way to ensure that mission-critical traffic has an acceptable level of performance. QoS options for tunnels include support for applying generic traffic shaping (GTS) directly on the tunnel interface and support for class-based shaping using the modular QoS CLI (MQC). Tunnel interfaces also support class-based policing, but they do not support committed access rate (CAR).

GRE tunnels allow the router to copy the IP precedence bit values of the ToS byte to the tunnel or the GRE IP header that encapsulates the inner packet. Intermediate routers between the tunnel endpoints can use the IP precedence values to classify packets for QoS features such as policy routing, weighted fair queueing (WFQ), and weighted random early detection (WRED).

When packets are encapsulated by tunnel or encryption headers, QoS features are unable to examine the original packet headers and correctly classify the packets. Packets that travel across the same tunnel have the same tunnel headers, so the packets are treated identically if the physical interface is congested. Tunnel packets can, however, be classified before tunneling and encryption can occur when a user applies the QoS preclassify feature on the tunnel interface or on the crypto map.

Note Class-based WFQ (CBWFQ) inside class-based shaping is not supported on a multipoint interface.

For examples of how to implement some QoS features on a tunnel interface, see the section [“Configuring QoS Options on Tunnel Interfaces Examples, on page 478”](#) on page 32.

Information About IPv6 over IPv4 GRE Tunnels

Overlay Tunnels for IPv6

Overlay tunneling encapsulates IPv6 packets in IPv4 packets for delivery across an IPv4 infrastructure (a core network or the figure below). By using overlay tunnels, you can communicate with isolated IPv6 networks without upgrading the IPv4 infrastructure between them. Overlay tunnels can be configured between border devices or between a border device and a host; however, both tunnel endpoints must support both the IPv4 and IPv6 protocol stacks. IPv6 supports the following types of overlay tunneling mechanisms:

- Manual
- Generic routing encapsulation (GRE)

- IPv4-compatible
- 6to4
- Intrasite Automatic Tunnel Addressing Protocol (ISATAP)

Figure 20: Overlay Tunnels

Note Overlay tunnels reduce the maximum transmission unit (MTU) of an interface by 20 octets (assuming that the basic IPv4 packet header does not contain optional fields). A network that uses overlay tunnels is difficult to troubleshoot. Therefore, overlay tunnels that connect isolated IPv6 networks should not be considered a final IPv6 network architecture. The use of overlay tunnels should be considered as a transition technique toward a network that supports both the IPv4 and IPv6 protocol stacks or just the IPv6 protocol stack.

Use the table below to help you determine which type of tunnel that you want to configure to carry IPv6 packets over an IPv4 network.

Table 77: Suggested Usage of Tunnel Types to Carry IPv6 Packets over an IPv4 Network

Tunneling Type	Suggested Usage	Usage Notes
Manual	Simple point-to-point tunnels that can be used within a site or between sites.	Can carry IPv6 packets only.
GRE- and IPv4-compatible	Simple point-to-point tunnels that can be used within a site or between sites.	Can carry IPv6, Connectionless Network Service (CLNS), and many other types of packets.
IPv4-compatible	Point-to-multipoint tunnels.	Uses the <code>::/96</code> prefix. We do not recommend using this tunnel type.
6to4	Point-to-multipoint tunnels that can be used to connect isolated IPv6 sites.	Sites use addresses from the <code>2002::/16</code> prefix.
6RD	IPv6 service is provided to customers over an IPv4 network by using encapsulation of IPv6 in IPv4.	Prefixes can be from the SP's own address block.

Tunneling Type	Suggested Usage	Usage Notes
ISATAP	Point-to-multipoint tunnels that can be used to connect systems within a site.	Sites can use any IPv6 unicast addresses.

Individual tunnel types are discussed in detail in this document. We recommend that you review and understand the information about the specific tunnel type that you want to implement. When you are familiar with the type of tunnel you need, see the table below for a summary of the tunnel configuration parameters that you may find useful.

Table 78: Tunnel Configuration Parameters by Tunneling Type

Tunneling Type	Tunnel Configuration Parameter			
Tunnel Mode	Tunnel Source	Tunnel Destination	Interface Prefix or Address	
Manual	ipv6ip	An IPv4 address, or a reference to an interface on which IPv4 is configured.	An IPv4 address.	An IPv6 address.
GRE/IPv4	gre ip		An IPv4 address.	An IPv6 address.
IPv4-compatible	ipv6ip auto-tunnel		Not required. These are all point-to-multipoint tunneling types. The IPv4 destination address is calculated, on a per-packet basis, from the IPv6 destination.	Not required. The interface address is generated as <code>:: tunnel-source /96</code> .
6to4	ipv6ip 6to4		An IPv6 address. The prefix must embed the tunnel source IPv4 address.	
6RD	ipv6ip 6rd		An IPv6 address.	
ISATAP	ipv6ip isatap		An IPv6 prefix in modified eui-64 format. The IPv6 address is generated from the prefix and the tunnel source IPv4 address.	

GRE IPv4 Tunnel Support for IPv6 Traffic

IPv6 traffic can be carried over IPv4 GRE tunnels using the standard GRE tunneling technique that is designed to provide the services to implement any standard point-to-point encapsulation scheme. As in IPv6 manually configured tunnels, GRE tunnels are links between two points, with a separate tunnel for each link. The tunnels are not tied to a specific passenger or transport protocol but, in this case, carry IPv6 as the passenger protocol with the GRE as the carrier protocol and IPv4 or IPv6 as the transport protocol.

The primary use of GRE tunnels is for stable connections that require regular secure communication between two edge devices or between an edge device and an end system. The edge devices and the end systems must be dual-stack implementations.

Information About GRE IPv6 Tunnels

Overview of GRE IPv6 Tunnels

The GRE IPv6 Tunnels feature enables the delivery of packets from other protocols through an IPv6 network and allows the routing of IPv6 packets between private networks across public networks with globally routed IPv6 addresses.

For point-to-point GRE tunnels, each tunnel interface requires a tunnel source IPv6 address and a tunnel destination IPv6 address when being configured. All packets are encapsulated with an outer IPv6 header and a GRE header.

How to Implement Tunnels

Determining the Tunnel Type

Before configuring a tunnel, you must determine the type of tunnel you want to create.

SUMMARY STEPS

1. Determine the passenger protocol. A passenger protocol is the protocol that you are encapsulating.
2. Determine the **tunnel mode** command keyword, if appropriate.

DETAILED STEPS

Step 1 Determine the passenger protocol. A passenger protocol is the protocol that you are encapsulating.

Step 2 Determine the **tunnel mode** command keyword, if appropriate.

The table below shows how to determine the appropriate keyword to be used with the **tunnel mode** command.

Table 79: Determining the tunnel mode Command Keyword

Keyword	Purpose
dvmrp	Use the dvmrp keyword to specify that the Distance Vector Multicast Routing Protocol encapsulation will be used.
gre ip	Use the gre and ip keywords to specify that GRE encapsulation over IP will be used.
gre ipv6	Use the gre and ipv6 keywords to specify that GRE encapsulation over IPv6 will be used.
ipip [decapsulate-any]	Use the ipip keyword to specify that IP-in-IP encapsulation will be used. The optional decapsulate-any keyword terminates any number of IP-in-IP tunnels at one tunnel interface. Note that this tunnel will not carry any outbound traffic; however, any number of remote tunnel endpoints can use a tunnel configured as their destination.
ipv6	Use the ipv6 keyword to specify that generic packet tunneling in IPv6 will be used.

Keyword	Purpose
ipv6ip	Use the ipv6ip keyword to specify that IPv6 will be used as the passenger protocol and IPv4 as both the carrier (encapsulation) and transport protocol. When additional keywords are not used, manual IPv6 tunnels are configured. Additional keywords can be used to specify IPv4-compatible, 6to4, or ISATAP tunnels.
mpls	Use the mpls keyword to specify that MPLS will be used for configuring traffic engineering (TE) tunnels.

Configuring an IPv4 GRE Tunnel

Perform this task to configure a GRE tunnel. A tunnel interface is used to pass protocol traffic across a network that does not normally support the protocol. To build a tunnel, you must define a tunnel interface on each of the two routers, and the tunnel interfaces must reference each other. At each router, the tunnel interface must be configured with a Layer 3 address. The tunnel endpoints, tunnel source, and tunnel destination must be defined, and the type of tunnel must be selected. Optional steps can be performed to customize the tunnel.

Remember to configure the router at each end of the tunnel. If only one side of a tunnel is configured, the tunnel interface may still come up and stay up (unless keepalive is configured), but packets going into the tunnel will be dropped.

GRE Tunnel Keepalive

Keepalive packets can be configured to be sent over IP-encapsulated GRE tunnels. You can specify the rate at which keepalives are sent and the number of times that a device will continue to send keepalive packets without a response before the interface becomes inactive. GRE keepalive packets may be sent from both sides of a tunnel or from just one side.

Before you begin

Ensure that the physical interface to be used as the tunnel source in this task is up and configured with the appropriate IP address. For hardware technical descriptions and information about installing interfaces, see the hardware installation and configuration publication for your product.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	interface <i>type number</i> Example: <pre>Router(config)# interface tunnel 0</pre>	Specifies the interface type and number, and enters interface configuration mode. <ul style="list-style-type: none"> To configure a tunnel, use tunnel for the <i>type</i> argument.
Step 4	bandwidth <i>kb/s</i> Example: <pre>Router(config-if)# bandwidth 1000</pre>	Sets the current bandwidth value for an interface and communicates it to higher-level protocols. <ul style="list-style-type: none"> Specifies the tunnel bandwidth to be used to transmit packets. Use the <i>kb/s</i> argument to set the bandwidth, in kilobits per second (kb/s). <p>Note This is only a routing parameter; it does not affect the physical interface. The default bandwidth setting on a tunnel interface is 9.6 kb/s. You should set the bandwidth on a tunnel to an appropriate value.</p>
Step 5	keepalive [<i>period</i> [<i>retries</i>]] Example: <pre>Router(config-if)# keepalive 3 7</pre>	(Optional) Specifies the number of times the device will continue to send keepalive packets without response before bringing the tunnel interface protocol down. <ul style="list-style-type: none"> GRE keepalive packets may be configured either on only one side of the tunnel or on both. If GRE keepalive is configured on both sides of the tunnel, the <i>period</i> and <i>retries</i> arguments can be different at each side of the link. <p>Note This command is supported only on GRE point-to-point tunnels.</p> <p>Note The GRE tunnel keepalive feature should not be configured on a VRF tunnel. This combination of features is not supported.</p>
Step 6	tunnel source { <i>ip-address</i> <i>interface-type interface-number</i> } Example: <pre>Router(config-if)# tunnel source TenGigabitEthernet 4/1/0</pre>	Configures the tunnel source. <p>Note The tunnel source IP address and destination IP addresses must be defined on two separate devices.</p>
Step 7	tunnel destination { <i>hostname</i> <i>ip-address</i> } Example: <pre>Router(config-if)# tunnel destination 10.0.2.1</pre>	Configures the tunnel destination. <p>Note The tunnel source and destination IP addresses must be defined on two separate devices.</p>

	Command or Action	Purpose
Step 8	tunnel key <i>key-number</i> Example: Router(config-if)# tunnel key 1000	(Optional) Enables an ID key for a tunnel interface. Note This command is supported only on GRE tunnel interfaces. We do not recommend relying on this key for security purposes.
Step 9	tunnel mode gre { ip multipoint } Example: Device(config-if)# tunnel mode gre ip	Specifies the encapsulation protocol to be used in the tunnel.
Step 10	ip mtu <i>bytes</i> Example: Device(config-if)# ip mtu 1400	(Optional) Sets the MTU size of IP packets sent on an interface. <ul style="list-style-type: none"> • If an IP packet exceeds the MTU set for the interface, the Cisco software will fragment it unless the DF bit is set. • All devices on a physical medium must have the same protocol MTU in order to operate. • For IPv6 packets, use the ipv6 mtu command. Note If the tunnel path-mtu-discovery command is enabled do not configure this command.
Step 11	ip tcp mss <i>mss-value</i> Example: Device(config-if)# ip tcp mss 250	(Optional) Specifies the maximum segment size (MSS) for TCP connections that originate or terminate on a router.
Step 12	tunnel path-mtu-discovery [age-timer { <i>aging-mins</i> infinite }] Example: Device(config-if)# tunnel path-mtu-discovery	(Optional) Enables PMTUD on a GRE or IP-in-IP tunnel interface. <ul style="list-style-type: none"> • When PMTUD is enabled on a tunnel interface, PMTUD will operate for GRE IP tunnel packets to minimize fragmentation in the path between the tunnel endpoints.
Step 13	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

What to Do Next

Proceed to the “Verifying Tunnel Configuration and Operation” section.

Configuring 6to4 Tunnels

Before you begin

With 6to4 tunnels, the tunnel destination is determined by the border-router IPv4 address, which is concatenated to the prefix 2002::/16 in the format 2002:*border-router-IPv4-address* ::/48. The border router at each end of a 6to4 tunnel must support both the IPv4 and IPv6 protocol stacks.

Note The configuration of only one IPv4-compatible tunnel and one 6to4 IPv6 tunnel is supported on a router. If you choose to configure both of these tunnel types on the same router, Cisco recommends that they not share the same tunnel source.

A 6to4 tunnel and an IPv4-compatible tunnel cannot share the same interface because both of them are NBMA “point-to-multipoint” access links, and only the tunnel source can be used to reorder the packets from a multiplexed packet stream into a single packet stream for an incoming interface. When a packet with an IPv4 protocol type of 41 arrives on an interface, the packet is mapped to an IPv6 tunnel interface on the basis of the IPv4 address. However, if both the 6to4 tunnel and the IPv4-compatible tunnel share the same source interface, the router cannot determine the IPv6 tunnel interface to which it should assign the incoming packet.

Manually configured IPv6 tunnels can share the same source interface because a manual tunnel is a “point-to-point” link, and both IPv4 source and the IPv4 destination of the tunnel are defined.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>tunnel-number</i> Example: Router(config)# interface tunnel 0	Specifies a tunnel interface and number and enters interface configuration mode.
Step 4	ipv6 address <i>ipv6-prefix/prefix-length</i> [eui-64] Example: Router(config-if)# ipv6 address 2002:c0a8:6301:1::1/64	Specifies the IPv6 address assigned to the interface and enables IPv6 processing on the interface. <ul style="list-style-type: none"> • The 32 bits following the initial 2002::/16 prefix correspond to an IPv4 address assigned to the tunnel source. <p>Note See the "Configuring Basic Connectivity for IPv6" module for more information on configuring IPv6 addresses.</p>

	Command or Action	Purpose
Step 5	<p>tunnel source <i>{ip-address interface-type interface-number}</i></p> <p>Example:</p> <pre>Router(config-if)# tunnel source TenGigabitEthernet 4/1/0</pre>	<p>Specifies the source IPv4 address or the source interface type and number for the tunnel interface.</p> <p>Note The interface type and number specified in the tunnel source command must be configured with an IPv4 address.</p>
Step 6	<p>tunnel mode ipv6ip 6to4</p> <p>Example:</p> <pre>Router(config-if)# tunnel mode ipv6ip 6to4</pre>	Specifies an IPv6 overlay tunnel using a 6to4 address.
Step 7	<p>exit</p> <p>Example:</p> <pre>Router(config-if)# exit</pre>	Exits interface configuration mode and returns to global configuration mode.
Step 8	<p>ipv6 route <i>ipv6-prefix / prefix-length tunnel tunnel-number</i></p> <p>Example:</p> <pre>Router(config)# ipv6 route 2002::/16 tunnel 0</pre>	<p>Configures a static route to the specified tunnel interface.</p> <p>Note When configuring a 6to4 overlay tunnel, you must configure a static route for the IPv6 6to4 prefix 2002::/16 to the 6to4 tunnel interface.</p> <ul style="list-style-type: none"> The tunnel number specified in the ipv6 route command must be the same tunnel number specified in the interface tunnel command.
Step 9	<p>end</p> <p>Example:</p> <pre>Router(config)# end</pre>	Exits global configuration mode and returns to privileged EXEC mode.

What to Do Next

Proceed to the “Verifying Tunnel Configuration and Operation” section.

Verifying Tunnel Configuration and Operation

The **show** and **ping** commands in the steps below can be used in any sequence. The following commands can be used for GRE tunnels, IPv6 manually configured tunnels, and IPv6 over IPv4 GRE tunnels.

-
- Step 1** **enable**
- Enables privileged EXEC mode. Enter your password if prompted.
- Example:**
- ```
Device> enable
```
- Step 2**     **show interfaces tunnel** *number* [**accounting**]

Two routers are configured to be endpoints of a tunnel. Device A has TenGigabit Ethernet interface 4/1/0 configured as the source for tunnel interface 0 with an IPv4 address of 10.0.0.1 and an IPv6 prefix of 2001:0DB8:1111:2222::1/64. Device B has TenGigabit Ethernet interface 4/1/0 configured as the source for tunnel interface 1 with an IPv4 address of 10.0.0.2 and an IPv6 prefix of 2001:0DB8:1111:2222::2/64.

To verify that the tunnel source and destination addresses are configured, use the **show interfaces tunnel** command on Device A.

**Example:**

```
Device A# show interfaces tunnel 0

Tunnel0 is up, line protocol is up
 Hardware is Tunnel
 MTU 1514 bytes, BW 9 Kbit, DLY 500000 usec,
 reliability 255/255, txload 1/255, rxload 1/255
 Encapsulation TUNNEL, loopback not set
 Keepalive not set
 Tunnel source 10.0.0.1 (TenGigabitEthernet4/1/0), destination 10.0.0.2, fastswitch TTL 255
 Tunnel protocol/transport GRE/IP, key disabled, sequencing disabled
 Tunnel TTL 255
 Checksumming of packets disabled, fast tunneling enabled
 Last input 00:00:14, output 00:00:04, output hang never
 Last clearing of "show interface" counters never
 Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
 Queueing strategy: fifo
 Output queue :0/0 (size/max)
 5 minute input rate 0 bits/sec, 0 packets/sec
 5 minute output rate 0 bits/sec, 0 packets/sec
 4 packets input, 352 bytes, 0 no buffer
 Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
 0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
 8 packets output, 704 bytes, 0 underruns
 0 output errors, 0 collisions, 0 interface resets
 0 output buffer failures, 0 output buffers swapped out
```

**Step 3** ping [*protocol*] *destination*

To check that the local endpoint is configured and working, use the **ping** command on Device A.

**Example:**

```
DeviceA# ping 2001:0DB8:1111:2222::2

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 2001:0DB8:1111:2222::2, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 20/20/20 ms
```

**Step 4** show ip route [*address* [*mask*]]

To check that a route exists to the remote endpoint address, use the **show ip route** command.

**Example:**

```
DeviceA# show ip route 10.0.0.2

Routing entry for 10.0.0.0/24
 Known via "connected", distance 0, metric 0 (connected, via interface)
 Routing Descriptor Blocks:
 * directly connected, via TenGigabitEthernet4/1/0
 Route metric is 0, traffic share count is 1
```

**Step 5** ping *[protocol] destination*

To check that the remote endpoint address is reachable, use the **ping** command on Device A.

**Note** The remote endpoint address may not be reachable using the **ping** command because of filtering, but the tunnel traffic may still reach its destination.

**Example:**

```
DeviceA# ping 10.0.0.2
```

```
Type escape sequence to abort.
```

```
Sending 5, 100-byte ICMP Echos to 10.0.0.2, timeout is 2 seconds:
```

```
!!!!!
```

```
Success rate is 100 percent (5/5), round-trip min/avg/max = 20/21/28 ms
```

To check that the remote IPv6 tunnel endpoint is reachable, use the **ping** command again on Device A. The note regarding filtering earlier in step also applies to this example.

**Example:**

```
DeviceA# ping 2001:0DB8:1111:2222::2
```

```
Type escape sequence to abort.
```

```
Sending 5, 100-byte ICMP Echos to 1::2, timeout is 2 seconds:
```

```
!!!!!
```

```
Success rate is 100 percent (5/5), round-trip min/avg/max = 20/20/20 ms
```

These steps may be repeated at the other endpoint of the tunnel.

## Configuration Examples for Implementing Tunnels

### Example: Configuring a GRE IPv4 Tunnel

The following example shows a simple configuration of GRE tunneling. Note that TenGigabit Ethernet interface 4/1/0 is the tunnel source for Router A and the tunnel destination for Router B. TenGigabit Ethernet interface 4/1/1 is the tunnel source for Router B and the tunnel destination for Router A.

**Router A**

```
interface Tunnel 0
 ip address 10.1.1.2 255.255.255.0
 tunnel source TenGigabitEthernet 4/1/0
 tunnel destination 192.168.3.2
 tunnel mode gre ip
!
interface TenGigabitEthernet 4/1/0
 ip address 192.168.4.2 255.255.255.0
```

**Router B**

```
interface Tunnel 0
```

```

ip address 10.1.1.1 255.255.255.0
tunnel source TenGigabitEthernet 4/1/1
tunnel destination 192.168.4.2
tunnel mode gre ip
!
interface TenGigabitEthernet 4/1/1
ip address 192.168.3.2 255.255.255.0

```

The following example configures a GRE tunnel running both IS-IS and IPv6 traffic between Router A and Router B:

### Router A

```

ipv6 unicast-routing
clns routing
!
interface Tunnel 0
no ip address
ipv6 address 2001:0DB8:1111:2222::1/64
ipv6 router isis
tunnel source TenGigabitEthernet 4/1/0
tunnel destination 10.0.0.2
tunnel mode gre ip
!
interface TenGigabitEthernet 4/1/0
ip address 10.0.0.1 255.255.255.0
!
router isis
network 49.0000.0000.000a.00

```

### Router B

```

ipv6 unicast-routing
clns routing
!
interface Tunnel 0
no ip address
ipv6 address 2001:0DB8:1111:2222::2/64
ipv6 router isis
tunnel source TenGigabitEthernet 4/1/0
tunnel destination 10.0.0.1
tunnel mode gre ip
!
interface TenGigabitEthernet 4/1/0
ip address 10.0.0.2 255.255.255.0
!
router isis
network 49.0000.0000.000b.00
address-family ipv6
redistribute static
exit-address-family

```

## Configuring QoS Options on Tunnel Interfaces Examples

The following sample configuration applies GTS directly on the tunnel interface. In this example, the configuration shapes the tunnel interface to an overall output rate of 500 kb/s.

```

interface Tunnel 0
ip address 10.1.2.1 255.255.255.0

```

```

traffic-shape rate 500000 125000 125000 1000
tunnel source 10.1.1.1
tunnel destination 10.2.2.2

```

The following sample configuration shows how to apply the same shaping policy to the tunnel interface with the MQC commands:

```

policy-map tunnel
 class class-default
 shape average 500000 125000 125000
!
interface Tunnel 0
 ip address 10.1.2.1 255.255.255.0
 service-policy output tunnel
 tunnel source 10.1.35.1
 tunnel destination 10.1.35.2

```

## Policing Example

When an interface becomes congested and packets start to queue, you can apply a queueing method to packets that are waiting to be transmitted. Logical interfaces--tunnel interfaces in this example--do not inherently support a state of congestion and do not support the direct application of a service policy that applies a queueing method. Instead, you must apply a hierarchical policy. Create a "child" or lower-level policy that configures a queueing mechanism, such as low-latency queueing, with the **priority** command and CBWFQ with the **bandwidth** command.

```

policy-map child
 class voice
 priority 512

```

Create a "parent" or top-level policy that applies class-based shaping. Apply the child policy as a command under the parent policy because admission control for the child class is done according to the shaping rate for the parent class.

```

policy-map tunnel
 class class-default
 shape average 2000000
 service-policy child

```

Apply the parent policy to the tunnel interface.

```

interface tunnel 0
 service-policy tunnel

```

In the following example, a tunnel interface is configured with a service policy that applies queueing without shaping. A log message is displayed noting that this configuration is not supported.

```

Router(config)# interface tunnel1
Router(config-if)# service-policy output child
Class Based Weighted Fair Queueing not supported on this interface

```

# How to Configure IPv6 over IPv4 GRE Tunnels

## Configuring GRE on IPv6 Tunnels

GRE tunnels can be configured to run over an IPv6 network layer and to transport IPv4 and IPv6 packets in IPv6 tunnels.

### Before you begin

When GRE IPv6 tunnels are configured, IPv6 addresses are assigned to the tunnel source and the tunnel destination. The tunnel interface can have either IPv4 addresses or IPv6 addresses assigned (this is not shown in the task). The host or device at each end of a configured tunnel must support both the IPv4 and IPv6 protocol stacks.

### Procedure

|               | Command or Action                                                                                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> enable                                                                                                                                                                                                                                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                           |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                                                                                                                                                                                                                                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 3</b> | <b>interface tunnel <i>tunnel-number</i></b><br><b>Example:</b><br>Device(config)# interface tunnel 0                                                                                                                                                                                                                                                    | Specifies a tunnel interface and number, and enters interface configuration mode.                                                                                                                                                                                                                                                                                            |
| <b>Step 4</b> | Enter one of the following commands: <ul style="list-style-type: none"> <li>• <b>ipv6 address</b> {<i>ipv6-address/prefix-length</i>   <i>prefix-name sub-bits/prefix-length</i>}</li> <li>• <b>ipv6 address</b> <i>ipv6-prefix/prefix-length</i> [<b>eui-64</b>]</li> </ul> <b>Example:</b><br>Device(config-if)# ipv6 address<br>3ffe:b00:c18:1::3/127 | Specifies the IPv6 network assigned to the interface and enables IPv6 processing on the interface. <ul style="list-style-type: none"> <li>• If you specify the <b>eui-64</b> keyword, the software configures an IPv6 address for an interface and enables IPv6 processing on the interface using an EUI-64 interface ID in the low-order 64 bits of the address.</li> </ul> |
| <b>Step 5</b> | <b>tunnel source</b> { <i>ip-address</i>   <i>ipv6-address</i>   <i>interface-type interface-number</i> }<br><b>Example:</b><br>Device(config-if)# tunnel source Tengigabitethernet<br>4/1/0                                                                                                                                                             | Specifies the source IPv4 address, IPv6 address, or the source interface type and number for the tunnel interface. <ul style="list-style-type: none"> <li>• If an interface is specified, the interface must be configured with an IPv4 address.</li> </ul>                                                                                                                  |

|        | Command or Action                                                                                                                                                                                                 | Purpose                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <b>tunnel destination</b> {hostname   ip-address   ipv6-address}<br><b>Example:</b><br><pre>Device(config-if)# tunnel destination 2001:DB8:1111:2222::1/64</pre>                                                  | Specifies the destination IPv4 address, IPv6 address, or hostname for the tunnel interface.                                                     |
| Step 7 | <b>tunnel mode</b> {aurp   cayman   dvmrp   eon   gre   gre multipoint   gre ipv6   ipip [decapsulate-any]   iptalk   ipv6   mpls   nos}<br><b>Example:</b><br><pre>Device(config-if)# tunnel mode gre ipv6</pre> | Specifies a GRE IPv6 tunnel.<br><b>Note</b> The <b>tunnel mode gre ipv6</b> command specifies GRE as the encapsulation protocol for the tunnel. |
| Step 8 | <b>end</b><br><b>Example:</b><br><pre>Device(config-if)# end</pre>                                                                                                                                                | Returns to privileged EXEC mode.                                                                                                                |

## Configuration Examples for IPv6 over IPv4 GRE Tunnels

### Example: GRE Tunnel Running IS-IS and IPv6 Traffic

The following example configures a GRE tunnel running both IS-IS and IPv6 traffic between Router A and Router B:

#### Router A Configuration

```
ipv6 unicast-routing
clns routing
!
interface tunnel 0
no ip address
ipv6 address 3ffe:b00:c18:1::3/127
ipv6 router isis
tunnel source TenGigabitEthernet 4/1/0
tunnel destination 2001:DB8:1111:2222::1/64
tunnel mode gre ipv6
!
interface TenGigabitEthernet4/1/0
ip address 10.0.0.1 255.255.255.0
!
router isis
net 49.0000.0000.000a.00
```

#### Router B Configuration

```
ipv6 unicast-routing
clns routing
```

```

!
interface tunnel 0
 no ip address
 ipv6 address 3ffe:b00:c18:1::2/127
 ipv6 router isis
 tunnel source TenGigabitEthernet 4/1/0
 tunnel destination 2001:DB8:1111:2222::2/64
 tunnel mode gre ipv6
!
interface TenGigabitEthernet4/1/0
 ip address 10.0.0.2 255.255.255.0
!
router isis
 net 49.0000.0000.000b.00
 address-family ipv6
 redistribute static
 exit-address-family

```

## Example: Tunnel Destination Address for IPv6 Tunnel

```

Router(config)#interface Tunnel0
Router(config-if)#ipv6 address 2001:1:1::1/48
Router(config-if)#tunnel source TenGigabitEthernet 4/1/0
Router(config-if)#tunnel destination 10.0.0.2
Router(config-if)#tunnel mode gre ipv6
Router(config-if)#exit
!
Router(config)#interface TenGigabitEthernet4/1/0
Router(config-if)#ip address 10.0.0.1 255.255.255.0
Router(config-if)#exit
!
Router(config)#ipv6 unicast-routing
Router(config)#router isis
Router(config)#net 49.0000.0000.000a.00

```

# How to Configure GRE IPv6 Tunnels

## Configuring GRE IPv6 Tunnels

Perform this task to configure a GRE tunnel on an IPv6 network. GRE tunnels can be configured to run over an IPv6 network layer and transport IPv6 and IPv4 packets through IPv6 tunnels.

---

**Note** You must enable IPv6 or configure IPv6 MTU size more than 1500 on a tunnel's exit interface to avoid receiving warning messages.

---

### Before you begin

When GRE IPv6 tunnels are configured, IPv6 addresses are assigned to the tunnel source and the tunnel destination. The tunnel interface can have either IPv4 or IPv6 addresses (this is not shown in the task below). The host or device at each end of the configured tunnel must support both IPv4 and IPv6 protocol stacks.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *tunnel-number*
4. **tunnel source** {*ipv6-address* | *interface-type interface-number*}
5. **tunnel destination** *ipv6-address*
6. **tunnel mode gre ipv6**
7. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> enable                                                                                                      | Enables privileged EXEC mode.<br><br>• Enter your password if prompted.                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                                                              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                           |
| Step 3 | <b>interface tunnel</b> <i>tunnel-number</i><br><b>Example:</b><br>Device(config)# interface tunnel 0                                                   | Specifies a tunnel interface and number and enters interface configuration mode.                                                                                                                                                                                                                                                                            |
| Step 4 | <b>tunnel source</b> { <i>ipv6-address</i>   <i>interface-type interface-number</i> }<br><b>Example:</b><br>Device(config-if)# tunnel source ethernet 0 | Specifies the source IPv6 address or the source interface type and number for the tunnel interface.<br><br>• If an interface type and number are specified, the interface must be configured with an IPv6 address.<br><br><b>Note</b> Only the syntax used in this context is displayed. For more details, see the <a href="#">IPv6 Command Reference</a> . |
| Step 5 | <b>tunnel destination</b> <i>ipv6-address</i><br><b>Example:</b><br>Device(config-if)# tunnel destination 2001:0DB8:0C18:2::300                         | Specifies the destination IPv6 address for the tunnel interface.<br><br><b>Note</b> Only the syntax used in this context is displayed. For more details, see the <a href="#">IPv6 Command Reference</a> .                                                                                                                                                   |
| Step 6 | <b>tunnel mode gre ipv6</b><br><b>Example:</b><br>Device(config-if)# tunnel mode gre ipv6                                                               | Specifies a GRE IPv6 tunnel.<br><br><b>Note</b> The <b>tunnel mode gre ipv6</b> command specifies GRE as the encapsulation protocol for the tunnel interface. Only the syntax used in this context is displayed. For more details, see the <a href="#">IPv6 Command Reference</a> .                                                                         |

|        | Command or Action                                       | Purpose                                                                 |
|--------|---------------------------------------------------------|-------------------------------------------------------------------------|
| Step 7 | <b>end</b><br><b>Example:</b><br>Device(config-if)# end | Exits interface configuration mode and returns to privileged EXEC mode. |

## Configuration Examples for GRE IPv6 Tunnels

### Example: Configuring GRE IPv6 Tunnels

The following example shows how to configure a GRE tunnel over an IPv6 transport. In this example, Ethernet0/0 has an IPv6 address, and this is the source address used by the tunnel interface. The destination IPv6 address of the tunnel is specified directly. In this example, the tunnel carries both IPv4 and IS-IS traffic.

```
interface Tunnel0
 ip address 10.1.1.1 255.255.255.0
 ip router isis
 tunnel source Ethernet0/0
 tunnel destination 2001:DB8:1111:2222::1
 tunnel mode gre ipv6
!
interface Ethernet0/0
 no ip address
 ipv6 address 2001:DB8:1111:1111::1/64
!
router isis
 net 49.0001.0000.0000.000a.00
```

## Feature Information for Generic Routing Encapsulation

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

---

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

---

*Table 80: Feature Information for Generic Routing Encapsulation*

| Feature Name                  | Releases                    | Feature Information                                                              |
|-------------------------------|-----------------------------|----------------------------------------------------------------------------------|
| Generic Routing Encapsulation | Cisco IOS XE Fuji<br>16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 25

# Transparent LAN Service over Cable

This document describes the Transparent LAN Service (TLS) over Cable feature, which enhances existing Wide Area Network (WAN) support to provide more flexible Managed Access for multiple Internet service provider (ISP) support over a hybrid fiber-coaxial (HFC) cable network. This feature allows service providers to create a Layer 2 tunnel by mapping an upstream service identifier (SID) to an IEEE 802.1Q Virtual Local Area Network (VLAN).

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

Table 81: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Prerequisites for Transparent LAN Service over Cable

- You must know the hardware (MAC) addresses of the cable modems that are to be mapped to IEEE 802.1Q VLANs.
- You must create a bridge group for each separate customer on the Layer 2 bridge aggregator, so that traffic from all of the Customer Premises Equipment (CPE) devices for the customer is grouped together into the same 802.1Q tunnel.

## Restrictions for Transparent LAN Service over Cable

- Configuring 802.1Q for a particular cable modem removes any previous cable modem configuration on the router.
- We strongly recommend that TLS over Cable only be used when Baseline Privacy Interface (BPI) is enabled in the environment. If BPI is not enabled when using the TLS feature, traffic can flow between multiple virtual private networks (VPNs), and become vulnerable to denial-of-service attacks or snooping.

We also recommend that remote networks be isolated with a gateway or firewall router when BPI is not enabled.

When the TLS feature is used with Layer 2 VPNs, the participating cable modems *must* have the Baseline Privacy Interface security feature (BPI) enabled. Otherwise, the Cisco CMTS drops such Layer 2 traffic in the upstream or downstream.

- Packets are mapped to their Layer 2 tunnel only on the basis of Layer 2 information (the cable modem's MAC address and primary SID). Layer 3 services, such as access lists, IP address source-verify, and IP QoS, are not supported as packets are sent through the tunnel.
- All traffic from a cable modem is mapped to the same Layer 2 tunnel. It is not possible to differentiate traffic from different customer premises equipment (CPE) devices behind the cable modem.
- CPE learning is not available when using the Transparent LAN Service over Cable feature. When a cable modem is mapped to a Layer 2 tunnel, the **show interface cable modem** command shows that the IP addresses for its CPE devices are "unavailable."
- DOCSIS QoS is supported across the Layer 2 tunnel only on the primary SID. Traffic using secondary services uses the same Layer 2 tunnel as the primary SID.
- The Spanning Tree Protocol (STP) cannot be used with devices (cable modems, their CPE devices, and the endpoint CPE devices) that are using this feature. In particular, Spanning Tree Protocol cannot be used between the VLAN bridge aggregator and the endpoint customer devices.
- The following restrictions apply to Layer 2 tunnels over an Ethernet IEEE 802.1Q VLAN interface:
  - IEEE 802.1Q tunnels are supported only on Ten Gigabit Ethernet interfaces.
  - The Cisco CMTS router supports a maximum of 4095 VLAN IDs, but the switches acting as the bridge aggregator might support a lower number of VLAN IDs. If this is the case, the Cisco CMTS should be configured only for the maximum number of VLANs that are supported by the bridge aggregator switches.

## Information About Transparent LAN Service over Cable

This section contains the following:

### Feature Overview

The Transparent LAN Service over Cable feature enables service providers to provide Layer 2 tunnels for traffic to and from cable modems. This allows customers to create their own virtual local area network (VLAN) using any number of cable modems in multiple sites.

On the Cisco CMTS, you map each cable modem (on the basis of its MAC address) to the appropriate VLAN. The CMTS then creates an internal database of this one-to-one mapping of cable modems to VLANs, and uses it to encapsulate packets for the appropriate VLAN.

The CMTS encapsulates the CPE traffic from mapped cable modems using the following method:

- IEEE 802.1Q Mapping—The cable modem's MAC address is mapped to an IEEE 802.1Q VLAN on a specific Ten Gigabit Ethernet interface, so that all traffic from the cable modem is tagged with the specified VLAN ID.

Traffic to and from this group of cable modems is bridged into a single logical network (the VLAN) by the bridge aggregator, creating a secure Virtual Private Network (VPN) for that particular group of cable modems. Traffic in one VLAN cannot be sent into another VLAN, unless specifically done so by an external router.

The switch acting as the Layer 2 Bridge Aggregator uses the VLAN tagging to forward the traffic to the appropriate destination. This frees up service providers from needing to know the addressing, routing, and topological details of the customer's network.

## Transparent LAN Service and Layer 2 Virtual Private Networks

In addition, service providers can provide a Layer 2 VPN with only minimal configuration changes on the provider's routers. The service subscriber does not need to make any changes to their private network or cable modems, nor does the service provider have to provide any special DOCSIS configuration files to enable this feature.

For the TLS feature with Layer 2 VPNs:

- When the TLS feature is used with Layer 2 VPNs, the participating cable modems must have the Baseline Privacy Interface security feature (BPI) enabled. Otherwise, the Cisco CMTS drops such Layer 2 traffic in the upstream or downstream.
- Information about Customer Premises Equipment (CPE) does not display in the output of the **show cable modem** command.

## IEEE 802.1Q Mapping

This section describes the mapping of cable modems to an IEEE 802.1Q VLAN, as it is available in the Transparent LAN Service over Cable feature:

### Overview

The Transparent LAN Service over Cable feature enables service providers to provide Layer 2 tunnels over an Ethernet network, using IEEE 802.1Q standard tags. This allows customers to create their own virtual network using any number of cable modems in different sites.

On the Cisco CMTS, you map each cable modem (on the basis of its MAC address) to the appropriate VLAN. The CMTS then creates an internal database of this one-to-one mapping of cable modems to VLANs, and uses it to encapsulate packets for the appropriate VLAN.

The CMTS encapsulates the CPE traffic from mapped cable modems using VLAN tags, as defined in [IEEE 802.1Q-1993, IEEE Standards for Local and Metropolitan Area Networks: Virtual Bridged Local Area Networks](#). The switch acting as the Layer 2 Bridge Aggregator uses the VLAN tagging to forward the packets to the appropriate destination.

Traffic to and from this group of cable modems is bridged into a single logical network by the bridge aggregator, creating a secure Virtual Private Network (VPN) for that particular group of cable modems. Traffic in one VLAN cannot be sent into another VLAN, unless specifically done so by an external router.

### Details of IEEE 802.1Q Mapping

To implement the Transparent LAN Service over Cable feature using IEEE 802.1Q VLANs, a service provider must perform the following configuration steps:

1. Identify the cable modems and their MAC addresses that should be mapped to the IEEE 802.1Q VLANs.
2. Create the required VLANs on the router that is acting as the bridge aggregator.
3. Enable Layer 2 mapping on the Cisco CMTS, and then map each cable modem on that Cisco CMTS to the appropriate VLAN.

After the Transparent LAN Service over Cable feature has been enabled and configured to use IEEE 802.1Q mappings, the Cisco CMTS immediately begins mapping traffic between the associated cable modems and VLANs. For efficient mapping, the Cisco CMTS maintains an internal database that links each cable modem's primary service flow ID (SFID) and service ID (SID) to the appropriate VLAN and Ethernet interface. This ensures that all service flows from the cable modem are routed properly.

When the Cisco CMTS receives a packet on an upstream, it looks up its SID to see if it is mapped to a VLAN. If so, and if the packet's source MAC address is not the cable modem's MAC address, the Cisco CMTS inserts the appropriate IEEE 802.1Q VLAN tag into the packet's header and forwards the packet to the appropriate Ethernet interface. If the packet is not being mapped, or if the packet originated from the cable modem, the Cisco CMTS routes the packet using the normal Layer 3 processes.

When the Cisco CMTS receives a packet from a WAN interface that is encapsulated with an IEEE 802.1Q VLAN tag, it looks up the packet's SID to see if it belongs to a cable modem being mapped. If so, the Cisco CMTS strips off the VLAN tag, adds the proper DOCSIS header, and transmits the packet on the appropriate downstream interface. If the packet is not being mapped, the Cisco CMTS continues with the normal Layer 3 processing.

## Benefits

The Transparent LAN Service over Cable feature provides the following benefits to cable service providers and their partners and customers:

- Provides Layer 2 level mapping, which is transparent to Layer 3 protocols and services. This means that service providers do not need to know the details of their customers' network topologies, routing protocols, or IP addressing.
- Allows service providers to maximize the use of their existing Ethernet WAN networks. Multiple customers can be combined on the same outgoing interface, while still ensuring that each customer's network is kept private while it is transmitted over the tunnel.
- Provides a highly flexible and scalable solution for multiple customers. The service provider needs to create only one bridge group for each VPN, and then only one VLAN mapping for each cable modem should participate in that VPN tunnel.
- Customers retain full control over their private networks, while service providers retain full control over cable modems and the rest of the cable and WAN networks. Only the CPE traffic from the cable modems is mapped into the L2VPN tunnel, while traffic originating at the cable modem continues to be processed as normal by the service provider's network.
- Allows service providers to mix tunneled and non-tunneled cable modems on the same DOCSIS cable network.
- Allows customers to create a single, secure virtual network with Ethernet Layer 2 connectivity for multiple sites.
- Allows multiple tunnels from different customers and endpoints to be aggregated into a single bridge, so as to maximize the use of bandwidth and other network resources.
- Supports the tunneling of multiple Layer 3, non-IP protocols, and not just IP Layer 3 services, as is the case with Layer 3 solutions, such as Multiprotocol Label Switching (MPLS) VPNs.
- All DOCSIS services, including BPI+ encryption and authentication, continue to be supported for all cable modems.

## How to Configure the Transparent LAN Service over Cable

This section contains the following:

## Configuring IEEE 802.1Q VLAN Mapping

This section describes how to enable Layer 2 mapping on the Cisco CMTS, and then to map particular cable modems to an IEEE 802.1Q VLAN.

### Enabling and Configuring Layer 2 Tunneling for IEEE 802.1Q Mapping

This section describes how to enable Layer 2 mapping on the Cisco CMTS, and then to map particular cable modems to IEEE 802.1Q VLANs on a Ten Gigabit Ethernet interface.

#### Procedure

|               | Command or Action                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Router> enable                                                                                                                               | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                   |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# configure terminal                                                                                                       | Enters global configuration mode.                                                                                                                                                                                                                |
| <b>Step 3</b> | <b>cable l2-vpn-service xconnect nsi dot1q</b><br><b>Example:</b><br><br>Router(config)# cable l2-vpn-service xconnect nsi dot1q                                                     | Enables Layer 2 tunneling for IEEE 802.1Q VLAN mapping.<br><br><b>Note</b> It is not required to configure VLAN trunking on the Cisco CMTS. Though VLAN trunking is supported, be aware of additional impact of VLAN trunking on the Cisco CMTS. |

| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br><br>Router(config)# end                                                                                                                             | Exits global configuration mode and returns to privileged EXEC mode.                                                                                                                                                                             |

### Creating the IEEE 802.1Q VLAN Bridge Group

This section describes the minimum configuration needed to configure a Cisco router, which is acting as an IEEE 802.1Q VLAN bridge aggregator, so that it can terminate the VLANs being used with the Transparent LAN Service over Cable feature.

## Procedure

|               | Command or Action                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                               |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre> <b>Example:</b>                                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                            |
| <b>Step 3</b> | <b>interface TenGigabitEthernet slot/subslot/port</b><br><b>Example:</b><br><pre>Router(config)# interface TenGigabitEthernet4/1/0</pre>      | Enters interface configuration mode for the Ten Gigabit Ethernet interface.                                                                                                                                                                                                                                                                                  |
| <b>Step 4</b> | <b>ip address ip-address mask</b><br><b>Example:</b><br><pre>Router(config-if)# ip address 10.10.10.85 255.255.255.0</pre>                    | Configures the interface with the specified IP address and subnet mask.                                                                                                                                                                                                                                                                                      |
| <b>Step 5</b> | <b>exit</b><br><b>Example:</b><br><pre>Router(config-if)# exit</pre>                                                                          | Exits interface configuration and returns to global configuration mode.                                                                                                                                                                                                                                                                                      |
| <b>Step 6</b> | <b>interface TenGigabitEthernet slot/subslot/port.y</b><br><b>Example:</b><br><pre>Router(config)# interface TenGigabitEthernet4/1/0.10</pre> | Creates a subinterface on the Ten Gigabit Ethernet interface.<br><b>Note</b> To simplify network management, set the subinterface number to the same value as the VLAN ID that will use this subinterface (which in this case is 10).<br><b>Note</b> The steps to create a subinterface is not essential for dot1q tagging of frames, but it is recommended. |
| <b>Step 7</b> | <b>bridge group number</b><br><b>Example:</b><br><pre>Router(config-if)# bridge group 20</pre>                                                | Configures this subinterface to belong to the specified bridge group.<br><b>Note</b> Repeat steps Step 5 through Step 7 for each subinterface to be created and bridged.                                                                                                                                                                                     |
| <b>Step 8</b> | <b>end</b><br><b>Example:</b><br><pre>Router(config-if)# end</pre>                                                                            | Exits interface configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                      |

# Configuration Examples for Transparent LAN Service over Cable

This section lists sample configurations for the Transparent LAN Service over Cable feature on a CMTS router and on a Cisco router acting as a bridge aggregator:

## Example: Configuring IEEE 802.1Q VLAN Mapping

The following partial configuration shows a typical configuration that shows a number of cable modems being mapped to two different IEEE 802.1Q VLANs.

```

cable l2-vpn-service xconnect nsi dot1q
! Customer 1
cable dot1q-vc-map 000C.0e03.69f9 TenGigabitEthernet 4/1/0 10 Customer1
cable dot1q-vc-map 0010.7bea.9c95 TenGigabitEthernet 4/1/0 11 Customer1
cable dot1q-vc-map 0010.7bed.81c2 TenGigabitEthernet 4/1/0 12 Customer1
cable dot1q-vc-map 0010.7bed.9b1a TenGigabitEthernet 4/1/0 13 Customer1
! Customer 2
cable dot1q-vc-map 0002.fdfa.137d TenGigabitEthernet 4/1/0 20 Customer2
cable dot1q-vc-map 0006.28f9.9d19 TenGigabitEthernet 4/1/0 21 Customer2
cable dot1q-vc-map 000C.7b6b.58c1 TenGigabitEthernet 4/1/0 22 Customer2
cable dot1q-vc-map 000C.7bed.9dbb TenGigabitEthernet 4/1/0 23 Customer2
cable dot1q-vc-map 000C.7b43.aa7f TenGigabitEthernet 4/1/0 24 Customer2
cable dot1q-vc-map 0050.7302.3d83 TenGigabitEthernet 4/1/0 25 Customer2
...

```

## Example: Configuring IEEE 802.1Q Bridge Aggregator

The following example shows a router being used as a bridge aggregator to transmit VLANs across the same Ten Gigabit Ethernet interface, using IEEE 802.1Q tagging.

```

!
interface TenGigabitEthernet4/1/0
ip address 10.10.10.31 255.255.255.0
duplex full
speed auto
!
interface TenGigabitEthernet4/1/0.10
description Customer1-site10
encapsulation dot1Q 10
bridge-group 200
interface TenGigabitEthernet4/1/0.11
description Customer1-site11
encapsulation dot1Q 11
bridge-group 200
interface TenGigabitEthernet4/1/0.12
description Customer1-site12
encapsulation dot1Q 12
bridge-group 200
interface TenGigabitEthernet4/1/0.13
description Customer1-site13
encapsulation dot1Q 13
bridge-group 200
!-----
interface TenGigabitEthernet4/1/0.20
description Customer2-site20
encapsulation dot1Q 20

```

```

bridge-group 201
interface TenGigabitEthernet4/1/0.21
 description Customer2-site21
 encapsulation dot1Q 21
 bridge-group 201
interface TenGigabitEthernet4/1/0.22
 description Customer2-site22
 encapsulation dot1Q 22
 bridge-group 201
interface TenGigabitEthernet4/1/0.23
 description Customer2-site23
 encapsulation dot1Q 23
 bridge-group 201
interface TenGigabitEthernet4/1/0.24
 description Customer2-site24
 encapsulation dot1Q 24
 bridge-group 201
interface TenGigabitEthernet4/1/0.25
 description Customer2-site25
 encapsulation dot1Q 25
 bridge-group 201
!
bridge 200 protocol ieee
bridge 201 protocol ieee
...

```

## Verifying the Transparent LAN Service over Cable Configuration

- **show cable l2-vpn xconnect dot1q-vc-map**—Displays the mapping information of the cable modems to IEEE 802.1Q VLANs.

Following is a sample output of the command:

```
Router# show cable l2-vpn xconnect dot1q-vc-map
```

| MAC Address    | Ethernet Interface      | VLAN ID | Cable Intf | SID | Customer Name/VPNID |
|----------------|-------------------------|---------|------------|-----|---------------------|
| 38c8.5cac.4a62 | TenGigabitEthernet4/1/2 | 56      | Cable3/0/0 | 4   | Customer2           |
| 38c8.5cfe.f6fa | TenGigabitEthernet4/1/2 | 34      | Cable3/0/0 | 3   | Customer1           |
| 602a.d083.2e1c | TenGigabitEthernet4/1/4 | 43      | Cable3/0/0 | 5   | Customer3           |

- **show cable l2-vpn xconnect dot1q-vc-map customer *name***—Displays the mapping information of the cable modems to IEEE 802.1Q VLANs for the specified customer name.

Following is a sample output of the command.

```
Router# show cable l2-vpn xconnect dot1q-vc-map customer Customer1
```

| MAC Address    | Ethernet Interface      | VLAN ID | Cable Intf | SID | Customer Name/VPNID |
|----------------|-------------------------|---------|------------|-----|---------------------|
| 38c8.5cfe.f6fa | TenGigabitEthernet4/1/2 | 34      | Cable3/0/0 | 3   | Customer1           |

- **show cable l2-vpn xconnect dot1q-vc-map mac-address**—Displays the mapping information of the cable modems to IEEE 802.1Q VLANs for the specified MAC address.

Following is a sample output of the command:

```
Router# show cable l2-vpn xconnect dot1q-vc-map 38c8.5cac.4a62
```

| MAC Address | Ethernet Interface | VLAN ID | Cable Intf | SID | Customer Name/VPNID |
|-------------|--------------------|---------|------------|-----|---------------------|
|-------------|--------------------|---------|------------|-----|---------------------|

```
38c8.5cac.4a62 TenGigabitEthernet4/1/2 56 Cable3/0/0 4 Customer2
```

- **show cable l2-vpn xconnect dot1q-vc-map mac-address verbose**—Displays additional information about the Layer 2 mapping, including the number of packets and bytes received on the upstream and downstream.

Following is a sample output of the command:

```
Router# show cable l2-vpn xconnect dot1q-vc-map 38c8.5cac.4a62 verbose
```

```
MAC Address : 38c8.5cac.4a62
Customer Name : Customer2
Prim Sid : 4
Cable Interface : Cable3/0/0
Ethernet Interface : TenGigabitEthernet4/1/2
DOT1Q VLAN ID : 56
Total US pkts : 1
Total US bytes : 342
Total DS pkts : 4
Total DS bytes : 512
```

## Feature Information for Transparent LAN Service over Cable

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmg.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 82: Feature Information for Upstream Channel Bonding**

| Feature Name                       | Releases                 | Feature Information                                                             |
|------------------------------------|--------------------------|---------------------------------------------------------------------------------|
| Transparent LAN Service over Cable | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Router. |

## CHAPTER 26

# Downgrading Channel Bonding in Battery Backup Mode

---

Cisco CMTS supports downgrading the channel bonding for cable modems and media terminal adapters (MTAs) in battery backup mode.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Prerequisites for Downgrading Channel Bonding in Battery Backup Mode

- The cable modem must be DOCSIS3.0-compliant with battery backup capability.
- At least one free Downstream Resilient Bonding Group (RBG) must be available.

**Note** For information about how to reserve RBG and verify reserved RBG, refer to [Downstream Resiliency Bonding Group](#) , on page 335

## Restrictions for Downgrading Channel Bonding in Battery Backup Mode

- If the cable modem does not support the CM-STATUS events 9 and 10, channel bonding is not downgraded for the cable modem in battery backup mode.

---

**Note** We recommend that you configure separate dynamic bonding groups for each primary channel in a MAC domain.

---

- If the cable modem has an active voice call, channel bonding is not downgraded for the cable modem in battery backup mode.
- If the cable modem is working on the protect line card, channel bonding is not downgraded if its primary channel is not included in the dynamic bonding group.
- If the line card switches over when the cable modem is entering or exiting the battery backup mode, the cable modem may go offline.

## Information About Downgrading Channel Bonding in Battery Backup Mode

When this feature is enabled and the cable modem enters the battery backup mode, channel bonding is downgraded to one downstream and one upstream channels (battery backup 1x1 mode). This feature reduces the power usage when the cable modem is running on battery backup. When the cable modem returns to the AC power mode, the channel bonding is returned to its original configuration. You can configure this feature globally and for each MAC domain.

---

**Note** We recommend that you enable this feature globally and for each MAC domain.

---

The cable modem uses the following CM-STATUS events to indicate its power status to the Cisco CMTS:

- 9—Indicates that the cable modem is operating in battery backup mode.
- 10—Indicates that the cable modem has returned to AC power mode.

When this feature is disabled, cable modem cannot downgrade the channel bonding even if it is running on battery backup.

# How to Configure Downgrading Channel Bonding in Battery Backup Mode

This section contains the following:

## Configuring Channel Bonding Downgrade in Battery Backup Mode Globally

### Procedure

|        | Command or Action                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                             |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                                                                      | Enters global configuration mode.                                                                                                                                                                                                                                                              |
| Step 3 | <b>cable reduction-mode mta-battery enable</b><br><b>Example:</b><br>Router(config)# <b>cable reduction-mode mta-battery enable</b>                                                                    | Enables the channel bonding downgrade for cable modems in battery backup mode.                                                                                                                                                                                                                 |
| Step 4 | <b>cable reduction-mode mta-battery dampen-time <i>seconds</i></b><br><b>Example:</b><br>Router(config)# <b>cable reduction-mode mta-battery dampen-time 40</b>                                        | (Optional) Configures the dampen time, in seconds, to defer the cable modems from entering or exiting the channel bonding downgrade 1x1 mode.                                                                                                                                                  |
| Step 5 | <b>cable reduction-mode mta-battery ranging-init-technique <i>us-ranging-init-technique</i></b><br><b>Example:</b><br>Router(config)# <b>cable reduction-mode mta-battery ranging-init-technique 3</b> | (Optional) Configures the init-ranging technique.                                                                                                                                                                                                                                              |
| Step 6 | <b>cable reduction-mode mta-battery dynamic-channel-percent <i>percent</i></b><br><b>Example:</b><br>Router(config)# <b>cable reduction-mode mta-battery dynamic-channel-percent 10</b>                | (Optional) Configures the maximum and first try percentage of dynamic channel bandwidth in battery backup mode.<br><br><b>Note</b> Ensure to leave enough bandwidth for primary channel so that it can allocate dynamic channel bandwidth when it joins a newly created dynamic bonding group. |
| Step 7 | <b>exit</b><br><b>Example:</b><br>Router(config)# <b>exit</b>                                                                                                                                          | Returns to the privileged EXEC mode.                                                                                                                                                                                                                                                           |

## Configuring Channel Bonding Downgrade in Battery Backup Mode for MAC Domain

### Procedure

|        | Command or Action                                                                                                                                          | Purpose                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                          | Enters global configuration mode.                                                                                                 |
| Step 3 | <b>interface wideband-cable</b><br><i>slot/subslot/port:wideband-channel</i><br><b>Example:</b><br>Router(config)# <b>interface wideband-cable 1/0/0:7</b> | Configures a wideband cable interface.                                                                                            |
| Step 4 | <b>cable ds-resiliency</b><br><b>Example:</b><br>Router(config-if)# <b>cable ds-resiliency</b>                                                             | Reserves a resiliency bonding group or WB interface for usage on a line card, on a per controller basis.                          |
| Step 5 | <b>exit</b><br><b>Example:</b><br>Router(config-if)# <b>exit</b>                                                                                           | Returns to the global configuration mode.                                                                                         |
| Step 6 | <b>interface cable</b> <i>slot/subslot/port</i><br><b>Example:</b><br>Router(config)# <b>interface cable 9/0/0</b>                                         | Specifies the cable interface on the router and enters the interface configuration mode.                                          |
| Step 7 | <b>cable reduction-mode mta-battery enable</b><br><b>Example:</b><br>Router(config-if)# <b>cable reduction-mode mta-battery enable</b>                     | Enables the channel bonding downgrade for cable modems in battery backup mode for each MAC domain.                                |
| Step 8 | <b>cable cm-status enable 9</b><br><b>Example:</b><br>Router(config-if)# <b>cable cm-status enable 9</b>                                                   | Enables the CM-STATUS event 9 for the MAC domain. The value 9 indicates that the cable modem is operating in battery backup mode. |
| Step 9 | <b>cable cm-status enable 10</b><br><b>Example:</b><br>Router(config-if)# <b>cable cm-status enable 10</b>                                                 | Enables the CM-STATUS event 10 for the MAC domain. The value 10 indicates that the cable modem has returned to AC power mode.     |

|         | Command or Action                                                  | Purpose                              |
|---------|--------------------------------------------------------------------|--------------------------------------|
| Step 10 | <b>end</b><br><br><b>Example:</b><br>Router(config-if)# <b>end</b> | Returns to the privileged EXEC mode. |

## Verifying the Configuration for Channel Bonding Downgrade in Battery Backup Mode

- **show cable modem**—Displays information if the cable modem is running in battery backup mode.

Following is a sample output of the command:

```
Router# show cable modem

D
MAC Address IP Address I/F MAC Prim RxPwr Timing Num
I
 State Sid (dBmv) Offset CPE

```

- **show cable modem reduction-mode mta-battery**—Displays the channel bonding downgrade information for cable modems in battery backup mode.

Following is a sample output of the command:

```
Router# show cable modem reduction-mode mta-battery

I/F MAC Address ID Orig BG RFs ID Curr BG Upstream

C7/0/0 0025.2eaf.843e 897 Wi7/0/0:0 4 252 Wi7/0/0:1 US0
C7/0/0 0025.2eaf.8356 897 Wi7/0/0:0 4 252 Wi7/0/0:1 US0
C7/0/0 0015.d176.5199 897 Wi7/0/0:0 4 252 Wi7/0/0:1 US0
```

Following is a sample output of the command for a cable modem when the MAC address is specified:

```
Router# show cable modem 0025.2eaf.843e reduction-mode mta-battery

I/F MAC Address ID Orig BG RFs ID Curr BG Upstream

```

```
C7/0/0 0025.2eaf.843e 897 Wi7/0/0:0 4 252 Wi7/0/0:1 US0
```

Following is a sample output of the command for a cable modem when the IP address is specified:

```
Router# show cable modem 90.18.0.9 reduction-mode mta-battery
```

| I/F    | MAC Address    | ID  | Orig BG   |     |     | Curr BG   |     | Upstream |
|--------|----------------|-----|-----------|-----|-----|-----------|-----|----------|
|        |                |     | I/F       | RFs | ID  | I/F       |     |          |
| C7/0/0 | 0025.2eaf.843e | 897 | Wi7/0/0:0 | 4   | 252 | Wi7/0/0:1 | US0 |          |

Following is a sample output of the command for a cable modem when the IPv6 address is specified:

```
Router# show cable modem 2001:18::9 reduction-mode mta-battery
```

| I/F    | MAC Address    | ID  | Orig BG   |     |     | Curr BG   |     | Upstream |
|--------|----------------|-----|-----------|-----|-----|-----------|-----|----------|
|        |                |     | I/F       | RFs | ID  | I/F       |     |          |
| C7/0/0 | 0025.2eaf.843e | 897 | Wi7/0/0:0 | 4   | 252 | Wi7/0/0:1 | US0 |          |

- **show cable modem verbose**—Displays the detailed information for the cable modem.

Following is a sample output of the command:

```
Router# show cable modem 54d4.6ffb.30fd verbose
```

```

**Note** *Battery Mode* indicates if the cable modem is in battery backup mode or AC power mode.

*Battery Mode Status* indicates the status of the cable modem:

- When the cable modem is in AC\_POWER\_MODE/BATTERY\_MODE status, it is in stable state.
- When the cable modem is in AC\_POWER\_PENDING/BATTERY\_PENDING status, it is in transfer state.
- When the cable modem is in AC\_POWER\_HOLD/BATTERY\_HOLD status, it is updating status of the last event received until the dampen time expires.

- **show cable modem cm-status**—Displays the cable modem CM-STATUS event information.

Following is a sample output of the command:

```
Router# show cable modem e448.c70c.9d80 cm-status
```

| I/F       | MAC Address    | Event          | TID | Count | Error | Dups | Time           |
|-----------|----------------|----------------|-----|-------|-------|------|----------------|

## Feature Information for Downgrading Channel Bonding in Battery Backup Mode

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 84: Feature Information for Downgrading Channel Bonding in Battery Backup Mode*

| Feature Name            | Releases                    | Feature Information                                                                                                 |
|-------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------|
| Battery Backup 1x1 Mode | Cisco IOS XE Everest 16.6.1 | This feature was introduced in the Cisco IOS XE Everest 16.6.1 on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 27

# Upstream Bonding Support for D-PON

---

The DOCSIS Passive Optical Network (D-PON) architecture, also known as RF over Glass (RFoG), helps the cable operators enter fiber-to-home market space and utilize the DOCSIS infrastructure effectively.

## Prerequisites for Upstream Bonding Support for D-PON

- DOCSIS 3.0 cable modems (CMs)
- DOCSIS 2.0 capable set-top boxes (STBs)
- You should configure the **cable upstream ranging-init-technique 2** command to prevent the use of additional broadcast initial ranging opportunities for the non D-PON reference upstream channels.

## Restrictions for Upstream Bonding Support for D-PON

- Multiple CMs cannot work at the same time. Each CM must get a separate time slot for upstream data transmission. Configuring D-PON ensures that the upstream scheduler allows only a single CM to transmit at a particular time.
- cBR8 does not support Upstream Bonding for D-PON on Remote-PHY.
- It is possible to enable or disable D-PON for individual Mac domain.

- When D-PON is enabled in a MAC domain, you must manually shut down and enable the MAC domain using **shutdown** and **no shutdown** command.
- All frequencies in a MAC domain must have the same configuration for:
  - minislot size
  - channel-width
  - modulation profile
- Supports only ATDMA DOCSIS mode.
- The following features are not supported in MAC domains configured for D-PON:
  - Load balancing
  - Spectrum management
  - Upstream configuration (to change upstream configuration, you should shut down the MAC domain)
  - S-CDMA logical channels
  - Lower modulations profiles (D-PON uses only 16 QAM and 64 QAM modulation profiles)
  - Channel-width other than 3.2 MHz and 6.4 MHz
  - In-service Software Upgrade (ISSU)
  - Mixing of D-PON and HFC on the same MAC domain
  - Software licensing

## Information About Upstream Bonding Support for D-PON

D-PON is a type of networking that allows the CMTS to transmit RF signals over the optical network. This technology enables the cable operators to use the RF technologies in a Hybrid Fiber-Coaxial (HFC) network.

The downstream data from the CMTS is combined with other RF signals at the hub and is sent to the transmitter. The signal from the transmitter is intended for multiple PONs. Each PON serves 32 homes from a single fiber.

The upstream data from the Optical Network Terminal (ONT) is combined at the splitter and sent to the hub, which is then routed to the optical receiver (RX). Upstream data from multiple optical receivers are combined and sent to the CMTS.

The upstream data to the CMTS contains signals from multiple PONs. Each upstream optical receiver is dedicated to a PON that can have multiple DOCSIS upstream sources (multiple modems and DSG terminals).

A PON can be configured in different ways, depending on the coaxial network. These configurations broadly fall under the following categories:

- Internal Control Configuration—In this configuration, the internal CM of the ONT controls the laser. Upstream signals go to the Ethernet interface of the CM allowing the ONT to control upstream timing. The device that uses this type of configuration is the Digital Audio Visual Council (DAVIC) set top terminal (STT).

- **External Control Configuration**—In this configuration, the presence of the RF at the ONT upstream input activates the laser. The device that uses this type of configuration is the DOCSIS Set-top Gateway (DSG) device.
- **Dual Control Configuration**—In this configuration, the home that contains an ONT with an internal CM and other DOCSIS upstream sources, like DSG devices. The RF presence detector or the internal CM control line detects the upstream signal and activates the upstream laser.

## D-PON on Upstream Scheduling

In D-PON implementation, the native upstream scheduling software of the CMTS controls the timing of the upstream data transmission. Only one PON Receiver Domain (PRD) is allowed to transmit upstream data at any given point of time, irrespective of the upstream frequency allocation. The reason for this is that two lasers from the ONT of a PRD cannot work simultaneously as it leads to an Optical Beat Interference (OBI). Moreover, the use of a frequency modulation (FM) for an upstream signal transmission results in PHY errors when multiple ONTs within a PON transmit simultaneously.

Initial maintenance regions are scheduled on all upstream channels to prevent the DOCSIS 3.0 CMs in a D-PON environment from failing initial ranging on any upstream channel. When a ranging request is received within a MAC domain configured for D-PON, the CM receives an upstream channel override to the D-PON reference channel (US0).

In this implementation of D-PON, a DOCSIS device within a PRD is given a timeslot to transmit the upstream data, irrespective of the upstream frequency. Therefore, there is no benefit in having more than one upstream in a MAC domain without using the upstream channel bonding feature.

The D-PON feature supports the following service types:

- Best effort (BE) 3.0 using up to four frequencies concurrently
- BE 2.0 using only a single frequency
- Unsolicited grant service (UGS) using only a single frequency
- Real-time polling service (RTPS) using only a single frequency
- Non-real-time polling service (nRTPS) using only a single frequency

## How to Configure Upstream Bonding Support for D-PON

This section describes how to enable D-PON for a MAC domain on the Cisco cBR router. The bonding group must include a reference channel which is default to the upstream channel 0.

**Note** The USCB can support a maximum of 4 US channels in a RFOG MAC domain in the following combination:

- US0
- US0, US1
- US0, US1, US2
- US0, US1, US2, US3

All US channels must be configured to have the same number of minislots, channel width (only 3.2 and 6.4 MHz supported), DOCSIS mode (only ATDMA supported) and modulation profile.

### Procedure

|               | Command or Action                                                                                                            | Purpose                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                    | Enables privileged EXEC mode. Enter your password if prompted.              |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                                            | Enters global configuration mode.                                           |
| <b>Step 3</b> | <b>interface cable slot/subslot/cable-interface-index</b><br><b>Example:</b><br>Router(config)# <b>interface cable 8/0/0</b> | Enters interface configuration mode for the specified cable interface.      |
| <b>Step 4</b> | <b>cable upstream dpon</b><br><b>Example:</b><br>Router(config-if)# <b>cable upstream dpon</b>                               | Enables D-PON for a MAC domain.                                             |
| <b>Step 5</b> | <b>shutdown</b><br><b>Example:</b><br>Router(config-if)# <b>shutdown</b>                                                     | Shuts down the interface.                                                   |
| <b>Step 6</b> | <b>no shutdown</b><br><b>Example:</b><br>Router(config-if)# <b>no shutdown</b>                                               | Enables the interface.                                                      |
| <b>Step 7</b> | <b>end</b><br><b>Example:</b><br>Router(config-if)# <b>end</b>                                                               | Exits interface configuration mode and returns to the privileged EXEC mode. |

## DOCSIS 3.0 Cable Modems Upstream Bonding Enters Partial Bonding

Sometimes, upstream bonding enters partial bonding while reverting to the original CLC after switchover.

In the following example, the switchover is performed between CLC in slot 1 and 0. After reverting to CLC in slot 1, C1/0/3/UB turns to C1/0/3/p. The following output highlights the change:

```
Router# show cable modem
Load for five secs: 1%/0%; one minute: 2%; five minutes: 2% Time source is NTP, 13:00:25.570
UTC Thu Feb 18 2016
```

| MAC Address    | IP Address   | I/F             | MAC State | Prim Sid | RxPwr (dBmv) | Timing Offset | Num CPE | D I P |
|----------------|--------------|-----------------|-----------|----------|--------------|---------------|---------|-------|
| 4844.8789.e0fc | 10.78.100.6  | C1/0/0/UB       | w-online  | 6        | -0.50        | 1787          | 0       | N     |
| c8fb.2639.33d0 | 10.78.100.7  | C1/0/1/UB       | w-online  | 1        | -1.00        | 1793          | 0       | N     |
| 4844.8789.e10e | 10.78.100.10 | C1/0/2/UB       | w-online  | 1        | -0.50        | 1784          | 0       | N     |
| 602a.d0a2.9b3e | 10.78.100.11 | <b>C1/0/3/p</b> | w-online  | 4        | 1.50         | 1789          | 0       | N     |
| 0025.2ecf.f922 | 10.78.100.8  | C1/0/4/UB       | w-online  | 1        | -1.00        | 1788          | 0       | N     |

This partial bonding can be recovered using the **shutdown** and **no shutdown** commands on the related upstream port under the controller. The following is a sample configuration:

```
Router(config)# controller Upstream-Cable 1/0/3
Router(config-controller)# us-channel 0 shutdown
Router(config-controller)# no us-channel 0 shutdown
```

## Verifying the Upstream Bonding Support for D-PON

To verify the upstream scheduler output for a MAC domain configured with D-PON, use the **show interface cable mac-scheduler** command.

**Note** The D-PON reference channel US0 (US channel-id 1) MAP serves as a template for producing other MAPs within the MAC domain. Therefore, some of the statistics related to upstream scheduling is not relevant for other channels, except for the D-PON reference channel.

```
Router# show interface cable 8/0/0 mac-scheduler 1
DOCSIS 1.1 MAC scheduler for Cable8/0/0/U1 : rate 30720000

## CHAPTER 28

# Energy Management Mode

Data-over-Cable Service Interface Specifications (DOCSIS) cable modems (CM) and CMTS support a low power energy mode referred to as the Energy Management 1x1 (EM) mode. During idle times, when the data rate demand of a user is met by the available capacity on a single upstream and downstream channel pair to which it is assigned, the CM switches to the Energy Management 1x1 mode. When the CM requires a higher data rate than that can be reliably provided on the single channel pair, the CMTS instructs the CM to return to the larger transmit and receive channel set.

## Information About Energy Management Mode

The following sections provide more information about the Energy Management mode.

---

**Note** DOCSIS 3.1 CM's do not support the Energy Management mode in cBR-8 routers.

---

## Dynamic Downstream Bonding Group

To support the Energy Management 1x1 (EM) mode feature, CMTS selects an upstream and a downstream channel pair for CM. The downstream and upstream channel assigned to the CMs should be available. If CMTS selects a channel that is not available, the downstream bonding channel might fail.

To simplify the process, CMTS chooses the 1x1 bonding group for the CM according to the following rules:

- For upstream, it chooses the highest actual available bandwidth channel from the upstream channels currently used by the CM.
- For downstream, CMTS chooses the current primary downstream channel used by the CM.

- If the CM is online with channel bonding 1xN or Nx1, and requests to enter into the EM mode, CMTS does not change the upstream and the downstream channel if the original channel bonding is 1 and the Quality of Service (QoS) parameter is not updated.
- CMTS checks the existing dynamic bonding groups (DBG), for an exact match in the target channel.
  - If found, CMTS uses this bonding group to instruct the CM to enter into EM mode.
  - If there is no available DBG and there is an unused DBG, CMTS adds the primary channel into the unused DBG and instructs the CM to enter the EM mode.
  - If there is no available DBG and no unused DBG, CMTS logs a warning to notify you that a new DGB should be configured.

## Flow Chart of the CM Power State

The following figure shows the flow chart of the CM power state:

Figure 21: Flow Chart for the Power State of the Cable Modem

## Interaction with the Battery Mode

Energy management mode is similar to battery mode as they both enter the 1x1 mode to save power. But, both have a different purpose to enter the 1x1 mode, so there are some differences in their behavior. The purpose of EM mode is to save power when the traffic is low, and it has minimum impact on the normal service. The purpose of the battery mode is try to guarantee the voice service, especially the 911 call service, for which it may drop other services, if necessary.

The table below describes the behavior difference between energy management mode and battery mode.

|           | Energy Management (EM) Mode                                                                                                                                                                                                                                                                                                                                                       | Battery Mode (BM)                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QoS       | Minimum reserved rate service up to 200k.                                                                                                                                                                                                                                                                                                                                         | No minimum reserved rate.                                                                                                                                                                                                                                       |
| Multicast | <ul style="list-style-type: none"> <li>• IGMP request is guaranteed.</li> <li>• If the CM has joined the Internet Group Management Protocol (IGMP) groups, CMTS rejects the EM request to enter the EM mode and keeps the CM in the IGMP groups.</li> <li>• If the CM is in the EM mode and IGMP join request is received, CMTS instructs the CM to leave the EM mode.</li> </ul> | <ul style="list-style-type: none"> <li>• If the CM has joined IGMP groups and CMTS receives a CM-STATUS event with code 9, CMTS lets the CM leave the IGMP group.</li> <li>• If the CM is in the BM, CMTS rejects the IGMP join request from the CM.</li> </ul> |

BM has higher priority than the EM mode. If a CM is already in EM mode and a power off occurs, CM enters into the BM. After the power is restored, the CM returns to the normal mode, and if the traffic is lower than the threshold, it re-enters the EM mode. The CM does not directly transfer from the BM to the EM mode.

The interaction between the battery mode and the energy management mode is illustrated in the figure below:

**Figure 22: Interaction Between the BM and the EM Modes**

1. When the CM is in normal mode and CMTS receives a request to enter the EM mode, CMTS instructs the CM to enter the EM mode with downstream bonding channel (DBC).
2. When the CM is in EM mode and CMTS receives a request to leave the EM mode, CMTS instructs the CM to leave the EM mode to normal mode with DBC.
3. When the CM is in normal mode and CMTS receives a message: CM operating on battery backup, CMTS instructs the CM to enter the BM mode with DBC.
4. When the CM is in BM mode and CMTS receives a message: CM operating on AC power, CMTS instructs the CM to leave the BM mode to normal mode with DBC.

5. When the CM is in EM mode and CMTS receives a message: CM operating on battery backup, CMTS instructs the CM to enter the BM mode with service flow re-admin.
6. When the CM is in BM mode and CMTS receives a request to enter EM mode, CMTS waits until it receives the message: CM operating on AC power. It then instructs the CM to return to normal mode.

## Handling Energy Management Request Load

When many CMs send EM requests at the same time, such as at the beginning or end of work hours, the traffic soars or slumps in a very short period and causes heavy load for CMTS. A throttle mechanism is adopted to avoid such load surge for CMTS.

The line card EM process defines a variable that indicates the current transactions handled by the process. When an energy management request is received and the maximum number of transactions is not met, CMTS handles this request and updates the counter of current transactions. When the maximum number of transactions is met, CMTS sends a temporary reject response. After a transaction is over or a CM goes offline, the counter of current transactions is updated.

## Supervisor High Availability and Line Card Switchover

Energy Management feature supports supervisor high availability and line card switchover with limitations.

The active supervisor or line card syncs the EM mode data of a CM to the standby SUP or protected line card when the CM enters a stable EM status. When a CM enters or leaves the EM mode with an ongoing DBC process, the supervisor high availability or line card switchover causes the CM to enter into an offline or online status.

## Prerequisites for Energy Management Mode

To enable the energy management mode, you must configure resiliency bonding group (RBG) and dynamic bonding group.

## Restrictions for the Energy Management Mode

### Restrictions for CMTS High Availability

- If there is no DBG available, CMTS cannot create a new DBG on the protected line card and CMs cannot enter the EM mode.
- Line card switchover is not supported when the CM enters the EM mode from the normal mode or exits the EM mode to the normal mode.
- To reduce the operation of the EM mode, the information about the EM status is not synced with the protected line card. Hence, the EM status is cleared after the line card high availability.

## Restrictions for Dynamic Bonding Group

To support the EM feature, CMTS configures separate DBG for each primary channel in each MAC domain. For example, if a MAC domain has eight primary channels, it will create eight DBGs for the MAC domain. This ensures that the EM does not fail due to lack of DBGs.

## Restrictions for Interaction of CMTS with Other Features

The following sections describe the restrictions for CMTS interaction with other features.

### Voice

If a voice call is in progress, CMTS does not instruct the CM to enter into the EM mode.

When the CM is in the EM mode, and it receives a voice call, it adds a dynamic Unsolicited Grant Service (UGS) or Unsolicited Grant Service with activity detection (UGS-AD) service flow. During the voice call, the CM does not exit from the EM mode irrespective of the flow of traffic. Voice service is given the highest priority

### Dynamic Bonding Change and Dynamic Channel Change and Related Applications

In D2.0 and D3.0 load-balance (static and dynamic), CM is not moved by load-balance when it is in EM mode.

For RF-adapt, CM is not relocated to an alternate logical channel by the RF-adapt when it is in EM mode.

### Multicast

- When the CM is in a multicast group, CMTS would reject the EM request for both bonded and non bonded multicast cases.
- When the CM is in EM state and a multicast join request is received, CMTS discards this join request and forces the CM to exit the EM mode.
- When the CM is in EM state and a voice call is in progress, and a new multicast join request is received, CMTS discards this join request and does not force the CM to exit the EM mode since the voice call is in progress.
- There is a threshold for currently handled transactions. When there is multicast join request and the maximum transaction threshold has been reached, CMTS cannot instruct the CM to exit the EM mode. The multicast join is also be denied until the CM can exit the EM mode.
- When the CM is in EM mode and needs to join PacketCable Multimedia (PCMM) multicast, you should send a GateSet request twice, so that the gate can be setup successfully. The first GateSet request only forces the modem to exit the EM mode, but does not set up the gate

### Committed Information Rate

If the QoS is defined by the Minimum Reserved Rate service flow QoS parameter in excess of 200 kbps, when the CM enters into the EM mode, CMTS only provides 200 kbps as the minimum reserved rate. If the minimum reserved rates is less than 200 kbps, CMTS schedules the minimum reserved rate according to the service flow configuration when the CM enters into the EM mode.

CMTS records the Minimum Reserved Rate service flow QoS parameter when the CM enters into the EM mode. When the CM exits the EM mode, CMTS uses the original parameter.

When the CM enters the EM mode, it selects one of the CM upstream channels. If the service flow is completely on that upstream channel, the service flow parameter is not changed. This behavior is because the service flow is not moved into the DBC operation, and the change of the service flow parameter has no benefit

## Admission Control

When a request is received to exit the EM mode and recovery to the original wideband interface is restricted due to an admission control failure, CMTS forces the CM to go offline and re-register to prevent it from getting stuck in the EM mode. In such a case, CMTS logs a warning message.

## Battery Mode

When CMTS receives the status of the CM as operating on battery power, CMTS instructs the CM to enter into the BM. If the CM rejects the instruction received, CMTS keeps the modem in normal status.

When the CM is in BM and CMTS receives the status of the CM as operating on A/C power, CMTS instructs the CM to exit the BM. If the CM rejects the instruction received, CMTS forces the CM to go offline to prevent it from getting stuck in the battery mode. In such a case, CMTS logs a warning message.

## Attribute Mask

When selecting an upstream or a downstream channel pair for energy management mode, CMTS selects channels that meet the requirements of the attribute masks for the existing service flows for the corresponding CM.

In some cases, adherence to the service flow attribute-based assignment may not be possible when selecting an upstream and downstream channel pair for energy management mode of operation. To resolve this conflict, CMTS supports one or both of the following approaches:

1. CMTS may require strict adherence to the required and forbidden attribute masks and thus deny entry into the EM mode if these masks cannot be met by the available individual channels in the MD-CM-SG.
2. CMTS may allow the CM to enter the EM mode while not meeting all the criteria for the attribute masks. In this case, CMTS logs a warning event notifying that the attribute masks are not maintained.

For the following case, CMTS supports approach two:

When the CM is instructed to enter into the EM mode and the selected target upstream and downstream channels do not adhere to the service flow attribute mask. For this conflict CMTS instructs the modem to enter into the EM mode. CMTS also logs a warning message to notify this conflict.

## Dynamic Service Addition

When the CM is in EM mode, DSA request can still be set up even if the requested attributes can not be met with a single channel. In order to not effect voice services, the CM is not forced to exit the EM mode.

## Restrictions for Configuration Change and Interface Shutdown

1. **Shutdown of the upstream channel**—Shutdown of the upstream channel recalculates the MD-US-SG-ID and assigns a new MD-US-SG-ID. In this case, the CM is not offline and internal data structure of the CM instance is not updated. DBC operation checks the MD-US-SG-ID, so when the CM enters into the EM mode there is a mismatch between the MD-US-SD-ID on the CM and the new MD-US-SG-ID. Hence, DBC fails and the CM cannot get into the EM mode.

2. **Change in Upstream Service Group makes the CM in EM mode go offline**—The US-SG configuration change blocks the DBC behavior and the CM gets stuck in the EM mode. To avoid this scenario, when there is a change in the Upstream Service Group (US-SG), such as shutdown or no shutdown of the upstream channels, CMTS makes the CM go offline. The CM should re-register as a normal CM with the wideband channel bonding including multiple channels.
3. **Modify the original wideband interface**—When the CM is in EM mode, change in the original wideband interface channels on the CM makes the CM go offline and re-register as a normal CM.
4. **Disable or enable feature**— When you disable this feature, CMTS does not force CMs to exit from the EM mode unless CMs sends a request. CMTS does not accept EM requests after the EM feature is disabled from the CLI.

## How to Configure the Energy Management Mode

This section describes how to configure the energy management feature on the Cisco cBR-8.

### Contents

## Enabling Energy Management Mode

To enable the energy management mode, complete the following procedure:

```
configure terminal
cable reduction-mode energy-management enable
```

### Verifying the Energy Management Mode

- To verify if the CM is in EM mode, use the **show cable modem** command. If the cable modem is working in energy management mode, the MAC state is displayed with an "em" flag.

```
show cable modem
```

| MAC Address    | IP Address | I/F    | MAC    | Prim       | RxPwr         |
|----------------|------------|--------|--------|------------|---------------|
| Timing Num     | I          |        |        |            | State         |
|                | Sid        | (dBmv) | Offset | CPE        | P             |
| 7cb2.1b0f.ea72 | 1231       | 1      | Y      | 40.4.58.4  | C7/0/0/UB     |
|                |            |        |        |            | w-online (em) |
|                |            |        |        |            | 2             |
|                |            |        |        |            | 0.00          |
| 54d4.6ffb.2f6b | 1241       | 0      | Y      | 40.4.58.24 | C7/0/0/UB     |
|                |            |        |        |            | w-online      |
|                |            |        |        |            | 3             |
|                |            |        |        |            | -0.50         |
| 0025.2ed9.9a22 | 1240       | 0      | Y      | 40.4.58.3  | C7/0/0/UB     |
|                |            |        |        |            | w-online      |
|                |            |        |        |            | 4             |
|                |            |        |        |            | 0.50          |

- To verify which CM is in EM mode and to get the original wideband and upstream channel information, use the **show cable modem reduction-mode energy-management-mode** command.

```
show cable modem reduction-mode energy-management-mode
```

| I/F      | MAC Address    | ID  | Orig BG I/F | Orig US bitmap | RFs | ID  | Curr BG I/F   |
|----------|----------------|-----|-------------|----------------|-----|-----|---------------|
| Upstream |                |     |             |                |     |     |               |
| C7/0/0   | 0025.2eaf.843e | 897 | Wi7/0/0:0   | 0x3B           | 4   | 252 | Wi7/0/0:1 US0 |

```
C7/0/0 0025.2eaf.8356 897 Wi7/0/0:0 0x3B 4 252 Wi7/0/0:1 US0
C7/0/0 0015.d176.5199 897 Wi7/0/0:0 0x3B 4 252 Wi7/0/0:1 US0
```

## Enabling Energy Management Mode per MAC Domain

CMTS supports the EM feature when enabled both globally and per MAC domain. Use the following procedure to enable energy management feature per MAC domain.

To enable the EM mode per MAC domain, complete the following procedure:

```
configure terminal
interface cable slot/subslot/cable-interface-index
cable reduction-mode energy-management enable
```

## Configuring Initialization Ranging Technique in Dynamic Bonding Channel

The default value for the technique in init-ranging is set to 1 and the valid range is 1-4.

To configure the technique in init-ranging, complete the following procedure:

```
configure terminal
cable reduction-mode energy-management ranging-init-technique value
```

## Configuring the Percentage for the Dynamic Channel Bandwidth

Make sure that you leave enough bandwidth for the primary channel so that it can allocate dynamic channel bandwidth when it joins to a newly created DBG. The default percentage value is set to 5 and the valid range is 1-96.

To configure the percentage of dynamic channel bandwidth, complete the following procedure:

```
configure terminal
cable reduction-mode energy-management dynamic-channel-percent value
```

## Configuring the Queue Size for Energy Management

The default value for the queue size is set to 150 and the valid range is 50-10000.

To set the queue size of the energy management requests, complete the following procedure:

```
configure terminal
cable reduction-mode energy-management process-queue-size value
```

-

## Verifying the Energy Management Mode

This section describes how to verify the EM mode.

## Contents

# Viewing the Basic Statistics for Energy Management Receive Request

To view the basic statistics for all energy management receive request events for a specific CM, use the **show cable modem <cable if | mac\_addr | ip\_addr> reduction-mode energy-management-status** command.

```
show cable modem c8/0/0 reduction-mode energy-management-status
```

| I/F    | MAC Address    | Event         | TID | Count | Error | Dups | Time            |
|--------|----------------|---------------|-----|-------|-------|------|-----------------|
| C8/0/0 | 54d4.6ffb.2e21 | Enter EM mode | 1   | 1     | 0     | 1    | Jul 16 21:38:18 |
|        |                | Exit EM mode  | 1   | 1     | 0     | 0    | Jul 16 21:38:39 |
| C8/0/0 | 602a.d07c.4ec6 | Enter EM mode | 1   | 1     | 0     | 0    | Jul 16 21:40:57 |
|        |                | Exit EM mode  | 1   | 1     | 0     | 0    | Jul 16 21:41:17 |

To clear the basic receive statistics for all EM\_REQ events for a specified CM, use the **clear cable modem <cable if | mac\_addr | ip\_addr> em-status** command.

## Verifying the Configuration Parameters

To verify the configuration parameters used in the CM configuration file, use the **show cable modem <mac address> reduction-mode energy-management-param** command.

```
show cable modem 54d4.6ffb.2e21 reduction-mode energy-management-param
```

```
Energy Management feature enable : Y
DS entry bitrate threshold(bps) : 100000
DS entry time threshold(s) : 120
DS exit bitrate threshold(bps) : 200000
DS exit time threshold(s) : 2
US entry bitrate threshold(bps) : 100000
US entry time threshold(s) : 120
US exit bitrate threshold(bps) : 200000
US exit time threshold(s) : 2
cycle period(s) : 300
```

## Viewing Information Regarding a Cable Modem

To view all the information regarding a CM, use the **show cable modem mac address verbose** command.

```
show cable modem 54d4.6ffb.30fd verbose
```

```

## Feature Information for Energy Management Mode

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfnng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 87: Feature Information for Downgrading Channel Bonding in Battery Backup Mode**

| Feature Name           | Releases                 | Feature Information                                                              |

## CHAPTER 29

# Cable Modem Steering

---

The cable modem steering feature helps to redirect or steer cable modems to multiple CMTS routers. A configurable string is used to bond the cable modem to the proper CMTS. Once the bonding is done, the CMTS can move the cable modem within itself for load balancing.

## Cable Modem Steering on the Cisco cBR Series Converged Broadband Routers

**First Published:** July 13, 2016

The cable modem steering feature helps to redirect or steer cable modems to multiple CMTS routers. A configurable string is used to bond the cable modem to the proper CMTS. Once the bonding is done, the CMTS can move the cable modem within itself for load balancing.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Contents

# Prerequisites for Cable Modem Steering

DOCSIS 3.0-defined type, length, values (TLVs) are required to aid channel selection. All TLVs encoded as general extension information in cable modem configuration files are backward compatible with DOCSIS 1.1 and DOCSIS 2.0 cable modems.

---

**Note** The hardware components introduced in a given Cisco IOS Release are supported in all subsequent releases unless otherwise specified.

---

# Restrictions for Cable Modem Steering

The Cable Modem Steering feature has the following general restrictions:

- To restrict the cable modem on the exact downstream on the target CMTS, the redirection must be configured on the target CMTS.
- You must manually execute the **clear cable modem service-type** command to clear the cable modem service type identifier stored at the CMTS during registration.
- You must manually execute the **clear cable modem attribute-masks** command to clear the cable modem attribute masks stored at the CMTS during registration. These attribute masks are used to restrict usage of upstream channels during ranging time.
- Cable modem steering supports only upstream masks.
- Channel steering does not take place when the cable modem fails in initial ranging.
- The cable modem will take more time to come online when channel steering is deployed. The time taken is proportional to the number of modems, and the downstreams and upstreams that the cable modem can reach.
- A modem cannot be load balanced to any upstream channel with attributes that conflict with attribute masks of the modem.
- Do not configure to use UCC in DOCSIS LBG.

# Information About Cable Modem Steering

Cable modem steering allows you to redirect or steer the cable modems to one or more CMTS routers using downstream frequency overrides. Once a cable modem registers on a downstream on the proper CMTS router, the CMTS router can move the cable modem to any location for load balancing.

The DOCSIS 3.0-compliant Service Type Identifier used as the configurable string in the cable modem configuration file is backward-compatible with DOCSIS 1.1 and DOCSIS 2.0 cable modems.

The CMTS router can also impose restrictions on the number of channels a cable modem can use. DOCSIS 3.0 defines several TLVs to aid the channel selection.

The following TLVs are used in cable modem steering:

- TLV 43.9 (Cable Modem Attribute Masks) limits the set of channels the CMTS router can assign to the cable modem by allowing or forbidding certain binary attributes. The cable modem attribute masks have four sub-TLVs and cable modem steering makes use of two sub-TLVs, which are listed below:
  - TLV 43.9.3—Cable Modem Upstream Required Attribute Mask (C.1.1.18.1.8.3 of CM-SP-MULPIv3.0-I07-080215). It is a 32-bit mask representing the set of binary upstream channel attributes required for the cable modem.
  - TLV 43.9.4—Cable Modem Upstream Forbidden Attribute Mask (C.1.1.18.1.8.4 of CM-SP-MULPIv3.0-I07-080215). It is a 32-bit mask representing the set of binary upstream channel attributes forbidden for the cable modem.
- TLV 43.11 is used for a redirection action based on the service type identifier field. The cable modem sends the TLV 43.11 in the REG-REQ MAC message. The DOCSIS 1.1 and DOCSIS 2.0 modems will also send this file ID when doing the registration.
- TLV 43.1, defined as Policy ID in DOCSIS 2.0 and DOCSIS 3.0, is parsed and stored in the cable modem during registration. Before moving the cable modem during load balancing (LB), the CMTS router checks whether the cable modem has a preconfigured policy with the same Policy ID. If the policy does exist, the CMTS router disables LB for this cable modem and moves to the next cable modem. If the policy does not exist on the CMTS router, or the Policy ID is missing from the cable modem configuration file, LB prohibition is not performed.

The following TLVs are supported in cable modem steering:

- TLV 43.11 (Service type identifier) from section C.1.1.18.1.10 in CM-SP-MULPIv3.0-I07-080215.
- Cable modem attribute masks (TLV 43.9) from C.1.1.18.1.8.3 and C.1.1.18.1.8.4 of CM-SP-MULPIv3.0-I07-080215.
- TLV portion (43.1, Policy ID) of REG-REQ
- TLV 18--- Ranging Hold-off Priority Field
- TLV 19---Channel Class ID

## Upstream Channel Descriptor TLV for Ranging Hold-off

The Upstream Channel Descriptor (UCD) TLV for Ranging Hold-off feature, enables the Cisco cBR Series Converged Broadband router to hold off a cable modem from initial ranging based on TLV 18 and 19 specified in the upstream channel descriptor (UCD) messages. The router can hold off a cable modem from initial ranging only for 5 minutes. This default value cannot be changed. This feature is supported with DOCSIS 2.0 and later releases cable modems using upstream logical channels.

### Ranging Class ID

The CMTS enables UCD TLV for ranging hold-off after detecting the TLVs from the cable modem registration request (REG-REQ) or multipart registration request (REG-REQ-MP), and saves these TLVs as a cable modem ranging class ID.

By default, DOCSIS load balance is supported for all cable modems with all types of ranging class IDs. In the event of DOCSIS load balance, a cable modem moves to the target upstream channel only if the ranging class ID matches with the upstream channel class ID.

### Cable Modem Exclusion for DOCSIS Load Balance

You can exclude a cable modem or a group of cable modems from DOCSIS load balance based on their device type, MAC address, and Organizational Unique Identifier (OUI) using the **cable load-balance exclude** command in global configuration mode.

# How to Configure Cable Modem Steering on the CMTS Router

This section describes the following required and optional procedures:

## Configuring an Upstream Channel Class ID

This configuration is optional. A channel class ID must be configured for an upstream logical channel if you want to configure UCD TLV ranging hold-off on the CMTS router.

### Procedure

|               | Command or Action                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 3</b> | <b>controller upstream-cable</b><br><i>slot/subslot/controller-port-number</i><br><b>Example:</b><br>Router(config)# <b>controller Upstream-Cable 3/0/0</b>           | Specifies the cable interface and enters cable interface configuration mode. Arguments for this command may vary depending on the CMTS router, line card, and Cisco IOS software release. For details, see the <a href="#">Cisco IOS CMTS Cable Command Reference</a> . <ul style="list-style-type: none"> <li>• <i>Slot</i>— Slot where the interface card resides. The valid range is from 0 to 3 and 6 to 9 on the Cisco cBR-8 router.</li> <li>• <i>Subslot</i>—Subslot where the interface card resides. The valid value is 0 on the Cisco cBR-8 router.</li> <li>• <i>controller-port-number</i>—Controller port number. The valid values are from 0 to 7 on the Cisco cBR-8 router.</li> </ul> |
| <b>Step 4</b> | <b>us-channel</b> <i>us-channel-id</i> <b>chan-class-id</b> <i>id</i><br><b>Example:</b><br>Router(config-controller)# <b>us-channel 3</b><br><b>chan-class-id ff</b> | Configures the channel class ID for an upstream logical channel. <ul style="list-style-type: none"> <li>• <i>us-channel-id</i>—Specifies the upstream channel id.</li> <li>• <i>id</i>—Channel class ID for the logical upstream channel in the hexadecimal format. The valid range is from 0 to ffffffff. The default value is 0.</li> </ul>                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Router(config-controller)# <b>end</b>                                                                                                | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring an Upstream Ranging Hold-off Priority Value

This configuration is optional.

Maximum time that a cable modem can inhibit transmissions on an upstream channel in response to its ranging class ID matching a bit value in the Ranging Hold-off Priority field in the cable modem configuration file is 300 seconds (five minutes) per *DOCSIS 3.0 MAC and Upper Layer Protocols Interface Specification*. This default timer value cannot be changed.

### Procedure

|        | Command or Action                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                           | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 3 | <b>controller upstream-cable</b><br><i>slot/subslot/controller-port-number</i><br><b>Example:</b><br>Router(config)# <b>controller upstream-cable 3/0/0</b> | Specifies the cable interface and enters cable interface configuration mode. Arguments for this command may vary depending on the CMTS router, line card, and Cisco IOS software release. For details, see the <a href="#">Cisco IOS CMTS Cable Command Reference</a> . <ul style="list-style-type: none"> <li>• <i>Slot</i>—Slot where the interface card resides. The valid range is from 0 to 3 and 6 to 9 on the Cisco cBR-8 router.</li> <li>• <i>Subslot</i>—Subslot where the interface card resides. The valid value is 0 on the Cisco cBR-8 router.</li> <li>• <i>controller-port-number</i>—Controller port number. The valid values are from 0 to 7 on the Cisco cBR-8 router.</li> </ul> |
| Step 4 | <b>us-channel us-channel-id rng-holdoff priority</b><br><b>Example:</b><br>Router(config-controller)# <b>us-channel 3 rng-holdoff 1</b>                     | Configures the ranging hold-off priority value for an upstream logical channel. <ul style="list-style-type: none"> <li>• <i>us-channel-id</i>—Specifies the upstream channel id.</li> <li>• <b>rng-holdoff priority</b>—Specifies the ranging hold-off priority value in the hexadecimal format. The valid range is from 0 to ffffffff. The default value is 0.</li> </ul>                                                                                                                                                                                                                                                                                                                           |
| Step 5 | <b>end</b><br><b>Example:</b><br>Router(config-controller)# <b>end</b>                                                                                      | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# Verifying and Troubleshooting Cable Modem Steering

This section provides the verification and troubleshooting information:

## Verifying an Upstream Ranging Class ID Configuration

To verify an upstream ranging class ID of a cable modem, use the **show cable modem** command with the **verbose** keyword.

Following is a sample output of the **show cable modem verbose** command:

```
Router# show cable modem 68b6.fcfe.22e5 verbose

MAC Address : 68b6.fcfe.22e5
IP Address : 192.168.0.8
IPv6 Address : 2001:DB8:10:1:9951:1972:33F9:9867
Dual IP : Y
Prim Sid : 8
Host Interface : C8/0/0/UB

## Feature Information for Cable Modem Steering

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 88: Feature Information for Cable Modem Steering on the Cisco CMTS Routers**

| Feature Name         | Releases                    | Feature Information                                                                                               |
|----------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------|
| Cable Modem Steering | Cisco IOS XE Everest 16.6.1 | This feature was integrated into Cisco IOS XE Everest 16.6.1 on the Cisco cBR Series Converged Broadband Routers. |

## Information about OFDM Channel Configuration

### OFDM Channels

DOCSIS 3.1 introduces modes for higher throughput and higher spectral efficiency while still allowing backward compatibility to DOCSIS 3.0. OFDM Channel support includes one OFDM channel per port with channel bandwidth from 24 MHz to 192 MHz wide.

Each OFDM channel supports a control profile, an NCP profile, and up to five data profiles. Profiles support one or more modulations.

Starting from Cisco IOS-XE release 3.18.1SP, you can configure the guard band of an OFDM channel to potentially trade off some performance margin using command **guardband-override**. By default, Cisco cBR-8 router use the default guard band, which is based on the roll off and spacing in OFDM channel profile.

DOCSIS 3.1 OFDM support also allows the user to configure the RF-channels 158 to 162 under the mac-domain as primary channel.

## Channel Profile

A globally configured OFDM channel profile contains channel parameters, and the modulation or modulation profile associated with the control, NCP, and data profiles.

Each OFDM channel must specify an OFDM channel profile in its configuration.

## Modulation Profile

A globally configured OFDM modulation profile assigns different modulations to ranges of sub-carriers, or lists of individual sub-carriers.

A modulation profile may be assigned to a control, NCP, or data profile in a channel profile.

## OFDM Channel Exclusion Band

Ranges of frequencies can be excluded from all OFDM channels on a port using the **ofdm-freq-excl-band** command.

# How to Configure OFDM Channel

## Configuring OFDM Modulation Profile

To configure the OFDM modulation profile, follow the steps below:

```
enable
configure terminal
cable downstream ofdm-modulation-profile id
description text
subcarrier-spacing value
width value
start-frequency value
assign {modulation-default mod_prof_id | modulation mod_prof_id {list-subcarriers
{freq-abs | freq-offset} value | range-subcarriers {freq-abs | freq-offset}
value width value}}
```

---

**Note** Subcarrier spacing must match the subcarrier spacing of each channel profile in which it is configured.

---

## Verifying OFDM Modulation Profile Configuration

To display the OFDM modulation profile details, use the **show cable ofdm-modulation-profiles** command as shown in the example below:

```
Router# show cable ofdm-modulation-profile 10

**** OFDM Modulation Profile Configuration ****
```

```

Prof FFT Width Start-freq Modulations
ID KHz Hz Hz
10 50 96000000 627000000 64 default
 512 freq-abs 709050000 width 12000000
 2048 freq-abs 629000000 width 6000000

Profile Subcarrier Modulations
Modulation: Start-freq-abs[start-sc] - End-freq-abs[end-sc] Width-freq[num-sc]

## Configuring OFDM Channel as Primary Channel

To configure an RF-channel in the mac-domain as an OFDM primary channel, use the following commands.

```
enable
configure terminal
interface cable <slot/subslot/port> downstream Integrated-Cable <slot/subslot/port>
rf-channel <ofdm-channel-number: 158-162>
end
```

## Verifying OFDM Primary Channel Configuration

To display the OFDM channel configuration details, where the OFDM channel is the primary channel, use the command as shown in the following example:

```
Router#sh run int c3/0/3
Building configuration...

Current configuration : 539 bytes
!
interface Cable3/0/3
```

```

load-interval 30
downstream Integrated-Cable 3/0/3 rf-channel 0
downstream Integrated-Cable 3/0/3 rf-channel 158
upstream 0 Upstream-Cable 3/0/6 us-channel 0
upstream 1 Upstream-Cable 3/0/6 us-channel 1
upstream 2 Upstream-Cable 3/0/6 us-channel 2
upstream 3 Upstream-Cable 3/0/6 us-channel 3
cable upstream bonding-group 1
 upstream 0
 upstream 1
 upstream 2
 upstream 3
 attributes 80000000
cable bundle 1
cable cm-status enable 3 6-11 16-18 20-27
cable privacy accept-self-signed-certificate
end

```

You can also use the following command to display the OFDM primary channel configuration details as shown in this example.

```

Router#sh cable mac-domain c3/0/3 cgd-associations
CGD Host Resource DS Channels Upstreams (ALLUS) Active DS
Ca3/0/3 3/0/3 0 0-3 Yes 0
 158 0-3 Yes 158

```

The **show cable mac-domain Cable <slot>/<subslot>/<port> mdd** command also displays the OFDM primary channel configuration details as shown in the example.

```

...
Downstream Active Channel List
Channel ID: 159
Frequency: 836000000Hz
Primary Capable: Primary-Capable
CM-STATUS Event Bitmask:0x36
MDD Timeout
QAM FEC failure
MDD Recovery
QAM FEC recovery
MAP/UCD Transport Indicator: Can carry MAPs and UCDs
OFDM PLC Params Bitmask:
Tukey raised cosine window: 0.625
Cyclic Prefix: 5.0
Sub carrier spacing: 50

```

RF channels use a zero-based numbering scheme, whereas the downstream channel IDs are numbered starting from one. Thus RF channel 158 is equivalent to channel ID 159. The Channel ID in this example is 159. The MAP/UCD Transport Indicator shows that MAPs and UCDs are sent only on Primary Channels.

## Configuring Port/Controller and Channel

To configure the port/controller and channel, follow the steps below:

```

enable
configure terminal
controller integrated-cable slot/subslot/port
max-ofdm-spectrum value
ofdm-freq-excl-band start-frequency value width value
rf-chan start_id [end_id]
ofdm channel-profile id start-frequency value width value [plc value]

```

**Note** The range of *start\_id* is 158 to 162 in the OFDM channel configuration.

The maximum OFDM spectrum is assigned to OFDM channels, which is used by the the CMTS to calculate default port base power.

Ranges of frequencies can be excluded from all OFDM channels using the **ofdm-freq-excl-band** command.

## Verifying Port/Controller and Channel Configuration

To display the RF port details, use the **show controller integrated-cable** command with **rf-port** option as shown in the example below:

```
Router# show controller integrated-cable 3/0/0 rf-port

Admin: UP MaxCarrier: 128 BasePower: 33 dBmV Mode: normal
Rf Module 0: UP
Free freq block list has 3 blocks:
 45000000 - 107999999
 624000000 - 644999999
 837000000 - 1217999999
Rf Port Status: UP
MaxOfdmSpectrum: 192000000 Equivalent 6MHz channels: 32
UsedOfdmSpectrum: 192000000 AvailOfdmSpectrum: 0
DefaultBasePower: 33 dBmV Equivalent 6MHz channels: 160
OFDM frequency exclusion bands: None
```

To display the summary information on OFDM channel, use the **show controller integrated-cable** command with **rf-channel** option as shown in the example below:

```
Router# show controller integrated-cable 3/0/0 rf-channel 158

Chan State Admin Mod-Type Start Width PLC Profile-ID dcid power
output
 Frequency
 158 UP UP OFDM 627000000 96000000 663000000 20 159 34
NORMAL
```

To display detailed information on OFDM channel, use the **show controller integrated-cable** command with **rf-channel** and **verbose** options as shown in the example below:

```
Router# show controller integrated-cable 3/0/0 rf-channel 158 verbose

Chan State Admin Mod-Type Start Width PLC Profile-ID dcid power
output

## Configuration Examples

This section provides examples for configuring the OFDM channel.

### Example1: Configuring OFDM Channel

**Note** The OFDM modulation profile must be configured before the OFDM channel profile which references it.

The following example shows how to configure the OFDM channel:

```

enable
configure terminal
cable downstream ofdm-modulation-profile 9
description 512-1k-4k
subcarrier-spacing 50KHz
width 96000000
start-frequency 627000000
assign modulation-default 512-QAM
assign modulation 1024-QAM range-subcarriers freq-abs 635000000 width 74050000
assign modulation 4096-QAM range-subcarriers freq-abs 629000000 width 6000000

```

```

exit
configure terminal
cable downstream ofdm-chan-profile 20
description Data profiles: 2 single mod, 1 mixed mod
cyclic-prefix 192
interleaver-depth 16
pilot-scaling 48
roll-off 128
subcarrier-spacing 50KHz
profile-ncp modulation-default 16-QAM
profile-control modulation-default 256-QAM
profile-data 1 modulation-default 1024-QAM
profile-data 2 modulation-default 2048-QAM
profile-data 3 modulation-profile 9
exit
configure terminal
controller integrated-cable 3/0/0
max-ofdm-spectrum 96000000
ofdm-freq-excl-band start-frequency 683000000 width 10000000
rf-chan 158
power-adjust 0
docsis-channel-id 159
ofdm channel-profile 20 start-frequency 627000000 width 96000000 plc 663000000

```

### Example 2: Configuring OFDM Primary Channel in the MAC Domain

```

enable
configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
interface cable 3/0/0
downstream Integrated-Cable 3/0/3 rf-channel 158
end

```

## Feature Information for DOCSIS 3.1 OFDM Channel Configuration

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmg.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 90: Feature Information for DOCSIS 3.1 OFDM Channel Configuration**

| Feature Name                                                      | Releases                 | Feature Information                                                              |
|-------------------------------------------------------------------|--------------------------|----------------------------------------------------------------------------------|
| DOCSIS 3.1 OFDM Channel Support                                   | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| Full Spectrum 108-1218 MHz Support                                | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| DOCSIS 3.1 OFDM Primary Channel Support                           | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| Enhanced support for subcarrier spacing, exclusion band, and LCPR | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 31

# OFDM Channel Power Profile

---

The OFDM Channel Power Profile feature helps in adjusting the power-level of 6 MHz bands in a DOCSIS 3.1 downstream OFDM channel.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

- [Hardware Compatibility Matrix for the Cisco cBR Series Routers, on page 555](#)
- [Information About OFDM Channel Power Profile, on page 556](#)
- [How to Configure the OFDM Channel Power Profile, on page 557](#)
- [Configuration Example for OFDM Power Profile, on page 559](#)
- [Feature Information for OFDM Channel Power Profile, on page 559](#)

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

---

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

---

Table 91: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Information About OFDM Channel Power Profile

The OFDM power profile provides a better, consistent power-level output at the cable modem, compensating the power levels at a finer granularity. It reduces the differing amounts of cable-loss over the bandwidth of OFDM channel.

This feature enables the Cisco cBR Series Converged Broadband Router to correct the transmission loss due to the cable in the plant.

The OFDM power profile (`ofdm-power-profile`) adjusts the transmission power level of each 6 MHz in an OFDM channel. The OFDM channel width can range from 24 MHz to 192 MHz, resulting in band-counts between 4 and 32 for the profile.

Each 6 MHz band is referenced by a band index (`band-index`) that is zero-based, with a maximum band range of 192 MHz OFDM channel being 0 to 31. Each band within the OFDM channel can have a unique power level setting. The OFDM power profile allows a total band adjustment range of 8 dB. Under some specific conditions, if the OFDM channel's downstream controller's base channel power is set to exceed the maximum DRFI specification power level, the OFDM power profile adjustment range can become as high as 9 dB.

In a power profile, you can set the power level (`power-adjust-default`) to a default value. This default value is applied to any band that is not configured through any other means.

You can configure band power levels in two methods: through the power tilt config (power-tilt-linear) or by configuring the power level for a band or range of bands (band-index). You can use both methods for configuring the band power levels simultaneously within an OFDM power profile.

The power tilt configuration applies a linear power-adjust value between the `power-adjust-default` value applied to the band index 0, and the `power-tilt-linear` adjust value applied to the highest band index of the profile. For example, an OFDM Power Profile of 96 MHz, with a `power-tilt-linear` of 4 dB, and `power-adjust-default` of 0 dB, has 16 bands numbered 0 to 15, band index 0 is +0 dB, band index 15 is +4 dB, and bands 1 to 14 contain the linear power level setting based on the slope of the line between the band 0 and band 15 to the nearest 1/10th dB.

The band-index configuration applies a specified value to the indicated bands. The band-index configuration can specify a single band or a range of bands. A `power-adjust` configuration is used to specify the power level for the bands to the nearest 1/10th dB.

You can simultaneously use both power tilt and band index, where band-index is applied last. When you use both, the `power-tilt-linear` values can be overridden using the band-index `power-adjust` values.

A maximum of 64 OFDM power profiles can be configured on the Cisco cBR routers, numbered from 1 to 64. You can apply a single OFDM power profile to multiple controller OFDM channels, across line cards, as long as all validity checks pass during configuration. The router console displays an error message explaining any configuration errors or warnings.

## Restrictions for Configuring OFDM Power Profile

The following restrictions are applicable for configuring an OFDM power profile:

- OFDM power profile can be configured only on DOCSIS 3.1 system
- The power profile can be applied only to downstream controller OFDM channels (RF-channels 158 to 162)

## How to Configure the OFDM Channel Power Profile

### Configuring OFDM Power Profile Using Band-index

Use the following commands along with the band-index configuration to configure OFDM Power Profile, where the band-index values act as an override.

```
enable
configure terminal
cable downstream ofdm-power-profile <profile_id>
 power-adjust-default -2.1
 band-index 0 7
 power-adjust -1.0
 band-index 8 15
 power-adjust -0.5
 band-index 16 23
 power-adjust 0.5
 band-index 24 31
 power-adjust 1.5

controller Integrated-Cable {slot}/{subslot}/{port}
```

```
rf-channel {158 - 162 }
power-profile {ofdm-power-profile-id}
```

## Verifying the Power Profile Configuration

To display the power profile configuration details, use the **show cable ofdm-power-profile** command as given in the following example. This command also displays the actual power-band power levels as set by the profile.

```
Router> show cable ofdm-power-profile 3
OFDM Power Profile 3

Power-Adjust-Default(*): -2.1

Power-Band:
[00-07] -1.0 -1.0 -1.0 -1.0 -1.0 -1.0 -1.0 -1.0

 band-index
```

## Configuring OFDM Power Profile with Linear Power-tilt

Use the following commands to configure the OFDM power profile with a linear power-tilt and the band-index override.

```
enable
configure terminal
cable downstream ofdm-power-profile <profile_id>
 power-adjust-default 0.0
 power-tilt-linear 3.5
 band-index 0
 power-adjust 4.0
```

## Verifying the Power Profile Using show controller Command

Use the **show controller** command to display the absolute power-band levels as set by the power profile. When the power-profile is applied to the controller, the power level displayed is the actual transmit power level in dBmV.

```

Router>show controller Integrated-Cable 3/0/0 rf-channel 158 verbose

## Configuration Example for OFDM Power Profile

This section provides example for the OFDM Power Profile configuration.

### Example: OFDM Power Profile with Linear Power-tilt Configuration

```

enable
configure terminal
cable downstream ofdm-power-profile 3
 power-adjust-default 0.0
 power-tilt-linear 3.5
 band-index 0
 power-adjust 4.0

```

## Feature Information for OFDM Channel Power Profile

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 92: Feature Information for OFDM Channel Power Profile**

| Feature Name               | Releases                 | Feature Information                                                                |

## CHAPTER 32

# DOCSIS 3.1 Path Selection

---

This document describes how to configure the path selection on the Cisco cBR Series Converged Broadband Router.

- [Information about Path Selection, on page 561](#)
- [How to Configure Path Selection, on page 561](#)
- [Additional References, on page 565](#)
- [Feature Information for DOCSIS 3.1 Path Selection, on page 565](#)

## Information about Path Selection

DOCSIS 3.1 Path Selection feature is enhanced to support OFDM downstream channels and OFDMA upstream channels. The RCC selection process is enhanced to include OFDM channels. The TCC selection process is enhanced to include OFDMA channels.

## How to Configure Path Selection

### Configuring Downstream Bonding Group with OFDM Channel

To configure the downstream bonding group with OFDM channel, follow the steps below:

```
enable
configure terminal
interface wideband-cable slot/subslot/bay:wideband-channel
description text
cable bundle id
cable rf-channels channel-list grouplist bandwidth-percent percentage-bandwidth
```

---

**Note** Channel 158 to 162 are specified as OFDM channel.

---

## Verifying Downstream Bonding Group with OFDM Channel Configuration

To display the details of the downstream bonding group with OFDM channel, use the **show running-config interface** command as shown in the example below:

```
Router# show running-config interface wideband-cable 3/0/0:13

Building configuration...

Current configuration : 212 bytes
!
interface Wideband-Cable3/0/0:13
 description D31-DSBG: 1 SC-QAM plus 1 OFDM
 cable bundle 1
 cable rf-channels channel-list 8 bandwidth-percent 30
 cable rf-channels channel-list 158 bandwidth-percent 25
end
```

## Configuring Upstream Bonding Group with OFDMA Channel

To configure the upstream bonding group with OFDMA channel, follow the steps below:

```
enable
configure terminal
interface cable slot/subslot/bay
cable upstream bonding-group id
upstream id
```

## Verifying Upstream Bonding Group with OFDMA Channel Configuration

To display the details of the upstream bonding group with OFDMA channel, use the **show running-config interface** command as shown in the example below:

```
Router# show running-config interface cable 6/0/3
Building configuration...

Current configuration : 212 bytes
!
interface Cable6/0/3
 load-interval 30
 downstream Integrated-Cable 6/0/1 rf-channel 158
 upstream 0 Upstream-Cable 1/0/0 us-channel 0
 upstream 1 Upstream-Cable 1/0/0 us-channel 1
 upstream 2 Upstream-Cable 1/0/0 us-channel 2
 upstream 3 Upstream-Cable 1/0/0 us-channel 3
 upstream 6 Upstream-Cable 1/0/0 us-channel 12
 cable upstream balance-scheduling
 cable upstream bonding-group 2
 upstream 0
 upstream 1
 upstream 2
 upstream 3
 upstream 6
 attributes 80000000
 cable bundle 1
 cable privacy accept-self-signed-certificate
!
```

## Verifying the Path Selection Status

To display the path selection status of a cable modem, use the **show cable modem path-sel** command as shown in the example below:

```
router#show cable modem 38c8.5cfe.efa6 path-sel

CM 38c8.5cfe.efa6 Path-Sel Info: 07:20

RCS Filter Result: Succeed
Candidate RCS List: 2
 RCC-Id Owner-Id Preliminary RCP TLV-56 LBG SF-Attr CM-Attr
 1 1 :12289 Pass Pass -- Pass Pass Pass
 2 1 :12290 Pass Pass -- Pass Pass Pass

TCS Filter Result: Succeed
TCS Info:
 TCS in CGD : 0x7 UCID: 1 2 3
 TCS in Freq Range : 0x7 UCID: 1 2 3
 TCS Impaired : 0x0

TCS Passed filters:
 Preliminary : 0x7 UCID: 1 2 3
 LB Group : 0x7 UCID: 1 2 3
 SF Attr Mask : 0x7 UCID: 1 2 3
 CM Attr Mask : 0x7 UCID: 1 2 3

Candidate US-BG List: 4
 UBG-Id Chan-Mask Preliminary TLV-56 LBG SF-Attr CM-Attr
 1 0x7 Pass -- Pass Pass Pass
 65537 0x2 Pass -- Pass Pass Pass
 65538 0x4 Pass -- Pass Pass Pass
 65536 0x1 Pass -- Pass Pass Pass

Primary DS Chan Result: Skipped
Candidate Primary DS Chan List: 0

Primary US Chan Result: Skipped
Candidate Primary US Chan List: 0
```

## Clearing the Path Selection Status

To clear the path selection status for all CMs, use the **clear cable modem all path-sel** command as shown in the example below:

```
Router# clear cable modem all path-sel

Router# show cable modem c8fb.26a6.c46a path-sel

CM c8fb.26a6.c46a Path-Sel Info: N/A
Path-Sel status has been cleared after register online.
```

## Verifying the RCC Configuration

To verify the runtime RCCs on a cable interface, use the **show cable mac-domain rcc** command as shown in the example below:

```
Router# show cable mac-domain cable 7/0/0 rcc
```

| RCC-ID | RCP            | RCs | MD-DS-SG | CMs | WB/RCC-TMPL    | D3.0 | D3.1 |
|--------|----------------|-----|----------|-----|----------------|------|------|
| 4      | 00 00 00 00 00 | 16  | 0        | 1   | WB (Wi7/0/0:0) | Y    | Y    |
| 5      | 00 00 00 00 00 | 25  | 0        | 2   | WB (Wi7/0/0:1) | N    | Y    |
| 6      | 00 10 00 00 08 | 8   | 0        | 0   | RCC-TMPL (3:1) | Y    | N    |
| 7      | 00 00 00 00 00 | 4   | 0        | 0   | WB (Wi7/0/0:4) | Y    | Y    |

To display the detailed information for only DOCSIS 3.1 capable RCC, use the **show cable mac-domain rcc simplified** command as shown in the example below:

```
router#show cable mac-domain cable 7/0/0 rcc 5 simplified
```

```
RCC ID : 5
Created Via : Wideband - Wi7/0/0:1
CM attribute mask : 0x80000000
```

## Feature Information for DOCSIS 3.1 Path Selection

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 93: Feature Information for DOCSIS 3.1 Path Selection**

| Feature Name                       | Releases                 | Feature Information                                                              |
|------------------------------------|--------------------------|----------------------------------------------------------------------------------|
| DOCSIS 3.1 Path Selection          | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| DOCSIS 3.1 Upstream Path Selection | Cisco IOS XE Fuji 16.7.1 | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 33

# DOCSIS 3.1 Downstream Profile Selection

---

**First Published:** July 13, 2016

DOCSIS 3.1 introduces the concept of downstream profiles for OFDM channels.

## Information about Downstream Profiles

A profile is a list of modulation orders that are defined for each of the subcarriers within an OFDM channel. The CMTS can define multiple profiles for use in an OFDM channel, where the profiles differ in the modulation orders assigned to each subcarrier.

You can use the following commands to view the profiles:

- To display the profiles associated with the cable modems (CMs), use the **show cable modem** *[ip-address/mac-address/ cable/ {slot / subslot / cable-interface-index}] phy ofdm-profile* command.
- To display detailed profile management data associated with specific cable modem, use the **show cable modem** *[ip-address/ mac-address] prof-mgmt* command.

The CMTS can assign different profiles for different groups of CMs.

## Default Data Profile

The first time a CM registers, it is assigned a default data profile. The default data profile is "profile-data 1". If "profile-data 1" is not configured, "profile-control" is assigned to the CM.

---

**Note** Profile A, with profile ID 0, is also referred to as the control profile.

---

## Recommended Profile

Based on the Receive Modulation Error Ratio (RxMER) values collected from a modem using the **cable modem ip opt0** command, and collected automatically and periodically in the background, the CMTS finds among the existing profiles the one that may provide the highest speed, and yet at the same time may have sufficient Signal to Noise Ratio (SNR) margin for the modem to receive code words with acceptable error. This profile is called the recommended profile for that CM. The **show cable modem phy ofdm-profile** command displays the recommended profile for each CM.

Internal PMA is enabled by default on the cBR-8. If external PMA is enabled, internal PMA is disabled and can be enabled by running the following config command on the cBR-8:

```
no cable downstream ofdm-prof-mgmt prof-upgrade-pma
```

In external PMA, the cBR-8 does not automatically upgrade a CM's profile to the recommended profile. In internal PMA, the profile can be upgraded to the recommended profile in the next OFDM Profile Test (OPT) cycle.

A user configurable age is associated with each recommended profile, which can be configured as follows:

```
Router (config)#cable downstream ofdm-prof-mgmt recommend-profile-age age-in-minutes
```

If the recommended profile exceeds this age, it is no longer valid for that CM.

## Unfit Profile

When the CMTS receives CM-STATUS Event 16 (DS OFDM Profile Failure), the profile indicated in the CM-STATUS message is marked as 'unfit profile' for this modem.

A user configurable maximum age is associated with each unfit profile, which can be configured as follows:

```
Router (config)#cable downstream ofdm-prof-mgmt unfit-profile-age age-in-minutes
```

If the unfit profile for a modem exceeds this age, it is no longer valid.

## How to Configure Profiles

### Configuring Profile Downgrade

A CM sends a CM-STATUS Event 16 message to indicate a DS OFDM profile failure. When this indication is received by the CMTS, it takes immediate action to downgrade the modem to a lower profile, as per the profile ordering displayed by the following command:

```
Router# show controllers integrated-Cable 2/0/3 rf-channel 158 prof-order
```

The following table, extracted from [DOCSIS 3.1 MULPI], lists the CM-Status events that will trigger a profile downgrade:

**Table 95: Table: CM-Status Events for Profile Downgrade**

| Event Type | Event Condition         | Status Report Events                                                          |                                                                                                                                                                                                                            | Parameters reported by CM |            |
|------------|-------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|------------|
|            |                         | Trigger event to "on"                                                         | Trigger event to "off"                                                                                                                                                                                                     | DCID                      | Profile ID |
| 16         | DS OFDM profile failure | Loss of FEC lock on one of the assigned downstream OFDM profiles of a channel | Re-establishment of FEC lock for that OFDM profile;<br>OR<br>Removal of the channel from the active channel list in the primary channel MDD;<br>OR<br>Removal of the channel from the CM's Receive Channel set via DBC-REQ | Yes                       | Yes        |

To disable the automatic profile downgrade, use the following command in global configuration mode:

```
Router (config)#no cable downstream ofdm-prof-mgmt prof-dwngrd-auto
```

## Configuring RxMER to Bit Loading Mapping

There are many ways to map the Receive Modulation Error Ratio (RxMER) values to bit loading values. We use the following mapping recommended in [DOCSIS 3.1 OSSI], as our baseline mapping:

| RxMER (in ¼ DB) | QAM  | Bit Loading |
|-----------------|------|-------------|
| 60              | 16   | 4           |
| 84              | 64   | 6           |
| 96              | 128  | 7           |
| 108             | 256  | 8           |
| 122             | 512  | 9           |
| 136             | 1024 | 10          |
| 148             | 2048 | 11          |

| RxMER (in ¼ DB) | QAM   | Bit Loading |
|-----------------|-------|-------------|
| 164             | 4096  | 12          |
| 184             | 8192  | 13          |
| 208             | 16384 | 14          |

- To configure a margin to adjust the RxMER to bit loading mapping, use the following command:

```
Router(config)# cable downstream ofdm-prof-mgmt mer-margin-qdb interval-in-minutes
```

This configured value (*quarter-DB*) is added to the RxMER values collected by CMTS before using the above mapping table, thus giving a user more control in selecting the recommended profiles.

- To specify the percentage of subcarriers that can be ignored in the recommended profile calculation, use the following command:

```
Router(config)# cable downstream ofdm-prof-mgmt exempt-sc-pct percent
```

This provides a way to specify the extent that the outliers can be ignored.

- To configure the RxMER poll interval, use the following command:

```
Router(config)# cable downstream ofdm-prof-mgmt rxmer-poll-interval interval-in-minutes
```

The CMTS uses OPT message with bit-0 option to collect RxMER data from CMs, after the initial CM registration and periodically thereafter. The collected RxMER data is used to compute the recommended profile for each CM.

## Information About Commanded Power Feature for Upstream SC-QAMs

Commanded Power feature for UpStream Single Carrier Quadrature Amplitude Modulation (US SC-QAMs) supports a new method during ranging to dynamically set the transmit power level of a DOCSIS 3.1 cable modem.

To view the new commanded power levels pr upstream, use the following command:

```
Router# show cable modem [ip-address | mac-address | cable {slot /subslot /cable-interface-index}] verbose
```

**Note** DOCSIS 3.1 Commanded Power feature is enabled by default.

## Feature TLVs

### TLVs Affected by Commanded Power for US SC-QAMs

The following table lists the TLVs affected by the DOCSIS 3.1 Ranging Response (RNG-RSP) Commanded Power for upstream SC-QAMs:

| Name                            | Type   | DOCSIS 3.1 Value                                                                                                                                                                                      |
|---------------------------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power Level Adjust              | 2      | TX Power offset adjustment (signed 8-bit, 1/4-dB units)                                                                                                                                               |
| Power Offset                    | 12.4.4 | TX Power offset adjustment (signed 8-bit, 1/4-dB units)                                                                                                                                               |
| Dynamic Range Window Upper Edge | 14     | The upper edge of the Dynamic Range Window expressed in units 1/4 dB below the max allowable setting (Phi) [DOCSIS PHYv3.0].                                                                          |
| Commanded Power                 | 17     | This TLV contains the Dynamic Range Window value, P1.6load_min_set as well as the Transmit Power Level for each of the channels in the CM's Transmit Channel Set, expressed in units of quarter dBmV. |

### Commanded Power Sub-TLVs

The following table lists the sub-TLVs for DOCSIS 3.1 Commanded Power:

| Name                 | Type (1 byte) | Length (1 byte) | Value (Variable Length)                                                                                                                       |
|----------------------|---------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Commanded Power      | 17            | 5 + 3*N         |                                                                                                                                               |
| Dynamic Range Window | 17.1          | 1               | The range, in decibels, of the maximum difference in power per 1.6 MHz between multiple transmitters in a cable modem's Transmit Channel Set. |

| Name                                                                 | Type (1 byte) | Length (1 byte) | Value (Variable Length)                                                                                                                                                  |
|----------------------------------------------------------------------|---------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| List of Upstream Channel IDs and Corresponding Transmit Power Levels | 17.2          | 3*N             | Values for each channel in the TCS: <ul style="list-style-type: none"> <li>• Bits 23 to 16: UCID</li> <li>• Bits 15 to 0: Transmit Power Level (quarter dBmV)</li> </ul> |

## CHAPTER 35

# DOCSIS3.1 Downstream Resiliency for OFDM channel

---

This document describes how to configure the DOCSIS3.1 Downstream Resiliency for OFDM channel on the Cisco cBR Series Converged Broadband Router.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Information about DOCSIS3.1 Downstream Resiliency for OFDM Channel

When DOCSIS3.1 CM reports non-primary RF channel failure for SCQAM or OFDM channel, actions performed by downstream resiliency is the same as DOCSIS3.0 CM. In other words, if RF channel impairment is below the resiliency threshold, CMs service flows are moved to Resiliency Bonding Group (RBG) or Narrow Band (NB) interface. If RF channel impairment is above the resiliency threshold, the impaired RF channel is temporarily removed from the bonding group.

The following table summarizes the CM-STATUS events for OFDM channel, and the action to be taken by the downstream resiliency module:

Table 100: CM-STATUS events for OFDM channel

| Event Type Code | Event Description | DS Resiliency Action                                     |
|-----------------|-------------------|----------------------------------------------------------|
| 1               | MDD timeout       | Move CM's service flows to RBG/NB or suspend RF from BG. |

| Event Type Code | Event Description                                                                                         | DS Resiliency Action                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| 2               | FEC lock failure                                                                                          | Move CM's service flows to RBG/NB or suspend RF from BG.                                                     |
| 4               | MDD recovery                                                                                              | Move CM's service flows back to original BG.                                                                 |
| 5               | FEC lock recovery                                                                                         | Move CM's service flows back to original BG.                                                                 |
| 16              | DS OFDM profile failure. A loss of FEC lock on one of the assigned downstream OFDM profiles of a channel. | DS OFDM Profile Manager will handle this event and take action.                                              |
| 20              | NCP profile failure. Loss of FEC lock on NCP.                                                             | Move CM's service flows to RBG/NB or suspend RF from BG.                                                     |
| 21              | Loss of FEC lock on the PLC.                                                                              | Move CM's service flows to RBG/NB or suspend RF from BG.                                                     |
| 22              | NCP profile recovery.                                                                                     | Move CM's service flows back to original BG.                                                                 |
| 23              | FEC recovery on PLC channel.                                                                              | Move CM's service flows back to original BG.                                                                 |
| 24              | FEC recovery on OFDM profile.                                                                             | Recovery of impairment reported by event 16. DS OFDM Profile Manager will handle this event and take action. |

# How to Configure DOCSIS3.1 Downstream Resiliency for OFDM Channel

## Configuring DOCSIS3.1 Downstream Resiliency for OFDM Channel

User must configure the command **cable rf-change-trigger percent *value* count *number*** to enable the downstream resiliency functionality.

To configure the trigger thresholds specific to OFDM RF impairment, follow the steps below:

```
enable
configure terminal
cable ofdm-rf-change-trigger percent value counter number [no-ncp-plc]
```

Starting from Cisco IOS XE Fuji 16.10.1d release, you can exclude NCP and PLC reports separately by following these steps:

```
enable
configure terminal
cable ofdm-rf-change-trigger percent value counter number [no-ncp] [no-plc]
```

Trigger thresholds *value* and *number* apply globally to the non-primary OFDM RF channels. If this command is not configured, the trigger thresholds configured by the command **cable rf-change-trigger percent *value* count *number*** will be used for the non-primary OFDM channels.

With **no-ncp-plc** configured in the command, this feature will not take any action when CM reports CM-STATUS-EVENT 20 or 21.

**Note** The **cable rf-change-trigger percent *value* count *number*** command is optional and the configured trigger thresholds apply to non-primary OFDM channels only.

## Displaying OFDM Specific CM-STATUS Events

To display the statistics of the OFDM specific CM-STATUS events, use the **show cable modem wideband rcs-status** command as shown in the example below:

```
router#show cable modem 4800.33ea.7072 wideband rcs-status verbose
CM : 4800.33ea.7072

## Information about OFDMA Channel Configuration

### OFDMA Channels

DOCSIS 3.1 introduces modes for higher throughput and higher spectral efficiency while still allowing backward compatibility to DOCSIS 3.0. Orthogonal Frequency Division Multiple Access (OFDMA) channel has following features:

- Frequency-range up to 80 MHz
- Upstream spectrum 5 – 85 MHz
- 25 kHz subcarrier spacing
- OFDMA Channel-width up to 80 MHz - The Cisco IOS XE Fuji 16.7.x release supports configuration of a single 80 MHz OFDMA channel on every port of a line card.
- OFDMA Channel-width up to 96 MHz - The Cisco IOS XE 16.8.x release supports configuration of a single 96 MHz OFDMA channel on every port of a line card.

- OFDMA Upstream spectrum 5 – 85 MHz - The Cisco IOS XE Fuji 16.7.x supports a maximum frequency value of 85 Mhz for an OFDMA channel.
- OFDMA Upstream spectrum 5 – 204 MHz - The Cisco IOS XE 16.8.x extends the supported maximum frequency value of an OFDMA channel from 85 Mhz to 204 Mhz.

For a specific subcarrier spacing, the number of subcarriers on an OFDMA channel depends on the channel width.

| Channel Width | 50 kHz | 25 kHz |
|---------------|--------|--------|
| 48 MHz        | 960    | 1920   |
| 96 MHz        | 1920   | 3840   |

**Note** When the OFDMA is configured with SC-QAMs on the same port pair, it is recommended to configure no more than 45 MHz OFDMA per port, or 90 MHz per port pair in Cisco IOS XE Everest Release 16.6.1.

## Modulation Profile

A globally configured OFDMA modulation profile defines modulation orders and pilot patterns for different interval usage codes (IUC). It is also used to assign parameters for initial ranging and fine ranging.

## OFDMA Channel Exclusion Band

Ranges of frequencies can be excluded from all OFDMA channels on a port using the **ofdma-frequency-exclusion-band** command.

Exclusion and unused bands apply to OFDMA channels only. OFDMA channel never use frequencies in exclusion band. So the legacy SC-QAM channel can be placed in this band. OFDMA channel does not use frequencies in unused band set by **ofdma-frequency-unused-band** command for data traffic, but can send probes in them.

## Configure OFDMA Channel

**Note** To know more about the commands referenced in this module, see the [Cisco IOS Master Command List](#).

## Configuring OFDMA Controller Profile

To configure upstream controller profile, follow the steps below:

```
enable
configure terminal
cable mod-profile-ofdma id
```

```

subcarrier-spacing value
initial-rng-subcarrier value
fine-rng-subcarrier value
data-iuc id modulation value pilot-pattern value

```

Here is a configuration example:

```

Router# enable
Router# configure terminal
Router(config)# cable mod-profile-ofdma 466
Router(config-ofdma-mod-profile)# subcarrier-spacing 50KHz
Router(config-ofdma-mod-profile)# initial-rng-subcarrier 64
Router(config-ofdma-mod-profile)# fine-rng-subcarrier 128
Router(config-ofdma-mod-profile)# data-iuc 13 modulation 1024-QAM pilot-pattern 2
Router(config-ofdma-mod-profile)# exit
Router(config)# cable mod-profile-ofdma 423
Router(config-ofdma-mod-profile)# subcarrier-spacing 25KHz
Router(config-ofdma-mod-profile)# initial-rng-subcarrier 64
Router(config-ofdma-mod-profile)# fine-rng-subcarrier 128
Router(config-ofdma-mod-profile)# data-iuc 6 modulation 1024-QAM pilot-pattern 8
Router(config-ofdma-mod-profile)# data-iuc 9 modulation 1024-QAM pilot-pattern 8
Router(config-ofdma-mod-profile)# data-iuc 10 modulation 512-QAM pilot-pattern 8
Router(config-ofdma-mod-profile)# data-iuc 11 modulation 256-QAM pilot-pattern 8
Router(config-ofdma-mod-profile)# data-iuc 12 modulation 128-QAM pilot-pattern 9
Router(config-ofdma-mod-profile)# data-iuc 13 modulation 64-QAM pilot-pattern 9

```

**Note** Subcarrier spacing must match the subcarrier spacing of each channel profile in which it is configured.

## Verifying OFDMA Modulation Profile Configuration

To display the OFDMA modulation profile details, use the **show cable modulation-profile ofdma** command as shown in the example below:

```

Router# show cable modulation-profile ofdma
Mod Subc IUC type Act Preamble Bit Pilot
 Spacing (IR) (FR) subc Symbols Loading Pattern
421 25KHz 3 4 64 4
 4 192 1
 13 (data) 16-QAM 8
423 25KHz 3 4 64 4
 4 128 1
 6 (data) 1024-QAM 8
 10 (data) 512-QAM 8
 11 (data) 256-QAM 8
 12 (data) 128-QAM 9
 13 (data) 64-QAM 9
461 50KHz 3 4 32 4
 4 192 1
 13 (data) 16-QAM 1
466 50KHz 3 4 64 4
 4 128 1
 13 (data) 1024-QAM 2

```

## Configuring OFDMA Channel

To configure the OFDMA channel, follow the steps below:

```
enable
configure terminal
controller Upstream-Cable slot/subslot/port
us-channel id docsis-mode ofdma
us-channel id subcarrier-spacing value
us-channel id frequency-range start-value end-value
us-channel id modulation-profile id
us-channel id cyclic-prefix value roll-off-period value
us-channel id symbols-per-frame value
us-channel id data-iuc id band start-value end-value modulation value pilot-pattern
value
```

Here is a configuration example:

```
Router# enable
Router# configure terminal
Router(config)# controller Upstream-Cable 1/0/4
Router(config-controller)# us-channel 12 docsis-mode ofdma
Router(config-controller)# us-channel 12 subcarrier-spacing 25KHz
Router(config-controller)# us-channel 12 frequency-range 40000000 85000000
Router(config-controller)# us-channel 12 modulation-profile 423
Router(config-controller)# us-channel 12 cyclic-prefix 640 roll-off-period 224
Router(config-controller)# us-channel 12 symbols-per-frame 9
Router(config-controller)# us-channel 12 data-iuc 9 band 50000000 60000000 modulation 512-QAM
pilot-pattern 8
Router(config-controller)# no us-channel 12 shutdown
```

**Note**

- OFDMA use us-channel range 12–15.
- Change docsis-mode to **ofdma** to enable OFDMA configuration options. These options are enabled by default on us-channel 12–15.
- It is recommended to configure no more than 4 active SC-QAMs while an OFDMA channel is present.
- A maximum of one OFDMA channel can be configured per controller. Starting from Cisco IOS XE Gibraltar 16.10.x release, two OFDMA channels—us-channel 12 and us-channel 13 can be configured per controller.
- In Cisco IOS XE Everest 16.6.x release, OFDMA channel must be placed between 40 and 85 Mhz.
- Starting from Cisco IOS XE Fuji 16.7.x release, OFDMA channel must be placed between 5 and 85 Mhz.
- Values of the options are often interdependent, changing one value may change other values or make them invalid.
- It is recommended to set subcarrier spacing and frequency range first. Frequency range must be increment of 50 kHz.
- Two OFDMA channels are supported for each fiber node.
- Two OFDMA channels are supported for each bonding group.
- A maximum of 192 Mhz OFDMA spectrum is supported for each controller pair.

## Verifying OFDMA Channel Configuration

To display the OFDMA channel configuration, use the **show controllers upstream-Cable us-channel** command as shown in the example below:

```
Router# show controllers upstream-Cable 1/0/4 us-channel 12
USPHY OFDMA support: FULL

Controller 1/0/4 upstream 12 AdminState:UP OpState: UP
ofdma mode enabled

```

## Configure Exclusion / Unused Bands

An OFDMA channel never use frequencies located in exclusion bands. OFDMA probes will be sent on frequencies located in the unused bands. Therefore exclusion bands must be used to prevent interference with SC-QAM channels. To configure the Exclusion / Unused Bands, follow the steps below:

```

enable
configure terminal
controller Upstream-Cable slot/subslot/port
cable ofdma-frequency-exclusion-band start-value end-value
cable ofdma-frequency-unused-band start-value end-value

```

Here is a configuration example:

```

Router# enable
Router# configure terminal
Router(config)# controller Upstream-Cable 1/0/2
Router(config-controller)# cable ofdma-frequency-exclusion-band 48000000 54200000
Router(config-controller)# cable ofdma-frequency-unused-band 50000000 52000000
Router(config-controller)# us-channel 12 docsis-mode ofdma
Router(config-controller)# us-channel 12 subcarrier-spacing 25KHz
Router(config-controller)# us-channel 12 modulation-profile 423
Router(config-controller)# us-channel 12 frequency-range 45000000 70000000
Router(config-controller)# us-channel 12 cyclic-prefix 96 roll-off-period 64
Router(config-controller)# us-channel 12 symbols-per-frame 18

```

## Verifying Exclusion / Unused Bands

To display the Exclusion / Unused Band configuration, use the **show controllers upstream-Cable us-channel** command as shown in the example below:

```

Router# show controllers upstream-Cable 1/0/2 us-channel 12
USPHY OFDMA support: FULL

Controller Exclusion Freq List:
(40.000 MHz, 44.200 MHz),
Controller Unused Freq List:
(50.000 MHz, 52.000 MHz),

Controller 1/0/9 upstream 12 AdminState:UP OpState: UP
ofdma mode enabled
Channel Freq Range 28.500 MHz to 69.500 MHz
Channel Subcarrier Index Range Cfg: 148, 1787 Op: 148, 1787
Channel SCO Freq Cfg: 24.800 MHz Op: 24.800 MHz
#Excl bands: 3
(0, 147), (608, 776), (1788, 4095),

```

```
#Unused bands: 3
(596, 607), (1001, 1088), (1777, 1787),
```

## Override OFDMA Profile Per Channel

It is possible to override the modulation and pilot pattern used by a particular IUC on a given OFDMA channel as shown with the command below.

```
enable
configure terminal
controller Upstream-Cable slot/subslot/port
us-channel id data-iuc id band start-value end-value modulation value pilot-pattern
value
```

Here is a configuration example:

```
Router# enable
Router# configure terminal
Router(config)# controller Upstream-Cable 1/0/2
Router(config-controller)# us-channel 12 docsis-mode ofdma
Router(config-controller)# us-channel 12 subcarrier-spacing 25KHz
Router(config-controller)# us-channel 12 modulation-profile 423
Router(config-controller)# us-channel 12 frequency-range 28000000 70000000
Router(config-controller)# us-channel 12 cyclic-prefix 96 roll-off-period 64
Router(config-controller)# us-channel 12 symbols-per-frame 18
Router(config-controller)# us-channel 12 data-iuc 6 band 60000000 65000000 modulation 128-QAM
pilot-pattern 9
Router(config-controller)# no us-channel 12 shutdown
```

**Note** Override values will be removed from US channel when changing modulation profile, including when profile changes due to changes in subcarrier spacing.

From Cisco cBR Series Converged Broadband Router 16.12.1w and later, the limitation of one IUC override per IUC configuration no longer applies for cBR-8 on CBR-LC-8D31-16U31, CBR-CCAP-LC-40G-R and CBR-CCAP-LC-G2-R. The OFDMA - 4 override zones per IUC feature increases the number of overrides that can be defined to four per IUC.

A maximum channel configuration would appear as below:

```
controller Upstream-Cable 1/0/0
us-channel 12 data-iuc 5 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 5 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 5 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 5 band 46000000 47500000 modulation 512-QAM pilot-pattern 8
us-channel 12 data-iuc 6 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 6 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 6 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 6 band 46000000 47500000 modulation 512-QAM pilot-pattern 8
us-channel 12 data-iuc 9 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 9 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 9 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 9 band 46000000 47500000 modulation 512-QAM pilot-pattern 8
us-channel 12 data-iuc 10 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 10 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 10 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 10 band 46000000 47500000 modulation 512-QAM pilot-pattern 8
```

```

us-channel 12 data-iuc 11 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 11 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 11 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 11 band 46000000 47500000 modulation 512-QAM pilot-pattern 8
us-channel 12 data-iuc 12 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 12 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 12 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 12 band 46000000 47500000 modulation 512-QAM pilot-pattern 8
us-channel 12 data-iuc 13 band 40500000 41500000 modulation 64-QAM pilot-pattern 8
us-channel 12 data-iuc 13 band 42000000 43500000 modulation 128-QAM pilot-pattern 8
us-channel 12 data-iuc 13 band 44000000 45500000 modulation 256-QAM pilot-pattern 8
us-channel 12 data-iuc 13 band 46000000 47500000 modulation 512-QAM pilot-pattern 8

```

This allows nine modulation zones per profile across the channel. So, for example, for a modem using IUC 5, the channel modulation would be as follows:

```

router# show controller Upstream-Cable 1/0/0 us-channel 12 cdm-ump | beg Rang
Ranging profile:
IUC 3, preamble_len 256, sc mode 25KHz active_sc 64 guard_sc 0
IUC 4, preamble_len 192, sc mode 25KHz active_sc 192 guard_sc 0
Calculated Data burst profile:
 IUC Group Bit Pilot Start Consec
 Loading Pattern Mslot Mslot
 5 0 1024-QAM 8 0 24
 5 1 64-QAM 8 25 1
 5 2 1024-QAM 8 27 1
 5 3 128-QAM 8 29 2
 5 4 1024-QAM 8 32 1
 5 5 256-QAM 8 34 2
 5 6 1024-QAM 8 37 1
 5 7 512-QAM 8 39 2
 5 8 1024-QAM 8 42 42
...

```

#### Note

- All subcarriers within a single OFDMA minislot must be assigned the same modulation order. Different modulation orders cannot be assigned to different subcarriers within the same minislot.
- If a modulation override configuration is applied that places the frequency start and/or end within the middle of a minislot, the entire minislot will receive the override configuration.
- If two adjacent modulation overrides overlap the same minislot, the minislot receives the modulation configuration of the last override configuration. In most cases this will be the higher frequency override modulation.
- For the RPHY cards, the OFDMA - 4 override zones per IUC enhancement is supported with all RPD types that support OFDMA.

## Verifying Override Configuration

To display the override configuration, use the **show controllers upstream-Cable us-channel** command as shown in the example below:

```

Router# show controllers upstream-Cable 1/0/2 us-channel 12
.....
Modulation Profile (ID 423, Subcarrier Spacing 25KHz)
 IUC type Cfg Act Preamble Bit Pilot

```

|          |               | subc | subc | Symbols | Loading         | Pattern  |
|----------|---------------|------|------|---------|-----------------|----------|
| 3        | (IR)          | 64   | 64   | 4       | -               | -        |
| 4        | (FR)          | 128  | 128  | 1       | -               | -        |
| <b>6</b> | <b>(data)</b> | -    | -    | -       | <b>1024-QAM</b> | <b>8</b> |
| 10       | (data)        | -    | -    | -       | 512-QAM         | 8        |
| 11       | (data)        | -    | -    | -       | 256-QAM         | 8        |
| 12       | (data)        | -    | -    | -       | 128-QAM         | 9        |
| 13       | (data)        | -    | -    | -       | 64-QAM          | 9        |

**Overwrite Data Profile:**

| IUC | Start Freq (MHz) | End Freq (MHz) | Start Subc | End Subc | Bit Loading | Pilot Pattern |
|-----|------------------|----------------|------------|----------|-------------|---------------|
| 6   | 60.0             | 65.0           | 1408       | 1608     | 128-QAM     | 9             |

Calculated Data burst profile:

| IUC | Group | Bit Loading | Pilot Pattern | Start Mslot | Consec Mslot |
|-----|-------|-------------|---------------|-------------|--------------|
| 6   | 0     | 1024-QAM    | 8             | 0           | 61           |
| 6   | 1     | 128-QAM     | 9             | 62          | 11           |
| 6   | 2     | 1024-QAM    | 8             | 74          | 10           |
| 10  | 0     | 512-QAM     | 8             | 0           | 84           |
| 11  | 0     | 256-QAM     | 8             | 0           | 84           |
| 12  | 0     | 128-QAM     | 9             | 0           | 84           |
| 13  | 0     | 64-QAM      | 9             | 0           | 84           |

.....

## Apply OFDMA Upstream To Cable Interface

To associate upstream channels with a MAC domain and configure upstream bonding, follow the steps below:

```
enable
configure terminal
interface Cable slot/subslot/interface
cable upstream bonding-group id
upstream id
attributes value
cable bundle id
```

Here is a configuration example:

```
Router# enable
Router# configure terminal
Router(config)# interface Cable 1/0/4
Router(config-if)# downstream Integrated-Cable 1/0/4 rf-channel 0
Router(config-if)# downstream Integrated-Cable 1/0/4 rf-channel 16
Router(config-if)# upstream 0 Upstream-Cable 1/0/0 us-channel 0
Router(config-if)# upstream 1 Upstream-Cable 1/0/0 us-channel 1
Router(config-if)# upstream 2 Upstream-Cable 1/0/0 us-channel 2
Router(config-if)# upstream 3 Upstream-Cable 1/0/0 us-channel 3
Router(config-if)# upstream 6 Upstream-Cable 1/0/0 us-channel 12
Router(config-if)# cable upstream bonding-group 1
Router(config-upstream-bonding)# upstream 0
Router(config-upstream-bonding)# upstream 1
Router(config-upstream-bonding)# upstream 2
Router(config-upstream-bonding)# upstream 3
Router(config-upstream-bonding)# attributes 80000000
Router(config-upstream-bonding)# exit
Router(config-if)# cable upstream bonding-group 2
Router(config-upstream-bonding)# upstream 0
```

```

Router(config-upstream-bonding)# upstream 1
Router(config-upstream-bonding)# upstream 2
Router(config-upstream-bonding)# upstream 3
Router(config-upstream-bonding)# upstream 6
Router(config-upstream-bonding)# attributes 80000000
Router(config-upstream-bonding)# exit
Router(config-if)# cable bundle 1

```

## Determine DOCSIS 3.1 Cable Modems and the Cable Modems Using OFDMA Upstreams

To display the DOCSIS 3.1 cable modem, use the **show cable modem docsis version d31-capable** command as shown in the example below:

```

Router# show cable modem docsis version d31-capable
MAC Address I/F MAC Reg Oper DSxUS DS RCC US
 State Ver Ver OFDM ID OFDMA
4800.33ea.7012 C1/0/0/UB w-online(pt) 3.1 3.1 33x4 1 5 1
203d.66ae.4169 C1/0/0/UB w-online(pt) 3.1 3.1 33x4 1 5 1

```

To display DOCSIS PHY layer information for the cable modem, use the **show cable modem phy** command as shown in the example below:

```

Router# show cable modem 5039.5584.5bbe phy
MAC Address I/F Sid USPwr USMER Timing DSPwr DSMER Mode DOCSIS
 (dBmV) (SNR) Offset (dBmV) (SNR) (dB) (dB) Prov
5039.5584.5bbe C1/0/0/U0 15 38.75 ----- 2282 0.00 ----- ofdma 1.1

```

To display the cable modem using OFDMA upstream, use the **show cable modem phy** command as shown in the example below:

```

Router# show cable modem phy | include ofdma
5039.5584.5bbe C1/0/0/U0 15 38.75 ----- 2282 0.00 ----- ofdma 1.1
0895.2a9b.26f1 C1/0/0/U0 16 28.00 ----- 2146 0.00 ----- ofdma 1.1

```

To display the OFDMA channel capacity and utilization, use the **show interface cable mac-scheduler** command as shown in the example below:

```

Router# show interfaces cable 1/0/2 mac-scheduler 6
DOCSIS 1.1 MAC scheduler for Cable1/0/2/U6 : rate 279807192
Max potential performance for each configured IUC type
IUC: 6 rate: 279807192

## Verifying DOCSIS 3.1 Upstream OFDMA channel bonding across DOCSIS 3.0 ATDMA channels

Starting from Cisco IOS XE Everest 16.6.1 release, DOCSIS 3.1 Upstream OFDMA channel can be bonded with DOCSIS 3.0 ATDMA channel. If the user wants to utilize non-best effort flows, it is recommended to bond the OFDMA channel with one or more ATDMA channels. But be aware that in Cisco IOS XE Everest 16.6.1 release, a maximum of 1 OFDMA channel and 4 ATDMA channels can be bonded together.

Below is an output example showing the bonding group 8 has both OFDMA (channel 12) and ATDMA channels (channel 0, 1, 2, 3).

```

interface Cable6/0/0
downstream Integrated-Cable 6/0/0 rf-channel 1
downstream Integrated-Cable 6/0/0 rf-channel 158
upstream 0 Upstream-Cable 6/0/0 us-channel 0
upstream 1 Upstream-Cable 6/0/0 us-channel 1
upstream 2 Upstream-Cable 6/0/0 us-channel 2
upstream 3 Upstream-Cable 6/0/0 us-channel 3
upstream 6 Upstream-Cable 6/0/0 us-channel 12
cable upstream bonding-group 1
 upstream 0
 upstream 1
 upstream 2
 upstream 3

cable bundle 1
cable privacy accept-self-signed-certificate
end

```

# Feature Information for DOCSIS 3.1 OFDMA Channel Configuration

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 103: Feature Information for DOCSIS 3.1 OFDMA Channel Configuration**

| Feature Name                                                         | Releases                        | Feature Information                                                              |
|----------------------------------------------------------------------|---------------------------------|----------------------------------------------------------------------------------|
| DOCSIS 3.1 US 16 OFDMA channel support per line card                 | Cisco IOS XE Fuji 16.7.1        | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| DOCSIS 3.1 US OFDMA channel bonding across DOCSIS 3.0 ATDMA channels | Cisco IOS XE Fuji 16.7.1        | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| TaFDM OFDMA Support                                                  | Cisco IOS XE Fuji 16.7.1        | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| 204 Mhz Maximum Frequency OFDMA Support                              | Cisco IOS XE Fuji 16.8.1        | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| Remote PHY DOCSIS 3.1 OFDMA Channel Configuration                    | Cisco IOS XE Fuji 16.9.1        | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| iCCAP 2 OFDMA Channels per port                                      | Cisco IOS XE Gibraltar 16.10.1c | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| Remote PHY DOCSIS 3.1 OFDMA LCHA & LCPR                              | Cisco IOS XE Gibraltar 16.10.1c | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |
| OFDMA - 4 override zones per IUC                                     | Cisco IOS XE Gibraltar 16.12.1w | This feature was integrated on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 37

# Time and Frequency Division Multiplexing Configuration

---

This document provides information on the Cisco cBR-8 series routers support for Time and Frequency Division Multiplexing (TaFDM) feature in DOCSIS 3.1 upstream channels.

- [Information About TaFDM Support, on page 597](#)
- [How to Configure cBR for TaFDM Support, on page 598](#)
- [Configuration Example , on page 600](#)
- [Feature Information for TaFDM Configuration, on page 601](#)

## Information About TaFDM Support

Using the Time and Frequency Division Multiplexing (TaFDM) method, the OFDMA and SCQAM channels, which are allowed to overlap in DOCSIS 3.1, are also allowed to use the upstream at different times. With the implementation of TaFDM, both OFDMA and SC-QAM can simultaneously operate on separate frequencies. They can also operate on the same frequencies, but in different times.

TaFDM enables the OFDMA capability across the entire spectrum, while retaining the backward compatibility with legacy DOCSIS SC-QAM channels.

TaFDM is typically configured at the controller level. However, it is implemented at the Mac Domain level. Overlapping channels cannot be bound to different Mac Domains.

Overlapping SC-QAM and OFDMA channels using TaFDM may be bonded. However, we recommend this bonding only if the modems are provisioned with UGS flows and another non-overlapping SC-QAM is not available.

For a better performance of UGS flows on overlapped SC-QAM channel, configure OFDMA channel with 50kHz subcarrier spacing, lower symbols per frame, and lower cyclic prefix.

To achieve a higher OFDMA channel traffic throughput, configure OFDMA channel with 25kHz subcarrier spacing, and higher pilot pattern.

## Prerequisites for Configuring TaFDM Support

The following prerequisite is applicable to configuring TaFDM configuration:

- All overlapped SC-QAM channels and OFDMA channels on the same port must be bound to the same Mac Domain
- Reserve a minimum 0.8–3.2 MHz OFDMA exclusive spectrum with good signal quality to be used for OFDMA channel IM zone

## How to Configure cBR for TaFDM Support

### Configuring TaFDM Modulation Profile

The TaFDM modulation profile is used to configure initial ranging, fine ranging and data IUC parameters. To define the TaFDM modulation profile, run the configuration commands, as given in the following example:

```
cable mod-profile-ofdma 450
 subcarrier-spacing 25KHz
 initial-rng-subcarrier 64
 fine-rng-subcarrier 192
 data-iuc 9 modulation 1024-QAM pilot-pattern 11
 data-iuc 10 modulation 512-QAM pilot-pattern 11
 data-iuc 11 modulation 256-QAM pilot-pattern 8
 data-iuc 12 modulation 128-QAM pilot-pattern 8
 data-iuc 13 modulation 64-QAM pilot-pattern 8

cable mod-profile-ofdma 470
 subcarrier-spacing 50KHz
 initial-rng-subcarrier 64
 fine-rng-subcarrier 192
 data-iuc 9 modulation 1024-QAM pilot-pattern 1
 data-iuc 10 modulation 512-QAM pilot-pattern 1
 data-iuc 11 modulation 256-QAM pilot-pattern 1
 data-iuc 12 modulation 128-QAM pilot-pattern 1
 data-iuc 13 modulation 64-QAM pilot-pattern 1
```

### Configuring I/O Controller for TaFDM

The following sample configuration defines a shared region in the areas of the SC-QAM upstream channels.

```
controller Upstream-Cable slot/subslot/port
 us-channel 0 frequency 35800000
 us-channel 0 channel-width 6400000 6400000
 us-channel 0 docsis-mode atdma
 us-channel 0 minislots-size 2
 us-channel 0 modulation-profile 221
 us-channel 0 equalization-coefficient
 no us-channel 0 shutdown
 us-channel 1 frequency 29400000
 us-channel 1 channel-width 6400000 6400000
 us-channel 1 docsis-mode atdma
 us-channel 1 minislots-size 2
 us-channel 1 modulation-profile 221
 us-channel 1 equalization-coefficient
 no us-channel 1 shutdown
 us-channel 2 frequency 23000000
 us-channel 2 channel-width 6400000 6400000
 us-channel 2 docsis-mode atdma
 us-channel 2 minislots-size 2
```

```

us-channel 2 modulation-profile 221
us-channel 2 equalization-coefficient
no us-channel 2 shutdown
us-channel 3 frequency 16600000
us-channel 3 channel-width 6400000 6400000
us-channel 3 docsis-mode atdma
us-channel 3 minislot-size 2
us-channel 3 modulation-profile 221
us-channel 3 equalization-coefficient
no us-channel 3 shutdown

```

## Enhancing OFDMA Channel Throughput

The following example shows how to enhance the OFDMA channel throughput:

```

controller Upstream-Cable 1/0/0
...
us-channel 12 docsis-mode ofdma
us-channel 12 subcarrier-spacing 25KHz
us-channel 12 modulation-profile 450
us-channel 12 frequency-range 10000000 85000000 #Overlap with SC-QAM channels
us-channel 12 initial-rng-frequency-start 50000000 # Specify the preferred start
frequency for IM zone
us-channel 12 cyclic-prefix 96 roll-off-period 64
us-channel 12 symbols-per-frame 9
no us-channel 12 shutdown

```

## Enhancing SC-QAM Channel UGS Flow Performance

The following example shows how to enhance the UGS flow performance of the SC-QAM channel:

```

controller Upstream-Cable 1/0/0
...
us-channel 12 docsis-mode ofdma
us-channel 12 subcarrier-spacing 50KHz
us-channel 12 modulation-profile 470
us-channel 12 frequency-range 10000000 85000000 #Overlap with SC-QAM channels
us-channel 12 initial-rng-frequency-start 50000000 #Specify the preferred frequency for
IM zone
us-channel 12 cyclic-prefix 96 roll-off-period 64
us-channel 12 symbols-per-frame 8
no us-channel 12 shutdown

```

## Configuring Cable Interface-MAC Domain

The following example shows how to configure a cable interface for MAC Domain:

```

interface Cable1/0/0
load-interval 30

upstream 0 Upstream-Cable 1/0/0 us-channel 0
upstream 1 Upstream-Cable 1/0/0 us-channel 1
upstream 2 Upstream-Cable 1/0/0 us-channel 2
upstream 3 Upstream-Cable 1/0/0 us-channel 3
upstream 6 Upstream-Cable 1/0/0 us-channel 12
cable upstream bonding-group 1
upstream 0
upstream 1

```

```

upstream 2
upstream 3
attributes 80000000
cable upstream bonding-group 2
upstream 0
upstream 1
upstream 2
upstream 3
upstream 6
attributes 80000000
cable bundle 1
cable sid-cluster-group num-of-cluster 2 #Maximize single modem throughput
cable sid-cluster-switching max-request 4
cable cm-status enable 3 6-11 16-18 20-27
cable privacy accept-self-signed-certificate

```

## Configuring Service Class

The following example shows how to configure service classes:

```

cable service class 198 name mega_up
cable service class 198 upstream
cable service class 198 max-concat-burst 16384
cable service class 198 max-rate 1000000000 # Maximize single modem throughput
cable service class 198 max-burst 250000
cable service class 198 priority 0
cable service class 198 peak-rate 0

```

## Excluding a Frequency Band from TaFDM

If you want the SC-QAM to exclusively use a specific frequency range, configure Cisco cBR to exclude the band using the following sample commands.

```

controller Upstream-Cable slot/subslot/port
cable frequency-exclusion-band 18700000 22100000

```

## Verifying TaFDM Configuration

The following example shows how to verify the TaFDM configuration:

```

show controllers upstream-Cable slot/subslot/port us-channel uschan-number-in-controller

#show controllers upstream-Cable slot/subslot/port us-channel uschan-number-in-controller
cdm-ump

show interfaces cable slot/subslot/port mac-scheduler uschan-number-in-mac-domain

```

## Configuration Example

### TaFDM Configuration

```

controller Upstream-Cable 1/0/0
us-channel 0 frequency 15000000

```

```

us-channel 0 channel-width 3200000 3200000
us-channel 1 frequency 22000000
us-channel 1 channel-width 6400000 6400000
us-channel 2 frequency 29000000
us-channel 2 channel-width 6400000 6400000
us-channel 3 frequency 36000000
us-channel 3 channel-width 6400000 6400000
us-channel 4 frequency 11000000
us-channel 4 channel-width 1600000 1600000
us-channel 12 frequency-range 14000000 85000000

```

## Feature Information for TaFDM Configuration

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 104: Feature Information for for TaFDM Configuration**

| Feature Name        | Releases                 | Feature Information                                                              |
|---------------------|--------------------------|----------------------------------------------------------------------------------|
| TaFDM Configuration | Cisco IOS XE Fuji 16.7.1 | This feature was introduced on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 38

# DOCSIS 3.1 Upstream Profile Selection

---

DOCSIS 3.1 introduces the concept of upstream profiles for OFDMA channels. This document describes how to configure the DOCSIS 3.1 Upstream Profile Selection on the Cisco cBR Series Converged Broadband Router.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

- [Hardware Compatibility Matrix for the Cisco cBR Series Routers, on page 603](#)
- [Information about Upstream Profiles, on page 604](#)
- [How to Configure Upstream Profiles, on page 605](#)
- [Feature Information for Upstream Profile Selection, on page 606](#)

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

---

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

---

Table 105: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Information about Upstream Profiles

A modulation profile is a list of interval usage codes (IUCs) that are defined for an OFDMA channel. Each IUC will have a modulation order and pilot pattern. Multiple IUCs within a modulation profile allow for different modulation orders on the same OFDMA channel. The CMTS can define multiple profiles for use in an OFDMA channel, where the profiles differ in the modulation orders assigned to each minislot.

You can use the following commands to view the profiles:

- To display the profiles associated with the cable modems (CMs), use the **show cable modem** [*ip-address/ mac-address/ cable/ {slot | subslot | cable-interface-index}*] **phy ofdm-profile upstream** command.
- To display detailed profile management data associated with specific cable modem, use the **show cable modem** [*ip-address/ mac-address*] **prof-mgmt upstream** command.

The CMTS can assign different data IUCs for different groups of CMs.

A DOCSIS 3.1 CM can only have two active OFDMA Upstream Data Profile IUCs on a given channel.

## Default Data IUC

Data IUC 13 is intended to be the most robust IUC and able to be used by all cable modems.

## Recommended Interval Usage Code (IUC)

Based on the receive modulation error ratio (RxMER) values collected periodically during upstream probing, the CMTS finds among the existing IUCs up to two that provide the highest speed while having sufficient signal to noise ratio (SNR) margin for the CMTS to receive code words with acceptable error rates. The **show cable modem phy ofdm-profile upstream** command displays the one or two recommended IUCs for each CM.

In Cisco IOS XE Everest 16.6.1 release, data IUC 13 will be one of the IUCs assigned to the CM.

To disable the automatic profile downgrade, use **no cable upstream ofdma-prof-mgmt prof-upgrade-auto** command in global configuration mode.

## How to Configure Upstream Profiles

### Configuring RxMER to Bit Loading Mapping

There are many ways to map the Receive Modulation Error Ratio (RxMER) values to bit loading values. We use the following mapping recommended in DOCSIS 3.1 OSSI, as our baseline mapping:

| RxMER (in ¼ DB) | QAM   | Bit Loading |
|-----------------|-------|-------------|
| 60              | 16    | 4           |
| 84              | 64    | 6           |
| 96              | 128   | 7           |
| 108             | 256   | 8           |
| 122             | 512   | 9           |
| 136             | 1024  | 10          |
| 148             | 2048  | 11          |
| 164             | 4096  | 12          |
| 184             | 8192  | 13          |
| 208             | 16384 | 14          |

- To configure a margin to adjust the RxMER to bit loading mapping, use the following command:

```
Router(config)# cable upstream ofdma-prof-mgmt mer-margin-qdb interval-in-minutes
```

This configured value (*quarter-DB*) is added to the RxMER values collected by CMTS before using the above mapping table, thus giving a user more control in selecting the recommended profiles.

- To specify the percentage of minislot average RxMER that can be ignored in the recommended profile calculation, use the following command:

```
Router(config)# cable upstream ofdma-prof-mgmt exempt-mslot-pct percent
```

This provides a way to specify the extent that the outliers can be ignored.

- To configure the RxMER poll interval, use the following command:

```
Router(config)# cable upstream ofdma-prof-mgmt rxmer-poll-interval interval-in-minutes
```

The CMTS uses upstream probing to collect RxMER data per CM. This occurs during registration and periodically thereafter. The collected RxMER data is averaged per minislot and used to compute the recommended IUCs for each CM.

## Feature Information for Upstream Profile Selection

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 106: Feature Information for Upstream Profile Selection**

| Feature Name                   | Releases                 | Feature Information                                                                                            |
|--------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------|
| DOCSIS3.1 US Profile Selection | Cisco IOS XE Fuji 16.7.1 | This feature was integrated into Cisco IOS XE Fuji 16.7.1 on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 39

# DOCSIS 3.1 Upstream Triggered Spectrum Capture - Proactive Network Management

---

This document describes how to configure the DOCSIS 3.1 Upstream Triggered Spectrum Capture – Proactive Network Management on the Cisco cBR Series Converged Broadband Router.

- [Hardware Compatibility Matrix for the Cisco cBR Series Routers](#), on page 607

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

---

**Note** The hardware components that are introduced in a given Cisco IOS-XE release are supported in all subsequent releases unless otherwise specified.

---

Table 107: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                    | Interface Cards                                                                                                                                                                                              |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cisco cBR-8 Converged Broadband Router | <p><b>Cisco IOS-XE Release 3.15.0S and Later Releases</b></p> <p>Cisco cBR-8 Supervisor:</p> <ul style="list-style-type: none"> <li>• PID—CBR-CCAP-SUP-160G</li> <li>• PID—CBR-CCAP-SUP-60G<sup>3</sup></li> <li>• PID—CBR-SUP-8X10G-PIC</li> </ul> | <p><b>Cisco IOS-XE Release 3.15.0S and Later Releases</b></p> <p>Cisco cBR-8 CCAP Line Cards:</p> <ul style="list-style-type: none"> <li>• PID—CBR-CCAP-LC-40G-R</li> <li>• PID—CBR-CCAP-LC-80G-R</li> </ul> |

<sup>3</sup> Effective with Cisco IOS-XE Release 3.17.0S, CBR-CCAP-SUP-60G supports 8 cable line cards. The total traffic rate is limited to 60 Gbps. The total number of downstream service flows is limited to 72268, and downstream unicast low-latency flow does not count against the limits.

## Information About Upstream Triggered Spectrum Capture – Proactive Network Management

Proactive Network Management (PNM) enables you to measure and report conditions in the network. The PNM detects, identifies, and quantifies undesired impacts to the network, such as cable faults and ingress noise. The DOCSIS 3.1 PHY specification defines the different types of tests and measurements that can be performed at CCAP and CM. You can leverage this information to make the necessary modifications that can improve conditions and monitor networking trends to detect when network improvements are needed.

Cisco cBR supports Upstream Triggered Spectrum Capture. The upstream triggered spectrum analysis measurement provides a wideband spectrum analyzer in the CCAP which can be triggered to examine desired upstream transmissions as well as underlying noise or interference during a quiet period.

The PNM tests and receives data output from the CMTS using the Simple Network Management Protocol (SNMP) objects. The PNM feature is supported on RPHY.

The following Upstream Triggered Spectrum Capture objects are supported:

- UsTriggeredSpectrumCaptureFile
- UsTriggeredSpectrumCaptureCfg
- UsTriggeredSpectrumCaptureCtrl
- UsTriggeredSpectrumCaptureStatus
- UsTriggeredSpectrumCaptureCapabilities
- CCAPBulkDataControl

The Cisco cBR router provides the ability to trigger spectrum sample capture and perform spectrum analysis using the FreeRun mode, which is a continuous mode with a maximum of 10 samples per second stacked on each capture file).

## Proactive Network Management for Supervisor High Availability, Line Card High Availability and containers

PNM Supervisor High Availability support ensures that all captures are stopped and all the captures states in the Line Card and Supervisor client are cleaned up when Supervisor High Availability happens. You can create new capture configurations and initiate tests on the newly active supervisor through SNMP.

cBR supports Line Card High Availability and Line Card Process Restart for Proactive Network Management, and will support the restart of any test in progress.

Active syncing of capture data between active and standby SUP is not supported for Proactive Network Management. After switchover, all new captures must be configured by the user/client again.

Bulk Data Transfer MIBs enables configuration of the following parameters for PNM:

- TFTP server bulk data transfer IP address
- TFTP server bulk data transfer path

## Proactive Network Management Using Upstream Triggered Spectrum Capture

Cisco cBR-8 supports Upstream Triggered Spectrum Capture (UTSC). The upstream triggered spectrum analysis measurement provides a wideband spectrum analyzer in the CCAP which can be triggered to examine upstream transmissions and underlying noise or interference during a quiet period.

The Cisco cBR-8 supports the following Upstream Triggered Spectrum Capture objects:

- `UsTriggeredSpectrumCaptureFile`
- `UsTriggeredSpectrumCaptureCfg`
- `UsTriggeredSpectrumCaptureCtrl`
- `UsTriggeredSpectrumCaptureStatus`
- `UsTriggeredSpectrumCaptureCapabilities`
- `CCAPBulkDataControl`

The Cisco cBR-8 router enables you to trigger a spectrum sample capture and perform spectrum-analysis using the FreeRun mode. FreeRun mode is a continuous-mode with a maximum of 10 samples per second stacked on each capture file).

The CCAP supports one client configuration per port on a line card. Create a capture configuration entry before attempting to start or stop the capture tests. The interface index key for the `UsTriggeredSpectrumCaptureCfg` object defines the one capture configuration for the FreeRun trigger mode.

The Cisco cBR-8 supports only one capture per end-user client per port simultaneously. Hence, the CCAP sets the Upstream Triggered Spectrum Capture configuration index to 1. The Cisco cBR-8 does not support a PNM MIB query for an Upstream Triggered Spectrum Capture configuration index other than 1. The Cisco cBR-8 supports a maximum of eight captures on upstream ports per line card. The Cisco cBR-8 supports a maximum of 20 captures per router for RPHY.

The Cisco cBR-8 does not support the following scenarios:

- `UsTriggeredSpectrumCaptureResult` MIB
- Simultaneous captures on adjacent ports on CLC
- RPD support captures only one us-port per RPD at a given time.
- `docsPnmCmtsUtscCfgFilename` OID

**Note** The `UsTriggeredSpectrumCaptureConfiguration` MIB is supported. The `docsPnmCmtsUtscCfgFilename` OID under this MIB is not supported only for UTSC capture mode for PNM.

The PNM IOX container is used for the TFTP transfer of capture files to a user configured destination server. The **guestshell** IOX container for TFTP transfer of PNM files is supported. The PNM executable is built into the guestshell that is packaged as part of `cbr8` image. This executable must be installed on both active and standby SUP manually.

**Step 1** Ensure that the `guestshell` container is running before the captures are started to ensure successful TFTP operation. Use the **show app-hosting list** command to check if the `guestshell` container is running.

**Example:**

```
Router# show app-hosting list
App id Stat

guestshell RUNNING
```

**Step 2** The `app-hosting` CLI is used to install, deploy, start, and stop the IOX container.

**Example:**

```
Router# show run | begin app-hosting
app-hosting appid guestshell
app-vnic gateway0 virtualportgroup 4 guest-interface 0
guest-ipaddress 9.32.254.2 netmask 255.255.255.0
app-default-gateway 9.32.254.1 guest-interface
```

**Step 3** Ensure that the `python` is running on the `guestshell` container.

**Example:**

```
cBR8#guestshell run python -V
Python 2.7.5
```

**Step 4** Ensure that the PNM TFTP process is active and running on the `guestshell` container.

**Example:**

```
cBR8#guestshell run systemctl status pnm
pnm.service - cbr pnm telemetry delivery system
Loaded: loaded (/etc/systemd/system/pnm.service; disabled; vendor preset: disabled)
Active: active (running) since Wed 2019-01-09 15:13:40 UTC; 9min ago
```

The PNM capture tests generate files to report measurements or test results. The results file includes header information that is common to all types of PNM tests and fields. The file also includes data that is specific to the type of PNM test. The abstract `PnmCaptureFile` object defines the attributes and format of the header information common to all PNM test files. File header fields are right-justified within the field and left-padded with zero values if necessary.

The following fields define the header for the `PnmCaptureFile` object for Upstream Spectrum Triggered Capture tests.

- **FileType** - A four-byte hexadecimal identifier specific to the type of PNM test that generated the data file.  
For Upstream Triggered Spectrum Capture, the file type is 0x504e4e6a.
- **Major Version** - This attribute represents the file header version. This value is incremented by one when the header format is modified by this specification.  
For Upstream Triggered Spectrum Capture, major version is 0x1.
- **Minor Version** - This attribute is reserved for vendor-specific and vendor-defined version information.  
For Upstream Triggered Spectrum Capture, minor version is 0x0.
- **CaptureTime** - This attribute represents the epoch time (also known as 'UNIX time') which is the number of seconds that have elapsed since midnight Coordinated Universal Time (UTC), Thursday, 1 January 1970.
- **IfIndex** - This attribute represents the ifIndex of the upstream RF port sampled.
- **UniqueCcapId** - A 256-byte hexadecimal field representing a unique CCAP identifier (either a loopback address (IPv4 or IPv6) or FQDN). This value is a null-terminated string.  
For Upstream Triggered Spectrum Capture, this value is the 'hostname' of the CMTS.

## Proactive Network Management Interface Index

To determine which slot/subslot/port of an ifindex translates to that of RPHY, see the mapping in the running configuration.

### Before you begin

The Upstream Triggered Spectrum Capture – The Cisco cBR-8 router supports multiple RPDs per line card with multiple US-ports. However, on RPDs, you can configure only one US-port and initiate the captures anytime.

For RPHY, it is not mandatory that the US port is bound to a MAC domain. If it is configured under an RPD, it can be configured for PNM.

The SNMP ifindex for MIB objects can be obtained using the show CLI:

```
Router# show snmp mib ifmib ifindex | i 0053.0013.2be0
RPD(0053.0013.2be0)-usport0: Ifindex = 435564
```

where 0053.0013.2be0 is the RPD identifier.

---

**Step 1** Run the following show command to identify the SNMP ifindex value:

```
Router# show snmp mib ifmib ifindex | i 435564
RPD(0053.0013.2be0)-usport0: Ifindex = 435564
```

**Step 2** Run the following command to identify the slot/subslot/port an ifindex that translates to RPHY:

```
Router# show run | b 0053.0013.2be0
identifier 0053.0013.2be
core-interface Tel/1/0
principal
rpd-ds 0 downstream-cable 1/0/2 profile 2
rpd-us 0 upstream-cable 1/0/2 profile 21
```

---

The slot/subslot/port is upstream-cable 1/0/2 profile 21.

**Note** Cisco IOS XE Gibraltar 16.10.1g introduces an RPHY ifIndex change. Ensure that you have gone through the following updates to enable the changes:

- The RPHY ifIndex feature removes the Cisco private ifIndex for PRHY channels (ifIndex starting from 41,000). The ifIndex are not created manually. All the ifIndex are created automatically when configuring RPD. It is applicable for ifIndex starting from 41w for US (if-type 205) and DS (if-type 128). The RPHY ifIndex feature does not work for ifIndex values that are greater than 41w.

Before the ifIndex feature, in 16.10.1f and earlier releases:

```
Router# show snmp mib ifmib ifindex | i RPD
Upstream-Cable3/0/63:0-RPD(0053.0013.420c)-usport0: Ifindex = 421224
.....
RPD(0053.0013.420c)-usport0: Ifindex = 435560
RPD(0053.0013.420c)-dsport0: Ifindex = 436584
Downstream-Cable3/0/31:0-RPD(0053.0013.420c)-dsport0: Ifindex = 437608
Downstream-Cable3/0/31:1-RPD(0053.0013.420c)-dsport0: Ifindex = 437609
```

With the ifIndex feature, in 16.10.1g:

```
Router# show snmp mib ifmib ifindex | s RPD
RPD(0053.0013.420c)-usport0: Ifindex = 415080
RPD(0053.0013.420c)-dsport0: Ifindex = 416104
```

- The RPHY ifIndex reimplement CoreToRpdMap/RpdToCoreMap tables to keep them aligned with DOCS-RPHY-MIB-2018-07-26 definition.

You do not need to create a new ifIndex for US (if-type 205) and DS (if-type 128) channels when they are configured to RPD. For versions before Cisco IOS XE Gibraltar 16.10.1g, it was required to create a new ifIndex (>41k) for US (if-type 205) and DS (if-type 128) channels when they are configured to RPD:

```
[CBR]#show snmp mib ifmib ifindex | s RPD
RPD(0053.0013.420c)-usport0: Ifindex = 415080
RPD(0053.0013.420c)-dsport0: Ifindex = 416104
```

With the Cisco cBR-8 16.10.1g RPHY ifIndex feature, you do not need to manually populate any extra item in legacy MIBs.

With the Cisco cBR-8 16.10.1g RPHY ifIndex feature, you must reimplement docsRphyRpdIfCoreToRpdMapTable / docsRphyRpdIfRpdToCoreMapTable, not mapping to ifIndex (>41k) for US (if-type 205) and DS (if-type 128). See the following:

```
/* docsRphyRpdIfCoreToRpdMapRpdRfChanType OID :1.3.6.1.4.1.4491.2.1.30.1.2.6.1.5
 Table Index: docsRphyRpdIfCoreToRpdMapRpdCoreIndex, docsRphyRpdIfCoreToRpdMapRpdUniqueId,
 docsRphyRpdIfCoreToRpdMapRpdRfPortDirection, docsRphyRpdIfCoreToRpdMapRpdRfPortIndex*/
SNMPv2-SMI::enterprises.4491.2.1.30.1.2.6.1.5.403561.0.4.159.51.0.145.2.0 = INTEGER:
usAtdma(5)
SNMPv2-SMI::enterprises.4491.2.1.30.1.2.6.1.5.322358.0.4.159.51.0.145.1.0 = INTEGER:
dsScQam(1)
IF-MIB::ifType.403561 = INTEGER: docsCableUpstream(129)
IF-MIB::ifType.322358 = INTEGER: other(1)
```

```
[CBR]#show snmp mib ifmib ifindex
Cable9/0/0-upstream1: Ifindex = 403561
Downstream-Cable9/0/4-downstream14: Ifindex = 322358
```

- If RfChanType is usAtdma(5), ifType of docsRphyRpdIfCoreToRpdMapRpdCoreIndex is ifType docsCableUpstream(129)
- If RfChanType is dsScQam(1), ifType of docsRphyRpdIfCoreToRpdMapRpdCoreIndex is other(1).

## Upstream Triggered Spectrum Capture Configuration Parameters – Proactive Network Management

The following configuration parameters for Upstream Triggered Spectrum Capture – Proactive Network Management are supported. Examples of using the MIBs are also included.

**Note** PNM capture configuration on cBR8 is supported only through SNMP user interface. Configuration examples for MIB commands for PNM are provided in the following sections with examples using both snmpr (setany/getone commands) as well as net-snmp tools (snmpset/snmpget commands).

### Upstream Triggered Spectrum Capture Configuration Objects

The following Upstream Triggered Spectrum Capture configuration objects are supported:

- PNM UTSC OBJECTS OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10
- PNM UTSC CAPTURE CONFIGURATION OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.X.Y.Z

Where X is the capture config parameter, Y is Ifindex, and Z is the PNM UTSC Config Index – Which is always 1. Currently only one capture configuration per upstream port is supported.

- The following capture configuration parameters are supported, and the corresponding MIB OID value is listed.

**Table 108: Supported capture configuration parameters and the corresponding MIB OID value**

| Capture configuration parameters      | Corresponding MIB OID value           |

## Upstream Triggered Spectrum Capture Configuration MIB Objects

The following Upstream Triggered Spectrum Capture configuration MIB objects are supported for PNM:

- `CaptureCfg` – Contains the test trigger mode and its required configuration.
- `CaptureCtrl` – Controls when the test is started and stopped.
- `CaptureStatus` – Contains the current status of the test.
- `CaptureCapability` – Exposes CCAP Upstream Triggered Spectrum Capture capabilities.

The following Upstream Triggered Spectrum Capture configuration MIBs are supported. SNMP walk is supported for all the MIB objects.

- `docsPnmCmtsUtscCfgTriggerMode` - This attribute indicates which upstream triggered spectrum capture function trigger modes are supported. Only FreeRun is supported. The following are the enumerated values for trigger mode for PNM.

- `D_docsPnmCmtsUsSpecAnTrigMode_other` 1
- `D_docsPnmCmtsUsSpecAnTrigMode_freeRunning` 2
- `D_docsPnmCmtsUsSpecAnTrigMode_minislotCount` 3
- `D_docsPnmCmtsUsSpecAnTrigMode_sid` 4
- `D_docsPnmCmtsUsSpecAnTrigMode_idleSid` 5
- `D_docsPnmCmtsUsSpecAnTrigMode_minislotNumber` 6
- `D_docsPnmCmtsUsSpecAnTrigMode_cmMac` 7
- `D_docsPnmCmtsUsSpecAnTrigMode_quietProbeSymbol` 8

- For FreeRun mode, the CCAP initiates sampling and continues sampling until the time duration configured in the attribute `FreeRunDuration` has transpired. Sampling terminates when the time duration configured in `FreeRunDuration` has elapsed or when FFT is disabled. The interval between captures is the greater of `RepeatPeriod` and the minimum period that is supported by the CCAP.
- From Cisco IOS XE Gibraltar 16.12.1x release, PNM output format ‘timeIQ’ and UTSC trigger mode ‘cmMac’ are supported in upstream triggered spectrum capture configuration objects.
- Trigger mode set and get examples:

- **snmpr** commands:

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.3.<ifIndex>.1 -i 2
clabProjDocsis.27.1.3.10.2.1.3.<ifIndex>.1 = 2

server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.3.<ifIndex>.1
clabProjDocsis.<ifIndex> = 2

```

- **net-snmp** commands:

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.3.<ifIndex>.1 i 2
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.3.<ifIndex>.1 = INTEGER: 2

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.3.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.3.<ifIndex>.1 = INTEGER: 2

```

- docsPnmCmtsUtscCfgCenterFreq - This attribute specifies the center frequency of the upstream spectrum to be sampled for analysis.

- **snmpr** commands:

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1 -g 102400000
clabProjDocsis.27.1.3.10.2.1.8.<ifIndex> = 102400000

server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1
clabProjDocsis.27.1.3.10.2.1.8.<ifIndex>.1 = 102400000

```

- **net-snmp** commands:

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1 u 102400000
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1 = Gauge32: 102400000

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1 = Gauge32: 102400000

```

- docsPnmCmtsUtscCfgSpan - This attribute determines the frequency span of the upstream spectrum sample capture. When this attribute is read, it provides the actual span, which may be different from the requested (configured) span due to implementation effects.

- **snmpr** commands:

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1 -g 204800000
clabProjDocsis.27.1.3.10.2.1.9.<ifIndex>.1 = 204800000

server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1
clabProjDocsis.27.1.3.10.2.1.9.<ifIndex>.1 = 204800000

```

- **net-snmp** commands:

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1 u 204800000
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1 = Gauge32: 204800000

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1 = Gauge32: 204800000

```

**Note** The center frequency and span capture parameters are set to zero as per OSSI specifications on capture configuration entry creation. For freerun trigger mode, you must set these values in the valid range to run capture tests on the port.

- `docsPnmCmtsUtscCfgNumBins` - This attribute determines the number of frequency bins or samples per span when sampling the upstream spectrum. This attribute provides the actual number of bins, which may be different from the configured number due to implementation effects.

- **snmpr** commands

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.10.<ifIndex>.1 -g 4096
clabProjDocsis.27.1.3.10.2.1.10.<ifIndex>.1 = 4096

server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.10.<ifIndex>.1
clabProjDocsis.27.1.3.10.2.1.10.<ifIndex>.1 = 4096

```

- **net-snmp** commands

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.10.<ifIndex>.1 u 4096
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.10.<ifIndex>.1 = Gauge32: 4096

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.10.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.10.<ifIndex>.1 = Gauge32: 4096

```

- `docsPnmCmtsUtscCfgAveraging` - This attribute specifies whether the CCAP should average spectral frequency domain sample power to remove spurious spectral peaks and troughs and the number of samples to use to calculate the average power. The CCAP must not calculate the average of the upstream spectrum samples when the value of Averaging is zero. The CCAP MUST calculate the average power of upstream spectrum samples, over the number of samples that are specified, when the value of the Averaging attribute is nonzero.

- **snmpr** commands

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.11.<ifIndex>.1 -g 245
clabProjDocsis.27.1.3.10.2.1.11.<ifIndex>.1 = 245

server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.11.<ifIndex>.1
clabProjDocsis.27.1.3.10.2.1.11.<ifIndex>.1 = 245

```

- **net-snmp** commands

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.11.<ifIndex>.1 u 245
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.11.<ifIndex>.1 = Gauge32: 245

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.11.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.11.<ifIndex>.1 = Gauge32: 245

```

- `docsPnmCmtsUtscCfgCmMacAddr` - This attribute specifies the cable modem from which the CCAP captures upstream transmissions. This attribute is used only when the `TriggerMode` is `CmMac` and is ignored otherwise.
  - **net-snmp** commands
    - `server > snmpset -v2c -c <community_name> <cmts_ip>`  
`1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.6.<ifIndex>.1`

---

**Note**

- Flat-top, Gaussian, and Chebyshev window-modes are not supported.
- 

- `docsPnmCmtsUtscCfgOutputFormat` - This attribute indicates the upstream triggered spectrum capture function data output formats that are supported by the CCAP. The CCAP is capable of reporting upstream spectrum sample FFT output data in power format. The enumeration value for power format is `fftPower`. CCAP supports time-IQ and `fftPower` output format. The time-IQ is supported from Cisco IOS XE Gibraltar 16.12.1x. The following are the enumerated values for output format mode for PNM.

- `D_docsPnmCmtsUtscCfgOutputFormat_timeIQ` 1
- `D_docsPnmCmtsUtscCfgOutputFormat_fftPower` 2
- `D_docsPnmCmtsUtscCfgOutputFormat_rawAdc` 3
- `D_docsPnmCmtsUtscCfgOutputFormat_fftIQ` 4
- `D_docsPnmCmtsUtscCfgOutputFormat_fftAmplitude` 5
- `D_docsPnmCmtsUtscCfgOutputFormat_fftDb` 6

- Output format mode set and get examples:

- **snmpr** commands:

```

• server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.17.<ifIndex>.1 -i 2

```

---

**Note** Only the `fft-pwr` and `time-IQ` output formats are currently supported.

---

- `docsPnmCmtsUtscCfgRepeatPeriod` - This attribute specifies the length of time in milliseconds for which the CCAP continues to capture and return FFT results when in free running mode. The CCAP is permitted to trigger at larger intervals if unable to support the requested interval. Configuring a zero value indicates that the test is to run once only.
- The Repeat Period is configured in microseconds and default is 50000 usec. The CCAP MUST reject an attempt to set RepeatPeriod to a value greater than the current value of FreeRunDuration.
- Repeat Period set and get examples:

- **snmpr** commands:

```

• server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 -g 25000
clabProjDocsis.27.1.3.10.2.1.18.<ifIndex>.1 = 25000

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1
clabProjDocsis.27.1.3.10.2.1.18.<ifIndex>.1 = 25000

```

- **net-snmp** commands:

```

• server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 u 25000
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 = Gauge32: 25000

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 = Gauge32: 25000

```

- `docsPnmCmtsUtscCfgFreeRunDuration` - This attribute specifies the length of time in milliseconds for which the CCAP continues to capture and return FFT results when in free running mode. Sample captures are expected to take a few microseconds. If `FreeRunDuration` is set for longer than a sample capture duration, the CCAP could potentially capture more sample data than it can store.
- The CCAP MUST reject an attempt to set `FreeRunDuration` to a value less than the current value of `RepeatPeriod`. Freerun duration is configured in millisecond and the default value is 1000ms (1 second). The CCAP CLC currently captures 10 samples per second stacked in a single file. With default freerun duration configuration, there will be 11 samples.

- FreeRun Duration set and get examples:

- **snmp** commands

- `server > setany -v2c <cmts_ip> <community_name>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1 -g 5000  
clabProjDocsis.27.1.3.10.2.1.19.<ifIndex>.1 = 5000`
- `server > getone -v2c <cmts_ip> <community_name>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1  
clabProjDocsis.27.1.3.10.2.1.19.<ifIndex>.1 = 5000`

- **net-snmp** commands

- `server > snmpset -v2c -c <community_name> <cmts_ip>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1 u 5000  
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1 = Gauge32: 5000`
- `server > snmpget -v2c -c <community_name> <cmts_ip>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1  
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1 = Gauge32: 5000`

- `docsPnmCmtsUtscCfgTriggerCount` - This attribute determines the number of times to trigger upstream spectrum sample capture when `Enable` and `InitiateTest` are set to true and configured trigger conditions are met. The trigger count configuration does NOT apply and is ignored by CCAP for captures in `FreeRun` trigger mode.

- Trigger count set and get examples:

- **snmp** commands

- `server > setany -v2c <cmts_ip> <community_name>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.20.<ifIndex>.1 -g 200  
clabProjDocsis.27.1.3.10.2.1.20.<ifIndex>.1 = 200`
- `server > getone -v2c <cmts_ip> <community_name>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.20.<ifIndex>.1  
clabProjDocsis.27.1.3.10.2.1.20.<ifIndex>.1 = 200`

- **net-snmp** commands

- `server > snmpset -v2c -c <community_name> <cmts_ip>

SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.20.<ifIndex>.1 = Gauge32: 200`
- `server > snmpget -v2c -c <community_name> <cmts_ip>  
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.20.<ifIndex>.1  
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.20.<ifIndex>.1 = Gauge32: 200`

- `docsPnmCmtsUtscCfgStatus` - This attribute determines the creation, deletion, and change of status of an actual capture configuration entry on any port of the CCAP CLC. All capture entries must first be created by a client on a port before attempting to initiate any tests on the port. Thereby the client 'owns' that port and its configuration after creation. No other client can run any tests on the port till the currently active client 'destroys' the configuration entry and thereby releases ownership of that port.
- Any tests on a given port that is owned by a client can be run only when the capture configuration status is 'Active'. When a configuration is created, it is created with certain default values and marked 'Not Ready'. All capture parameters must be configured in valid range for the capture entry status to become 'Active'. If the configuration values for various capture parameters are modified by the user/client and not according to the OSSI specification, the configuration status of the entry will be marked 'NotReady'.
- A capture configuration entry cannot be modified to any state unless created first. An entry cannot be recreated without destroying the previous version first. An entry cannot be modified when capture tests are currently running on the port.

- The following are the enumerated values for configuration entry status for PNM:

- `D_docsPnmCmtsUtscCfgStatus_active` 1
- `D_docsPnmCmtsUtscCfgStatus_notInService` 2
- `D_docsPnmCmtsUtscCfgStatus_notReady` 3
- `D_docsPnmCmtsUtscCfgStatus_createAndGo` 4
- `D_docsPnmCmtsUtscCfgStatus_createAndWait` 5
- `D_docsPnmCmtsUtscCfgStatus_destroy` 6

- Utsc Configuration Entry set/get example:

- **snmpr** commands

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1 -i 4
clabProjDocsis.27.1.3.10.2.1.21.<ifIndex>.1 = 4

server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1
clabProjDocsis.27.1.3.10.2.1.21.<ifIndex>.1 = 1

```

- **net-snmp** commands

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1 i 4
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1 = INTEGER: 4

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1 = INTEGER: 3

```

---

**Note** A configuration can be created with certain default values and is marked 'Not Ready'. It is only changed to 'Active' when valid capture configuration parameters are configured by the user. Capture tests can only be run on configurations that are 'Active'.

---

- Set multiple capture config parameters at the same time.
  - Server > setany -v2c <cmts\_ip> <community\_name>
 

```
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 -g 45000
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.20.<ifIndex>.1 -g 10

SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 = Gauge32: 45000
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.18.<ifIndex>.1 = Gauge32: 50000
<<!snip>>
```

## Upstream Triggered Spectrum Capture Control Objects and MIBs

The following Upstream Triggered Spectrum Capture control objects and MIBs are supported:

- PNM UTSC OBJECTS OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10
- PNM UTSC CAPTURE CONTROL OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.Y.Z

Where Y is Ifindex, and Z is the PNM Upstream Triggered Spectrum Capture Configuration Index – Which is always 1. Currently only one capture configuration per upstream port is supported.

- The capture control entry can be used to start captures or stop any active captures. The docsPnmCmtsUtscCtrlInitiateTest is a boolean value which when set, initiates a capture.
- Starting a capture (You can only start a capture only if you have configured and owned the port, and if the capture configuration entry is active).

- **snmp** commands:

```
• server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 -i 1
clabProjDocsis.27.1.3.10.3.1.1.<ifIndex>.1 = 1

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1
clabProjDocsis.27.1.3.10.3.1.1.<ifIndex>.1 = 1
```

- **net-snmp** commands:

```
• server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 i 1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 = INTEGER: 1
```

```

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 = INTEGER: 1

```

- Stop a capture (You can stop an active capture only if you own that port):

- **snmpr** commands:

```

• server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 -i 0
clabProjDocsis.27.1.3.10.3.1.1.<ifIndex>.1 = 0

```

```

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1
clabProjDocsis.27.1.3.10.3.1.1.<ifIndex>.1 = 0

```

- **net-snmp** commands:

```

• server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 i 0
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 = INTEGER: 0

```

```

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 = INTEGER: 0

```

## Upstream Triggered Spectrum Capture Status Objects and MIBs

The following Upstream Triggered Spectrum Capture status objects and MIBs are supported:

- PNM UTSC OBJECTS OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10
- PNM UTSC CAPTURE STATUS OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10.4.1.1.Y.Z

Where Y is Ifindex, and Z is the PNM Upstream Triggered Spectrum Capture Configuration Index – Which is always 1. Currently only one capture configuration per upstream port is supported.

- The capture status MIB is a read-only MIB. It reports the status of the capture on a given port (if owned by that client).
- When the value is sampleReady, the CCAP has completed capturing and recording samples. Following are the enumerated values for capture status entry for PNM.

- D\_docsPnmCmtsUtscStatusMeasStatus\_other 1
- D\_docsPnmCmtsUtscStatusMeasStatus\_inactive 2
- D\_docsPnmCmtsUtscStatusMeasStatus\_busy 3
- D\_docsPnmCmtsUtscStatusMeasStatus\_sampleReady 4
- D\_docsPnmCmtsUtscStatusMeasStatus\_error 5
- D\_docsPnmCmtsUtscStatusMeasStatus\_resourceUnavailable 6
- D\_docsPnmCmtsUtscStatusMeasStatus\_sampleTruncated 7

- The status is inactive when the capture configuration entry is created and is marked busy when the tests are actively running on the port. Any platform resource limitation to run a test to make the status 'resource unavailable' and the error encountered while running a test would mark the status as 'error'.
- Get capture status on a port (You can get the status of capture on the port only if you own that port).

- **snmp** commands:

```
server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.4.1.1.<ifIndex>.1
clabProjDocsis.27.1.3.10.4.1.1.<ifIndex>.1 = 4
```

- **net-snmp** commands:

```
server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.4.1.1.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.4.1.1.<ifIndex>.1 = INTEGER: 4
```

## Upstream Triggered Spectrum Capture Capability Objects and MIBs

The following Upstream Triggered Spectrum Capture capability objects and MIBs are supported for PNM:

- PNM UTSC OBJECTS OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10
- PNM UTSC CAPTURE CAPABILITY OID: 1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.X.Y

Where X is the capability parameter and Y is the Ifindex.

- The capture capability MIB is a read-only MIB. The Upstream Triggered Spectrum Capture Capabilities object exposes capabilities that are supported by the CCAP for Upstream Triggered Spectrum Capture trigger modes, data output formats, and windowing function used when performing the discrete Fourier transform.
- The following are the enumerated values for capture capability entry for PNM for CCAP.
  - docsPnmCmtsUtscCapabTriggerMode 1
  - docsPnmCmtsUtscCapabOutputFormat 2
  - docsPnmCmtsUtscCapabWindow 3
  - docsPnmCmtsUtscCapabDescription 4

- Get capture capability on a port:

- **snmp** commands:

```
• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.<ifIndex>
docsPnmCmtsObjects.10.1.1.1.<ifIndex> = 00 02

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.2.<ifIndex>
docsPnmCmtsObjects.10.1.1.2.<ifIndex> = 04

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.3.<ifIndex>
docsPnmCmtsObjects.10.1.1.3.<ifIndex> = 1e

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.4.<ifIndex>
docsPnmCmtsObjects.10.1.1.4.<ifIndex> = Center Frequency range and resolution
```

- **net-snmp** commands:

```

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.1.<ifIndex>
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.1.1.1.<ifIndex> = Hex-STRING: 00 02

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.2.<ifIndex>
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.1.1.2.<ifIndex> = Hex-STRING: 04

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.3.<ifIndex>
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.1.1.3.<ifIndex> = Hex-STRING: 1

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.1.1.4.<ifIndex>
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.1.1.4.<ifIndex> = STRING: "Center
Frequency range and resolution"

```

## Upstream Triggered Spectrum Capture Bulk Data Control Objects and MIBs

The following Upstream Triggered Spectrum Capture bulk data control objects and MIBs are supported for PNM:

- PNM Bulk Data Control Objects OID: 1.3.6.1.4.1.4491.2.1.27.1.1.1
- PNM BULK DATA CONTROL OID: 1.3.6.1.4.1.4491.2.1.27.1.1.1.X

Where X is the bulk data transfer control parameter.

- The Bulk Data Transfer (BDT) control objects that are supported are the IPAddress type, BDT server IP and BDT destination path. This indicates to the CCAP the location where the capture results files should be sent through TFTP transfer. In CBR8, the TFTP transfer is done through IOX container and as such, other BDT objects are not relevant to this design model. IP address type can be automatically set by CCAP based on the server IP value specified.

- The following are the enumerated values for BDT for PNM:

- docsPnmBulkDestIpAddrType 1
- docsPnmBulkDestIpAddr 2
- docsPnmBulkDestPath 3

- Set the BDT IPv4 IP address type and TFTP IP address

- **snmpr** commands:

```

• server > setany -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
-o 20:01:0d:b8
docsPnmBulkDestIpAddr.0 = 20 01 0d b8

• server > getone -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.1.0
docsPnmBulkDestIpAddrType.0 = ipv4(1)

• server > getone -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
docsPnmBulkDestIpAddr.0 = 20 01 0d b8

```

- **net-snmp** commands:

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0 x 20010db8
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.2.0 = Hex-STRING: 20 01 0D B8

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.1.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.1.0 = INTEGER: 1

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.2.0 = Hex-STRING: 20 01 0D B8

```

- Set the BDT IPv6 IP address type and TFTP IP address

- **snmpr** commands:

```

server > setany -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
-o 20:01:0d:b8:85:a3:00:00:00:00:8a:2e:03:70:73:11

docsPnmBulkDestIpAddr.0 = 2001 0db8 85a3 0000 0000 8a2e 0370 7311

server > getone -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.1.0

docsPnmBulkDestIpAddrType.0 = ipv6(2)

server > getone -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
docsPnmBulkDestIpAddr.0 = 2001 0db8 85a3 0000 0000 8a2e 0370 7311

```

- **net-snmp** commands:

```

server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0 x 20010db885a3000000008a2e03707311
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.2.0 = Hex-STRING: 20 01 0D B8 85 A3
00 00 00 00 8A 2E 03 70 73 11

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.1.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.1.0 = INTEGER: 2

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.2.0 = Hex-STRING: 20 01 0D B8 85 A3
00 00 00 00 8A 2E 03 70 73 11

```

- Set the BDT destination TFTP path

- **snmpr** commands:

```

server > setany -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0
-o pnm
docsPnmBulkDestPath.0 = pnm

server > getone -v2c <cmts_ip> <community_name> 1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0

docsPnmBulkDestPath.0 = pnm

```

- **net-snmp** commands:

```

• server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0 s 'pnm/test'
SSNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.3.0 = STRING: "pnm/test"

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.3.0 = STRING: "pnm/test"

```

## Configuring the PNM MAX-HOLD Trigger Mode

When RPHY configuration is for MAX-HOLD PNM mode, RPHY sends PNM data continuously, until the user issues stop command or the duration is complete.

To configure for MAX-HOLD trigger mode on the Supervisor, complete the following steps:

**Step 1** Configure the PNM `docsPnmCmtsUsSpecAnTrigMode` to 'other' mode. Both the SNMP and CLI can set the trigger mode. See the following examples:

- For SNMP:

```
snmpset -v2c -c private 80.4.2.11 1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.3.435572.1 i 1
```

- For CLI:

```
test cable pnm uts configure trigger-mode other
```

Adding a new TrigMode to MIB might take long and cause many specification changes.

**Step 2** Set the PNM bulk destination IP address.

- For SNMP:

```
snmpset -v2c -c private 80.4.2.11 1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0 x "20 01 0d b8"
```

- For CLI:

```
test cable pnm bdt config set-ip 32.1.13.184
```

**Step 3** Start and stop the capture test.

- Starting the SNMP:

```
snmpset -v2c -c private 80.4.2.11 1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.435572.1 i 1
```

- Starting the CLI:

```
test cable pnm uts start client-id 1 test-id 1 0004.9f00.0591 0
```

- Stopping the SNMP:

```
snmpset -v2c -c private 80.4.2.11 1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.435572.1 i 0
```

- Stopping the CLI:

```
test cable pnm uts stop client-id 1 test-id 1 0004.9f00.0591 0
```

- Step 4** Enable GCP message support. Send the TFTP server IP address and Static L2TP session ID through TLV58 message, and the TrigMode 'other' is send to RPD through TLV41 message.

## Proactive Network Management MAX-HOLD trigger mode

The cBR enables MAX-HOLD trigger mode support in PNM. The non-CCAP defined MAX-HOLD mode offers significant advantages over the existing FREE-RUN mode that was used earlier. With the MAX-HOLD trigger mode, the RPD sends samples much faster - one sample every 2ms, compared to the earlier rate of one sample per 100ms. The RPD also sends the sample to the server, instead of the Line Card.

The MAX-HOLD trigger mode support functionality includes:

- cBR support for the configuration of the MAX-HOLD trigger mode
- cBR support for notify UBUNTU server IP and Static L2tp session IDs to RPD
- RPD usage of the max hold mode to capture the upstream spectrum
- RPD sending the captured BIN to UBUNTU server

## Debugging the PNM feature on cBR8

cBR supports debugging on Upstream Triggered Spectrum Capture – Proactive Network Management by using the debug commands available for the UTSCOM client on supervisor.

Use the CLI to enable the debug commands:

- **debug cable pnm utscm-error**
- **debug cable pnm utscm-debug**

Use the following show command to check the state of capture on the Line Card. It lists the total number of samples per capture context in the CLC. When the capture tests are running, the packet counts on the corresponding Line Card would keep incrementing.

```
Router# show cable card 6/0 us-triggered-spectrum its-commonLAST event
UTSCOM event STATUS
client_id 1
test_id 1
port 0
dev 8
phy_chan 0
logi_chan 0
status 4
WBFFT Dev trig-mode, data-ready, packets on WBFFT dev, countdown :
wbfft dev 0: 0 0 11 0
wbfft dev 1: 0 0 0 0
wbfft dev 2: 0 0 0 0
wbfft dev 3: 0 0 0 0
wbfft dev 4: 0 0 0 0
wbfft dev 5: 0 0 0 0
wbfft dev 6: 0 0 0 0
wbfft dev 7: 0 0 0 0
total packets: 11
```

The **dtrack** utility can also be used for debugging the packets punted through CPP from CLC to container. To use the **dtrack** utility, complete the following steps:

1. On the supervisor, use the following CLI:

```
test platform hardware qfp active feature docsis dtrack mac 0001.aaaa.cccc
test platform hardware qfp active feature docsis dtrack packe
```

2. Start the trigger and use the following CLI to dump the packets (this can be very verbose as there are 10 samples per file per second):

```
show platform hardware qfp active feature docsis dtrack statistics verbose
```

To obtain the dumping statistics on the IOX container, use the following CLI:

- **dir harddisk:/iox/repo-lxc/lxc-data/<CAF id>/logs/**
- **more harddisk:/iox/repo-lxc/lxc-data/<CAF id>/logs/.stats**
- **more harddisk:/iox/repo-lxc/lxc-data/<CAF id>/logs/pnm.log**

To change configuration on the container console, complete the following steps:

1. Log onto the CAF console as root.
2. Run the **echo "DEBUG" > /data/logs/.loglevel** command.

```
debug level are: ERROR, WARNING, INFO, DEBUG, DEBUG1, DEBUG2, DEBUG3, DEBUG4
```

3. Run the **echo "0" > /data/logs/.resend** command.

```
value "0" disable "tftp resend" due to tftp error.
value "12" enable clc log pnm file at local.
```

Ensure that the PNM TFTP process is active and running on the `guestshell` container as listed:

```
cbr8# guestshell run systemctl status pnm
â pnm.service - cbr pnm telemetry delivery system
Loaded: loaded (/etc/systemd/system/pnm.service; disabled; vendor preset: disabled)
Active: active (running) since Wed 2019-01-09 15:13:40 UTC; 1min 28s ago
```

- If the PNM service is not active, attempt recovery by going through the following steps:
  1. Destroy the `guestshell` instance. Run the `guestshell destroy` command.
  2. Recreate the `gusetshell` by running the `guestshell enable` command.
  3. Check if the `guestshell` instance is running by using the `show app-hosting list` command. Verify that the PNM service is active.
- Verify that the TFTP server IP is reachable from the `guestshell` container and ping is successful.

```
guestshell run ping -c5 <tftp_server_ip>
```

# Quick Install Guide - Proactive Network Management

You can bring up the Proactive Network Management and get the captures running using a minimal configuration. Complete the following steps to enable PNM with a minimal configuration:

1. Find the correct PNM Interface Index for the RPD. Run the `show snmp mib ifmib ifindex | include <rpd_mac>` command.

```
Router# show snmp mib ifmib ifindex | i badb.ad13.2be0
RPD(badb.ad13.2be0)-usport0: Ifindex = 435564
```

Where `badb.ad13.2be0` is the RPD identifier.

2. Ensure that the `guestshell` container is up and running on both active and standby SUP. Run the `show app-hosting list` command.

```
Router# show app-hosting list
App id State

guestshell RUNNING
```

3. Ensure that the `pnm` process is running on the `guestshell`. Run the `guestshell run systemctl status pnm` command. For more information on the command usage, go through [Step 4, on page 610](#).
4. Configure the Bulk Data Transfer parameters. Go through the following steps to set the TFTP IP address and TFTP path. Alternatively, also go through [Upstream Triggered Spectrum Capture Bulk Data Control Objects and MIBs, on page 627](#) for detailed information.

- Set the BDT IPv4 IP address type and TFTP IP address

- **snmpr** commands:

```
server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0 -o 20:01:0d:b8

docsPnmBulkDestIpAddr.0 = 20 01 0d b8
```

- **net-snmp** commands:

```
server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0 x 20010db8
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.2.0 = Hex-STRING: 20 01 0D B8

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.1.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.1.0 = INTEGER: 1

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.2.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.2.0 = Hex-STRING: 20 01 0D B8
```

- Set the BDT destination TFTP path

- **snmpr** commands:

```
server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0 -o pnm
docsPnmBulkDestPath.0 = pnm
```

- **net-snmp** commands:

```

• server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0 s 'pnm/test'
SSNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.3.0 = STRING: "pnm/test"

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.1.1.3.0
SNMPv2-SMI::enterprises.4491.2.1.27.1.1.1.3.0 = STRING: "pnm/test"

```

5. Create and configure a capture config entry. Go through the [Upstream Triggered Spectrum Capture Control Objects and MIBs](#), on page 624 for information on creating and configuring a capture config entry.

6. Set the minimum capture config parameters that are needed (center-frequency, span and duration).

a. Set the `D_docsPnmCmtsUtscCfgStatus_createAndGo` 4.

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1 -i 4
clabProjDocsis.27.1.3.10.2.1.21.<ifIndex>.1 = 4

```

b. Set the `docsPnmCmtsUtscCfgCenterFreq`.

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.8.<ifIndex>.1 -g 102400000
clabProjDocsis.27.1.3.10.2.1.8.<ifIndex>.1 = 102400000

```

c. Set the `docsPnmCmtsUtscCfgSpan`.

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.9.<ifIndex>.1 -g 204800000
clabProjDocsis.27.1.3.10.2.1.9.<ifIndex>.1 = 204800000

```

d. Set the `docsPnmCmtsUtscCfgFreeRunDuration`. Increase the duration to a large value to keep the freerun capture running.

```

server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.19.<ifIndex>.1 -g 5000
clabProjDocsis.27.1.3.10.2.1.19.<ifIndex>.1 = 5000

```

e. Ensure that the config entry status is active.

```

server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.2.1.21.<ifIndex>.1 = INTEGER: 1

```

**Note**

Ensure that the capture center frequency and span are in a valid range. IOS error messages are triggered if the user attempts to start capture tests with an invalid capture configuration. The recommended configuration values are provided in the messages.

7. Start the PNM capture.

- **snmpr** commands:

```

• server > setany -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 -i 1
clabProjDocsis.27.1.3.10.3.1.1.<ifIndex>.1 = 1

```

```

• server > getone -v2c <cmts_ip> <community_name>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1
clabProjDocsis.27.1.3.10.3.1.1.<ifIndex>.1 = 1

```

- **net-snmp** commands:

```

• server > snmpset -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 i 1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 = INTEGER: 1

• server > snmpget -v2c -c <community_name> <cmts_ip>
1.3.6.1.4.1.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1
SNMPv2-SMI::enterprises.4491.2.1.27.1.3.10.3.1.1.<ifIndex>.1 = INTEGER: 1

```

8. The captures are running and files should appear on the TFTP server under the BDT TFTP path configured.

## Troubleshooting Upstream Triggered Spectrum Capture – Proactive Network Management Issues

The Upstream Triggered Spectrum Capture – Proactive Network Management issues, their possible causes, and resolution are listed.

- Capture configuration failure:
  - Ensure that the ifindex that is used is correct and the port is configured correctly under RPD for RPHY.
  - Ensure that the capture configuration entry was created properly and the client/snmp owns the capture port using MIB commands.
  - Ensure that the parameters being configured are supported and within the valid range.
  - Enable **debug cable pnm utscom-error** to check for any errors.
- Capture control or initiate test failure:
  - Ensure that the capture configuration is created and configured correctly by the client using MIB commands.
  - Verify that the capture configuration entry status is active using MIB commands.
  - The total number of captures is below the enforced limit.
  - Ensure that no other tests are already running on the port using MIB commands.
  - Ensure that only one port per RPD is running the test.
- TFTP file transfer failure:
  - Ensure that the BDT TFTP information is configured correctly on the CMTS.
  - Ensure that the TFTP server is reachable and the destination location is writable.
  - Ensure that the container is in running state using show commands.

- Ensure that the PNM TFTP process is active and running on the `guestshell` container and the TFTP server IP is reachable from the `guestshell` container.
  - Ensure that the capture tests are running correctly and with the CLC show, CLI show, files are being generated.
  - Check `dtrack` to ensure that the punt path is working and packets are being sent to the container.
  - Use the PNM debug and the container statistics/log file to check for any errors.
- PNM packets are not reaching guestshell:
    - Check `dtrack`. All PNM packets should be punted with punt-cause Service-Engine.
    - Run `bash` in `guestshell`, and check **RX packets** in `ifconfig`.
    - Run `bash` in `guestshell`, and use `tcpdump` to check if the PNM packets are arriving.
    - PNM packets from CLC use the Global Routing Table, and there is no mechanism to allow these packets to use anything other than GRT. If the `guestshell` and `VirtualPortGroup` are in the VRF, you can add a static route which directs the PNM packets into VRF. For example:

The current configuration is:

```
!
ip vrf vrf_pnm
 rd yyy:zzz
 route-target export yyy:w
 route-target import yyy:w
!
interface VirtualPortGroup0
 ip vrf forwarding vrf_pnm
 ip address P.Q.R.253 255.255.255.252
 no mop enabled
 no mop sysid
!
app-hosting appid guestshell
 app-vmnic gateway0 virtualportgroup 0 guest-interface 0
 guest-ipaddress P.Q.R.254 netmask 255.255.255.252
 app-default-gateway P.Q.R.253 guest-interface 0
!
```

Add a static route:

```
(config)# ip route P.Q.R.254 255.255.255.255 VirtualPortGroup0
```

## Feature Information for Upstream Triggered Spectrum Capture – Proactive Network Management

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 109: Feature Information for Upstream Triggered Spectrum Capture - Proactive Network Management**

| Feature Name                                                                  | Releases                        | Feature Information                                                                                                   |
|-------------------------------------------------------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| DOCSIS 3.1 Upstream Triggered Spectrum Capture – Proactive Network Management | Cisco IOS XE Gibraltar 16.10.1  | This feature was integrated into Cisco IOS XE Gibraltar 16.10.1 on the Cisco cBR Series Converged Broadband Routers.  |
| Proactive Network Management MAX-HOLD trigger mode                            | Cisco IOS XE Gibraltar 16.10.1d | This feature was integrated into Cisco IOS XE Gibraltar 16.10.1d on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 40

# Downstream Power Tilt

---

The Downstream Power tilt feature is used to correct cable loss in the head-end to produce a flat power spectrum for all channels in the controller port.

## Information about Downstream Power Tilt

The downstream power tilt feature is used to correct cable loss in the head-end to produce a flat power spectrum for all channels on the controller port.

**Note** There may be noise floor degradation on the failover path (following linecard switchover) with this feature enabled.

## Restrictions for Configuring Downstream Power Profile

The downstream power tilt feature and OFDM power profile feature are mutually exclusive. They cannot be configured at the same time.

# How to Configure the Downstream Power Tilt

## Configuring Downstream Power Tilt

Downstream power tilt applies to all the SCQAM or OFDM channels on the downstream. To configure downstream power tilt for a controller port, use the power-tilt configuration command under the downstream controller port.

```

enable
configure terminal
controller Integrated-Cable slot/subslot/port
max-ofdm-spectrum value
max-carrier value
base-channel-power value
power-tilt mode loss max-frequency freq-max
rf-chan start_id [end_id]
type value
rf-output value
power-adjust value
qam-profile id
docsis-channel-id id
ofdm channel-profile id start-frequency value width value [plc value]

```

Below is an example:

```

controller Integrated-Cable 3/0/0
 max-ofdm-spectrum 192000000
 max-carrier 32
 base-channel-power 34
 power-tilt linear 4.0 max-frequency 696000000
 rf-chan 0 31
 type DOCSIS
 frequency 261000000
 rf-output NORMAL
 power-adjust -2.0
 qam-profile 1
 docsis-channel-id 1
 rf-chan 158
 power-adjust 0
 docsis-channel-id 159
 ofdm channel-profile 20 start-frequency 600000000 width 96000000 plc 645000000

```

In the above configuration steps, there is a command **power-tilt mode loss max-frequency freq-max**, where the *mode* represent a formula that calculates the loss of a coax cable at a frequency F, given the loss at *freq-max* is known. It provides two options to select:

- linear:  $\text{loss}_F = \text{loss}_{\text{freq-max}} * (F / \text{freq-max})$
- cable-loss-approx:  $\text{loss}_F = \text{loss}_{\text{freq-max}} * \text{SQRT}((\text{freq-max} - F) / \text{freq-max})$

*loss* is the measured cable loss at *freq-max*, specified in 1/10 dB.

## Verifying Downstream Power Tilt Configuration

To display the downstream power tilt details, use the **show cable controller integrated-cable** command as given in the following example. This command will display the actual SCQAM and OFDM channel power levels as set by the DS Power Tilt command. For OFDM channels, the power level displayed represents the center frequency 6-MHz band power level.

```
Router# show controller Integrated-Cable 1/0/1 rf-chan 0-162

## Information about Controller Profile Configuration

As density increases with the merging of CMTS and UEQAM functions in the same device, the current controller configuration method becomes too complex and difficult. There are too many identical lines of configuration.

To simplify the controller configuration, a new concept called controller profile is introduced. A controller profile is a group of configuration parameters that apply to downstream and upstream controller, the benefits include:

- Speed up deployment
- Simplify cBR-8 deployment, configuration and troubleshooting
- Common configurations across nodes/regions
- Consistency across Cisco products for common functions

# How to Configure the Controller Profile

User configures I-CMTS controllers using legacy controller configuration commands by default. If user wants to use I-CMTS controller profile, needs to enable it first with **cable controller-profile I-CMTS enable** command.

## Note

- If user wants to configure controller using profile, it is recommended to start configuration on a “clean” CMTS without any legacy command configured in Integrated-Cable and Upstream-Cable controllers. Do not switch over between legacy configuration and profile.
- When modifying controller profile, all related controllers will be changed. So if user wants to configure a specific controller, for example, modify the base-channel power of a controller, user should not bind this controller to a profile together with other controllers.
- Legacy controller configuration commands are not supported if I-CMTS controller-profile is enabled.
- Legacy controller configuration cannot be shown in running-config if I-CMTS controller-profile is enabled.

## Configuring Downstream Controller Profile

To configure downstream controller profile, use the steps below:

```
enable
configure terminal
cable downstream controller-profile id [RPHY|I-CMTS]
base-channel-power value
max-carrier value
freq-profile id
max-ofdm-spectrum value
ofdm-freq-excl-band start-frequency value width value
rf-chan start_id [end_id]
type value
rf-output value
power-adjust value
qam-profile id
docsis-channel-id id
power-profile id
ofdm channel-profile id start-frequency value width value [plc value]

enable
configure terminal
controller integrated-cable slot/subslot/port
profile id
```

Below is an example:

```
cable downstream controller-profile 0 I-CMTS
max-carrier 32
base-channel-power 34
```

```

rf-chan 0 3
 type DOCSIS
 frequency 111000000
 rf-output NORMAL
 qam-profile 1
 docsis-channel-id 1

controller integrated-cable 2/0/0
 profile 0

```

**Note**

- When configure a new I-CMTS controller profile, keyword I-CMTS is needed. If input RPHY or do not input any keyword, the system will consider it as a RPHY controller profile. Once a profile type (RPHY/I-CMTS) is set, it cannot be modified.
- Updating a profile will affect all the controllers bond with it. To delete a profile that bond with controller, user must unbind all the controllers first. All rf-channel configuration in controller will be deleted after unbind.

## Verifying Downstream Controller Profile Configuration

Use the **show cable downstream controller-profile** command to verify the configuration of the downstream controller profile.

```

Router# show cable downstream controller-profile 0
Downstream controller-profile 0, type I-CMTS
Description:
Downstream controller-profile 0 is being used by controller Integrated-Cable:
 2/0/0,
 Admin: UP
 MaxOfdmSpectrum: 192000000
 MaxCarrier: 128
 BasePower: 33.0 dBmV
 Mode: normal
 Frequency profile: unconfigured
 DS Splitting: No
 OFDM frequency exclusion bands: None

```

## Configured RF Channels:

| Chan | Admin | Frequency | Type   | Annex | Mod | srate | Qam-profile | dcid | power | output |
|------|-------|-----------|--------|-------|-----|-------|-------------|------|-------|--------|
| 0    | UP    | 213000000 | DOCSIS | B     | 256 | 5361  | 1           | 1    | 33.0  | NORMAL |
| 1    | UP    | 219000000 | DOCSIS | B     | 256 | 5361  | 1           | 2    | 33.0  | NORMAL |
| 2    | UP    | 225000000 | DOCSIS | B     | 256 | 5361  | 1           | 3    | 33.0  | NORMAL |
| 3    | UP    | 231000000 | DOCSIS | B     | 256 | 5361  | 1           | 4    | 33.0  | NORMAL |
| 4    | UP    | 237000000 | DOCSIS | B     | 256 | 5361  | 1           | 5    | 33.0  | NORMAL |
| 5    | UP    | 243000000 | DOCSIS | B     | 256 | 5361  | 1           | 6    | 33.0  | NORMAL |

In the above output, integrated-cable 2/0/0 is bond to profile 0. So the output of the **show controllers integrated-Cable 2/0/0 rf-channel 0 5** should match the above output. See the example below:

```

Router# show controllers integrated-cable 2/0/0 rf-channel 0-5
...
Chan Admin Frequency Type Annex Mod srate Qam-profile dcid power output
0 UP 213000000 DOCSIS B 256 5361 1 1 33.0 NORMAL
1 UP 219000000 DOCSIS B 256 5361 1 2 33.0 NORMAL
2 UP 225000000 DOCSIS B 256 5361 1 3 33.0 NORMAL
3 UP 231000000 DOCSIS B 256 5361 1 4 33.0 NORMAL
4 UP 237000000 DOCSIS B 256 5361 1 5 33.0 NORMAL

```

```
5 UP 243000000 DOCSIS B 256 5361 1 6 33.0 NORMAL
```

To check if the parameters in a profile match with the ones configured, use the **show running-config [all] | section cable downstream controller-profile** command as shown in the example below:

```
Router# show running-config | section downstream controller-profile
cable downstream controller-profile 0 I-CMTS
max-carrier 32
base-channel-power 34
rf-chan 0 3
type DOCSIS
frequency 111000000
rf-output NORMAL
qam-profile 1
docsis-channel-id 1
```

## Configuring Upstream Controller Profile

To configure upstream controller profile, use the steps below:

```
enable
configure terminal
cable upstream controller-profile id [RPHY|I-CMTS]
us-channel id {chan-class-id id|channel-width {first-choice-width
[last-choice-width]}|docsis-mode{atdma| tdma|
tdma-atdma}|equalization-coefficient|frequency value|hop-priority{frequency
modulation channel-width| modulation frequency channel-width| frequency
channel-width modulation}|ingress-noise-cancellation
interval|maintain-psd|max-logical-chans id|minislot-size
value|modulation-profile
primary-profile-number[secondary-profile-number] [tertiary-profile-number] |power-level
value|rng-holdoff priority|specsvl error-adaptive-profile id|spectrum-group
id|threshold {cnr-profiles value [value]|corr-fec value|hysteresis
value|snr-profiles value [value]|corr-fec value}
```

```
enable
configure terminal
controller upstream-cable slot/subslot/port
profile id
```

### Note

- When configure a new I-CMTS controller profile, keyword I-CMTS is needed. If input RPHY or do not input any keyword, the system will consider it as a RPHY controller profile. Once a profile type (RPHY/I-CMTS) is set, it cannot be modified.
- Updating a profile will affect all the controllers bond with it. To delete a profile that bond with controller, user must unbind all the controllers first.
- OFDMA does not support the use of profile in this release.

## Verifying Upstream Controller Profile Configuration

Use the **show cable upstream controller-profile** command to verify the configuration of the upstream controller profile.

```
Router# show cable upstream controller-profile 0
Upstream controller-profile 0, type I-CMTS
Description:
Upstream controller-profile 0 is being used by controller Upstream-Cable:
9/0/0

Controller Upstream-Cable
...
Upstream-channel 0
 chan-class-id : 0x0
 channel-width : 1600000 1600000
 docsis-mode : atdma
 equalization-coefficient : TRUE
 frequency : 5000000
 ...
 modulation-profile : 221
 ...
 shutdown : FALSE
 ...
```

In the above output, upstream-cable 9/0/0 is bond to profile 0. So the output of the **show controllers upstream-Cable 9/0/0 us-channel 0** should match the above output. See the example below:

```
Router# show controllers upstream-Cable 9/0/0 us-channel 0
...
Controller 9/0/0 upstream 0 AdminState:UP OpState: UP
 atdma mode enabled
 Frequency 5.000 MHz, Channel Width 1.600 MHz, Symbol Rate 1.280 Msps
 Modulation Profile Group 221
```

To check if the parameters in a profile match with the ones configured, use the **show running-config [all] | section cable upstream controller-profile** command as shown in the example below:

```
Router# show running-config | s cable upstream controller-profile 0
cable upstream controller-profile 0 I-CMTS
us-channel 0 channel-width 1600000 1600000
us-channel 0 docsis-mode atdma
us-channel 0 minislots-size 4
us-channel 0 modulation-profile 221
us-channel 0 shutdown
...
```

## Feature Information for Controller Profile Configuration

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfnng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 113: Feature Information for Controller Profile Configuration**

| <b>Feature Name</b>              | <b>Releases</b>          | <b>Feature Information</b>                                                                                   |
|----------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------|
| SG Based Config (OpSimp) Phase 2 | Cisco IOS XE Fuji 16.7.1 | This feature was introduced on Cisco IOS XE Fuji 16.7.1 on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 42

# Voltage Thresholds for AC Power Supply Module Mode Control

---

This document describes how to configure the voltage thresholds for switching modes in AC Power SupplyModule (PSM).

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

- [Hardware Compatibility Matrix for the Cisco cBR Series Routers](#), on page 651
- [Information about Voltage Thresholds for AC PSM Mode Control](#), on page 652
- [How to Configure Voltage Thresholds for AC PSM Mode Control](#), on page 653
- [Configuration Examples](#), on page 654
- [Feature Information for Voltage Thresholds for AC PSM Mode Control](#), on page 654

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

---

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

---

Table 114: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Information about Voltage Thresholds for AC PSM Mode Control

Configuring voltage thresholds help switch between different modes when power budget provided by AC PSMs is not sufficient to power Field Replaceable Units (FRUs).

### Overview of Voltage Thresholds for AC PSM Mode Control

The AC PSM can operate in either 120V or 220V mode.

When the input voltage is between 70V and 197V, the PSM operates in the 120V mode with 1300W power capacity. When input voltage drops below 85V, the PSM powers down completely and its power capacity becomes 0W.

When the input voltage is greater than 197V, the PSM operates in the 220V mode with 3000W power capacity. When input voltage drops below 190V, the PSM switches to the 120V mode and its power capacity decreases to 1300W.

To allow users configure mode switching, two new hysteresis thresholds Voff\_3000W and Von\_3000W have been provided. The hysteresis thresholds define when the PSM should switch modes and can be configured using CLI commands.

For example, if *Voff\_3000W* is configured as 180V, the PSM switches to the 120V mode with 1300W capacity when input voltage drops below 180V. If *Von\_3000W* is configured as 200V, the PSM switches to the 220V mode when input voltage increases to more than 200V.

**Table 115: Voltage Thresholds for Mode Control**

| Threshold  | Default Value | Configurable Range                                                                                                 |
|------------|---------------|--------------------------------------------------------------------------------------------------------------------|
| Voff_3000W | 190V          | The value of Voff_3000W can be 170V or greater.                                                                    |
| Von_3000W  | 197V          | The value of Von_3000W can be 200V or lesser.<br>The value of Voff_3000W must be less than the value of Von_3000W. |

# How to Configure Voltage Thresholds for AC PSM Mode Control

## Configuring Voltage Thresholds for AC PSM Mode Control

To configure voltage thresholds, run the **platform power protection ac220v voff von** command as shown below:

```
Router# configure terminal
platform power protection ac220v voff von
```

To use the default voltage thresholds, run the **no platform power protection ac220v** command as shown below:

```
Router# configure terminal
no platform power protection ac220v
```

**Note** By default, power protection action is disabled to avoid service outage. If protection action is disabled, any online FRU is not powered down in the event of insufficient power budget, but any newly installed line card is not powered up.

To enable the power protection action, run the **platform power protection action shutdown linecard** command:

```
Router# configure terminal
platform power protection action shutdown linecard
```

## Verifying Voltage Thresholds for AC PSM Mode Control

To verify the voltage thresholds configuration, use the **sh run** command as shown in the example below:

```
Router# configure terminal
Router (config)# sh run | i protection
platform power protection ac220v 180 200
```

## Configuration Examples

This section provides configuration examples for the voltage threshold feature.

### Example: Configuring Voltage Thresholds for AC PSM Mode Control

The following example shows how to configure voltage thresholds:

```
Router# configure terminal
platform power protection ac220v 180 200
```

The following example shows how to disable DPS:

```
Router# configure terminal
no platform power protection ac220v
```

## Feature Information for Voltage Thresholds for AC PSM Mode Control

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 116: Feature Information for Voltage Thresholds for AC PSM Mode Control**

| Feature Name                               | Releases                 | Feature Information                                                                                          |
|--------------------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------|
| Voltage Thresholds for AC PSM Mode Control | Cisco IOS XE Fuji 16.7.1 | This feature was introduced in Cisco IOS XE Fuji 16.7.1 on the Cisco cBR Series Converged Broadband Routers. |

## Information about DOCSIS3.1 Downstream Zero Bit Loading

Zero Bit Loading (ZBL) is a subcarrier in an OFDM channel, it has power but does not carry any user data. ZBL can be used if the user wants to bypass one or more subcarrier because, for example, cable modem reports that Modulation Error Ratio (MER) is too low on these subcarriers.

Unlike the excluded subcarrier which is defined per RF port and applied to all modulation profiles used on that port's OFDM channels, ZBL is defined per profile and applied to individual OFDM channel.

ZBL is modulated using PRBS (Pseudo Randomness Binary Sequence), it can not be used for other purpose. Excluded subcarrier is not modulated, and does not have power, so it can be used for other purposes, such as video.

For more information about the OFDM, see [DOCSIS 3.1 OFDM Channel Configuration, on page 541](#).

# How to Configure DOCSIS3.1 Downstream Zero Bit Loading

## Configuring Downstream Zero Bit Loading

To configure downstream ZBL, follow these steps:

1. Configure ZBL for the data/control profile and the NCP profile.
2. Apply the modulation profiles to a channel profile.
3. Apply the channel profile to an OFDM channel.

Run the following commands as an example to configure ZBL:

```
Router# configure terminal
Router(config)# cable downstream ofdm-modulation-profile 159
Router(config-ofdm-mod-prof)# description an example of ZBL starting at 10MHZ for 1MHZ
Router(config-ofdm-mod-prof)# subcarrier-spacing 50KHZ
Router(config-ofdm-mod-prof)# width 96000000
Router(config-ofdm-mod-prof)# assign modulation-default 1024-QAM
Router(config-ofdm-mod-prof)# assign modulation zero-bit-load range-subcarriers freq-offset
10000000 width 1000000
```

```
Router# configure terminal
Router(config)# cable downstream ofdm-modulation-profile 160
Router(config-ofdm-mod-prof)# description an example for ZBL on NCP profile for one SC
starting 14MHZ
Router(config-ofdm-mod-prof)# subcarrier-spacing 50KHZ
Router(config-ofdm-mod-prof)# width 96000000
Router(config-ofdm-mod-prof)# assign modulation-default 16-QAM
Router(config-ofdm-mod-prof)# assign modulation zero-bit-load list-subcarriers freq-offset
14000000
```

```
Router# configure terminal
Router(config)# cable downstream ofdm-chan-profile 159
Router(config-ofdm-chan-prof)# cyclic-prefix 1024
Router(config-ofdm-chan-prof)# interleaver-depth 16
Router(config-ofdm-chan-prof)# pilot-scaling 48
Router(config-ofdm-chan-prof)# roll-off 128
Router(config-ofdm-chan-prof)# subcarrier-spacing 50KHZ
Router(config-ofdm-chan-prof)# profile-control modulation-profile 159
Router(config-ofdm-chan-prof)# profile-ncp modulation-profile 160
```

```
Router# configure terminal
Router(config)# controller Integrated-Cable 1/0/0
Router(config-controller)# max-ofdm-spectrum 192000000
Router(config-controller)# max-carrier 32
Router(config-controller)# base-channel-power 37
Router(config-controller)# rf-chan 0 3
Router(config-rf-chan)# type DOCSIS
Router(config-rf-chan)# frequency 261000000
Router(config-rf-chan)# rf-output NORMAL
Router(config-rf-chan)# power-adjust 0.0
Router(config-rf-chan)# qam-profile 1
Router(config-rf-chan)# docsis-channel-id 1
Router(config-rf-chan)# exit
```

```

Router(config-controller)# rf-chan 158
Router(config-rf-chan)# power-adjust 0.0
Router(config-rf-chan)# docsis-channel-id 159
Router(config-rf-chan)# ofdm channel-profile 159 start-frequency 627000000 width 96000000
plc 648000000

```

## Verifying Downstream Zero Bit Loading

To check if the ZBL is taking effect, use **show controllers verbose** command as shown in the example below:

```

router# show controllers integrated-Cable 1/0/0 rf-channel 158 verbose | in ZBL
1024 :634350000[1235] - 636950000[1287] ZBL :637000000[1288] - 637850000[1305]
 ZBL :637950000[1307] - 637950000[1307] 1024 :638000000[1308] - 641450000[1377]
 Active subcarrier count: 1804, ZBL count: 19
 ZBL :641000000[1368] - 641000000[1368] 16 :641050000[1369] - 641450000[1377]
 Active subcarrier count: 1804, ZBL count: 1

```

User can also check DPD messages as shown in the example below:

```

router# show cable mac-domain c1/0/0 dpd integrated-Cable 1/0/0 158

## Feature Information for DOCSIS3.1 Downstream Zero Bit Loading

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmg.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 118: Feature Information for DOCSIS3.1 Downstream Zero Bit Loading**

| Feature Name                          | Releases                 | Feature Information                                                                |
|---------------------------------------|--------------------------|------------------------------------------------------------------------------------|
| DOCSIS3.1 Downstream Zero Bit Loading | Cisco IOS XE Fuji 16.8.1 | This feature was introduced into the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 44

# Reducing Power Consumption

---

This document describes how to reduce power consumption on the Cisco cBR Series Converged Broadband Router.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

- [Finding Feature Information, on page 661](#)
- [Hardware Compatibility Matrix for the Cisco cBR Series Routers, on page 661](#)
- [Information About Reducing Power Consumption, on page 662](#)
- [Configure Reduction of Power Consumption, on page 663](#)
- [Feature Information for Reducing Power Consumption , on page 664](#)

## Finding Feature Information

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

---

**Note**

The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

---

Table 119: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Information About Reducing Power Consumption

A Cisco cBR-8 CCAP line card has two downstream PHY modules. The first downstream PHY module has port number 0 through port number 3. The second downstream PHY module has port number 4 through port number 7. Each downstream PHY module consumes approximately 70W of power even if no RF channels are used. By default, both downstream PHY modules are powered up.

To reduce power consumption in the Cisco cBR-8, you can power down the second downstream PHY module.

The power-saving configuration is retained for supervisor card reload, supervisor high availability, LCHA, and LCPR configurations.

## Restrictions for Setting Up Power-Saving Configuration

The following restrictions are applicable for setting up power-saving configuration:

- Before powering down the second downstream PHY module, you must shut down the downstream controllers.
- You cannot power down the downstream PHY module on a redundant line card.

- The redundant line card must be in the hot standby mode.

## Configure Reduction of Power Consumption

Before powering down the second downstream PHY module, you must shut down the downstream controllers.

To shut down downstream controllers 4 to 7, run the following commands:

```
Router# enable
Router# configure terminal
Router(config)# controller integrated-Cable slot/subslot/port
Router (config-controller)# shutdown
```

The following example shows how to shut down downstream controllers 4 to 7.

```
Router# enable
Router# configure terminal
Router(config)# controller integrated-Cable 1/0/4
Router (config-controller)# shutdown
```

To power down the second downstream PHY module, run the following commands:

```
Router# enable
Router# configure terminal
Router(config)# cable downstream power-down-2nd-module slot
```

The following example shows how to power down the PHY module in slot 1.

```
Router# enable
Router# configure terminal
Router(config)# cable downstream power-down-2nd-module slot 1
```

## Verifying the Power-Saving Configuration

After powering down the second downstream PHY module, the power consumption in downstream controllers 4 to 7 changes to 0.

To check power consumption in downstream controllers 4 to 7, run the following command:

```
Router# show cable card 1/0 ds-phy display | include Watts

Port0-3 Power Consumption 82781 (mWatts), Port4-7 Power Consumption 53443 (mWatts)
```

To check power consumption in downstream controllers 4 to 7 after powering down the downstream PHY module, run the following command.

```
Router#show cable card 1/0 ds-phy display | include Watts
Port0-3 Power Consumption 82781 (mWatts), Port4-7 Power Consumption 0 (mWatts)
```

The second downstream PHY module information shows *Powered down to save energy* when the **show cable card slot/sub-slot ds-phy display | include detected** command is run.

## Feature Information for Reducing Power Consumption

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 120: Feature Information for Reducing Power Consumption*

| Feature Name               | Releases                  | Feature Information                                                                                          |
|----------------------------|---------------------------|--------------------------------------------------------------------------------------------------------------|
| Reducing Power Consumption | Cisco IOS XE Fuji 16.9.1a | This feature was introduced in Cisco IOS XE Fuji 16.9.1 on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 45

# L2VPN Support over Cable

The Layer 2 VPN (L2VPN) Support over Cable feature on the Cisco CMTS provides point-to-point Transparent LAN Service (TLS) in support of the Business Services over DOCSIS (BSOD) Cable Labs specification.

The L2VPN Support over Cable feature supports the following:

- The feature uses an Ethernet trunking interface to transport traffic for multiple L2VPNTunnels in support of different cable modems (CMs) and service flows (SFs) based on IEEE 802.1qVLAN IDs. For the legacy TLS service, only the primary upstream or downstream SFs are used. With the new L2VPNSupport over Cable feature, both primary and secondary SFs can be used.
- The TLS feature uses CLI to provision the service. The L2VPN Support over Cable feature uses the CM configuration file to provision the service, and a single CLI to identify the default Ethernet Network System Interface (NSI).
- Downstream traffic is forwarded on a per-CM basis and upstream traffic is forwarded on a per-SF basis. For L2VPN Support over Cable feature, upstream traffic for the same L2VPN can use multiple upstream service flows and downstream traffic can use different downstream service flows.

## Prerequisites for L2VPN Support over Cable

- You should use crypto-supported images.
- Cable modems must be configured to support BPI+.

# Restrictions for L2VPN Support over Cable

The L2VPN Support over Cable feature has the following general restrictions:

- DOCSIS 1.0 CMs are not supported.
- Load balancing and Dynamic Channel Change (DCC) are not supported for CMs that are enabled for L2VPN support.
- DSx messages (Dynamic Service Add [DSA], Dynamic Service Change [DSC], and Dynamic Service Delete [DSD]) are supported for L2VPN-provisioned CMs. However, DSx with L2VPN type, length, values (TLVs) are not supported.
- Multipoint L2VPN is not supported, and any Simple Network Management Protocol (SNMP) MIBs for multipoint L2VPN are not supported.
- eSAFE (embedded Service/Application Functional Entities) DHCP snooping is not supported (L2VPN subtype 43.5.3)
- Maximum of 1024 L2VPNs are supported on a single MAC domain.
- Maximum of eight upstream SFs are supported per L2VPN service.
- Maximum of eight downstream classifiers are supported per L2VPN service.
- eSAFE exclusion is supported for only one eSAFE host. If the REG-REQ message for a compliant CM specifies multiple eSAFE hosts, then the eMTA (ifIndex 16) is selected as the eSAFE host to be excluded by the Cisco CMTS router. If the eMTA is not included as part of the capability of the CM, then the first eSAFE host in the capability is selected for exclusion.
- Maximum length of the Cable Modem Interface Mask (CMIM) is 4 bytes.
- Areas of the Business Services over DOCSIS (BSOD) Layer 2 Virtual Private Networks specification that are not supported are:
  - Vendor-specific L2VPN encodings for the replacement of the required VPN ID and NSI Encapsulation subtype are not supported.
  - Mapping of egress user priority to an NSI port transmission traffic class as specified by IEEE 802.1s is not supported.
  - Forwarding with non-zero default user priority values with vendor-specific configuration is not supported.
  - Accepting multiple Downstream Classifier L2VPN Encoding with the same VPN ID to classify packets to different service flows is not supported.
  - Assigning multiple SAIDs to the same L2VPN on the same CM is not supported. The primary SAID is used for encrypting all downstream traffic.
  - Assigning of the same group-level L2VPN SAID to different CMs on the same MAC domain attached to the same L2VPN identifier is not supported.
  - Implementing the DOCSIS Spanning Tree Protocol (DSTP) and transmission of DSTP BPDUs on all NSI and RF interfaces configured for L2VPN operation is not supported.
  - Implementing a DSTP SAID specifically for DSTP forwarding to the customer premises equipment (CPE) ports of all L2VPN CMs is not supported.
  - dot1q L2VPN is not supported over a port-channel with load-balancing vlan configured.

## VPN ID Restrictions

- A maximum of four VPN IDs are supported for each CM.

- A maximum of one VPN ID can be associated with each SF in a CM; although multiple SFs in a CM can belong to the same L2VPN.
- A maximum of 4093 unique VPN IDs are supported per Cisco CMTS router.
- The maximum length of a VPN ID is 16 bytes.
- All L2VPN encodings must contain a VPN ID, except for upstream classifier encodings.

## Information About L2VPN Support over Cable

L2VPN Support Over Cable provides the following benefits and functions on a Cisco CMTS router:

- Supports point-to-point L2VPN forwarding mode.
- Supports up to four VPN IDs per CM.
- Supports multiple upstream SFs per CM, with one or more SFs belonging to the same VPN ID.
- Supports a single Ethernet NSI that serves as a trunking port for one or more L2VPN tunnels on the Cisco CMTS router.
- Supports BPI+ encryption using primary SAID of the CM.
- Supports L2VPN encodings in the CM configuration file and CM registration (REG-REQ with L2VPN encoding).
- Supports upstream L2VPN tunnel in support of per-CM and per-SF forwarding.
- Supports synchronization and recovery of the L2VPN database and upstream and downstream SFs during SUP NSF/SSO and N+1 line card redundancy switchovers.
- Supports QoS in upstream and downstream.
- Supports stacked IEEE 802.1q tags.
- Supports exclusion of traffic from the L2VPN tunnel for a single Embedded Service/Application Functional Entity (eSAFE) host.
- Supports Layer 2 classifier via CMIM and IEEE 802.1p priority bits.
- Supports detection of provisioning errors, such as duplicate VLAN IDs across CMs or existing VLAN IDs in use, and moves a CM offline with a corresponding error message.
- Supports coexistence of L2VPN and non-L2VPN traffic on the same RF MAC domain, with non-L2VPN traffic isolated from other tunnel traffic.
- Supports voice calls from L2VPN-provisioned CMs. However, voice calls are not part of the L2VPN.
- Supports BSOD VLAN Redundancy feature, which allows users to configure a backup WAN interface in addition to the primary WAN interface. When the primary WAN interface is down, the L2VPN traffic flows through the backup WAN interface.
- Supports manual switchover for VLAN Redundancy feature, which allows users to manually switch active uplink port from the current port to another port when both the uplink ports are up.
- Supports 2000 bytes layer 2 MTU.

## Point-to-Point L2VPN Forwarding Mode

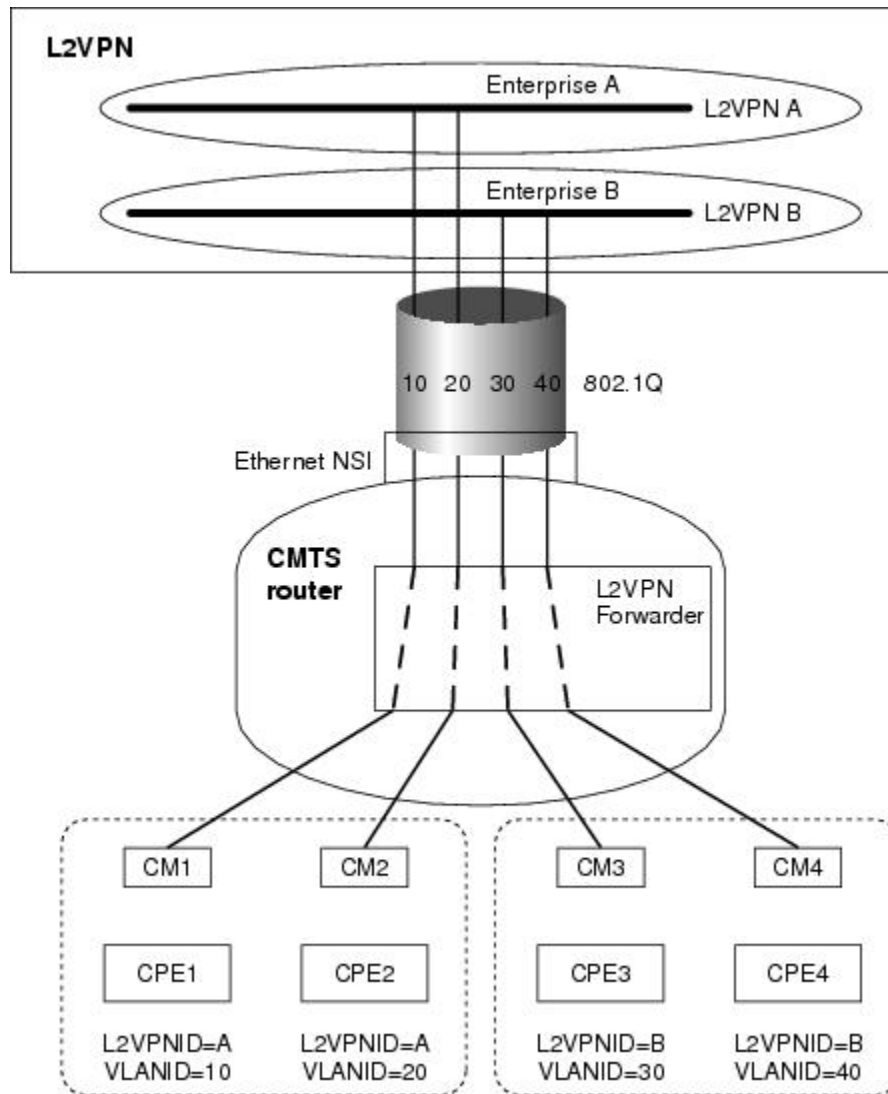

The Cisco CMTS routers supports the point-to-point L2VPN forwarding mode described in the BSOD specification. Each attachment circuit (either SF or CM) on the Cisco CMTS router has a NSI encapsulation value, and is configured with an IEEE 802.1q VLAN ID.

The L2VPN forwarder on the Cisco CMTS router forwards both upstream and downstream traffic between the NSI port on the router and an attachment circuit without using MAC address learning for the forwarding

decision. A L2VPN bridge on the backbone network of the cable operator performs the MAC-address learning to bridge packets between VLAN IDs.

The image below shows an example of a point-to-point L2VPN network using IEEE 802.1q NSI encapsulation. In this example, four CMs are associated with four different VLAN IDs: 10, 20, 30, and 40. The L2VPN encoding of the CM includes the logical L2VPN ID (in this case, A or B) with an NSI encapsulation subtype for IEEE 802.1q with the associated VLAN ID.

Figure 23: Point-to-Point L2VPN Network Diagram

The logical L2VPN IDs allow creation of separate broadcast domains for certain VLAN IDs. In the diagram, traffic for VLANs 10 and 20 from CM1 and CM2 can be sent to the network of Enterprise A, and traffic for VLAN's 30 and 40 from CM3 and CM4 can be sent to the network of Enterprise B.

## L2VPN Encodings in the CM Configuration File

The CM configuration file contains a set of L2VPN encodings that control how the Cisco CMTS processes L2VPN forwarding of upstream and downstream CPE packets. As per the BSOD specification, the L2VPN encoding is encapsulated using a General Extension Information (GEI) encoding, which uses the type code 43 and subtype of 5 (43.5) with the reserved Vendor ID of 0xFFFFF.

L2VPN defines the following types of encodings:

- Per-CM L2VPN encodings—An encoding that appears at the top level of the CM configuration file.
- Per-SF L2VPN Encoding—An encoding that appears as a subtype of the Upstream Service Flow Encoding (type 24).
- Upstream Classifier L2VPN Encoding—An encoding that appears in an Upstream Packet Classification Configuration Setting (type 22).
- Downstream Classifier L2VPN Encoding—An encoding that appears in a Downstream Packet Classification Configuration Setting (type 23).

The simplest CM configuration file has a single per-SF L2VPN Encoding within the primary upstream SF definition and a single per-CM L2VPN Encoding with a NSI Encapsulation subtype for that L2VPN.

---

**Note** When BSOD (CM configuration file) is used for L2VPN configuration, and QoS policy-map settings are applied to Cisco CMTS WAN interfaces, the packets do not match the QoS policy-map. When CLI mode is used for L2VPN configuration, and QoS policy-map settings are applied to Cisco CMTS WAN interfaces, the packets will match the QoS policy-map first.

---

---

**Note** Cisco CMTS supports BSOD VLAN redundancy feature with support for two Ethernet Network Side Interface (NSI) configuration and a backup WAN interface. When the active NSI WAN interface is down, the L2VPN traffic flows through the backup WAN interface.

---

## Supported L2VPN Encodings

This section describes the supported L2VPN encodings in the CM configuration file that are supported by the Cisco CMTS routers.

- The Cisco CMTS routers support the following CM capabilities:
  - L2VPN capability (5.17)
  - eSAFE host capability (5.18)
  - Downstream Unencrypted Traffic (DUT) filtering (5.19)
- The Cisco CMTS routers support the following top-level encodings:
  - VPN identifier (43.5.1)
  - CMIM (43.5.4)—When provided, applies to all upstream SFs associated with an L2VPN tunnel; Supports only one eSAFE host.

- NSI encapsulation (43.5.2) with format code 2 for IEEE 802.1q (43.5.2.2)
- DUT filtering encoding
- The Cisco CMTS routers support the following per-SF encodings:
  - VPN identifier (43.5.1)
  - Ingress user priority (43.5.8)
- The Cisco CMTS routers support the following downstream classifier encodings:
  - VPN identifier (43.5.1)
  - CMIM (43.5.4) and (22/23.13)
  - User priority range (43.5.9)

For more information about the CM configuration file and L2VPN encodings, see the "Business Services over DOCSIS (BSOD) Layer 2 Virtual Private Networks" specification.

For information about how to use the configuration file generator on the Cisco CMTS, see the "DOCSIS Internal Configuration File Generator for the Cisco CMTS" document.

## Voice-Call Support on L2VPN CM

Voice calls are supported on L2VPN CMs. This feature enables the Cisco CMTS routers to support dynamic service flows on L2VPN-provisioned cable modems to permit voice calls from a non-L2VPN CPE.

To provide voice-call support on a L2VPN CM, you have to configure correct classifiers and create two static service flows (primary and secondary) using the cable modem configuration file. If the eMTA is L2VPN-capable with the embedded CPE configured as an eSAFE host, then only one service flow is required. When correct CMIM bits are configured, the Cisco CMTS does not send packets from the eSAFE host to the L2VPN.

Though the L2VPN can be configured on the primary or secondary service flow, it cannot coexist with eMTAs on the same service flow. The eMTAs should always use a different service flow from that of L2VPN. The classifiers to direct the traffic should also be based on the service flows the L2VPN and eMTAs are using. When the above configuration is in place, the dynamic service flows are created automatically whenever voice calls are initiated.

## How to Configure L2VPN Support over Cable

This section contains the following procedures:

### Configuring the Ethernet Network System Interface

To configure the L2VPN Support over Cable feature, you need to specify an Ethernet NSI to operate as the trunking interface for the L2VPN traffic. You must configure the NSI using a command on the Cisco CMTS router. It is not configurable through the CM configuration file.

**Before you begin**

The following interface types can be configured as an NSI for L2VPN Support over Cable:

- Cisco cBR Series Converged Broadband Router—GigabitEthernet and TenGigabitEthernet

**Note** The Cisco CMTS routers only support the configuration of a single L2VPN NSI per CMTS.

>

**Procedure**

|               | Command or Action                                                                                                                                                                                                                           | Purpose                                                                                                                                                              |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                                                                                                                            | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                   |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                                                                                                                                       | Enters global configuration mode.                                                                                                                                    |
| <b>Step 3</b> | <b>cable l2-vpn-service xconnect nsi dot1q interface ethernet-intf [backup-interface ethernet-intf]</b><br><b>Example:</b><br><pre>Router(config)# cable l2-vpn-service xconnect nsi dot1q interface Te4/1/0 backup-interface Te4/1/4</pre> | Configures WAN interface for DOT1Q L2VPN .<br>(Optional) Backup-interface - If backup-interface is configured it means that BSoD VLAN redundancy feature is enabled. |

## Preparing the DOCSIS Configuration File for L2VPN Support

To support L2VPN, the DOCSIS configuration file must be configured with the appropriate encodings. For information about the supported encodings by the Cisco CMTS routers, see the [L2VPN Encodings in the CM Configuration File, on page 672](#).

## Manual Switchover Command Line Interface

For BSoD VLAN Redundancy feature, users can manually switch active uplink ports from the active port to another port when both the uplink ports are up through the command line interface. To manually switchover, perform the following steps:

### SUMMARY STEPS

1. **enable**
2. **cable l2-vpn dot1q-nsi-redundancy force-switchover from active-nsi-interface**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                 | Purpose                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> enable                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted</li> </ul> |
| Step 2 | <b>cable l2-vpn dot1q-nsi-redundancy force-switchover from active-nsi-interface</b><br><b>Example:</b><br>Router# cable l2-vpn dot1q-nsi-redundancy force-switchover from Te4/0/1 | Switches the active uplink port from the current active port to the specified port.                               |

To display the dot1q L2VPN uplink redundancy information, use the **show cable l2-vpn dot1q-nsi-redundancy** as shown in the following example:

```
Router# show cable l2-vpn dot1q-nsi-redundancy
Primary-NSI Backup-NSI Active-NSI Elapsed-after-SW
Te4/1/0 Te4/0/4 Te4/1/0 31m9s
Te4/1/2 Te4/0/5 Te4/1/2 59s
```

## Verifying L2VPN Support over Cable

To verify L2VPN information on the Cisco CMTS router, use the **show cable l2-vpn xconnect dot1q-vc-map** command.

## SUMMARY STEPS

1. To display VLAN information for all cable modems, use the **show cable l2-vpn xconnect dot1q-vc-map** command as shown in the following example:
2. To display VLAN information for a particular L2VPN ID or customer, use the **show cable l2-vpn xconnect dot1q-vc-map customer** form of the command as shown in the following example:
3. To display information for a particular L2VPN ID on a specific cable modem, use the **show cable l2-vpn xconnect dot1q-vc-map vpn** form of the command along with specification of the cable modem MAC address, as shown in the following example:
4. To display detailed information for a particular L2VPN ID on a specific cable modem, use the **show cable l2-vpn xconnect dot1q-vc-map vpn verbose** form of the command along with specification of the cable modem MAC address, as shown in the following example:
5. To display detailed information and the current redundancy information for a particular cable modem, use the **show cable l2-vpn xconnect dot1q-vc-map verbose** form of the command along with specification of the cable modem MAC address, as shown in the following example:
6. To display the dot1q L2VPN uplink redundancy information, use the **show cable l2-vpn dot1q-nsi-redundancy** as shown in the following example:

## DETAILED STEPS

- 
- Step 1** To display VLAN information for all cable modems, use the **show cable l2-vpn xconnect dot1q-vc-map** command as shown in the following example:

**Example:**

```
Router# show cable l2-vpn xconnect dot1q-vc-map
MAC Address Ethernet Interface VLAN ID Cable Intf SID Customer Name/VPN ID
0014.f8c1.fd66 GigabitEthernet4/0/0 68 Cable6/0/0 3 0234560001
```

- Step 2** To display VLAN information for a particular L2VPN ID or customer, use the **show cable l2-vpn xconnect dot1q-vc-map customer** form of the command as shown in the following example:

**Example:**

```
Router# show cable l2-vpn xconnect dot1q-vc-map customer 0234560001

MAC Address Ethernet Interface VLAN ID Cable Intf SID Customer Name/VPNID
0014.f8c1.fd66 GigabitEthernet4/0/0 68 Cable6/0/0 3 0234560001
```

- Step 3** To display information for a particular L2VPN ID on a specific cable modem, use the **show cable l2-vpn xconnect dot1q-vc-map vpn** form of the command along with specification of the cable modem MAC address, as shown in the following example:

**Example:**

```
Router# show cable l2-vpn xconnect dot1q-vc-map 0014.f8c1.fd66 vpn 0234560001

MAC Address Ethernet Interface VLAN ID Cable Intf SID Customer Name/VPNID
0014.f8c1.fd66 GigabitEthernet4/0/0 68 Cable6/0/0 3 0234560001
```

- Step 4** To display detailed information for a particular L2VPN ID on a specific cable modem, use the **show cable l2-vpn xconnect dot1q-vc-map vpn verbose** form of the command along with specification of the cable modem MAC address, as shown in the following example:

**Example:**

```
Router# show cable l2-vpn xconnect dot1q-vc-map 0014.f8c1.fd66 vpn 0234560001 verbose
MAC Address : 0014.f8c1.fd66
Prim Sid : 3
Cable Interface : Cable6/0/0
VPN ID : 0234560001
L2VPN SAID : 12294
Upstream SFID : 23
Downstream CFRID[SFID] : 2[24]
CMIM : 0x60
Ethernet Interface : GigabitEthernet4/0/0
DOT1Q VLAN ID : 68
Total US pkts : 1372
Total US bytes : 500226
Total US pkt Discards : 0
Total US byte Discards : 0
Total DS pkts : 1248
Total DS bytes : 415584
Total DS pkt Discards : 0
Total DS byte Discards : 0
```

- Step 5** To display detailed information and the current redundancy information for a particular cable modem, use the the **show cable l2-vpn xconnect dot1q-vc-map verbose** form of the command along with specification of the cable modem MAC address, as shown in the following example:

**Example:**

```
Router# show cable l2-vpn xconnect dot1q-vc-map 0014.f8c1.fd66 verbose
```

```

MAC Address : 5039.5589.4302
Prim Sid : 45
Cable Interface : Cable6/0/2
L2VPNs provisioned : 1
DUT Control/CMIM : Disable/0x8000FFFF

VPN ID : 000234560001
L2VPN SAID : 45
Upstream SFID Summary : 77
Upstream SFID [77] : SID 45
Downstream CFRID[SFID] Summary : Primary SF
CMIM : 0x60
Primary Ethernet Interface : GigabitEthernet4/0/0
Backup Ethernet Interface : GigabitEthernet4/0/1
Active Ethernet Interface : GigabitEthernet4/0/0
DOT1Q VLAN ID : 207
Total US pkts : 151269
Total US bytes : 211755224
Total DS pkts : 150502
Total DS bytes : 210463324

```

**Step 6** To display the dot1q L2VPN uplink redundancy information, use the **show cable l2-vpn dot1q-nsi-redundancy** as shown in the following example:

**Example:**

```

Router# show cable l2-vpn dot1q-nsi-redundancy
Primary-NSI Backup-NSI Active-NSI Elapsed-after-SW
Te4/1/0 Te4/0/4 Te4/1/0 31m9s
Te4/1/2 Te4/0/5 Te4/1/2 59s

```

## Enabling Voice-Call on a L2VPN CM

You can enable the Voice-Call Support on a L2VPN CM feature by registering a cable modem with a SID to VPN mapping cable modem configuration file (MPLS or 802.1q).

- If the L2VPN is on the primary service flow, you should use a cable modem configuration file with static secondary service flow and the classifiers should be configured on the secondary service flow for non-L2VPN packets.
- If the L2VPN is on the secondary service flow, then classifiers should be configured for L2VPN packets.

**Note** The cable modem configuration file based L2VPN configuration provides the flexibility to configure L2VPN on the primary or secondary service flow. However, we recommend that you configure L2VPN on the secondary service flow and the primary service flow is used for the default traffic.

**Note** In a CLI-based L2VPN configuration, the L2VPN is on the primary service flow; therefore the static secondary service flow should be used for the eMTAs.

## Verifying Dynamic Service Flows

To verify dynamically created service flows on the Cisco CMTS router, use the **show interface cable service-flow** command.

---

**Note** To verify information about PacketCable operations, use **show packetcable** commands.

---

```
Router# show interface cable 5/1/0 service-flow
Sfid : 30191
Mac Address : 000a.739e.140a
Type : Secondary(Dynamic)
Direction : Upstream
Current State : Active
Current QoS Indexes [Prov, Adm, Act] : [0, 24, 24]
Active Time : 00:55
Sid : 7140
Admitted QoS Timeout : 200 seconds
Active QoS Timeout : 0 seconds
Packets : 1824
Bytes : 466944
Rate Limit Delayed Grants : 0
Rate Limit Dropped Grants : 0
Current Throughput : 68356 bits/sec, 32 packets/sec
Classifiers:
Classifier Id : 41
Service Flow Id : 30191

Destination Port High : 7052
```

## Configuration Examples for L2VPN over Cable

This section provides configuration examples for the L2VPN over Cable feature:

### Example: Specifying the Ethernet NSI Interface

You can specify the Ethernet NSI within the CM configuration file, or using the **cable l2-vpn-service xconnect** global configuration command as shown in the following example:

```
cable l2-vpn-service xconnect nsi {dot1q|mpls}
```

## Example: Enabling Voice Call Support on MPLS L2VPN

The following is a sample cable modem configuration file that enables voice call support on MPLS L2VPN. In this example the L2VPN is applied to the primary service flow.

```
03 (Net Access Control) = 1
18 (Maximum Number of CPE) = 16
43 (Vendor Specific Options)
 S08 (Vendor ID) = ff ff ff
 S005 (Unknown sub-type) = 01 04 32 30 32 30 02 07 04 05 01 0a 4c 02 01 2b 06 26 04

24 (Upstream Service Flow Encodings)
 S01 (Service Flow Reference) = 1
 S06 (QoS Parameter Set Type) = 7
24 (Upstream Service Flow Encodings)
 S01 (Service Flow Reference) = 2
 S06 (QoS Parameter Set Type) = 7
 S43 (Vendor Specific Options)
 T08 (Vendor ID) = ff ff ff
 T005 (Unknown sub-type) = 01 05 02 34 56 00 01 08 01 01
25 (Downstream Service Flow Encodings)
 S01 (Service Flow Reference) = 3
 S06 (QoS Parameter Set Type) = 7
25 (Downstream Service Flow Encodings)
 S01 (Service Flow Reference) = 4
 S06 (QoS Parameter Set Type) = 7

```

## Example: Enabling Voice Call Support on CLI-based L2VPN

The following is a sample cable modem configuration file that enables voice call support on L2VPN configured using CLI. L2VPN configured using the CLI is always applied to the primary service flow.

```

03 (Net Access Control) = 1
18 (Maximum Number of CPE) = 16
22 (Upstream Packet Classification Encoding Block)
 S01 (Classifier Reference) = 2
 S03 (Service Flow Reference) = 2
 S09 (IP Packet Encodings)
 T03 (IP Source Address) = 050 001 005 000
 T04 (IP Source Mask) = 255 255 255 000
22 (Upstream Packet Classification Encoding Block)
 S01 (Classifier Reference) = 3
 S03 (Service Flow Reference) = 2
 S10 (Ethernet LLC Packet Classification Encodings)
 T02 (Source MAC Address) = 00 e0 f7 5a c9 21
23 (Downstream Packet Classification Encoding Block)
 S01 (Classifier Reference) = 21
 S03 (Service Flow Reference) = 21

```

```

S05 (Rule Priority) = 5
S09 (IP Packet Encodings)
 T05 (IP Destination Address) = 050 001 005 000
 T06 (IP Destination Mask) = 255 255 255 000
23 (Downstream Packet Classification Encoding Block)
 S01 (Classifier Reference) = 22
 S03 (Service Flow Reference) = 21
 S05 (Rule Priority) = 5
 S10 (Ethernet LLC Packet Classification Encodings)
 T01 (Destination MAC Address) = 00 e0 f7 5a c9 21 ff ff ff ff ff ff
24 (Upstream Service Flow Encodings)
 S01 (Service Flow Reference) = 1
 S06 (QoS Parameter Set Type) = 7
24 (Upstream Service Flow Encodings)
 S01 (Service Flow Reference) = 2
 S06 (QoS Parameter Set Type) = 77
25 (Downstream Service Flow Encodings)
 S01 (Service Flow Reference) = 20
 S06 (QoS Parameter Set Type) = 7
 S07 (Traffic Priority) = 0
25 (Downstream Service Flow Encodings)
 S01 (Service Flow Reference) = 21
 S06 (QoS Parameter Set Type) = 7
 S07 (Traffic Priority) = 1
29 (Privacy Enable) = 1

```

## Feature Information for L2VPN Support over Cable

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfnng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 122: Feature Information for L2VPN Support Over Cable*

## CHAPTER 46

# L2VPN Over Port-Channel

The Layer 2 VPN (L2VPN) over port-channel feature supports IEEE 802.1Q (dot1q) L2VPN WAN interface port-channel. Using this feature, you can configure the dot1q L2VPN traffic to pass through port-channel uplink

### Contents

- [Verifying Port-Channel Configuration, on page 686](#)
- [Feature Information for L2VPN Over Port-Channel, on page 687](#)

## Information About L2VPN Over Port-Channel

The Cisco cBR-8 supports L2VPN, where the Ethernet frames from the cable modem are cross connected to a specific VLAN interface. The VLAN ID to be inserted is specified. With the L2VPN over port-channel feature, you can now support port-channel uplink interface as well as the 10 Gb uplink interface.

### TLS L2VPN

For the Transparent LAN Service (TLS) L2VPN, the dot1q maps contain the cable modem MAC address, the VLAN ID, and the outbound interface. Traffic received from a specific cable modem is tagged with a VLAN ID and is sent out from the uplink interface.

### DOCSIS L2VPN

For the Data-over-Cable Service Interface Specifications (DOCSIS) L2VPN, cable modem (CM) configuration file holds the L2VPN encodings for both, the CM and the service flow. At the CMTS level you have to specify the default port-channel Network Side Interface (NSI). L2VPN encodings are passed by the CM to the CMTS during registration. The CMTS installs DOCSIS service flow VLAN mapping based on the information passed to it during the registration. For upstream traffic, the CMTS sends the dot1q VLAN tagged traffic out from the uplink interface. On downstream, the CMTS receives the dot1q tagged traffic from the aggregator. The CMTS replaces the VLAN header with a DOCSIS header to the corresponding service flow.

## Benefits of L2VPN Over Port-Channel

By using the dot1q L2VPN, you can utilize the port-channel interface feature instead of a single 10 Gb port.

## Restrictions for L2VPN Over Port-Channel

The CMTS dot1q L2VPN is designed to support traffic from customer premises equipment to the network or verse vice. For CMTS L2VPN NSI port, port-channel interface does not support VLAN redundancy.

## How to Configure the L2VPN Over Port-Channel

This section describes how to configure L2VPN over port-channel on the Cisco cBR-8.

### Configuring the Port-Channel Uplink Port for TLS L2VPN

For TLS L2VPN, you must configure the overall enable CLI and the dot1q map. In dot1q map, you have to designate the port-channel uplink port.

To configure the port-channel uplink port for TLS L2VPN, complete the following procedure:

```
cable l2-vpn-service xconnect nsi dot1q
cable dot1q-vc-map mac address port-channel number vlan id custom name
```

### Configuring the Port-Channel Uplink Port for DOCSIS L2VPN

For DOCSIS L2VPN, you only have to configure the overall enable CLI with port-channel uplink port. The other L2VPN related parameters are setup by the CM configuration file type-length-value parsing.

To configure the port-channel uplink port for DOCSIS L2VPN, complete the following procedure:

```
configure terminal
cable l2-vpn-service xconnect nsi dot1q interface port-channel number
```

## Verifying Port-Channel Configuration

### Verify the Port-Channel Mapping

To verify the port-channel mapping, use the **show cable l2-vpn xconnect dot1q-vc-map** command as shown in the example below:

```
show cable l2-vpn xconnect dot1q-vc-map
```

```
MAC Address Ethernet Interface VLAN ID Cable Intf SID Customer Name/VPNID
c8fb.26a5.551c Port-channel164 1200 Cable6/0/0 17 Topgun
```

### View the Port-Channel Interface

To view the port-channel interface, use the **show cable l2-vpn xconnect dot1q-vc-map verbose** command as shown in the example below:

```
show cable l2-vpn xconnect dot1q-vc-map c8fb.26a5.551c verbose
```

```
MAC Address : c8fb.26a5.551c
Customer Name : ats
Prim Sid : 17
Cable Interface : Cable6/0/0
Ethernet Interface : Port-channel164
DOT1Q VLAN ID : 1200
Total US pkts : 189
Total US bytes : 18200
Total DS pkts : 615
Total DS bytes : 39360
```

## Feature Information for L2VPN Over Port-Channel

## Finding Feature Information

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

# Hardware Compatibility Matrix for the Cisco cBR Series Routers

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

**Table 124: Hardware Compatibility Matrix for the Cisco cBR Series Routers**

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Prerequisites for MPLS Pseudowire for Cable L2VPN

- Enable Baseline Privacy Interface Plus (BPI+) to provide a simple data encryption scheme to protect data sent to and from cable modems in a data over cable network.
- Enable Cisco Express Forwarding (CEF) to optimize network performance.
- Ensure that the primary and backup pseudowires on the remote provider edge (PE) routers have the same pseudowire type as the Cisco cable modem termination system (CMTS).

- Create the remote pseudowire using a pw-class with VLAN as the interworking for remote PEs, if the CMTS is using VLAN as pseudowire type.

## Restrictions for MPLS Pseudowire for Cable L2VPN

The following are the general restrictions for the MPLS Pseudowire for Cable L2VPN feature:

- Supports only Ethernet over MPLS (EoMPLS) pseudowires per RFC 4448.
- Supports only point-to-point forwarding. Ethernet switching is not supported.
- Requires DOCSIS 2.0, 3.0 and 3.1-certified cable modems (CMs). This feature is not supported on DOCSIS 1.0-certified cable modems.
- Supports a maximum of four VPNs per cable modem.
- Supports a maximum of eight upstream service flows and eight downstream classifiers.
- Supports a maximum of 16000 EoMPLS pseudowires per Cisco CMTS router.
- Requires the backup pseudowire to be up on the remote PE for the Cisco CMTS to switchover.
- Requires the backup pseudowire to become active on the Cisco CMTS only after the primary pseudowire fails.

---

**Note** The CLI-based (static provisioning) L2VPN supports traffic forwarding to VPN only on primary upstream and downstream service flows. Hence only primary upstream and downstream service flows must be configured in the cable modem configuration file.

---

## Information About MPLS Pseudowire for Cable L2VPN

The MPLS Pseudowire for Cable L2VPN feature enables Ethernet-based Layer 2 VPN service over an MPLS network by encapsulating and transmitting the Layer 2 protocol data units (PDUs) over pseudowires (PWs). This feature enables service providers to offer site-to-site connectivity to their business and enterprise customers.

Layer 2 services emulated over an MPLS network are commonly referred to as MPLS-based L2VPNs or MPLS L2VPNs. Subsequently, Ethernet service emulated over an MPLS network is referred to as Ethernet over MPLS (EoMPLS) service.

The MPLS Pseudowire for Cable L2VPN feature is fully compliant with CableLabs Business Services over DOCSIS (BSOD) L2VPN specification, and is an extension to the existing DOCSIS L2VPN features supported on Cisco CMTS routers.

The MPLS Pseudowire for Cable L2VPN feature provides the following capabilities:

- Transport Ethernet frames over an MPLS network.
- Handle a DOCSIS service flow as an attachment circuit that is mapped to an EoMPLS pseudowire.
- Enable the Cisco CMTS router to be the MPLS provider edge (PE) router.
- Enable forwarding of Ethernet frames over DOCSIS (between a CM and a Cisco CMTS router) to MPLS (towards Metropolitan Area Network or Wide Area Network).

- Provide a common framework to encapsulate and transport supported Layer 2 traffic types over an MPLS network.

The MPLS Pseudowire for Cable L2VPN feature differs from the existing DOCSIS L2VPN features such as 802.1q-based L2VPN (L2VPN Support over Cable). The MPLS Pseudowire for Cable L2VPN feature uses IP/MPLS network to transport layer 2 protocol data units (PDUs), whereas 802.1q-based L2VPN feature uses layer 2 Ethernet network to transport PDUs.

## How MPLS Transports Layer 2 Packets

The MPLS subsystem removes DOCSIS encapsulation for Layer 2 Ethernet frames and adds MPLS labels at the ingress provider edge (PE) Cisco CMTS router. Then, the MPLS subsystem sends resulting MPLS packets to the corresponding PE router at the other end of the pseudowire. The PE routers must be configured for successful transmission of IP/MPLS packets between the two PE routers.

The cable modem classifies Ethernet frames from the customer premise equipment (CPE) in the upstream direction using upstream classifiers. Then, a DOCSIS header is added to these frames, and they are sent on a given upstream service flow with a different service identifier. On the Cisco CMTS router, the upstream packet is classified as an L2VPN packet based on the cable interface and service identifier. The Cisco CMTS router removes the DOCSIS header and adds an MPLS header. An MPLS header contains two MPLS labels: the outer label corresponding to the remote PE router and the inner label corresponding to the pseudowire label. The Cisco CMTS router forwards the MPLS packet towards the remote PE router, which is the other end of the pseudowire, over the MPLS network.

In the downstream direction, the Cisco CMTS router receives MPLS packets having only one MPLS header that contains the label that the Cisco CMTS router previously allocated for the corresponding EoMPLS pseudowire. The Cisco CMTS router uses the MPLS label to identify one of the L2VPN cable modems. Then, the Cisco CMTS router classifies the MPLS packet using the L2VPN downstream classifiers based on MPLS experimental (MPLS-EXP) bits in the MPLS header of the received MPLS packet, and removes the MPLS header. Then, the Cisco CMTS router sends the packet on the classified downstream service flow by adding the DOCSIS header. The cable modem then removes the DOCSIS header and delivers the Ethernet frame to the CPE.

A unique combination of a cable modem MAC address, VPN ID (if present in the CM configuration file), peer IP address, and a virtual circuit ID (VCID) identifies the MPLS pseudowire on the Cisco CMTS router.

Figure 24: Transporting Layer 2 Packets

The table illustrates how MPLS transports Layer 2 packets in a DOCSIS-based cable communications system.

|   |                                                                                                                                    |    |                                                                                                                                |
|---|------------------------------------------------------------------------------------------------------------------------------------|----|--------------------------------------------------------------------------------------------------------------------------------|
| 1 | A router sends an untagged Ethernet frame.                                                                                         | 6  | MPLS packets are label switched.                                                                                               |
| 2 | A CM adds a DOCSIS header to the frame.                                                                                            | 7  | The Cisco CMTS router receives an MPLS packet and looks up the MPLS forwarding table using the label value in the MPLS header. |
| 3 | The Cisco CMTS router removes the DOCSIS header from the frame.                                                                    | 8  | The Cisco CMTS router replaces the MPLS header with DOCSIS header (containing the right SID value).                            |
| 4 | The Cisco CMTS router looks up the Service ID (SID) database using the SID value from the DOCSIS header and finds the MPLS header. | 9  | The DOCSIS header is removed.                                                                                                  |
| 5 | The Cisco CMTS router adds the MPLS header to the frame.                                                                           | 10 | The Ethernet frame is delivered untagged.                                                                                      |

## Supported Ethernet Encapsulation on UNI

The Ethernet User-Network Interface (UNI) is the connection between a cable modem and a customer premise equipment such as a router or a switch. The service provider may or may not use any encapsulation on the UNI.

The MPLS Pseudowire for Cable L2VPN feature supports the following transport types on an Ethernet UNI:

- Port-based UNI (independent of any VLAN)—The port-based UNI provides Metro Ethernet Forum (MEF)-defined Ethernet Private Line (EPL) service. In this transport type, an MPLS pseudowire is mapped to the Ethernet port.
- VLAN-based UNI—Ethernet VLAN using 802.1q encapsulation (including stacked VLANs). The VLAN-based UNI provides MEF-defined Ethernet Virtual Private Line (EVPL) service. In this transport type, the MPLS pseudowire is mapped to the 802.1q VLAN.

---

**Note** The Ethernet UNI must be attached to the Ethernet port of a cable modem.

---

Before configuring this feature, you should understand the following concepts:

## MPLS Pseudowire

Pseudowire is a point-to-point Layer 2 connection between two PE routers. The MPLS Pseudowire for Cable L2VPN feature supports the following pseudowire types:

- Type-4 pseudowire—This is used to transport only VLAN tagged Layer 2 Ethernet frames.
- Type-5 pseudowire—This is used to transport VLAN tagged and untagged Layer 2 Ethernet frames. This is the default pseudowire type.

## Bundle254 Interface

The bundle254 (Bu254) interface is an internal bundle interface on a Cisco CMTS router that is used as a circuit identifier for all MPLS pseudowires. This internal bundle interface is created automatically on a Cisco CMTS router when you enable the MPLS pseudowire functionality using the **cable l2-vpn-service xconnect** command. Only one Bu254 interface is created to handle all the MPLS pseudowires available on the Cisco CMTS router.

The output of the **show xconnect** or **show cable l2-vpn xconnect** command displays the circuit identifier created by the Cisco CMTS router for all the MPLS pseudowires.

## Ingress Process

When an upstream packet received from a cable interface of the Cisco CMTS router is identified as an L2VPN packet based on the cable modem interface and Service ID (SID), the packet goes through the ingress process. The ingress process ensures that the DOCSIS header is removed, and an MPLS label header is added to the packet according to the MPLS pseudowire configuration and the packet is sent out from the Ethernet interface of the Cisco CMTS router. The ingress process is also known as the label imposition process.

## Egress Process

When a downstream packet received from an Ethernet interface of the Cisco CMTS router is identified as an L2VPN packet by the innermost MPLS label, the packet goes through the egress process. The egress process ensures that the MPLS label header is deleted from the packet and the DOCSIS header is added to the packet. Then the packet is sent out from the cable interface of the Cisco CMTS router. The egress process is also known as the label disposition process.

## MPLS Pseudowire Control Plane Process

When an L2VPN-compliant CM registers with a Cisco CMTS router and conveys the L2VPN related parameters to the router, the router follows the standard Label Distribution Protocol (LDP) procedures to set up an Ethernet over MPLS pseudowire with the remote PE router. When the L2VPN-compliant CM goes offline, the Cisco CMTS router brings down the pseudowire as well. If the Cisco CMTS router has no L2VPN-compliant CM registered, then the router tears down the targeted LDP session with the remote PE router.

## L2VPN Pseudowire Redundancy

The L2VPN Pseudowire Redundancy feature enables a PE router to detect a pseudowire failure and reroute the Layer 2 service to a backup pseudowire that can continue to provide the service. The pseudowire redundancy can be implemented with either Cisco CMTS or a generic router as the PE router. When the primary pseudowire recovers from the failure, the L2VPN Pseudowire Redundancy feature provides the option to bring back the Layer 2 service to the primary pseudowire.

Each primary pseudowire can have up to three backup pseudowires, with unique priorities. For example, priority one cannot be given to two different pseudowires in the backup list. When the primary pseudowire goes down, the Cisco CMTS sends the traffic to the backup pseudowire with the highest priority. For a successful service transfer, the remote state of the backup pseudowire should already be 'up'. Only the local state of the active pseudowire will be 'up' when the modem is BPI online. Similarly, if the backup pseudowire is in use, the local state of only that backup pseudowire will be 'up'.

If the active backup pseudowire goes down, the Cisco CMTS will use the next highest backup pseudowire whose remote state is 'up'. However, the Cisco CMTS will not switchover from the lower priority pseudowire to the higher priority pseudowire when the backup pseudowire with the highest priority comes 'up'. This is to prevent unnecessary switchovers between the backup pseudowires.

When the primary pseudowire recovers from the failure, the L2VPN Pseudowire Redundancy feature brings back the service to the primary pseudowire, after waiting for the time period set using the backup delay command. The local state of the active backup pseudowire will be marked as 'down' after the primary pseudowire comes up.

## MPLS Pseudowire Provisioning Methods

The MPLS Pseudowire for Cable L2VPN feature supports the following provisioning methods for pseudowires:

---

**Note** Before performing the static or dynamic provisioning of MPLS pseudowires, you must enable MPLS on a Cisco CMTS router. For details on the tasks required to enable MPLS, see the [How to Enable MPLS on a Cisco CMTS Router](#).

---

## Static Provisioning Method for MPLS Pseudowires

The static provisioning method requires the MPLS pseudowire to be statically provisioned on the CMTS using the command line interface (CLI). This type of provisioning does not require the CM configuration file to use BSOD L2VPN-compliant TLVs. For details on how to statically provision MPLS pseudowires, see the *Static Provisioning of MPLS Pseudowires*.

## Dynamic Provisioning Method for MPLS Pseudowires

The dynamic provisioning method is a CM configuration file-based provisioning method and is the recommended provisioning method for creating MPLS pseudowires. For details on how to dynamically provision MPLS pseudowires, see the [Dynamic Provisioning of MPLS Pseudowires, on page 704](#).

The following are the benefits of dynamic provisioning of pseudowires:

- Multiple VPNs can be specified in a CM configuration file and a pseudowire can be provisioned for each VPN.
- Multiple upstream service flows and downstream classifiers can be associated with each VPN.
- Each upstream service flow can be tagged to an MPLS experimental (EXP) level for the egress WAN traffic.
- Downstream ingress WAN traffic can be classified based on the downstream MPLS-EXP range specified in each downstream classifier.
- The Cisco CMTS router will have finer control of MPLS quality of service (QoS) over cable and WAN interfaces.

For dynamic provisioning of MPLS pseudowires, you use an L2VPN-compliant CM configuration file that is stored on the Trivial File Transfer Protocol (TFTP) server. You use a common CM configuration file editor such as CableLabs Config File Editor, or a sophisticated provisioning backend system such as Broadband Access Center for Cable (BACC) to create CM configuration files.

This provisioning method requires the usage of CableLabs defined L2VPN encodings such as type, length, value (TLV) objects in the CM configuration file. These L2VPN encodings control L2VPN forwarding of upstream and downstream Ethernet frames.

You can specify the L2VPN encodings in the following ways:

- Per CM
- Per downstream classifier
- Per service flow
- Per upstream classifier

---

**Note** The CM L2VPN encoding is mandatory.

---

The CM L2VPN encoding contains many TLVs, out of which the two most important TLVs are VPN Identifier and NSI Encapsulation. To configure an MPLS pseudowire, you must set the NSI Encapsulation to MPLS. The other TLVs are used to specify the pseudowire identifiers in the form of source attachment individual identifier (SAII), target attachment individual identifier (TAII), and attachment group identifier (AGI).

The L2VPN encoding parameter is encoded as a general extension information (GEI) parameter in the CM configuration file. This indicates that the parameter is encoded as a subtype of the vendor-specific information type parameter using the vendor ID (0xFFFFF).

The table lists the important CableLabs defined TLVs that are used at the top level of the CM configuration file for the MPLS Pseudowire for Cable L2VPN feature. See the BSOD specification, *Business Services over DOCSIS (BSOD) Layer 2 Virtual Private Networks*, from CableLabs for a complete list of CableLabs defined TLVs.

Table 125: CableLabs Defined L2VPN TLVs

| TLV Name                                     | Type   | Length  | Value and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|--------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Downstream Unencrypted Traffic (DUT) Control | 45.1   | 1       | Bit 0 DUT Filtering<br>DUT Filtering = 0: Disable (default)<br>DUT Filtering = 1: Enable DUT Filtering                                                                                                                                                                                                                                                                                                                                                                                      |
| Downstream Unencrypted Traffic (DUT) CMIM    | 45.2   | N       | DUT CMIM (optional)<br>CM Interface Mask (CMIM) limiting outgoing interfaces of DUT traffic. If the DUT CMIM is omitted, its default value includes the eCM and all implemented eSAFE interfaces, but not any CPE interfaces.                                                                                                                                                                                                                                                               |
| VPN Identifier                               | 43.5.1 | 1 to N  | An opaque octet string that identifies an L2VPN. N is vendor-specific, and the valid range is from 6 to 255.                                                                                                                                                                                                                                                                                                                                                                                |
| NSI Encapsulation Subtype                    | 43.5.2 | n       | A single NSI encapsulation format code/length/value tuple. This TLV uses any of the following values:<br>NSI encapsulation = 0 : Other<br>NSI encapsulation = 1 : IEEE 802.1Q (specify VLAN ID)<br>NSI encapsulation = 2 : IEEE 802.1AD (specify Q-in-Q)<br>NSI encapsulation = 3 : MPLS peer (specify IPv4 or IPv6 address)<br>The value must be set to 3 to ensure MPLS pseudowire usage. The address must identify the remote PE (by its IP address assigned to the loopback interface). |
| Attachment Group ID                          | 43.5.5 | 0 to 16 | Opaque byte string that identifies the CM or SF as an attachment circuit for IETF Layer 2 VPN signaling protocols.                                                                                                                                                                                                                                                                                                                                                                          |
| Source Attachment Individual ID              | 43.5.6 | 0 to 16 | Opaque byte string signaled as SAII circuit for IETF Layer 2 VPN signaling protocols.                                                                                                                                                                                                                                                                                                                                                                                                       |
| Target Attachment Individual ID              | 43.5.7 | 0 to 16 | Opaque byte string that identifies the CM or SF as an attachment circuit for IETF Layer 2 VPN signaling protocols.                                                                                                                                                                                                                                                                                                                                                                          |
| Ingress User Priority                        | 43.5.8 | 1       | Ingress IEEE 802.1 user priority value in the range of 0 to 7 encoded in the least significant three bits. Higher values indicate higher priority.                                                                                                                                                                                                                                                                                                                                          |
| User Priority Range                          | 43.5.9 | 2       | The lower user priority value of the user priority range is encoded in the least significant three bits of the first byte, and the higher value of the range is encoded in the least significant three bits of the second byte.                                                                                                                                                                                                                                                             |

## Cisco-Specific L2VPN TLVs

Even though CableLabs defined L2VPN TLVs are sufficient for dynamic provisioning of MPLS pseudowires, CMTS operators can use Cisco-specific TLVs at the top level of the CM configuration file to enable additional functions.

This table lists the new Cisco-specific TLVs that are defined for the MPLS Pseudowire for Cable L2VPN feature.

Table 126: Cisco-Specific L2VPN TLVs

| TLV Name      | Type       | Length | Value                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|------------|--------|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MPLS-PW-TYPE  | 43.5.43.36 | 1      | <ul style="list-style-type: none"> <li>• 4 = Type-4 Ethernet VLAN</li> <li>• 5 = Type-5 Ethernet port</li> </ul> | The Cisco CMTS router interprets this subtype as MPLS pseudowire type (Type-4 or Type-5). If this TLV value is not specified, then the router accepts the default value (5) for Type-5.                                                                                                                                                                                                                                     |
| MPLS-VCID     | 43.5.43.38 | 4      | 4 bytes unsigned number = MPLS VCID                                                                              | <p>This subtype is interpreted as MPLS VCID.</p> <p>This TLV is ignored, and the value of TAIL is used as VCID for the pseudowire, if the following conditions are met:</p> <ul style="list-style-type: none"> <li>• The CableLabs BSOD specification-compliant TLVs, SAIL and TAIL, are present in the CM configuration file.</li> <li>• Both are of 4 bytes length.</li> <li>• Value of SAIL is equal to TAIL.</li> </ul> |
| MPLS-PEERNAME | 43.5.43.39 | N      | ASCII encoded data                                                                                               | The Cisco CMTS router interprets this optional subtype as MPLS peer name in ASCII encoded data.                                                                                                                                                                                                                                                                                                                             |

This table lists the new Cisco-specific type, length, values (TLVs) that are defined for the L2VPN Pseudowire Redundancy feature.

Table 127: Cisco-Specific L2VPN TLVs for Pseudowire Redundancy

| TLV Name        | Type         | Length | Value                                | Description                                                                                                                                                                |
|-----------------|--------------|--------|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BACKUP-PW       | 45.5.43.40   | N      | Backup pseudowire related parameters | The Cisco CMTS router interprets this subtype as related parameters for the MPLS backup pseudowire. This TLV indicates the start of a new backup pseudowire.               |
| BACKUP-PEERIP   | 43.5.43.40.1 | 4      | IP address of the backup peer (IPv4) | The Cisco CMTS router interprets this optional subtype as the peer IP address of the MPLS backup pseudowire. This TLV is an IPv4 address.                                  |
| BACKUP-PEERNAME | 43.5.43.40.2 | N      | ASCII encoded data                   | <p>The Cisco CMTS router interprets this optional subtype as the MPLS backup peer name in ASCII encoded data.</p> <p>This TLV is resolved to IPv4 address through DNS.</p> |

| TLV Name             | Type         | Length | Value                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|--------------|--------|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BACKUP-MPLS-VCID     | 43.5.43.40.3 | 4      | 4 bytes unsigned number = MPLS VCID for backup pseudowire   | <p>The Cisco CMTS router interprets this subtype as the VCID of the backup pseudowire.</p> <p>This TLV is ignored, and the value of TAIL is used as the VCID for the pseudowire, if the following conditions are met:</p> <ul style="list-style-type: none"> <li>• The CableLabs BSOD specification-compliant TLVs, SAIL, and TAIL, are present in the CM configuration file.</li> <li>• SAIL, and TAIL are of 4 bytes length.</li> <li>• Value of SAIL is equal to TAIL.</li> </ul> |
| BACKUP-MPLS-PRIORITY | 43.5.43.40.4 | 1      | 1 byte unsigned number = priority for the backup pseudowire | <p>The Cisco CMTS router interprets this subtype as the MPLS priority.</p> <p>Each primary pseudowire can have up to three backup pseudowires, with unique priorities. The priority indicates the order in which the CMTS should switch to the backup peer when the primary peer is down.</p>                                                                                                                                                                                        |
| BACKUP-ENABLE-DELAY  | 43.5.43.41   | 1      | 1 byte unsigned number = number of seconds                  | <p>The Cisco CMTS router interprets this subtype as the number of seconds the backup pseudowire should wait to take over after the primary pseudowire goes down.</p> <p>If the TLV value is not specified, then the router uses the default value of 0 seconds.</p>                                                                                                                                                                                                                  |
| BACKUP-DISABLE-DELAY | 43.5.43.42   | 1      | 1 byte unsigned number = number of seconds                  | <p>The Cisco CMTS router interprets this subtype as the number of seconds the primary pseudowire should wait to take over after the remote state of the primary pseudowire comes up.</p> <p>If the TLV value is not specified, then the router uses the default value of 0 seconds.</p>                                                                                                                                                                                              |
| BACKUP-DISABLE-NEVER | 43.5.43.43   | 1      | 1 byte unsigned number = never disable backup pseudowire    | <p>The Cisco CMTS router interprets this subtype as a flag indicating that the backup pseudowire should not be disabled even after the primary pseudowire comes up.</p> <p>If this TLV is not present, the router takes the default action of reverting back to the primary pseudowire.</p>                                                                                                                                                                                          |

## How to Enable MPLS on a Cisco CMTS Router

Perform the following tasks in the same order to enable MPLS on a Cisco CMTS router:

**Note** Before performing the static or dynamic provisioning of MPLS pseudowires, you must enable MPLS on a Cisco CMTS router.

## Configuring an LDP Router ID

The **mpls ldp router-id** command allows you to assign an interface IP address as the LDP router ID.

The normal process to determine the LDP router ID is as follows:

1. The router considers all the IP addresses of all operational interfaces.
2. If these addresses include loopback interface addresses, the router selects the largest loopback address. Configuring a loopback address helps ensure a stable LDP ID for the router, because the state of loopback addresses does not change. However, configuring a loopback interface and IP address on each router is not required.

The loopback IP address is not considered as the router ID of the local LDP ID under the following circumstances:

1. If the loopback interface has been explicitly shut down.
2. If the **mpls ldp router-id** command specifies that a different interface should be used as the LDP router ID.
3. If you use a loopback interface, make sure that the IP address for the loopback interface is configured with a /32 network mask. In addition, ensure that the routing protocol in use is configured to advertise the corresponding /32 network. Otherwise, the router selects the largest interface address.

The router might select a router ID that is not usable in certain situations. For example, the router might select an IP address that the routing protocol cannot advertise to a neighboring router. The router implements the router ID the next time it is necessary to select an LDP router ID. The effect of the **mpls ldp router-id** command is delayed until it is necessary to select an LDP router ID, which is the next time the interface is shut down or the address is deconfigured.

If you use the **force** keyword with the **mpls ldp router-id** command, the router ID takes effect more quickly. However, implementing the router ID depends on the current state of the specified interface:

- If the interface is up (operational) and its IP address is not currently the LDP router ID, the LDP router ID is forcibly changed to the IP address of the interface. This forced change in the LDP router ID tears down any existing LDP sessions, releases label bindings learned via the LDP sessions, and interrupts MPLS forwarding activity associated with the bindings.
- If the interface is down, the LDP router ID is forcibly changed to the IP address of the interface when the interface transitions to up. This forced change in the LDP router ID tears down any existing LDP sessions, releases label bindings learned via the LDP sessions, and interrupts MPLS forwarding activity associated with the bindings.

### Before you begin

Ensure that the specified interface is operational before assigning it as the LDP router ID.

## Procedure

|               | Command or Action                                                                                                                                   | Purpose                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                                    | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                                               | Enters global configuration mode.                                                                                  |
| <b>Step 3</b> | <b>mpls ip</b><br><b>Example:</b><br><pre>Router(config)# mpls ip</pre>                                                                             | Enables the dynamic MPLS forwarding function on the specified Gigabit Ethernet interface.                          |
| <b>Step 4</b> | <b>mpls ldp router-id loopback interface-number [force]</b><br><b>Example:</b><br><pre>Router(config)# mpls ldp router-id loopback 2030 force</pre> | Specifies the IP address of the loopback interface as the LDP router ID.                                           |
| <b>Step 5</b> | <b>exit</b><br><b>Example:</b><br><pre>Router(config)# exit</pre>                                                                                   | Exits global configuration mode and enters privileged EXEC mode.                                                   |

## Configuring MPLS on a Gigabit Ethernet Interface

MPLS forwarding and Label Distribution Protocol must be enabled on 1-port or 10-port GE interfaces of the Cisco CMTS router to ensure that the router establishes MPLS label-switched path (LSP) to the remote PE routers. This section explains how to enable MPLS forwarding and LDP on a Gigabit Ethernet interface.

**Note** Configuration steps are similar for 1-port and 10-port GE interfaces.

## Procedure

|               | Command or Action                                                | Purpose                                                                                                            |
|---------------|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |

|               | Command or Action                                                                                                            | Purpose                                                                                   |
|---------------|------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# configure terminal                                               | Enters global configuration mode.                                                         |
| <b>Step 3</b> | <b>interface gigabitethernet slot/subslot/port</b><br><b>Example:</b><br><br>Router(config)# interface gigabitethernet 3/0/0 | Enters interface cable configuration mode and specifies the Gigabit Ethernet interface.   |
| <b>Step 4</b> | <b>mpls ip</b><br><b>Example:</b><br><br>Router(config-if)# mpls ip                                                          | Enables the dynamic MPLS forwarding function on the specified Gigabit Ethernet interface. |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br><br>Router(config-if)# end                                                                  | Exits interface cable configuration mode and enters privileged EXEC mode.                 |

## Configuring an MPLS Label Distribution Protocol

The MPLS label distribution protocol (LDP) allows the construction of highly scalable and flexible IP VPNs that support multiple levels of services. This section explains how to configure an MPLS label distribution protocol on a Gigabit Ethernet interface.

MPLS LDP graceful-restart may also be configured for faster L2VPN traffic recovery after a LDP session disruption. For more information see the [MPLS LDP Graceful Restart](#) guide.

**Note** Ensure that the loopback interface with the IP address is present on each PE router using the **show ip interface brief** command before configuring an MPLS label distribution protocol. This loopback interface identifies the Cisco CMTS router as the peer IP address of the pseudowire.

### Procedure

|               | Command or Action                | Purpose                                                                                                            |
|---------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b> | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |

|               | Command or Action                                                                                                                     | Purpose                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
|               | <code>Router&gt; enable</code>                                                                                                        |                                                                                         |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><code>Router# configure terminal</code>                                               | Enters global configuration mode.                                                       |
| <b>Step 3</b> | <b>interface gigabitethernet slot/subslot/port</b><br><b>Example:</b><br><code>Router(config)# interface gigabitethernet 3/0/0</code> | Enters interface cable configuration mode and specifies the Gigabit Ethernet interface. |
| <b>Step 4</b> | <b>mpls label protocol ldp</b><br><b>Example:</b><br><code>Router(config-if)# mpls label protocol ldp</code>                          | Enables MPLS LDP parameters on the specified Gigabit Ethernet interface.                |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br><code>Router(config-if)# end</code>                                                                  | Exits interface cable configuration mode and enters privileged EXEC mode.               |

## Enabling the Cisco CMTS Support for MPLS Pseudowire for Cable L2VPN

You must enable the MPLS tunnel traffic on the network side of the interface to support configuration of MPLS pseudowires on a Cisco CMTS router.

### Procedure

|               | Command or Action                                                                       | Purpose                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><code>Router&gt; enable</code>                      | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><code>Router# configure terminal</code> | Enters global configuration mode.                                                                                  |

|               | Command or Action                                                                                                                     | Purpose                                                          |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| <b>Step 3</b> | <b>cable l2-vpn-service xconnect nsi mpls</b><br><b>Example:</b><br><pre>Router(config)# cable l2-vpn-service xconnect nsi mpls</pre> | Enables the MPLS tunnel traffic, where:                          |
| <b>Step 4</b> | <b>exit</b><br><b>Example:</b><br><pre>Router(config)# exit</pre>                                                                     | Exits global configuration mode and enters privileged EXEC mode. |

## How to Provision MPLS Pseudowires

You can provision MPLS pseudowires in the following ways:

**Note** Before performing the static or dynamic provisioning of MPLS pseudowires, you must [enable MPLS](#) on a Cisco CMTS router.

## Dynamic Provisioning of MPLS Pseudowires

The dynamic provisioning method supports the following types of configurations:

- BSOD Specification-Based MPLS Pseudowire Provisioning
- Type-4 MPLS Pseudowire Provisioning Using the CM Configuration File
- Type-5 MPLS Pseudowire Provisioning Using the CM Configuration File

See the [Configuration Examples for Dynamic Provisioning of MPLS Pseudowires](#) for details about the dynamic provisioning method using the CM configuration file.

**Note** We recommend that you use the dynamic provisioning method instead of the static provisioning method for MPLS pseudowires.

## Static Provisioning Method for MPLS Pseudowires

The static provisioning method requires the MPLS pseudowire to be statically provisioned on the CMTS using the command line interface (CLI). This type of provisioning does not require the CM configuration file to use BSOD L2VPN-compliant TLVs. For details on how to statically provision MPLS pseudowires, see the *Static Provisioning of MPLS Pseudowires*.

# How to Configure L2VPN Pseudowire Redundancy

The L2VPN Pseudowire Redundancy feature enables you to switch to backup pseudowires when the primary pseudowire fails. The feature also allows the Cisco CMTS to resume operation on the primary pseudowire after it comes back up.

## Configuring the Backup Pseudowire

You can configure up to three backup pseudowires for a primary pseudowire. The priority of each backup pseudowire has to be unique.

A backup pseudowire is uniquely identified by a combination of IP address or hostname and VCID. Only the IP address or hostname and VCID can be configured for the backup peer, the remaining parameters are the same as the primary pseudowire.

Backup pseudowires can also be configured using the DOCSIS configuration files.

Perform the steps given below to configure a backup pseudowire.

### Procedure

|               | Command or Action                                                                                                          | Purpose                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                      | Enters global configuration mode.                                                                                  |
| <b>Step 3</b> | <b>cable l2vpn mac-address</b><br><b>Example:</b><br><pre>Router(config)# cable l2vpn 0011.0011.0011</pre>                 | Specifies L2VPN MAC address and enters L2VPN configuration mode.                                                   |
| <b>Step 4</b> | <b>service instance id service-type</b><br><b>Example:</b><br><pre>Router(config-l2vpn)# service instance 1 ethernet</pre> | Specifies the service instance ID and enters Ethernet service configuration mode.                                  |

|               | Command or Action                                                                                                                                                             | Purpose                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 5</b> | <b>xconnect</b> <i>peer-ip-address</i> <i>vc-id</i> <b>encapsulation mpls</b><br><b>Example:</b><br><pre>Router(config-ethsrv)# xconnect 10.2.2.2 22 encapsulation mpls</pre> | Specifies the tunneling method to encapsulate the data in the MPLS pseudowire and enters xconnect configuration mode.                                                                             |
| <b>Step 6</b> | <b>backup peer</b> <i>peer-ip-address</i> <i>vc-id</i> [priority value]<br><b>Example:</b><br><pre>Router(config-xconn)# backup peer 10.3.3.3 33 priority 2</pre>             | Specifies the backup pseudowire and its priority. The priority keyword is optional, if only one backup pseudowire is configured. When multiple backup pseudowires are configured, it is required. |
| <b>Step 7</b> | <b>end</b><br><b>Example:</b><br><pre>Router(config-xconn)# end</pre>                                                                                                         | Exits xconnect configuration mode and enters Privileged EXEC mode.                                                                                                                                |

## Configuring Backup Delay

Perform the steps given below to configure the period the backup pseudowire should wait to take over after the primary pseudowire goes down. You can also specify how long the primary pseudowire should wait after it becomes active to take over from the backup pseudowire.

### Procedure

|               | Command or Action                                                                                                 | Purpose                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                               |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                             | Enters global configuration mode.                                                                                                                              |
| <b>Step 3</b> | <b>cable l2vpn</b> <i>mac-address</i><br><b>Example:</b><br><pre>Router(config)# cable l2vpn 0011.0011.0011</pre> | Specifies the L2VPN MAC address and enters L2VPN configuration mode. <ul style="list-style-type: none"> <li><i>mac-address</i>—MAC address of a CM.</li> </ul> |

|        | Command or Action                                                                                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <p><b>service instance</b> <i>id</i> <i>service-type</i></p> <p><b>Example:</b></p> <pre>Router(config-l2vpn)# service instance 1 ethernet</pre>                                                                                                                                                                                             | <p>Specifies the service instance ID and enters Ethernet service configuration mode.</p> <ul style="list-style-type: none"> <li>• <i>id</i>—Service instance ID.</li> <li>• <i>service-type</i>—Service type for the instance.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 5 | <p><b>xconnect</b> <i>peer-ip-address</i> <i>vc-id</i> <b>encapsulation mpls</b></p> <p><b>Example:</b></p> <pre>Router(config-ethsrv)# xconnect 10.2.2.2 22 encapsulation mpls</pre>                                                                                                                                                        | <p>Specifies the tunneling method to encapsulate the data in the MPLS pseudowire and enters xconnect configuration mode.</p> <ul style="list-style-type: none"> <li>• <i>peer-ip-address</i>—IP address of the remote PE router. The remote router ID can be any IP address, as long as it is reachable.</li> <li>• <i>vc-id</i>—32-bit identifier of the virtual circuit between the PE routers.</li> <li>• <b>encapsulation mpls</b>—Specifies MPLS as the tunneling method.</li> </ul>                                                                                                                                                                                                                        |
| Step 6 | <p>Do one of the following:</p> <ul style="list-style-type: none"> <li>• <b>backup delay</b> <i>enable-delay-period</i> {<i>disable-delay-period</i>   never}</li> <li>•</li> </ul> <p><b>Example:</b></p> <pre>Router(config-xconn)# backup delay 10 10</pre> <p><b>Example:</b></p> <pre>Router(config-xconn)# backup delay 10 never</pre> | <p>Specifies the period to wait before enabling or disabling the backup pseudowire.</p> <ul style="list-style-type: none"> <li>• <i>enable-delay-period</i>—Number of seconds the backup pseudowire should wait to take over after the primary pseudowire goes down. The valid range is from 0 to 180 seconds, with a default value of 0.</li> <li>• <i>disable-delay-period</i>—Number of seconds the primary pseudowire should wait after it becomes active to take over from the backup pseudowire. The valid range is from 0 to 180 seconds, with a default value of 0.</li> <li>• <b>never</b>—Specifies the primary pseudowire should not be reactivated after moving to the backup pseudowire.</li> </ul> |
| Step 7 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Router(config-xconn)# end</pre>                                                                                                                                                                                                                                                                | <p>Exits xconnect configuration mode and enters privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Performing Manual Switchover

Perform the steps given below to perform a manual switchover to the primary or backup pseudowire. The **xconnect backup force-switchover** command can also be used to forcefully switch to the backup pseudowire for planned outages of the primary remote peer.

**Note** A manual switchover can be made only to an available member in the redundancy group. If the pseudowire specified in the command is not available, the command will be rejected.

## Procedure

|               | Command or Action                                                                                                                                       | Purpose                                                                                                            |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>xconnect backup force-switchover peer 10.10.1.1 123</b><br><b>Example:</b><br><pre>Router# xconnect backup force-switchover peer 10.10.1.1 123</pre> | Specifies that the router should switch to the backup or to the primary pseudowire.                                |

## Troubleshooting Tips

The following commands help you troubleshoot an improper MPLS pseudowire configuration:

- **show ip interface brief**—Helps verify that the loopback interface with the IP address is present on each PE router.
- **show mpls l2transport vc**—Helps verify information about primary and backup pseudowires that have been enabled to route Layer 2 packets on a router.
- **show xconnect all**—Helps verify information about all xconnect attachment circuits and primary and backup pseudowires.
- **show cable l2-vpn xconnect mpls-vc-map**—Helps verify that the primary and backup pseudowires are configured properly.

## Configuration Examples for MPLS Pseudowire for Cable L2VPN

The following sections provide MPLS pseudowire configuration examples for the static and dynamic provisioning methods:

### Configuration Example for Static Provisioning of MPLS Pseudowires

The following example shows CLI-based provisioning of an MPLS pseudowire:

```
Router> enable
Router# configure terminal
Router(config)# cable l2vpn 0000.396e.6a68 customer2
Router(config-l2vpn)# service instance 2000 ethernet
Router(config-ethsrv)# xconnect 101.1.0.2 221 encapsulation mpls pw-type 4
Router(config-ethsrv)# cable set mpls-experimental 7
```

## Configuration Examples for Dynamic Provisioning of MPLS Pseudowires

The following sections provide MPLS pseudowire provisioning examples based on BSOD CableLabs specification, Type-4, and Type-5 TLVs using the CM configuration file:

### BSOD Specification-Based MPLS Pseudowire Provisioning: Example

The following example shows an MPLS pseudowire configuration based on BSOD CableLabs specification:

```

## Type-5 MPLS Pseudowire Provisioning Using the CM Configuration File: Example

The following example shows a CM configuration file-based provisioning of a Type-5 MPLS pseudowire:

```
03 (Net Access Control) = 1
43 (Vendor Specific Options)
 S08 (Vendor ID) = ff ff ff
 S005 (L2VPN Options) =
T001 (VPN ID) = 02 34 56 00 02 # VPN-ID = "0234560002"
T043 (Cisco Vendor Specific) = 2b 16
S008 (Vendor ID) = 00 00 0c # Vendor ID = "00 00 0C" - CISCO
S036 (MPLSPWTYPE) = 24 01 05 # MPLSPWTYPE= Type5 - Ethernet-Port Type
S039 (MPLSPEERNAME) = 27 06 63 37 36 30 30 32 # MPLSPEERNAME= "c76002" in ascii
S038 (MPLSVCID) = 26 04 00 00 07 d1 # = 2001 VCID
45 (L2VPN CMIM) = 02 04 ff ff ff ff 01 01 01
18 (Maximum Number of CPE) = 16
24 (Upstream Service Flow Encodings)
 S01 (Service Flow Reference) = 1
 S06 (QoS Parameter Set Type) = 7
 S43 (Vendor Specific Options)
 T08 (Vendor ID) = ff ff ff
 T001 (VPN ID) = 02 34 56 00 02 # VPN-ID = "0234560002"
 T043 (Cisco Vendor Specific) = 2b 0A
S008 (Vendor ID) = 00 00 0c # Vendor ID = "00 00 0C" - CISCO
S034 (MPLS-EXP-SET) = 22 04 # MPLS-EXP-SET at INGRESS= 4
25 (Downstream Service Flow Encodings)
 S01 (Service Flow Reference) = 12
 S06 (QoS Parameter Set Type) = 7
```

## Configuration Examples for L2VPN Pseudowire Redundancy

The following sections provide L2VPN pseudowire redundancy configuration examples using the CM configuration file:

### Example: Configuring Backup Pseudowire Peer and VC ID

The following example shows how to provision a file-based backup peer router based on the CM configuration:

#### PE Router 1

```
cable l2vpn 0025.2e2d.7252
service instance 1 ethernet
 encapsulation default
 xconnect 10.76.2.1 400 encapsulation mpls
 backup peer 10.76.2.1 600 priority 4
```

#### PE Router2

```
cable l2vpn 0011.0011.0011
service instance 1 ethernet
 encapsulation default
```

**Example: Configuring Backup Delay**

```
xconnect 10.2.2.2 22 encapsulation mpls
 backup peer 10.3.3.3 33 priority 2
 backup delay 10 10
```

**Example: Configuring Backup Delay**

The following example shows how to configure a backup delay to determine how much time should elapse before a secondary line status change after a primary line status has been changed.

```
cable l2vpn 0011.0011.0011
 service instance 1 ethernet
 encapsulation default
 xconnect 10.2.2.2 22 encapsulation mpls
 backup delay 10 10
```

**Example: L2VPN Backup MPLS Pseudowire Provisioning Using the CM Configuration File**

The following example shows how to provision an L2VPN Backup MPLS pseudowire based on the CM configuration file:

```
03 (Net Access Control) = 1
18 (Maximum Number of CPE) = 3
43 (Vendor Specific Options)
 S08 (Vendor ID) = ff ff ff
 S005 (Unknown sub-type) = 01 04 32 30 32 30 02 07 04 05 01 0a 4c 02 01 2b 15 26 04
00 00 00 14 28 10 01 05 01 0a 4c 02 01 03 04 00 00 07 08 04 01 05 28 0d 01 05 01 0a 4c 02
03 03 04 00 00 00 15 28 10 01 05 01 0a 4c 02 01 03 04 00 00 b1 8e 04 01 01 29 01 03 2a 01
01
24 (Upstream Service Flow Encodings)
 S01 (Service Flow Reference) = 4
 S06 (QoS Parameter Set Type) = 7
 S08 (Max Sustained Traffic Rate) = 2000000
 S09 (Max Traffic Burst) = 3200
 S15 (Service Flow Sched Type) = 2
 S43 (Vendor Specific Options)
 T08 (Vendor ID) = ff ff ff
 T005 (Unknown sub-type) = 01 04 32 30 32 30
25 (Downstream Service Flow Encodings)
 S01 (Service Flow Reference) = 2
 S06 (QoS Parameter Set Type) = 7
 S08 (Max Sustained Traffic Rate) = 3000000
 S09 (Max Traffic Burst) = 250000
29 (Privacy Enable) = 1
```

**Verifying the MPLS Pseudowire Configuration**

Use the following **show** commands to verify the MPLS pseudowire configuration:

- **show mpls ldp discovery**
- **show cable l2-vpn xconnect**
- **show xconnect**
- **show mpls l2transport vc**

To verify the mapping between the MPLS pseudowire and virtual circuits for all cable modems, use the **show cable l2-vpn xconnect** command as shown in the following example:

```
Router# show cable l2-vpn xconnect mpls-vc-map
MAC Address Peer IP Address VCID Type Prio CktID Cable Intf SID Customer Name/VPNID
0023.bee1.eb48 123.1.1.1 30 Prim* Bu254:4101 Cable3/0/0 3
38c8.5cac.4a62 123.1.1.1 20 Prim* Bu254:4100 Cable3/0/0 4 customer1
602a.d083.2e1c 123.1.1.1 60 Prim* Bu254:4102 Cable3/0/0 5
```

To verify the mapping between the MPLS pseudowire and virtual circuits for all cable modems when pseudowire redundancy is not configured, use the **show cable l2-vpn xconnect mpls-vc-map** command as shown in the following example:

```
Router# show cable l2-vpn xconnect mpls-vc-map
MAC Address Peer IP Address VCID Type Prio CktID Cable Intf SID Customer Name/VPNID
0025.2e2d.7252 10.76.2.1 400 Prim* Bu254:400 Cable8/0/3 1
0014.f8c1.fd46 10.2.3.4 1000 Prim* Bu254:1000 Cable8/0/0 1 2020
0014.f8c1.fd46 10.76.2.1 1800 Prim* Bu254:1800 Cable8/0/0 1 2021
```

To verify the mapping between the MPLS pseudowire and virtual circuits for all cable modems when pseudowire redundancy is configured, use the **show cable l2-vpn xconnect mpls-vc-map** command as shown in the following example:

```
Router# show cable l2-vpn xconnect mpls-vc-map
MAC Address Peer IP Address VCID Type Prio CktID Cable Intf SID Customer Name/VPNID
602a.d083.2e1c 123.1.1.1 60 Prim* Bu254:4102 Cable3/0/0 5
38c8.5cac.4a62 123.1.1.1 20 Prim* Bu254:4103 Cable3/0/0 4 000232303230
 156.1.3.1 30 Bkup 3 Bu254:4103
 123.1.1.1 50 Bkup 8 Bu254:4103
38c8.5cac.4a62 156.1.3.1 56 Prim* Bu254:4104 Cable3/0/0 4 000232303231
 123.1.1.1 40 Bkup 1 Bu254:4104
```

To obtain the state of all virtual circuits associated with an MPLS pseudowire when pseudowire redundancy is not configured, use the **show cable l2-vpn xconnect mpls-vc-map state** command as shown in the following example:

```
Router# show cable l2-vpn xconnect mpls-vc-map state
MAC Address Peer IP Address VCID Type Prio State Customer Name/VPNID State
602a.d083.2e1c 123.1.1.1 60 Prim* UP Customer Name/VPNID UP
38c8.5cac.4a62 123.1.1.1 20 Prim* UP 000232303230 UP
38c8.5cac.4a62 156.1.3.1 56 Prim* UP 000232303231 UP
```

To obtain the state of all virtual circuits associated with an MPLS pseudowire when pseudowire redundancy is configured, use the **show cable l2-vpn xconnect mpls-vc-map state** command as shown in the following example:

```
Router# show cable l2-vpn xconnect mpls-vc-map state
MAC Address Peer IP Address VCID Type Prio State Customer Name/VPNID State
602a.d083.2e1c 123.1.1.1 60 Prim* UP Customer Name/VPNID UP
38c8.5cac.4a62 123.1.1.1 20 Prim* UP 000232303230 UP
 156.1.3.1 30 Bkup 3 UP 000232303230 STDBY
 123.1.1.1 50 Bkup 8 DOWN 000232303230 STDBY
38c8.5cac.4a62 156.1.3.1 56 Prim* UP 000232303231 UP
 123.1.1.1 40 Bkup 1 UP 000232303230 STDBY
```

When the local state of the modem is DOWN, the L2VPN is not configured on the WAN interface and the remote state of the L2VPN will be shown as OFF.

```
Router#show cable l2-vpn xconnect mpls-vc-map state
MAC Address Peer IP Address VCID Type Prio State Customer Name/VPNID State
602a.d083.2e1c 123.1.1.1 60 Prim* OFF DOWN
38c8.5cac.4a62 123.1.1.1 20 Prim* UP 000232303230 UP
38c8.5cac.4a62 156.1.3.1 56 Prim* UP 000232303231 UP
```

To verify information about the MPLS pseudowire mapping for a particular MAC address of a CM when pseudowire redundancy is configured, use the **show cable l2-vpn xconnect mpls-vc-map** command as shown in the following example:

```
Router# show cable l2-vpn xconnect mpls-vc-map 0025.2e2d.7252
MAC Address Peer IP Address VCID Type Prio CktID Cable Intf SID Customer Name/VPNID
0025.2e2d.7252 10.76.2.1 400 Prim* Bu254:400 Cable8/0/3 1
 10.76.2.1 600 Bkup 4 Bu254:600
```

To verify the detailed information about the MPLS pseudowire mapping for a CM when pseudowire redundancy is configured, use the **show mpls l2-vpn xconnect mpls-vc-map verbose** command as shown in the following examples.

The following example shows the information for a modem for which pseudowires were configured using backup peer command:

```
Router# show cable l2-vpn xconnect mpls-vc-map 0025.2e2d.7252 verbose
MAC Address : 0025.2e2d.7252
Customer Name :
Prim Sid : 1
Cable Interface : Cable8/0/3

To verify information about all attachment circuits and pseudowires for online modems, use the **show xconnect** command as shown in the following example:

```

Router# show xconnect all
Legend: XC ST=Xconnect State S1=Segment1 State S2=Segment2 State
 UP=Up DN=Down AD=Admin Down IA=Inactive
 SB=Standby RV=Recovering NH=No Hardware
XC ST Segment 1 S1 Segment 2 S2
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
UP ac Bu254:2001 (DOCSIS) UP mpls 10.76.1.1:2001 UP
UP ac Bu254:2002 (DOCSIS) UP mpls 10.76.1.1:2002 UP
UP ac Bu254:2004 (DOCSIS) UP mpls 10.76.1.1:2004 UP
DN ac Bu254:22 (DOCSIS) UP mpls 101.1.0.2:22 DN

```

To verify information about MPLS virtual circuits and static pseudowires that have been enabled to route Layer 2 packets on a Cisco CMTS router, use the **show mpls l2transport vc** command as shown in the following example:

```

Router# show mpls l2transport vc
Local intf Local circuit Dest address VC ID Status

## Feature Information for MPLS Pseudowire for Cable L2VPN

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 128: Feature Information for MPLS Pseudowire for Cable L2VPN**

| Feature Name                    | Releases                    | Feature Information                                                                                               |
|---------------------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------|

## CHAPTER 48

# MPLS VPN Cable Enhancements

---

This feature module describes the Multiprotocol Label Switching Virtual Private Network (MPLS VPN) and cable interface bundling features. It explains how to create a VPN using MPLS protocol, cable interfaces, bundle interfaces and sub bundle interfaces. VPNs can be created in many ways using different protocols.

## Finding Feature Information

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Hardware Compatibility Matrix for the Cisco cBR Series Routers

---

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

---

Table 129: Hardware Compatibility Matrix for the Cisco cBR Series Routers

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Feature Overview

Using MPLS VPN technology, service providers can create scalable and efficient private networks using a shared hybrid fiber coaxial (HFC) network and Internet protocol (IP) infrastructure.

The cable MPLS VPN network consists of:

- The Multiple Service Operator (MSO) or cable company that owns the physical infrastructure and builds VPNs for the Internet Service Providers (ISPs) to move traffic over the cable and IP backbone.
- ISPs that use the HFC network and IP infrastructure to supply Internet service to cable customers.

Each ISP moves traffic to and from a subscriber's PC, through the MSO's physical network infrastructure, to the ISP's network. MPLS VPNs, created in Layer 3, provide privacy and security by constraining the distribution of a VPN's routes only to the routers that belong to its network. Thus, each ISP's VPN is insulated from other ISPs that use the same MSO infrastructure.

An MPLS VPN assigns a unique VPN Routing/Forwarding (VRF) instance to each VPN. A VRF instance consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine the contents of the forwarding table.

Each PE router maintains one or more VRF tables. It looks up a packet's IP destination address in the appropriate VRF table, only if the packet arrived directly through an interface associated with that table.

MPLS VPNs use a combination of BGP and IP address resolution to ensure security. See *Configuring Multiprotocol Label Switching*.

The table shows a cable MPLS VPN network. The routers in the network are:

- Provider (P) router—Routers in the core of the provider network. P routers run MPLS switching, and do not attach VPN labels (MPLS label in each route assigned by the PE router) to routed packets. VPN labels are used to direct data packets to the correct egress router.
- Provider Edge (PE) router— Router that adds the VPN label to incoming packets based on the interface or subinterface on which they are received. A PE router attaches directly to a CE router. In the MPLS-VPN approach, each Cisco CMTS router acts as a PE router.
- Customer (C) router—Router in the ISP or enterprise network.
- Customer Edge (CE) router—Edge router on the ISP's network that connects to the PE router on the MSO's network. A CE router must interface with a PE router.

The MPLS network has a unique VPN that exclusively manages the MSOs devices called the management VPN. It contains servers and devices that other VPNs can access. The management VPN connects the Cisco CMTS router to a PE router, which connects to management servers such as Cisco Network Registrar (CNR) and Time of Day (ToD) servers. A PE router connects to management servers and is a part of the management VPN. Regardless of the ISP they belong to, the management servers serve the Dynamic Host Configuration Protocol (DHCP), DNS (Domain Name System), and TOD requests coming from PCs or cable modems.

---

**Note** When configuring MPLS VPNs, you must configure the first subinterface created as a part of the management VPN.

---

Figure 25: MPLS VPN Network

Cable VPN configuration involves an:

- MSO domain that requires a direct peering link to each enterprise network (ISP), provisioning servers for residential and commercial subscribers, and dynamic DNS for commercial users. The MSO manages cable interface IP addressing, Data-over-Cable Service Interface Specifications (DOCSIS) provisioning, CM hostnames, routing modifications, privilege levels, and usernames and passwords.
- ISP or enterprise domain that includes the DHCP server for subscriber or telecommuter host devices, enterprise gateway within the MSO address space, and static routes back to the telecommuter subnets.

**Note** Cisco recommends that the MSO assign all addresses to the end user devices and gateway interfaces. The MSO can also use split management to let the ISP configure tunnels and security.

In an MPLS VPN configuration, the MSO must configure the following:

- CMTS
- P routers
- PE routers
- CE routers
- One VPN per ISP DOCSIS servers for all cable modem customers. The MSO must attach DOCSIS servers to the management VPN, and make them visible.

The MSO must configure the Cisco CMTS routers that serve the ISP, and remote PE routers connecting to the ISP, as PE routers in the VPN.

The MSO must determine the primary IP address range for all cable modems.

The ISP must determine the secondary IP address range for subscriber PCs.

To reduce security breaches and differentiate DHCP requests from cable modems in VPNs or under specific ISP management, MSOs can use the **cable helper-address** command in Cisco IOS-XE software. The MSO can specify the host IP address to be accessible only in the ISP's VPN. This lets the ISP use its DHCP server to allocate IP addresses. Cable modem IP address must be accessible from the management VPN.

The MPLS VPN approach of creating VPNs for individual ISPs or customers requires subinterfaces to be configured on the virtual bundle interface. Each ISP requires one subinterface. The subinterfaces are tied to the VPN Routing/Forwarding (VRF) tables for their respective ISPs. The first subinterface must be created on the cable interface bound to the management VPN.

To route a reply from the CNR back to the cable modem, the PE router that connects to the CNR must import the routes of the ISP VPN into the management VPN. Similarly, to forward management requests (such as DHCP renewal to CNR) to the cable modems, the ISP VPN must export and import the appropriate management VPN routes.

You can group all of the cable interfaces on a Cisco CMTS router into a single bundle so that only one subnet is required for each router. When you group cable interfaces, no separate IP subnet or each individual cable interface is required. This grouping avoids the performance, memory, and security problems in using a bridging solution to manage subnets, especially for a large number of subscribers.

Subinterfaces allow traffic to be differentiated on a single physical interface, and assigned to multiple VPNs. You can configure multiple subinterfaces, and associate an MPLS VPN with each subinterface. You can split a single physical interface (the cable plant) into multiple subinterfaces, where each subinterface is associated with a specific VPN. Each ISP requires access on a physical interface and is given its own subinterface. Create a management subinterface to support cable modem initialization from an ISP.

Using each subinterface associated with a specific VPN (and therefore, ISP) subscribers connect to a logical subinterface, which reflects the ISP that provides their subscribed services. When properly configured, subscriber traffic enters the appropriate subinterface and VPN.

## Benefits

- MPLS VPNs give cable MSOs and ISPs a manageable way of supporting multiple access to a cable plant. Service providers can create scalable and efficient VPNs across the core of their networks. MPLS VPNs provide systems support scalability in cable transport infrastructure and management.
- Each ISP can support Internet access services from a subscriber's PC through an MSO's physical cable plant to their networks.
- MPLS VPNs allow MSOs to deliver value-added services through an ISP, and thus, deliver connectivity to a wider set of potential customers. MSOs can partner with ISPs to deliver multiple services from multiple ISPs and add value within the MSO's own network using VPN technology.
- Subscribers can select combinations of services from various service providers.
- The MPLS VPN cable features set build on CMTS DOCSIS 1.0 and DOCSIS 1.0 extensions to ensure services are reliably and optimally delivered over the cable plant. MPLS VPN provides systems support domain selection, authentication per subscriber, selection of QoS, policy-based routing, and ability to reach behind the cable modem to subscriber end devices for QoS and billing while preventing session spoofing.
- MPLS VPN technology ensures both secure access across the shared cable infrastructure and service integrity.

- Cable interface bundling eliminates the need for an IP subnet on each cable interface. Instead, an IP subnet is only required for each cable interface bundle. All cable interfaces in a Cisco CMTS router can be added to a single bundle.

## Restrictions

- Each subinterface on the CMTS requires an address range from the ISP and from the MSO. These two ranges must not overlap and must be extensible to support an increased number of subscribers for scalability.

---

**Note** This document does not address allocation and management of MSO and ISP IP addresses. See *Configuring Multiprotocol Label Switching* for this information.

---

- The **cable source-verify dhcp** command enables Dynamic Host Control Protocol (DHCP) Lease query protocol from the CMTS to DHCP server to verify IP addresses of upstream traffic, and prevent MSO customers from using unauthorized, spoofed, or stolen IP addresses.
- When using only MPLS VPNs, create subinterfaces on the virtual bundle, assign it an IP address, and provide VRF configuration for each ISP. When you create subinterfaces and configure only MPLS VPNs, the cable interface bundling feature is independent of the MPLS VPN.
- When using cable interface bundling:
  - Define a virtual bundle interface and associate any cable physical interface to the virtual bundle.
  - Specify all generic IP networking information (such as IP address, routing protocols, and switching modes) on the virtual bundle interface. Do not specify generic IP networking information on bundle subsidiary interfaces.
  - An interface that has a subinterface(s) defined over it is not allowed to be a part of the bundle.
  - Specify generic (not downstream or upstream related) cable interface configurations, such as source-verify or ARP handling, on the virtual bundle interface. Do not specify generic configuration on bundle subsidiary interfaces.
- Interface bundles can only be configured using the command line interface (including the CLI-based HTML configuration).

## Prerequisites

Before configuring IP-based VPNs, complete the following tasks:

- Ensure your network supports reliable broadband data transmission. Your plant must be swept, balanced, and certified based on National Television Standards Committee (NTSC) or appropriate international cable plant recommendations. Ensure your plant meets all DOCSIS or European Data-over-Cable Service Interface Specifications (EuroDOCSIS) downstream and upstream RF requirements.
- Ensure your Cisco router is installed following instructions in the Hardware Installation Guide and the Regulatory Compliance and Safety Information guide.
- Ensure your Cisco router is configured for basic operations.

- The chassis must contain at least one port adapter to provide backbone connectivity and one Cisco cable modem card to serve as the RF cable TV interface.

## Other Important Information

- Ensure all other required headend or distribution hub routing and network interface equipment is installed, configured, and operational based on the services to support. This includes all routers, servers (DHCP, TFTP, and ToD), network management systems, other configuration or billing systems and backbone, and other equipment to support VPN.
- Ensure DHCP and DOCSIS configuration files have been created and pushed to appropriate servers such that each cable modem, when initialized, can transmit a DHCP request, receive an IP address, obtain TFTP and ToD server addresses, and download a DOCSIS configuration file. Configure each subinterface to connect to the ISP's VPN.
- Ensure DOCSIS servers are visible on the management VPN.
- Be familiar with your channel plan to assign appropriate frequencies. Outline your strategies for setting up bundling or VPN solution sets if applicable to your headend or distribution hub. Obtain passwords, IP addresses, subnet masks, and device names as appropriate.
- Create subinterfaces off of a virtual bundle interface. Configure each subinterface to connect to the ISP network.

The MPLS VPN configuration steps assume the following:

- IP addressing has already been determined and there are assigned ranges in the MSO and ISP network for specific subinterfaces.
- The MSO is using CNR and has configured it (using the **cable helper-address** command) to serve appropriate IP addresses to cable modems based on the cable modem MAC address. The CMTS forwards DHCP requests to the CNR based on the **cable helper-address** settings. The CNR server determines the IP address to assign the cable modem using the client-classes feature, which let the CNR assign specific parameters to devices based on MAC addresses.
- ISP CE routers are configured (using the **cable helper-address** command) to appropriately route relevant IP address ranges into the VPN.
- P and PE routers are already running Cisco Express Forwarding (CEF).
- MPLS is configured on the outbound VPN using the **tag switching ip** command in interface configuration mode.

## Configuration Tasks

To configure MPLS VPNs, perform the following tasks:

### Creating VRFs for each VPN

To create VRFs for each VPN, perform the following steps beginning in the router configuration mode.

---

**Note** Since only the CMTS has logical subinterfaces, assignments of VRFs on the other PE devices will be to specific physical interfaces.

---

## Procedure

|                | Command or Action                                                                                      | Purpose                                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b>  | Router(config)# <b>vrf definition</b> <i>mgmt-vpn</i>                                                  | Enters VRF configuration mode (config-vrf)# and maps a VRF table to the VPN (specified by <i>mgmt-vpn</i> ). The management VPN is the first VPN configured. |
| <b>Step 2</b>  | Router(config-vrf)# <b>rd</b> <i>mgmt-rd</i>                                                           | Creates a routing and forwarding table by assigning a route distinguisher to the management VPN.                                                             |
| <b>Step 3</b>  | Router(config-vrf)# <b>route-target</b> { <b>export</b>   <b>import</b>   <b>both</b> } <i>mgmt-rd</i> | Exports and/or imports all routes for the management VPNs route distinguisher. This determines which routes will be shared within VRFs.                      |
| <b>Step 4</b>  | Router(config-vrf)# <b>route-target import</b> <i>isp1-vpn-rd</i>                                      | Imports all routes for the VPNs ( <i>isp1-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 5</b>  | Router(config-vrf)# <b>route-target import</b> <i>isp2-vpn-rd</i>                                      | Imports all routes for the VPNs ( <i>isp2-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 6</b>  | Router(config-vrf)# <b>vrf definition</b> <i>isp1-vpn</i>                                              | Creates a routing and forwarding table by assigning a route distinguisher to <i>isp1-vpn</i> .                                                               |
| <b>Step 7</b>  | Router(config-vrf)# <b>rd</b> <i>mgmt-rd</i>                                                           | Creates a routing and forwarding table by assigning a route distinguisher (mgmt-rd) to the management VPN (mgmt-vpn).                                        |
| <b>Step 8</b>  | Router(config-vrf)# <b>route-target export</b> <i>isp1-vpn-rd</i>                                      | Exports all routes for the VPNs ( <i>isp1-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 9</b>  | Router(config-vrf)# <b>route-target import</b> <i>isp1-vpn-rd</i>                                      | Imports all routes for the VPNs ( <i>isp1-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 10</b> | Router(config-vrf)# <b>route-target import</b> <i>mgmt-vpn-rd</i>                                      | Exports all routes for the VPNs ( <i>mgmt-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 11</b> | Router(config-vrf)# <b>vrf definition</b> <i>isp2-vpn</i>                                              | Creates a routing and forwarding table by assigning a route distinguisher to <i>isp2-vpn</i> .                                                               |
| <b>Step 12</b> | Router(config-vrf)# <b>route-target export</b> <i>isp2-vpn-rd</i>                                      | Exports all routes for the VPNs ( <i>isp2-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 13</b> | Router(config-vrf)# <b>route-target import</b> <i>isp2-vpn-rd</i>                                      | Imports all routes for the VPNs ( <i>isp2-vpn</i> ) route distinguisher.                                                                                     |
| <b>Step 14</b> | Router(config-vrf)# <b>route-target import</b> <i>mgmt-vpn-rd</i>                                      | Imports all routes for the VPNs ( <i>mgmt-vpn</i> ) route distinguisher.                                                                                     |

## Defining Subinterfaces on a Virtual Bundle Interface and Assigning VRFs

To create a logical cable subinterface, perform the following steps beginning in the global configuration mode. Create one subinterface for each VPN (one per ISP). The first subinterface created must be configured as part of the management VPN (with the lowest subinterface number).

### Procedure

|                | Command or Action                                                        | Purpose                                                                                                                                 |
|----------------|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b>  | Router# <b>configure terminal</b>                                        | Enters configuration mode.                                                                                                              |
| <b>Step 2</b>  | Router(config)# <b>interface bundle n.x</b>                              | Enters virtual bundle interface configuration mode and defines the first (management) subinterface with the lowest subinterface number. |
| <b>Step 3</b>  | Router(config-subif)# <b>description string</b>                          | Identifies the subinterface as the management subinterface.                                                                             |
| <b>Step 4</b>  | Router(config-subif)# <b>vrf forwarding mgmt-vpn</b>                     | Assigns the subinterface to the management VPN (the MPLS VPN used by the MSO to supply service to customers).                           |
| <b>Step 5</b>  | Router(config-subif)# <b>ip address ipaddress mask</b>                   | Assigns the subinterface an IP address and a subnet mask.                                                                               |
| <b>Step 6</b>  | Router(config-subif)# <b>cable helper-address ip-address cable-modem</b> | Forwards DHCP requests from cable modems to the IP address listed.                                                                      |
| <b>Step 7</b>  | Router(config-subif)# <b>cable helper-address ip-address host</b>        | Forwards DHCP requests from hosts to the IP address listed.                                                                             |
| <b>Step 8</b>  | Router(config-if)# <b>interface bundle n.x</b>                           | Defines an additional subinterface for the ISP (such as isp1).                                                                          |
| <b>Step 9</b>  | Router(config-subif)# <b>description string</b>                          | Identifies the subinterface (such as subinterface for <i>isp1-vpn</i> ).                                                                |
| <b>Step 10</b> | Router(config-subif)# <b>vrf forwarding isp1-vpn</b>                     | Assigns the subinterface to <i>isp1-vpn</i> VPN.                                                                                        |
| <b>Step 11</b> | Router(config-subif)# <b>ip address ipaddress mask</b>                   | Assigns the subinterface an IP address and a subnet mask.                                                                               |
| <b>Step 12</b> | Router(config-subif)# <b>cable helper-address ip-address cable-modem</b> | Forwards DHCP requests from cable modems to the IP address listed.                                                                      |
| <b>Step 13</b> | Router(config-subif)# <b>cable helper-address ip-address host</b>        | Forwards DHCP requests from hosts to the IP address listed.                                                                             |
| <b>Step 14</b> | Router(config-if)# <b>interface bundle n.x</b>                           | Defines an additional subinterface for the ISP (such as isp2).                                                                          |
| <b>Step 15</b> | Router(config-subif)# <b>description string</b>                          | Identifies the subinterface (such as subinterface for <i>isp2-vpn</i> ).                                                                |
| <b>Step 16</b> | Router(config-subif)# <b>vrf forwarding isp2-vpn</b>                     | Assigns the subinterface to <i>isp2-vpn</i> VPN.                                                                                        |
| <b>Step 17</b> | Router(config-subif)# <b>ip address ipaddress mask</b>                   | Assigns the subinterface an IP address and a subnet mask.                                                                               |

|                | Command or Action                                                                         | Purpose                                                            |
|----------------|-------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <b>Step 18</b> | Router(config-subif)# <b>cable helper-address</b> <i>ip-address</i><br><b>cable-modem</b> | Forwards DHCP requests from cable modems to the IP address listed. |
| <b>Step 19</b> | Router(config-subif)# <b>cable helper-address</b> <i>ip-address</i><br><b>host</b>        | Forwards DHCP requests from hosts to the IP address listed.        |
| <b>Step 20</b> | Router(config)# <b>exit</b>                                                               | Returns to configuration mode.                                     |

## Configuring Cable Interface Bundles

To assign a cable interface to a bundle, perform the following steps beginning in the interface configuration mode.

### Procedure

|               | Command or Action                                               | Purpose                                                                                                                                                                                                          |
|---------------|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>interface cable</b> <i>slot/port</i>         | Enters the cable interface configuration mode.<br><br>IP addresses are not assigned to this interface. They are assigned to the logical subinterfaces created within this interface.                             |
| <b>Step 2</b> | Router(config-if)# <b>cable bundle</b> <i>bundle-number</i>     | Defines the interface as the bundle interface.                                                                                                                                                                   |
| <b>Step 3</b> | Router(config)# <b>interface cable</b> <i>slot/subslot/port</i> | Enters the cable interface configuration mode for another cable interface.<br><br>IP addresses are not assigned to this interface. They are assigned to the logical subinterfaces created within this interface. |
| <b>Step 4</b> | Router(config-if)# <b>cable bundle</b> <i>bundle-number</i>     | Adds the interface to the bundle specified by <i>bundle-number</i> .                                                                                                                                             |

## Configuring Subinterfaces and MPLS VPNs on a Virtual Bundle Interface

To configure subinterfaces on a virtual bundle interface and assign each subinterface a Layer 3 configuration:

Configure cable interface bundles.

Define subinterfaces on the virtual bundle interface and assign a Layer 3 configuration to each subinterface.

Create one subinterface for each customer VPN (one per ISP).

## Configuring MPLS in the P Routers in the Provider Core

To configure MPLS in the P routers in the provider core, perform the following steps.

**Procedure**

|               | <b>Command or Action</b>                                                               | <b>Purpose</b>                                                                                                                                                                                   |
|---------------|----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Router# <b>configure terminal</b>                                                      | Enters configuration mode.                                                                                                                                                                       |
| <b>Step 2</b> | Router(config)# <b>ip cef</b>                                                          | Enables Cisco Express Forwarding (CEF) operation.<br>For information about CEF configuration and command syntax, see Cisco Express Forwarding Overview and Configuring Cisco Express Forwarding. |
| <b>Step 3</b> | Router(config)# <b>interface</b> <b>Tengigabitethernet</b><br><i>slot/subslot/port</i> | Enters GigabitEthernet interface configuration mode.                                                                                                                                             |
| <b>Step 4</b> | Router(config-if)# <b>ip address</b> <i>ip-address mask</i>                            | Defines the primary IP address range for the interface.                                                                                                                                          |
| <b>Step 5</b> | Router(config-if)# <b>mpls ip</b>                                                      | Enables the interface to be forwarded to an MPLS packet.                                                                                                                                         |
| <b>Step 6</b> | Router(config-if)# <b>exit</b>                                                         | Returns to global configuration mode.                                                                                                                                                            |
| <b>Step 7</b> | Router(config)# <b>mpls label-protocol ldp</b>                                         | Enables Label Distribution Protocol (LDP).<br>For information about LDP and MPLS, see Configuring Multiprotocol Label Switching.                                                                 |
| <b>Step 8</b> | Router(config)# <b>exit</b>                                                            | Returns to the configuration mode.                                                                                                                                                               |

## Verifying the MPLS VPN Configuration

Use the following commands to verify MPLS VPN operations on PE routers. For more MPLS VPN verification commands, see Configuring Multiprotocol Label Switching.

**Procedure**

|               | <b>Command or Action</b>                         | <b>Purpose</b>                                                             |
|---------------|--------------------------------------------------|----------------------------------------------------------------------------|
| <b>Step 1</b> | Router# <b>show ip vrf</b>                       | Displays the set of VRFs and interfaces.                                   |
| <b>Step 2</b> | Router# <b>show ip route vrf [vrf-name]</b>      | Displays the IP routing table for a VRF.                                   |
| <b>Step 3</b> | Router# <b>show ip protocols vrf [vrf-name]</b>  | Displays the routing protocol information for a VRF.                       |
| <b>Step 4</b> | Router# <b>show ip route vrf</b> <i>vrf-name</i> | Displays the Local and Remote CE devices that are in the PE routing table. |
| <b>Step 5</b> | Router# <b>show mpls forwarding-table</b>        | Displays entries for a VPN Routing/Forwarding instance.                    |

**What to do next**

For more verification instructions, see the [MPLS: Layer 3 VPNs Configuration Guide](#).

# Configuration Examples

This section provides the following configuration examples:

## VRF Definition Configuration

```
vrf definition Basketball
 rd 100:2

## Feature Information for MPLS VPN Cable Enhancements

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 130: Feature Information for MPLS VPN Cable Enhancements*

| Feature Name                                                     | Releases                    | Feature Information                                                                                              |
|------------------------------------------------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------|

## CHAPTER 49

# Multicast VPN and DOCSIS 3.0 Multicast QoS Support

---

The CMTS enhanced multicast new features are consistent with DOCSIS 3.0 specifications and include:

- Enhanced multicast echo in which the Layer 3 multicast switching path uses a Cisco Packet Processor (CPP) parallel express forwarding multicast routing table.
- Enhanced multicast quality of service (MQoS) framework that specifies a group configuration (GC) to define a session range of multicast addresses and rule priorities and its associated multicast VPN (MVPN).
- Intelligent multicast admission control to include multicast service flows.
- Enhanced multicast VPN feature to configure and support multicast traffic in a multiprotocol label switching (MPLS)-VPN environment.

## Finding Feature Information

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

# Hardware Compatibility Matrix for the Cisco cBR Series Routers

**Note** The hardware components that are introduced in a given Cisco IOS-XE Release are supported in all subsequent releases unless otherwise specified.

**Table 131: Hardware Compatibility Matrix for the Cisco cBR Series Routers**

| Cisco CMTS Platform                    | Processor Engine                                                                                                                                                                                                                                                   | Interface Cards                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Restrictions for the Multicast VPN and DOCSIS 3.0 Multicast QoS Support

The type of service (ToS) parameter is not recognized by the Cisco cBR series routers.

To avail 40000 multicast sessions, a minimum of one bundle should be present for each LC.

# Information About the Multicast VPN and DOCSIS 3.0 Multicast QoS Support

IP multicast—transmission of the same information to multiple cable network recipients—improves bandwidth efficiency and allows service providers to offer differentiated quality of service for different types of traffic. Enhanced multicast introduces multicast improvements as mandated by the introduction of DOCSIS 3.0 specifications.

---

**Note** DOCSIS 3.0 standards retain backwards compatibility with the DOCSIS 2.0 multicast mode of operation.

---

The Cisco cBR routers support 40000 DSG multicast sessions per chassis.

The following are the benefits of CMTS enhanced multicast are:

## Enhanced Quality of Service

In the new multicast QoS (MQoS) framework, you can specify a group configuration (GC) that defines a session range of multicast addresses and rule priorities and its associated multicast VPN (MVPN). For every GC, there is attached a group QoS configuration (GQC) and a group encryption rule.

Based on the session range, rule priority, and MVPN, a multicast service flow is admitted into a GC and the associated GQC and group encryption rule are applied to the flow. In MQoS implementation, the source address of the multicast session is not checked because the current implementation for cable-specific multicast supports IGMP Version 2 but not IGMP Version 3. The downstream service flow, service identifier (SID), and MAC-rewrite string are created at the time of a new IGMP join (or static multicast group CLI on the interface) and MQoS is applied to the new multicast group join.

The benefits of enhanced QoS are the following:

- Group classifiers can be applied at cable interface level and also at bundle interface level.
- Group service flow (GSF) definition is based on service class names. The GSF is similar to individual service flows and commonly includes the minimum rate and maximum rate parameters for the service class. GSF is shared by all cable modems on a particular downstream channel set (DCS) that is matched to the same group classifier rule (GCR). A default service flow is used for multicast flows that do not match to any GCR. A GSF is always in the active state.
- CMTS replicates multicast packets and then classifies them.
- Single-stage replication and two-stage replication are supported.
- Enhanced QoS is compatible and integrated with DOCSIS Set-Top Gateway (DSG).

## Intelligent Multicast Admission Control

Admission control allows you to categorize service flows into buckets. Examples of categories are the service class name used to create the service flow, service flow priority, or the service flow type such as unsolicited grant service (UGS). Bandwidth limits for each bucket can also be defined. For example, you can define bucket 1 for high priority packet cable service flows and specify that bucket 1 is allowed a minimum of 30 percent and a maximum of 50 percent of the link bandwidth.

Intelligent multicast admission control includes additional features such as the inclusion of multicast service flows using the GSF concept. GSFs are created based on the rules as defined in the GQC table. The rules link the multicast streams to a GSF through the session range. The service class name in the rule defines the QoS for that GSF. Additionally, another attribute is added to the rules and the group configuration table to specify the application type to which each GSF belongs. In this way, the QoS associated with each GSF is independent of the bucket category for the GSF.

The benefits of intelligent multicast admission control are the following:

- There is explicit acknowledgment of the establishment of each multicast session.
- Admission control does not consume additional bandwidth for multicast flows once the first flow is established.
- Service flows are cleaned up as the multicast session is torn down.

## Multicast Session Limit Support

In a multicast video environment, you can limit the number of multicast sessions admitted onto a particular service flow. The multicast session limit feature—which adds functionality on top of the multicast QoS infrastructure—enables you to specify the number of multicast sessions to be admitted on a particular service flow. If the current number of sessions has reached the defined limit, new sessions will be forwarded but they will make use of the default multicast service flow until a session ends to free up a slot for new sessions.

## Multicast Virtual Private Network

The new multicast VPN (MVPN) feature allows you to configure and support multicast traffic in a multiprotocol label switching (MPLS)-VPN environment. This feature supports routing and forwarding of multicast packets for each individual VPN virtual routing and forwarding (VRF) instance, and also provides a mechanism to transport VPN multicast packets across the service provider backbone.

MVPN allows you to connect multiple remote sites or devices over either a Layer 3 or Layer 2 VPN. A Layer 3 VPN enables the routing of traffic inside the VPN. A Layer 2 VPN provides a bridging transport mechanism for traffic between remote sites belonging to a customer. To support multicast over Layer 3 VPNs, each VPN receives a separate multicast domain with an associated MVPN routing and forwarding (mVRF) table maintained by the provider edge (PE) router. In a cable environment, the PE router is a routing CMTS. The provider network builds a default multicast distribution tree (default-MDT) for each VPN between all the associated mVRF-enabled PE routers. This tree is used to distribute multicast traffic to all PE routers.

To enable maximum security and data privacy in a VPN environment, the CMTS distinguishes between multicast sessions on the same downstream interface that belong to different VPNs. To differentiate multicast traffic between different VPNs, the CMTS implements a per-VRF subinterface multicast security association identifier (MSAID) allocation feature that is BPI+ enabled. The MSAID is allocated for each cable bundle group for each subinterface. A multicast group has a specific MSAID for each VRF instance.

## How to Configure the Multicast VPN and DOCSIS 3.0 Multicast QoS Support

This section contains the following procedures:

## Configuring a QoS Profile for a Multicast Group

To configure a QoS profile that can be applied to a QoS group configuration, use the **cable multicast group-qos** command. You must configure a QoS profile before you can add a QoS profile to a QoS multicast group.

### Procedure

|        | Command or Action                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# configure terminal                                                                                                                                    | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                              |
| Step 3 | <b>cable multicast group-qos number scn service-class-name control { single   aggregate [limit max-sessions]}</b><br><b>Example:</b><br>Router(config)#: cable multicast group-qos 2 scn name1 control single | Configures a QoS profile that can be applied to a multicast QoS group. <p><b>Note</b> If a number is not specified, a default QoS profile is applied. The default group qos configuration creates a default multicast service flow for each cable interface that is used when a multicast session does not match any classifiers of a GC on the interface.</p> |

## Configuring a Multicast QoS Group

You can specify a group configuration (GC) that defines a session range of multicast addresses and rule priorities and its associated multicast VPN (MVPN). For every GC, there is attached a group QoS configuration and a group encryption rule.

### Procedure

|        | Command or Action                                                          | Purpose                                                                                                            |
|--------|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                                                                                  |

|               | Command or Action                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Step 3</b> | <p><b>cable multicast group-qos</b> <i>number scn service-class-name</i><br/> <b>control</b> {<b>single</b>   <b>aggregate</b> [<i>limit max-sessions</i>]}</p> <p><b>Example:</b></p> <pre>Router(config-mqos) # cable multicast group-qos 5 scn name1 control single</pre> | <p>(Optional) Configures a QoS profile that can be applied to a multicast QoS group.</p> <p><b>Note</b> If a number is not specified, a default QoS profile is applied. The default group qos configuration creates a default multicast service flow for each cable interface that is used when a multicast session does not match any classifiers of a GC on the interface.</p>                                                                                             |
| <b>Step 4</b> | <p><b>cable multicast qos group</b> <i>id priority value</i> [<b>global</b> ]</p> <p><b>Example:</b></p> <pre>Router(config) # cable multicast qos group 2 priority 6</pre>                                                                                                  | Configures a multicast QoS group and enters multicast QoS configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 5</b> | <p><b>session-range</b> <i>ip-address ip-mask</i></p> <p><b>Example:</b></p> <pre>Router(config-mqos) # session-range 224.10.10.10 255.255.255.224</pre>                                                                                                                     | Specifies the session range IP address and IP mask of the multicast QoS group. You can configure multiple session ranges.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 6</b> | <p><b>tos</b> <i>low-byte high-byte mask</i></p> <p><b>Example:</b></p> <pre>Router(config-mqos) # tos 1 6 15</pre>                                                                                                                                                          | (Optional) Specifies the minimum type of service (ToS) data bytes, maximum ToS data bytes, and mask for a multicast QoS group.                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 7</b> | <p><b>vrfname</b></p> <p><b>Example:</b></p> <pre>Router(config-mqos) # vrf name1</pre>                                                                                                                                                                                      | <p>(Optional) Specifies the name for the virtual routing and forwarding (VRF) instance.</p> <p><b>Note</b> If a multicast QoS (MQoS) group is not defined for this VRF, you will see an error message. You must either define a specific MQoS group for each VRF, or define a default MQoS group that can be assigned in those situations where no matching MQoS group is found. See the <a href="#">Configuring a Default Multicast QoS Group for VRF, on page 744</a>.</p> |
| <b>Step 8</b> | <p><b>application-id</b><i>number</i></p> <p><b>Example:</b></p> <pre>Router(config-mqos) # application-id 25</pre>                                                                                                                                                          | (Optional) Specifies the application identification number of the multicast QoS group. This value is configured to enable admission control to the multicast QoS group.                                                                                                                                                                                                                                                                                                      |

## Configuring a Default Multicast QoS Group for VRF

Each virtual routing and forwarding (VRF) instance that is defined must match a defined MQoS group to avoid multicast stream crosstalk between VRFs. To avoid potential crosstalk, define a default MQoS group that is assigned to the VRF whenever the multicast traffic in the VRF does not match an existing MQoS group.

## Procedure

|        | Command or Action                                                                                                                                                                                                         | Purpose                                                                                                                                                                                    |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                         |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                                                                                                                     | Enters global configuration mode.                                                                                                                                                          |
| Step 3 | <b>cable multicastgroup-qosnumber scn service-class-name control {single   aggregate [limit max-sessions]}</b><br><b>Example:</b><br><pre>Router(config-mqos)# cable multicast group-qos 5 scn name1 control single</pre> | (Optional) Configures a QoS profile that can be applied to a multicast QoS group.                                                                                                          |
| Step 4 | <b>cable multicast qos group id priority 255 global</b><br><b>Example:</b><br><pre>Router(config)# cable multicast qos group 2 priority 255 global</pre>                                                                  | Configures a default multicast QoS group and enters multicast QoS configuration mode.                                                                                                      |
| Step 5 | <b>session-range 224.0.0.0 224.0.0.0</b><br><b>Example:</b><br><pre>Router(config-mqos)# session-range 224.0.0.0 224.0.0.0</pre>                                                                                          | Specifies the session-range IP address and IP mask of the default multicast QoS group. By entering 224.0.0.0 for the IP address and the IP mask you cover all possible multicast sessions. |
| Step 6 | <b>vrfname</b><br><b>Example:</b><br><pre>Router(config-mqos)# vrf name1</pre>                                                                                                                                            | Specifies the name of the virtual routing and forwarding (VRF) instance.                                                                                                                   |
| Step 7 | <b>application-idnumber</b><br><b>Example:</b><br><pre>Router(config-mqos)# application-id 5</pre>                                                                                                                        | (Optional) Specifies the application identification number of the multicast QoS group. This value is configured to enable admission control to the multicast QoS group.                    |

## Verifying Configuration of the Multicast VPN and DOCSIS 3.0 Multicast QoS Support

To verify the configuration of the Multicast VPN and DOCSIS 3.0 Multicast QoS Support feature, use the **show** commands described below.

- To show the configuration parameters for multicast sessions on a specific bundle, use the **show interface bundle *number* multicast-sessions** command as shown in the following example:

```
Router# show interface bundle 1 multicast-sessions
Multicast Sessions on Bundle1
Group Interface GC SAID SFID GQC GEn RefCount GC-Interface State
234.1.1.45 Bundle1.1 1 8193 --- 1 5 1 Bundle1 ACTIVE
234.1.1.46 Bundle1.1 1 8193 --- 1 5 1 Bundle1 ACTIVE
234.1.1.47 Bundle1.1 1 8193 --- 1 5 1 Bundle1 ACTIVE
Aggregate Multicast Sessions on Bundle1
Aggregate Sessions for SAID 8193 GQC 1 CurrSess 3
Group Interface GC SAID SFID AggGQC GEn RefCount GC-Interface
234.1.1.45 Bundle1.1 1 8193 --- 1 5 1 Bundle1
234.1.1.46 Bundle1.1 1 8193 --- 1 5 1 Bundle1
234.1.1.47 Bundle1.1 1 8193 --- 1 5 1 Bundle1
```

- To show the configuration parameters for multicast sessions on a specific cable, use the **show interface cable *ip-addr* multicast-sessions** command as shown in the following example:

```
Router# show interface cable 7/0/0 multicast-sessions
Default Multicast Service Flow 3 on Cable7/0/0
Multicast Sessions on Cable7/0/0
Group Interface GC SAID SFID GQC GEn RefCount GC-Interface State
234.1.1.45 Bundle1.1 1 8193 24 1 5 1 Bundle1 ACTIVE
234.1.1.46 Bundle1.1 1 8193 24 1 5 1 Bundle1 ACTIVE
234.1.1.47 Bundle1.1 1 8193 24 1 5 1 Bundle1 ACTIVE
Aggregate Multicast Sessions on Cable7/0/0
Aggregate Sessions for SAID 8193 SFID 24 GQC 1 CurrSess 3
Group Interface GC SAID SFID AggGQC GEn RefCount GC-Interface
234.1.1.45 Bundle1.1 1 8193 24 1 5 1 Bundle1
234.1.1.46 Bundle1.1 1 8193 24 1 5 1 Bundle1
234.1.1.47 Bundle1.1 1 8193 24 1 5 1 Bundle1
```

- To show the MSAID multicast group subinterface mapping, use the **show interface cable *address* modem** command as shown in the following example:

```
Router# show interface cable 6/1/0 modem
SID Priv Type State IP address method MAC address Dual
 bits
 9 11 modem online(pt) 101.1.0.6 dhcp 0006.28f9.8c79 N
 9 11 host unknown 111.1.1.45 dhcp 0018.1952.a859 N
 10 10 modem online(pt) 101.1.0.5 dhcp 0006.5305.ac19 N
 10 10 host unknown 111.1.0.3 dhcp 0018.1952.a85a N
 13 10 modem online(pt) 101.1.0.3 dhcp 0014.f8c1.fd1c N
8195 10 multicast unknown 224.1.1.51 static 0000.0000.0000 N
8195 10 multicast unknown 224.1.1.49 static 0000.0000.0000 N
8195 10 multicast unknown 224.1.1.50 static 0000.0000.0000 N
```

## Configuration Examples for the Multicast VPN and DOCSIS 3.0 Multicast QoS Support

This section provides the following configuration examples:

## Example: Configuring Group QoS and Group Encryption Profiles

**Note** To add group QoS and group encryption profiles to a QoS group, you must configure each profile first before configuring the QoS group.

In the following example, QoS profile 3 and encryption profile 35 are configured.

```
configure terminal
cable multicast group-qos 3 scn name1 control single
cable multicast group-encryption 35 algorithm 56bit-des
```

## Example: Configuring a QoS Group

In the following example, QoS group 2 is configured with a priority of 6 and global application. To QoS group 2, QoS profile 3 and encryption profile 35 are applied. Other parameters are configured for QoS group 2 including application type, session range, ToS, and VRF.

```
cable multicast qos group 2 priority 6 global
group-encryption 35
group-qos 3
session-range 224.10.10.01 255.255.255.254
tos 1 6 15
vrf vrf-name1
application-id 44
```

## Feature Information for Multicast VPN and DOCSIS3.0 Multicast QoS Support

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfngn.cisco.com/> link. An account on the Cisco.com page is not required.

---

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

---

*Table 132: Feature Information for Multicast VPN and DOCSIS3.0 Multicast QoS Support*

| <b>Feature Name</b>                               | <b>Releases</b>             | <b>Feature Information</b>                                                                                        |

## CHAPTER 50

# EtherChannel for the Cisco CMTS

This document describes the features, benefits and configuration of Cisco EtherChannel technology on the Cisco Cable Modem Termination System (CMTS).

EtherChannel is a technology by which to configure and aggregate multiple physical Ethernet connections to form a single logical port with higher bandwidth. The first EtherChannel port configured on the Cisco CMTS serves as the EtherChannel bundle primary by default, and each subsidiary interface interacts with the network using the MAC address of the EtherChannel bundle primary.

EtherChannel ports reside on a routing or bridging end-point. The router or switch uses EtherChannel to increase bandwidth utilization in either half- or full-duplex mode, and load balances the traffic across the multiple physical connections.

EtherChannel on the Cisco CMTS supports inter-VLAN routing with multiple devices and standards, and supports Ten Gigabit EtherChannel (GEC) on the Cisco cBR series routers.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Restrictions for EtherChannel on the Cisco CMTS

- EtherChannel on the Cisco CMTS is limited to Network Layer 3 functions, and does not support Data-Link Layer 2 EtherChannel functions as with certain other Cisco product platforms.
- The Port Aggregation Protocol (PAgP) is not supported on the Cisco CMTS as with other Cisco product platforms (such as the CatOS switch).
- Only the IEEE 802.1Q trunking protocol is supported on the Cisco CMTS. ATM trunking is not supported on the Cisco cBR series routers.
- The maximum supported links per bundle is 8.

- EtherChannel on Cisco CMTS supports only physical ports or interfaces that have the same speed.
- EtherChannel on the Cisco cBR series routers does not support MQC QoS. You can use Equal Cost Multi Path (ECMP) load balancing instead of EtherChannel.
- Layer 3 configurations on member interfaces of EtherChannel are not supported.
- MAC Address Accounting feature on port channel is not supported.

## Information About EtherChannel on the Cisco CMTS

This section contains the following:

### Introduction to EtherChannel on the Cisco CMTS

EtherChannel is based on proven industry-standard technology. The Cisco CMTS supports EtherChannel with several benefits, including the following:

- EtherChannel on the Cisco CMTS supports subsecond convergence times.
- EtherChannel can be used to connect two switch devices together, or to connect a router with a switch.
- A single EtherChannel connection supports a higher bandwidth between the two devices.
- The logical port channels on either Cisco CMTS platform provide fault-tolerant, high-speed links between routers, switches, and servers.
- EtherChannel offers redundancy and high availability on the Cisco CMTS. Failure of one connection causes a switch or router to use load balancing across the other connections in the EtherChannel.
- Load balancing on the Cisco CMTS supports dynamic link addition and removal without traffic interruption.
- EtherChannel supports inter-VLAN trunking. Trunking carries traffic from several VLANs over a point-to-point link between the two devices. The network provides inter-VLAN communication with trunking between the Cisco CMTS router and one or more switches. In a campus network, trunking is configured over an EtherChannel link to carry the multiple VLAN information over a high-bandwidth channel.

### Cisco Ten Gigabit EtherChannel on the Cisco cBR Series Routers

Cisco Ten Gigabit EtherChannel (GEC) is high-performance Ethernet technology that provides gigabit-per-second transmission rates. It provides flexible, scalable bandwidth with resiliency and load sharing across links for switches, router interfaces, and servers.

Ten GEC on the Cisco cBR series routers with the following EtherChannel capabilities:

- Supports IEEE 802.1Q encapsulation for inter-VLAN networking.
- Supports a maximum of eight physical Ten Gigabit Ethernet ports to be combined as one logical EtherChannel link.
- Supports bandwidth up to 40 Gbps (half duplex) for a combined total of up to 80 Gbps (full duplex).

## How to Configure EtherChannel on the Cisco CMTS

This section contains the following:

# Configuring Ten Gigabit EtherChannel on the Cisco CMTS

## Before you begin

- Ten Gigabit Ethernet cabling is completed and the ports are operational on the router and network.
- LAN interfaces are configured and operational on the router and network, with IP addresses and subnet masks.

**Note** The Cisco cBR series routers support up to eight physical connectors to be configured as one logical Ten GEC port.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface port-channel *n***
4. **exit**
5. **interface tengigabitethernet *slot/subslot/port***
6. **shutdown**
7. Use one of the following commands:
  - For static Ten GEC configuration, use the **channel-group *number*** command.
  - For dynamic Ten GEC configuration, use the **channel-group *number* mode {active | passive}** command.
8. **no shutdown**
9. **end**

## DETAILED STEPS

|        | Command or Action                                                                                            | Purpose                                                                                                                                                                                                                                                                 |
|--------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                    | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                      |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                            | Enters global configuration mode.                                                                                                                                                                                                                                       |
| Step 3 | <b>interface port-channel <i>n</i></b><br><b>Example:</b><br>Router(config)# <b>interface port-channel 1</b> | Creates an EtherChannel interface. The first EtherChannel interface configured becomes the bundle primary for all ports in the EtherChannel group. The MAC address of the first EtherChannel interface is the MAC address for all EtherChannel interfaces in the group. |

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                                                                                                                                                                                                                                                                                                                      | <p>To remove an EtherChannel interface from the EtherChannel group, use the <b>no</b> form of this command.</p> <p>If the first EtherChannel interface in the group is later removed, the second EtherChannel interface in the group becomes the bundle primary by default.</p> <p>Repeat this step on every EtherChannel port to be bundled into a Ten GEC group. This configuration must be present on all EtherChannel interfaces before the EtherChannel group can be configured.</p> |
| <b>Step 4</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Router(config-if)# exit</pre>                                                                                                                                                                                                                                                                                                                                                         | Exits interface configuration mode and returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 5</b> | <p><b>interface tengigabitethernet slot/subslot/port</b></p> <p><b>Example:</b></p> <pre>Router# interface gigabitethernet 4/1/0</pre>                                                                                                                                                                                                                                                                                               | <p>Selects the Ten Gigabit Ethernet interface that you wish to add as a member EtherChannel link in the EtherChannel bundle, and enters interface configuration mode.</p> <p><b>Note</b> We recommend that the link being added to the Cisco CMTS EtherChannel be shut down prior to configuring it as a member of the EtherChannel. Use the <b>shutdown</b> command in interface configuration mode immediately before completing the following steps in this procedure.</p>             |
| <b>Step 6</b> | <p><b>shutdown</b></p> <p><b>Example:</b></p> <pre>Router(config-if)# shutdown</pre>                                                                                                                                                                                                                                                                                                                                                 | Shuts down the interface selected in step 5 before configuring it as a member of the EtherChannel.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 7</b> | <p>Use one of the following commands:</p> <ul style="list-style-type: none"> <li>For static Ten GEC configuration, use the <b>channel-group number</b> command.</li> <li>For dynamic Ten GEC configuration, use the <b>channel-group number mode {active   passive}</b> command.</li> </ul> <p><b>Example:</b></p> <pre>Router(config-if)# channel-group 1</pre> <p>or</p> <pre>Router(config-if)# channel-group 1 mode active</pre> | <p>Adds the Ten Gigabit Ethernet interface to the EtherChannel Group, associating that interface with an EtherChannel link.</p> <p>To remove an EtherChannel group and the associated ports from the Cisco CMTS, use the <b>no</b> form of this command.</p>                                                                                                                                                                                                                              |
| <b>Step 8</b> | <p><b>no shutdown</b></p> <p><b>Example:</b></p>                                                                                                                                                                                                                                                                                                                                                                                     | Enables the interface on which EtherChannel is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                |

|               | Command or Action                                                 | Purpose                                                                                                             |
|---------------|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
|               | <code>Router(config-if)# no shutdown</code>                       |                                                                                                                     |
| <b>Step 9</b> | <b>end</b><br><b>Example:</b><br><code>Router(config)# end</code> | Returns to privileged EXEC mode.<br>IP traffic should be visible on the network with completion of the above steps. |

## Troubleshooting Tips

Once interface operations are confirmed (prior to this procedure), and EtherChannel configurations have been verified (next procedure), any difficulty experienced through the EtherChannel links may pertain to inter-VLAN or IP routing on the network, or perhaps very high bandwidth consumption.

## What to Do Next

Additional IP, access list, inter-VLAN or load balancing configurations may be made to the Cisco CMTS and these changes will be supported in the running EtherChannel configuration without service disruption from EtherChannel.

## Verifying EtherChannel on the Cisco CMTS

Links can be added or removed from an EtherChannel interface without traffic interruption. If an Ethernet link in an EtherChannel interface fails, traffic previously carried over the failed link switches to the remaining links within the EtherChannel. There are a number of events that can cause a link to be added or removed including adding or removing a link using commands and simulating link failure and recovery (as with (no)shutdown links).

Cisco EtherChannel supports online insertion and removal (OIR) of field-replaceable units (FRUs) in the Cisco CMTS chassis. Ports that remain active during OIR of one FRU will take over and support the traffic bandwidth requirements without service disruption. However, OIR is not described in this procedure.

### Procedure

|               | Command or Action                                                                                                    | Purpose                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><code>Router&gt; enable</code>                                                   | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>show interface port-channel <i>n</i></b><br><b>Example:</b><br><code>Router# show interface port-channel 1</code> | Verifies the EtherChannel configuration on the Cisco CMTS for the selected EtherChannel group.                     |

# Configuration Examples for EtherChannel on the Cisco CMTS

The following example illustrates Ten Gigabit EtherChannel information for the port-channel interface of 2.

This configuration is comprised of three Ten GEC port channels as follows:

- Member 0 is the Ten GEC interface bundle primary.
- Member 2 is the final subsidiary interface in this Ten GEC group.
- These three port-channel interfaces (members) comprise one Ten GEC group that is set up with a Ten GEC peer on the network.

```
Router# show interface port-channel 2
Port-channel2 is up, line protocol is up
Hardware is GEChannel, address is 8888.8888.8888 (bia 0000.0000.0000)
Internet address is 101.101.101.1/16
MTU 1500 bytes, BW 3000000 Kbit, DLY 10 usec,
 reliability 255/255, txload 1/255, rxload 1/255
Encapsulation ARPA, loopback not set
Keepalive set (10 sec)
ARP type: ARPA, ARP Timeout 04:00:00
 No. of members in this channel: 3
 No. of configured members in this channel: 3
 No. of passive members in this channel: 0
 No. of active members in this channel: 3
 Member 0 : TenGigabitEthernet4/1/0 , Full-duplex, 1000Mb/s
 Member 1 : TenGigabitEthernet4/1/1 , Full-duplex, 1000Mb/s
 Member 2 : TenGigabitEthernet4/1/2 , Full-duplex, 1000Mb/s
 No. of Non-active members in this channel: 0
Last input 00:00:02, output never, output hang never
Last clearing of "show interface" counters never
Input queue: 0/225/0/0 (size/max/drops/flushes); Total output drops: 0
Queueing strategy: fifo
Output queue: 0/120 (size/max)
30 second input rate 17292000 bits/sec, 9948 packets/sec
30 second output rate 17315000 bits/sec, 9935 packets/sec
866398790 packets input, 3324942446 bytes, 0 no buffer
Received 2 broadcasts, 0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
0 watchdog, 0 multicast, 0 pause input
0 input packets with dribble condition detected
866394055 packets output, 3323914794 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier, 0 pause output
0 output buffer failures, 0 output buffers swapped out
```

## Feature Information for EtherChannel on Cisco CMTS

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 134: Feature Information for EtherChannel on Cisco CMTS*

| Feature Name               | Releases                    | Feature Information                                                                                              |
|----------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------|
| EtherChannel on Cisco CMTS | Cisco IOS XE Everest 16.6.1 | This feature was integrated into Cisco IOS XE Everest 16.6.1 on the Cisco cBR Series Converged Broadband Router. |

## CHAPTER 51

# Flow-Based per Port-Channel Load Balancing

The Flow-Based per Port-Channel Load Balancing feature allows different flows of traffic over a Ten Gigabit EtherChannel (GEC) interface to be identified based on the packet header and then mapped to the different member links of the port channel. This feature enables you to apply flow-based load balancing and VLAN-manual load balancing to specific port channels.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Restrictions for Flow-Based per Port-Channel Load Balancing

- Supports up to 64 Ten GEC interfaces.
- Supports up to 8 member links per Ten GEC interface.
- dot1q L2VPN is not supported over a port-channel with load-balancing vlan configured.

## Information About Flow-Based per Port-Channel Load Balancing

### Flow-Based Load Balancing

Flow-based load balancing identifies different flows of traffic based on the key fields in the data packet. For example, IPv4 source and destination IP addresses can be used to identify a flow. The various data traffic flows are then mapped to the different member links of a port channel. After the mapping is done, the data traffic for a flow is transmitted through the assigned member link. The flow mapping is dynamic and changes

when there is any change in the state of a member link to which a flow is assigned. The flow mappings can also change if member links are added to or removed from the GEC interface. Multiple flows can be mapped to each member link.

## Buckets for Flow-Based Load Balancing

Load balancing dynamically maps traffic flows to the member links of a Ten GEC interface through the concept of buckets. The various defined traffic flows are mapped to the buckets and the buckets are evenly distributed among the member links. Each port channel maintains 16 buckets, with one active member link associated with each bucket. All traffic flows mapped to a bucket use the member link to which the bucket is assigned.

The router creates the buckets-to-member links mappings when you apply flow-based load balancing to a port channel and the port channel has at least one active member link. The mappings are also created when the first member link is added, or comes up, and the load-balancing method is set to flow-based.

When a member link goes down or is removed from a port channel, the buckets associated with that member link are redistributed among the other active member links in a round-robin fashion. When a member link comes up or is added to a port channel, some of the buckets associated with other links are assigned to this link.

If you change the load-balancing method, the bucket-to-member link mappings for flow-based load balancing are deleted. The mappings are also deleted if the port channel is deleted or the last member link in the port channel is deleted or goes down.

## Load Balancing on Port Channels

GEC interfaces can use either dynamic flow-based load balancing or VLAN-manual load balancing. You can configure the load-balancing method globally for all port channels or directly on specific port channels. The global configuration applies only to those port channels for which you have not explicitly configured load balancing. The port-channel configuration overrides the global configuration.

Flow-based load balancing is enabled by default at the global level. You must explicitly configure VLAN load balancing or the load-balancing method is flow-based.

The table below lists the load-balancing method that is applied to port channels based on the configuration:

**Table 136: Flow-Based Load Balancing Configuration Options**

| Global Configuration | Port-Channel Configuration | Load Balancing Applied |
|----------------------|----------------------------|------------------------|
| Not configured       | Not configured             | Flow-based             |
|                      | Flow-based                 | Flow-based             |
|                      | VLAN-manual                | VLAN-manual            |
| VLAN-manual          | Not configured             | VLAN-manual            |
|                      | Flow-based                 | Flow-based             |
|                      | VLAN-manual                | VLAN-manual            |

The table below lists the configuration that results if you change the global load-balancing method.

**Table 137: Results When Global Configuration Changes**

| Port-Channel Configuration | Global Configuration |                | Action Taken at Port-Channel           |
|----------------------------|----------------------|----------------|----------------------------------------|
|                            | From                 | To             |                                        |
| —                          | From                 | To             | —                                      |
| Not configured             | Not configured       | VLAN-manual    | Changed from flow-based to VLAN-manual |
|                            | VLAN-manual          | Not configured | Changed from VLAN-manual to flow-based |
| Configured                 | Any                  | Any            | No change                              |

The table below lists the configuration that results if you change the port-channel load-balancing method.

**Table 138: Results When Port-Channel Configuration Changes**

| Port-Channel Configuration | Global Configuration |                | Action Taken at Port-Channel           |
|----------------------------|----------------------|----------------|----------------------------------------|
|                            | From                 | To             |                                        |

# How to Enable Flow-Based per Port-Channel Load Balancing

## Configuring Load Balancing on a Port Channel

To configure load balancing on a port channel, perform the following steps. Repeat these steps for each GEC interface.

### Before you begin

If you have already configured your desired load-balancing method globally and want to use that method for all port channels, you need not perform this task. To configure load balancing globally, use the **port-channel load-balancing vlan-manual** command. If you do not configure the global command, flow-based load balancing is applied to all port channels.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface port-channel** *channel-number*
4. **load-balancing** { **flow** | **vlan** }
5. **end**

### DETAILED STEPS

|        | Command or Action                    | Purpose                                                                 |
|--------|--------------------------------------|-------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b> | Enables privileged EXEC mode.<br><br>• Enter your password if prompted. |

|               | Command or Action                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Router> enable                                                                                                     |                                                                                                                                                                                                                                                                                                                            |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Router# configure terminal                                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                          |
| <b>Step 3</b> | <b>interface port-channel <i>channel-number</i></b><br><b>Example:</b><br>Router(config)# interface port-channel 1 | Enters interface configuration mode and defines the interface as a port channel.                                                                                                                                                                                                                                           |
| <b>Step 4</b> | <b>load-balancing { flow   vlan }</b><br><b>Example:</b><br>Router(config-if)# load-balancing flow                 | Applies a load-balancing method to the specific port channel. <ul style="list-style-type: none"> <li>If you do not configure this command, the port channel uses the global load-balancing method configured with the <b>port-channel load-balancing vlan-manual</b> command. The global default is flow-based.</li> </ul> |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Router(config-if)# end                                                            | Exits configuration mode.                                                                                                                                                                                                                                                                                                  |

## Verifying Load Balancing Configuration on a Ten GEC Interface

- **show running-config interface port-channel *channel-number***—Displays the port channel configuration.

Following is a sample output of this command:

```
Router# show running-config interface port-channel 62
Building configuration...

Current configuration : 108 bytes
!
interface Port-channel62
 ip address 12.1.1.1 255.255.255.0
 ipv6 address 2001:12:1:1::1/64
 mpls
```

- **show etherchannel load-balancing**—Displays the load balancing method applied to each port channel.

The following is a sample output of this command:

```
Router# show etherchannel load-balancing

EtherChannel Load-Balancing Method:
Global LB Method: flow-based

Port-Channel: LB Method
```

```

Port-channel62 : flow-based
Port-channel63 : flow-based

```

- **show interfaces port-channel channel-number etherchannel** —Displays the bucket distribution currently in use.

The following is a sample output for an interface with load balancing set to flow-based:

```
Router(config)# show interface port-channel 62 etherchannel
```

```
All IDBs List contains 8 configured interfaces

# Configuration Examples for Flow-Based per Port-Channel Load Balancing

## Example: Flow-Based Load Balancing

The following example shows a configuration where flow-based load balancing is configured on port-channel 2 while the VLAN-manual method is configured globally:

```
!
no aaa new-model
port-channel load-balancing vlan-manual
ip source-route
.
.
.
interface Port-channel2
 ip address 10.0.0.1 255.255.255.0
 no negotiation auto
 load-balancing flow
!
interface Port-channel2.10
 ip rsvp authentication key 11223344
 ip rsvp authentication
!
interface Port-channel2.50
 encapsulation dot1Q 50
!
interface TenGigabitEthernet4/1/0
 no ip address
 negotiation auto
 cdp enable
 channel-group 2
!
```

## Feature Information for Flow-Based per Port-Channel Load Balancing

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 139: Feature Information for Flow-Based per Port-Channel Load Balancing*

| Feature Name                               | Releases                    | Feature Information                                                                                           |
|--------------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------|
| Flow-based per port-channel Load balancing | Cisco IOS XE Everest 16.6.1 | This feature was integrated into Cisco IOS XE Everest 16.6.1 on Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 52

# MPLS QoS via TLV for non-L2VPN Service Flow

The MPLS QoS via TLV for non-L2VPN Service Flow feature allows to mark TC bits for MPLS L3VPN imposition packets and classify downstream packets based on TC bits of MPLS disposition packets, using vendor-specific TLVs.

## Restrictions for MPLS QoS via TLV for non-L2VPN Service Flow

- This feature supports only IPv4. It will not support IPv6.
- This feature does not support SNMP.
- This feature does not support dynamic service flows.
- Only up to four VPNs and eight upstream service flows per CM can be configured.
- For a VPN, only a maximum of eight DS classifiers (using TC bits in the range from 0 to 7) can be configured.
- If TC bits downstream classifiers are configured for a VPN, then the downstream MPLS packets belonging to the VPN are processed only on TC bits classification. It will not process general IP header field classification.

# Information About MPLS QoS via TLV for non-L2VPN Service Flow

The MPLS QoS via TLV for non-L2VPN Service Flow feature is a QoS enhancement based on MPLS Traffic Class (TC) bits for MPLS L3VPN. The MPLS TC bits were previously known as MPLS EXP bits. RFC 5462 has renamed the MPLS EXP field to MPLS TC field.

For upstream service flow encoding, use Cisco-specific TLV to set TC bits value for MPLS imposition packets. For downstream classifier encoding, use Cisco-specific TLV to implement downstream classification based on TC bits of MPLS disposition packets.

## Configuring MPLS QoS via TLV for non-L2VPN Service Flow

**Note** This feature is configured using a cable modem configuration file and is dependent on the general configuration of the L3VPN.

This section describes how to configure traffic class bits for MPLS imposition and disposition packets and on how to use vendor-specific TLVs with AToM L2VPN and MPLS L3VPN.

### Traffic Class for MPLS Imposition Packets

The table lists the vendor-specific TLV to be included in the cable modem configuration file to configure TC bits for MPLS imposition packets. The MPLS-TC-SET TLV is defined in the upstream and is associated with the VPN RD in upstream service flow encoding.

*Table 141: TLV to Configure TC Bits for MPLS Imposition Packets*

| TLV Name        | SubType    | Length | Value                       |
|-----------------|------------|--------|-----------------------------|
| MPLS-TC-SET TLV | 43.5.43.34 | 1      | Imposition MPLS-TC-SET bits |

### Traffic Classification for MPLS Disposition Packets

The table lists the vendor-specific TLV to be included in the cable modem configuration file to classify DS packets based on TC bits of MPLS disposition packets.

The MPLS-TC-RANGE TLV is defined only under DS classifier encodings. It supports multi-downstream flow in a CM belonging to the same MPLS L3VPN, associated with the VPN RD in downstream classifier encoding.

*Table 142: TLV to Classify TC Bits for MPLS Disposition Packets*

| TLV Name      | SubType    | Length | Value                        |
|---------------|------------|--------|------------------------------|
| MPLS-TC-RANGE | 43.5.43.35 | 2      | MPLS-TC-low and MPLS-TC-high |

## Using Vendor-Specific TLVs with AToM L2VPN and MPLS L3VPN

If both AToM L2VPN (L2 MPLS) and MPLS L3VPN (L3 MPLS) are using the same set of TLVs (MPLS-TC-SET and MPLS-TC-RANGE), then you should differentiate them. Configure the TLVs for upstream service flow encoding and downstream classifier encodings as indicated below:

### Upstream Service Flow Encoding

- For L2VPN, configure MPLS-TC-SET (43.5.43.34) and L2VPN ID (43.5.1).
- For MPLS L3VPN, configure MPLS-TC-SET (43.5.43.34) and VPN RD (43.5.1).

**Note** Do not configure the TLVs for L2VPN and MPLS L3VPN at the same time for upstream service flow encodings, as it will result in a TLV error.

### Downstream Classifier Encoding

- L2VPN—Configure MPLS-TC-RANGE (43.5.43.35) and L2VPN ID (43.5.1).
- MPLS L3VPN—Configure MPLS-TC-RANGE (43.5.43.35) and VPN RD (43.5.1).

## Configuration Examples

This section provides the following configuration examples:

### Example: Upstream Service Flow Marking TLV

The following example shows a sample CM configuration TLV for the provisioning of TC bits for MPLS imposition packets:

```
24 (Upstream Service Flow Encoding)
 S01 (Service Flow Reference) = 2
 S06 (QoS Parameter Set Type) = 7
 S43 (Vendor Specific Options)
 T08 (Vendor ID) = 00 00 0c
 T004 (VPN Route Distinguisher) = xx xx xx xx xx xx xx xx
 S005 (Vendor specific L2VPN TLV)
 S043 (Cisco Vendor Specific)
 T034 (MPLS-TC-SET) = 04 # MPLSTC-SET = 4
```

### Example: Downstream Packet Classification TLV

The following example shows a sample CM configuration TLV for classifying downstream packets based on TC bits of MPLS disposition packets:

```
23 (Downstream Packet Classification Encoding)
 S01 (Classifier Reference) = 13
 S03 (Service Flow Reference) = 13
 S11 (IEEE 802.1P/Q Packet Classification Encodings)
 S43 (Vendor Specific Options)
 T08 (Vendor ID) = 00 00 0c
```

```

S004 (VPN Route Distinguisher) = xx xx xx xx xx xx xx xx
S005 (Vendor specific L2VPN TLV)
S043 (Cisco Vendor Specific)
S035 (MPLS-TC-RANGE) = 04 05 # MPLSTC-EGRESS_RANGE= 4 - 5

```

## Example: MPLS QoS Configuration File

The following example shows a cable modem being configured to mark TC bits for MPLS L3VPN imposition packets and classify downstream packets based on TC bits of MPLS L3VPN disposition packets, using vendor-specific TLVs:

```

CM-CONFIG
=====
03 (Net Access Control) = 1

## Feature Information for MPLS QoS via TLV for non-L2VPN Service Flow

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 143: Feature Information for MPLS QoS via TLV for non-L2VPN Service Flow**

# DHCP, ToD, and TFTP Services for CMTS Routers

This document describes how to configure Cisco Cable Modem Termination System (CMTS) platforms so that they support onboard servers that provide Dynamic Host Configuration Protocol (DHCP), Time-of-Day (ToD), and Trivial File Transfer Protocol (TFTP) services for use in Data-over-Cable Service Interface Specification (DOCSIS) networks. In addition, this document provides information about optional configurations that can be used with external DHCP servers.

- [Configuration Examples, on page 798](#)
- [Additional References, on page 799](#)
- [Feature Information for the DHCP, ToD, and TFTP Services for the CMTS Routers, on page 799](#)

## Prerequisites for DHCP, ToD, and TFTP Services

To use the Cisco CMTS as the ToD server, either standalone or with other external ToD servers, you must configure the DHCP server to provide the IP address of the Cisco CMTS as one of the valid ToD servers (DHCP option 4) for cable modems.

## Restrictions for DHCP, ToD, and TFTP Services

- The ToD server must use the UDP protocol to conform to DOCSIS specifications.
- For proper operation of the DOCSIS network, especially a DOCSIS 1.1 network using BPI+ encryption and authentication, the system clock on the Cisco CMTS must be set accurately. You can achieve this by manually using the **set clock** command, or by configuring the CMTS to use either the Network Time Protocol (NTP) or the Simple Network Time Protocol (SNTP).
- Cisco cBR series routers do not support internal DHCP servers.

# Information About DHCP, ToD, and TFTP Services

This section provides the following information about the DHCP, ToD, and TFTP Services feature, and its individual components:

## Feature Overview

All Cisco CMTS platforms support onboard servers that provide DHCP, ToD, and TFTP proxy-services for use in DOCSIS cable networks. These servers provide the registration services needed by DOCSIS 1.0- and 1.1-compliant cable modems:

- **External DHCP Servers**—Provides DHCP services. External DHCP servers are usually part of an integrated provisioning system that is more suitable when managing large cable networks.
- **Time-of-DayServer\_**—Provides an [RFC 868](#) -compliant ToD service so that cable modems can obtain the current date and time during the registration process. The cable modem connects with the ToD server after it has obtained its IP address and other DHCP-provided IP parameters.

Although cable modems do not need to successfully complete the ToD request before coming online, this allows them to add accurate timestamps to their event logs so that these logs are coordinated to the clock used on the CMTS. In addition, having the accurate date and time is essential if the cable modem is trying to register with Baseline Privacy Interface Plus (BPI+) encryption and authentication.

- **External TFTP\_Server**—Downloads the DOCSIS configuration file to the cable modem. The DOCSIS configuration file contains the operational parameters for the cable modem. The cable modem downloads its DOCSIS configuration file after connecting with the ToD server.

---

**Note** You can add additional servers in a number of ways. For example, most cable operators use Cisco Network Registrar (CNR) to provide the DHCP and TFTP servers. ToD servers are freely available for most workstations and PCs. You can install the additional servers on one workstation or PC or on different workstations and PCs.

---

## External DHCP Servers

The Cisco CMTS router provides the following optional configurations that can enhance the operation and security of external DHCP servers that you are using on the DOCSIS cable network:

### Cable Source Verify Feature

To combat theft-of-service attacks, you can enable the **cable source-verify** command on the cable interfaces on the Cisco CMTS router. This feature uses the router's internal database to verify the validity of the IP packets that the CMTS receives on the cable interfaces, and provides three levels of protection:

- At the most basic level of protection, the Cable Source Verify feature examines every IP upstream packet to prevent duplicate IP addresses from appearing on the cable network. If a conflict occurs, the Cisco CMTS recognizes only packets coming from the device that was assigned the IP address by the DHCP server. The devices with the duplicate addresses are not allowed network address. The CMTS also refuses to recognize traffic from devices with IP addresses that have network addresses that are unauthorized for that particular cable segment.

- Adding the **dhcp** option to the **cable source-verify** command provides a more comprehensive level of protection by preventing users from statically assigning currently-unused IP addresses to their devices. When the Cisco CMTS receives a packet with an unknown IP address on a cable interface, the CMTS drops the packet but also issues a DHCP LEASEQUERY message that queries the DHCP servers for any information about the IP and MAC addresses of that device. If the DHCP servers do not return any information about the device, the CMTS continues to block the network access for that device.
- When you use the **dhcp** option, you can also enable the **leasetimer** option, which instructs the Cisco CMTS to periodically check its internal CPE database for IP addresses whose lease times have expired. The CPE devices that are using expired IP addresses are denied further access to the network until they renew their IP addresses from a valid DHCP server. This can prevent users from taking DHCP-assigned IP addresses and assigning them as static addresses to their CPE devices.
- In addition to the **dhcp** option, you can also configure prefix-based source address verification (SAV) on the Cisco CMTS using the **cable source-verify** group command. A CM may have a static IPv4 or IPv6 prefix configured, which belongs to an SAV group. When the SAV prefix processing is enabled on the Cisco CMTS, the source IP address of the packets coming from the CM is matched against the configured prefix and SAV group (for that CM) for verification. If the verification fails, the packets are dropped, else the packets are forwarded for further processing. For more information on SAV prefix processing and SAV prefix configuration, see [Prefix-based Source Address Verification , on page 783](#) and [Configuring Prefix-based Source Address Verification, on page 793](#)

## Prefix-based Source Address Verification

The Source Address Verification (SAV) feature verifies the source IP address of an upstream packet to ensure that the SID/MAC and IP are consistent. The DOCSIS 3.0 Security Specification introduces prefix-based SAV where every CM may have static IPv4 or IPv6 prefixes configured. These prefixes are either preconfigured on the CMTS, or are communicated to the CMTS during CM registration. The Cisco CMTS uses these configured prefixes to verify the source IP address of all the incoming packets from that CM.

An SAV group is a collection of prefixes. A prefix is an IPv4 or IPv6 subnet address. You can use the **cable source-verify group** command in global configuration mode to configure SAV groups. A total of 255 SAV groups are supported on a CMTS, with each SAV group having a maximum of four prefixes. Prefixes can be configured using the **prefix** command.

During registration, CMs communicate their configured static prefixes to the CMTS using two TLVs, 43.7.1 and 43.7.2. The TLV 43.7.1 specifies the SAV prefix group name that the CM belongs to, and TLV 43.7.2 specifies the actual IPv4 or IPv6 prefix. Each CM can have a maximum of four prefixes configured. When the Cisco CMTS receives these TLVs, it first identifies if the specified SAV group and the prefixes are already configured on the Cisco CMTS. If they are configured, the Cisco CMTS associates them to the registering CM. However if they are not configured, the Cisco CMTS automatically creates the specified SAV group and prefixes before associating them to the registering CM.

The SAV group name and the prefixes that are provided by these TLVs are considered valid by the Cisco CMTS. The packets received (from the CM) with the source IP address belonging to the prefix specified by the TLV are considered authorized. For example, if a given CM has been configured with an SAV prefix of 10.10.10.0/24, then any packet received from this CM (or CPE behind the CM) that is sourced with this address in the subnet 10.10.10.0/24 is considered to be authorized.

For more information on how to configure SAV groups and prefixes see [Configuring Prefix-based Source Address Verification, on page 793](#).

## Smart Relay Feature

The Cisco CMTS supports a Smart Relay feature (the **ip dhcp smart-relay** command), which automatically switches a cable modem or CPE device to secondary DHCP servers or address pools if the primary server

runs out of IP addresses or otherwise fails to respond with an IP address. The relay agent attempts to forward DHCP requests to the primary server three times. After three attempts with no successful response from the primary, the relay agent automatically switches to the secondary server.

When you are using the **cable dhcp-giaddr policy** command to specify that the CPE devices should use the secondary DHCP pools corresponding to the secondary addresses on a cable interface, the smart relay agent automatically rotates through the available secondary in a round robin fashion until an available pool of addresses is found. This ensures that clients are not locked out of the network because a particular pool has been exhausted.

## GIADDR Field

When using separate IP address pools for cable modems and CPE devices, you can use the **cable dhcp-giaddr policy** command to specify that cable modems should use an address from the primary pool and that CPE devices should use addresses from the secondary pool. The default is for the CMTS to send all DHCP requests to the primary DHCP server, while the secondary servers are used only if the primary server does not respond. The different DHCP servers are specified using the **cable helper** commands.

## DHCP Relay Agent Sub-option

The DHCP Relay Agent Information sub-option (DHCP Option 82, Suboption 9) enhancement simplifies provisioning of the CPE devices. Using this sub-option, the cable operators can relay the service class or QoS information of the CPE to the DHCP server to get an appropriate IP address.

To provision a CPE, the DHCP server should be made aware of the service class or QoS information of the CPE. The DHCP server obtains this information using the DHCP DISCOVER message, which includes the service class or QoS information of the CM behind which the CPE resides.

During the provisioning process, the Cisco CMTS uses the DHCPv4 Relay Agent Information sub-option to advertise information about the service class or QoS profile of the CMs to the DHCP server. Using the same technique, the CPE information is relayed to the DHCP server to get an appropriate IP address.

To enable the service classes option, the service class name specified in the CM configuration file must be configured on the Cisco CMTS. This is done by using the **cable dhcp-insert service-class** command.

---

**Note** To insert service class relay agent information option into the DHCP DISCOVER messages, the **ip dhcp relay information option-insert** command must be configured on the bundle interface.

---

## Time-of-Day Server

The Cisco CMTS can function as a ToD server that provides the current date and time to the cable modems and other customer premises equipment (CPE) devices connected to its cable interfaces. This allows the cable modems and CPE devices to accurately timestamp their Simple Network Management Protocol (SNMP) messages and error log entries, as well as ensure that all of the system clocks on the cable network are synchronized to the same system time.

The DOCSIS 1.0 and 1.1 specifications require that all DOCSIS cable modems request the following time-related fields in the DHCP request they send during their initial power-on provisioning:

- Time Offset (option 2)—Specifies the time zone for the cable modem or CPE device, in the form of the number of seconds that the device's timestamp is offset from Greenwich Mean Time (GMT).

- Time Server Option (option 4)—Specifies one or more IP addresses for a ToD server.

After a cable modem successfully acquires a DHCP lease time, it then attempts to contact one of the ToD servers provided in the list provided by the DHCP server. If successful, the cable modem updates its system clock with the time offset and timestamp received from the ToD server.

If a ToD server cannot be reached or if it does not respond, the cable modem eventually times out, logs the failure with the CMTS, and continues on with the initialization process. The cable modem can come online without receiving a reply from a ToD server, but it must periodically continue to reach the ToD server at least once in every five-minute period until it successfully receives a ToD reply. Until it reaches a ToD server, the cable modem must initialize its system clock to midnight on January 1, 1970 GMT.

---

**Note** Initial versions of the DOCSIS 1.0 specification specified that the cable device must obtain a valid response from a ToD server before continuing with the initialization process. This requirement was removed in the released DOCSIS 1.0 specification and in the DOCSIS 1.1 specifications. Cable devices running older firmware that is compliant with the initial DOCSIS 1.0 specification, however, might require receiving a reply from a ToD server before being able to come online.

---

Because cable modems will repeatedly retry connecting with a ToD server until they receive a successful reply, you should consider activating the ToD server on the Cisco CMTS, even if you have one or more other ToD servers at the headend. This ensures that an online cable modem will always be able to connect with the ToD server on the Cisco CMTS, even if the other servers go down or are unreachable because of network congestion, and therefore will not send repeated ToD requests.

---

**Tip** To be able to use the Cisco CMTS as the ToD server, you must configure the DHCP server to provide the IP address Cisco CMTS as one of the valid ToD servers (DHCP option 4) for cable modems.

---

In addition, although the DOCSIS specifications do not require that a cable modem successfully obtain a response from a ToD server before coming online, not obtaining a timestamp could prevent the cable modem from coming online in the following situations:

- If DOCSIS configuration files are being timestamped, to prevent cable modems from caching the files and replaying them, the clocks on the cable modem and CMTS must be synchronized. Otherwise, the cable modem cannot determine whether a DOCSIS configuration file has the proper timestamp.
- If cable modems register using Baseline Privacy Interface Plus (BPI+) authentication and encryption, the clocks on the cable modem and CMTS must be synchronized. This is because BPI+ authorization requires that the CMTS and cable modem verify the timestamps on the digital certificates being used for authentication. If the timestamps on the CMTS and cable modem are not synchronized, the cable modem cannot come online using BPI+ encryption.

---

**Note** DOCSIS cable modems must use [RFC 868](#) -compliant ToD server to obtain the current system time. They cannot use the Network Time Protocol (NTP) or Simple Network Time Protocol (SNTP) service for this purpose. However, the Cisco CMTS can use an NTP or SNTP server to set its own system clock, which can then be used by the ToD server. Otherwise, you must manually set the clock on the CMTS using the **clock set** command each time that the CMTS boots up.

---

---

**Tip** Additional servers can be provided by workstations or PCs installed at the cable headend. UNIX and Solaris systems typically include a ToD server as part of the operating system, which can be enabled by putting the appropriate line in the `inetd.conf` file. Windows systems can use shareware servers such as Greyware and Tardis. The DOCSIS specifications require that the ToD servers use the User Datagram Protocol (UDP) protocol instead of the TCP protocol for its packets.

---

## TFTP Server

All Cisco CMTS platforms can be configured to provide a TFTP server that can provide the following types of files to DOCSIS cable modems:

- **DOCSIS Configuration File**—After a DOCSIS cable modem has acquired a DHCP lease and attempted to contact a ToD server, the cable modem uses TFTP to download a DOCSIS configuration file from an authorized TFTP server. The DHCP server is responsible for providing the name of the DOCSIS configuration file and IP address of the TFTP server to the cable modem.
- **Software Upgrade File**—If the DOCSIS configuration file specifies that the cable modem must be running a specific version of software, and the cable modem is not already running that software, the cable modem must download that software file. For security, the cable operator can use different TFTP servers for downloading DOCSIS configuration files and for downloading new software files.
- **Cisco IOS-XE Configuration File**—The DOCSIS configuration file for Cisco cable devices can also specify that the cable modem should download a Cisco IOS-XE configuration file that contains command-line interface (CLI) configuration commands. Typically this is done to configure platform-specific features such as voice ports or IPSec encryption.

---

**Note** Do not confuse the DOCSIS configuration file with the Cisco IOS-XE configuration file. The DOCSIS configuration file is a binary file in the particular format that is specified by the DOCSIS specifications, and each DOCSIS cable modem must download a valid file before coming online. In contrast, the Cisco IOS-XE configuration file is an ASCII text file that contains one or more Cisco IOS-XE CLI configuration commands. Only Cisco cable devices can download a Cisco IOS-XE file.

---

All Cisco CMTS platforms can be configured as TFTP servers that can upload these files to the cable modem. The files can reside on any valid device but typically should be copied to the Flash memory device inserted into the Flash disk slot on the Cisco CMTS.

## Benefits

- The Cisco CMTS can act as a primary or backup ToD server to ensure that all cable modems are synchronized with the proper date and time before coming online. This also enables cable modems to come online more quickly because they will not have to wait for the ToD timeout period before coming online.
- The ToD server on the Cisco CMTS ensures that all devices connected to the cable network are using the same system clock, making it easier for you to troubleshoot system problems when you analyze the debugging output and error logs generated by many cable modems, CPE devices, the Cisco CMTS, and other services.

- The Cisco CMTS can act as a TFTP server for DOCSIS configuration files, software upgrade files, and Cisco IOS configuration files.

## How to Configure ToD, and TFTP Services

See the following configuration tasks required to configure time-of-day service, and TFTP service on a Cisco CMTS:

### Configuring Time-of-Day Service

This section provides procedures for enabling and disabling the time-of-day (ToD) server on the Cisco CMTS routers.

#### Prerequisites

To be able to use the Cisco CMTS as the ToD server you must configure the DHCP server to provide the IP address Cisco CMTS as one of the valid ToD servers (DHCP option 4) for cable modems.

### Enabling Time-of-Day Service

To enable the ToD server on a Cisco CMTS, use the following procedure, beginning in EXEC mode.

#### Procedure

|        | Command or Action                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                              |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable Router#</pre>                                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal Router(config)#</pre>                                                                 | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                    |
| Step 3 | <b>service udp-small-servers max-servers no-limit</b><br><b>Example:</b><br><pre>Router(config)# service udp-small-servers max-servers no-limit Router(config)#</pre> | <p>Enables use of minor servers that use the UDP protocol (such as ToD, echo, chargen, and discard).</p> <p>The max-servers no-limit option allows a large number of cable modems to obtain the ToD server at one time, in the event that a cable or power failure forces many cable modems offline. When the problem has been resolved, the cable modems can quickly reconnect.</p> |
| Step 4 | <b>cable time-server</b><br><b>Example:</b>                                                                                                                           | Enables the ToD server on the Cisco CMTS.                                                                                                                                                                                                                                                                                                                                            |

|               | Command or Action                                                            | Purpose                          |
|---------------|------------------------------------------------------------------------------|----------------------------------|
|               | Router(config)# <b>cable time-server</b><br>Router(config)#                  |                                  |
| <b>Step 5</b> | <b>exit</b><br><b>Example:</b><br><br>Router(config)# <b>exit</b><br>Router# | Exits global configuration mode. |

## Disabling Time-of-Day Service

To disable the ToD server, use the following procedure, beginning in EXEC mode.

### Procedure

|               | Command or Action                                                                                                                    | Purpose                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Router> <b>enable</b><br>Router#                                                             | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                         |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# <b>configure terminal</b><br>Router(config)#                             | Enters global configuration mode.                                                                                                                                      |
| <b>Step 3</b> | <b>no cable time-server</b><br><b>Example:</b><br><br>Router(config)# <b>cable time-server</b><br>Router(config)#                    | Disables the ToD server on the Cisco CMTS.                                                                                                                             |
| <b>Step 4</b> | <b>no service udp-small-servers</b><br><b>Example:</b><br><br>Router(config)# <b>no service udp-small-servers</b><br>Router(config)# | (Optional) Disables the use of all minor UDP servers.<br><br><b>Note</b> Do not disable the minor UDP servers if you are also enabling the other DHCP or TFTP servers. |
| <b>Step 5</b> | <b>exit</b><br><b>Example:</b><br><br>Router(config)# <b>exit</b><br>Router#                                                         | Exits global configuration mode.                                                                                                                                       |

## Configuring TFTP Service

To configure TFTP service on a Cisco CMTS where the CMTS can act as a TFTP server and download a DOCSIS configuration file to cable modems, perform the following steps:

- Create the DOCSIS configuration files using the DOCSIS configuration editor of your choice.
- Copy all desired files (DOCSIS configuration files, software upgrade files, and Cisco IOS configuration files) to the Flash memory device on the Cisco CMTS. Typically, this is done by placing the files first on an external TFTP server, and then using TFTP commands to transfer them to the router's Flash memory.
- Enable the TFTP server on the Cisco CMTS with the **tftp-server** command.

Each configuration task is required unless otherwise listed as optional.

### Step 1

Use the **show file systems** command to display the Flash memory cards that are available on your CMTS, along with the free space on each card and the appropriate device names to use to access each card.

Most configurations of the Cisco CMTS platforms support both linear Flash and Flash disk memory cards. Linear Flash memory is accessed using the **slot0** (or **flash**) and **slot1** device names. Flash disk memory is accessed using the **disk0** and **disk1** device names.

For example, the following command shows a Cisco uBR7200 series router that has two linear Flash memory cards installed. The cards can be accessed by the **slot0** (or **flash**) and **slot1** device names.

#### Example:

```
Router# show file systems
```

```
File Systems:
 Size (b) Free (b) Type Flags Prefixes
 48755200 48747008 flash rw slot0: flash:
 16384000 14284000 flash rw slot1:
 32768000 31232884 flash rw bootflash:
* - - disk rw disk0:
 - - disk rw disk1:
 - - opaque rw system:
 - - opaque rw null:
 - - network rw tftp:
 522232 507263 nvram rw nvram:
 - - network rw rcp:
 - - network rw ftp:
 - - network rw scp:
```

```
Router#
```

The following example shows a Cisco uBR10012 router that has two Flash disk cards installed. These cards can be accessed by the **disk0** and **sec-disk0** device names.

#### Example:

```
Router# show file systems
```

```
File Systems:
 Size (b) Free (b) Type Flags Prefixes
 - - flash rw slot0: flash:
 - - flash rw slot1:
 32768000 29630876 flash rw bootflash:
* 128094208 95346688 disk rw disk0:
```

```

- - disk rw disk1:
- - opaque rw system:
- - flash rw sec-slot0:
- - flash rw sec-slot1:
* 128094208 95346688 disk rw sec-disk0:
- - disk rw sec-disk1:
32768000 29630876 flash rw sec-bootflash:
- - nvram rw sec-nvram:
- - opaque rw null:
- - network rw tftp:
522232 505523 nvram rw nvram:
- - network rw rcp:
- - network rw ftp:
- - network rw scp:
Router#

```

**Step 2** Verify that the desired Flash memory card has sufficient free space for all of the files that you want to copy to the CMTS.

**Step 3** Use the **ping** command to verify that the remote TFTP server that contains the desired files is reachable. For example, the following shows a **ping** command being given to an external TFTP server with the IP address of 10.10.10.1:

**Example:**

```

Router# ping 10.10.10.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.10.10.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 5/6/6 ms

```

**Step 4** Use the **copy tftp devname** command to copy each file from the external TFTP server to the appropriate Flash memory card on the CMTS, where *devname* is the device name for the destination Flash memory card. You will then be prompted for the IP address for the external TFTP server and the filename for the file to be transferred.

The following example shows the file `docsis.cm` being transferred from the external TFTP server at IP address 10.10.10.1 to the first Flash memory disk (disk0):

**Example:**

```

Router# copy tftp disk0
Address or name of remote host []? 10.10.10.1

Source filename []? config-files/docsis.cm

Destination filename [docsis.cm]?
Accessing tftp://10.10.10.1/config-file/docsis.cm.....
Loading docsis.cm from 10.10.10.1 (via Ethernet2/0): !!!
[OK - 276/4096 bytes]
276 bytes copied in 0.152 secs
Router#

```

**Step 5** Repeat [Step 4, on page 790](#) as needed to copy all of the files from the external TFTP server to the Flash memory card on the Cisco CMTS.

**Step 6** Use the **dir** command to verify that the Flash memory card contains all of the transferred files.

**Example:**

```

Router# dir disk0:

Directory of disk0:/
 1 -rw- 10705784 May 30 2002 19:12:46 ubr10k-p6-mz.122-2.8.BC
 2 -rw- 4772 Jun 20 2002 18:12:56 running.cfg.save

```

```
 3 -rw- 241 Jul 31 2002 18:25:46 gold.cm
 4 -rw- 225 Jul 31 2002 18:25:46 silver.cm
 5 -rw- 231 Jul 31 2002 18:25:46 bronze.cm
 6 -rw- 74 Oct 11 2002 21:41:14 disable.cm
 7 -rw- 2934028 May 30 2002 11:22:12 ubr924-k8y5-mz.bin
 8 -rw- 3255196 Jun 28 2002 13:53:14 ubr925-k9v9y5-mz.bin
128094208 bytes total (114346688 bytes free)
Router#
```

**Step 7** Use the **configure terminal** command to enter global configuration mode:

**Example:**

```
Router# configure terminal
Router(config)#
```

**Step 8** Use the **tftp-server** command to specify which particular files can be transferred by the TFTP server that is onboard the Cisco CMTS. You can also use the **alias** option to specify a different filename that the DHCP server can use to refer to the file. For example, the following commands enable the TFTP transfer of the configuration files and software upgrade files:

**Example:**

```
Router(config)# tftp-server disk0:gold.cm alias gold.cm
Router(config)# tftp-server disk0:silver.cm alias silver.cm
Router(config)# tftp-server disk0:bronze.cm alias bronze.cm
Router(config)# tftp-server disk0:ubr924-k8y5-mz.bin alias ubr924-codefile
Router(config)# tftp-server disk0:ubr925-k9v9y5-mz.bin alias ubr925-codefile
Router(config)#
```

**Note** The **tftp-server** command also supports the option of specifying an access list that restricts access to the particular file to the IP addresses that match the access list.

**Step 9** (Optional) Use the following command to enable the use of the UDP small servers, and to allow an unlimited number of connections at one time. This will allow a large number of cable modems that have gone offline due to cable or power failure to rapidly come back online.

**Example:**

```
Router(config)# service udp-small-servers max-servers no-limit
Router(config)#
```

---

## Optimizing the Use of an External DHCP Server

The Cisco CMTS offers a number of options that can optimize the operation of external DHCP servers on a DOCSIS cable network. See the following sections for details. All procedures are optional, depending on the needs of your network and application servers.

## Configuring Cable Source Verify Option

To enhance security when using external DHCP servers, you can optionally configure the Cable Source Verify feature with the following procedure.

### Restriction

- The Cable Source Verify feature supports only external DHCP servers. It cannot be used with the internal DHCP server.

### Procedure

|               | Command or Action                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable Router#</pre>                                                                                                                                                                       | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Step 3</b> | <b>interface cable x/y</b><br><b>Example:</b><br><pre>Router (config) # interface cable 4/0 Router (config-if) #</pre>                                                                                                                         | Enters cable interface configuration mode for the specified cable interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 4</b> | <b>cable source-verify [dhcp   leasetimer value ]</b><br><b>Example:</b><br><pre>Router (config-if) # cable source-verify dhcp</pre> <b>Example:</b><br><pre>Router (config-if) # cable source-verify leasetimer 30 Router (config-if) #</pre> | (Optional) Ensures that the CMTS allows network access only to those IP addresses that DHCP servers issued to devices on this cable interface. The CMTS examines DHCP packets that pass through the cable interfaces to build a database of which IP addresses are valid on which interface. <ul style="list-style-type: none"> <li>• <b>dhcp</b> = (Optional) Drops traffic from all devices with unknown IP addresses, but the CMTS also sends a query to the DHCP servers for any information about the device. If a DHCP server informs the CMTS that the device has a valid IP address, the CMTS then allows the device on the network.</li> <li>• <b>leasetimer value</b> = (Optional) Specifies how often, in minutes, the router should check its internal CPE database for IP addresses whose lease times have expired. This can prevent users from taking DHCP-assigned IP addresses and assigning them as static addresses to their CPE devices. The valid range for value is 1 to 240 minutes, with no default.</li> </ul> |

|               | Command or Action                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                           | <b>Note</b> The <b>leasetimer</b> option takes effect only when the <b>dhcp</b> option is also used on an interface.                                                                                                                                                                                                                                                                                                                  |
| <b>Step 5</b> | <b>no cable arp</b><br><b>Example:</b><br><pre>Router(config-if)# no cable arp Router(config-if)#</pre>                                   | (Optional) Blocks Address Resolution Protocol (ARP) requests originating from devices on the cable network. Use this command, together with the <b>cable source-verify dhcp</b> command, to block certain types of theft-of-service attacks that attempt to hijack or spoof IP addresses.<br><br><b>Note</b> Repeat <a href="#">Step 3, on page 792</a> through <a href="#">Step 5, on page 793</a> for each desired cable interface. |
| <b>Step 6</b> | <b>exit</b><br><b>Example:</b><br><pre>Router(config-if)# exit Router(config)#</pre>                                                      | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 7</b> | <b>ip dhcp relay information option</b><br><b>Example:</b><br><pre>Router(config)# ip dhcp relay information option Router(config)#</pre> | (Optional) Enables the CMTS to insert DHCP relay information (DHCP option 82) in relayed DHCP packets. This allows the DHCP server to store accurate information about which CPE devices are using which cable modems. You should use this command if you are also using the <b>cable source-verify dhcp</b> command.                                                                                                                 |
| <b>Step 8</b> | <b>exit</b><br><b>Example:</b><br><pre>Router(config)# exit Router#</pre>                                                                 | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring Prefix-based Source Address Verification

To enhance security when using external DHCP servers, you can configure a prefix-based SAV with the following procedure, beginning in global configuration (config) mode.

### Procedure

|               | Command or Action                                                        | Purpose                                                        |
|---------------|--------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable Router#</pre> | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b>                             | Enters global configuration mode.                              |

|               | Command or Action                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Configuring Optional DHCP Parameters

When using an external DHCP server, the Cisco CMTS supports a number of options that can enhance operation of the cable network in certain applications. To configure these options, use the following procedure, beginning in EXEC mode.

## Procedure

|               | Command or Action                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal Router(config)#</pre>                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 3</b> | <b>ip dhcp smart-relay</b><br><b>Example:</b><br><pre>Router(config)# ip dhcp smart-relay Router(config)#</pre>                         | (Optional) Enables the DHCP relay agent on the CMTS to automatically switch a cable modem or CPE device to a secondary DHCP server or address pool if the primary DHCP server does not respond to three successive requests. If multiple secondary servers have been defined, the relay agent forwards DHCP requests to the secondary servers in a round robin fashion.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 4</b> | <b>ip dhcp ping packet 0</b><br><b>Example:</b><br><pre>Router(config)# ip dhcp ping packet 0 Router(config)#</pre>                     | (Optional) Instructs the DHCP server to assign an IP address from its pool without first sending an ICMP ping to test whether a client is already currently using that IP address. Disabling the ping option can speed up address assignment when a large number of modems are trying to connect at the same time. However, disabling the ping option can also result in duplicate IP addresses being assigned if users assign unauthorized static IP addresses to their CPE devices.<br><br><b>Note</b> By default, the DHCP server pings a pool address twice before assigning a particular address to a requesting client. If the ping is unanswered, the DHCP server assumes that the address is not in use and assigns the address to the requesting client. |
| <b>Step 5</b> | <b>ip dhcp relay information check</b><br><b>Example:</b><br><pre>Router(config)# ip dhcp relay information check Router(config)#</pre> | (Optional) Configures the DHCP server to validate the relay agent information option in forwarded BOOTREPLY messages. Invalid messages are dropped.<br><br><b>Note</b> The <b>ip dhcp relay information</b> command contains several other options that might be useful for special handling of DHCP packets. See its command reference page in the Cisco IOS-XE documentation for details.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 6</b> | <b>interface cable <i>x/y</i></b><br><b>Example:</b>                                                                                    | Enters cable interface configuration mode for the specified cable interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|               | Command or Action                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <pre>Router(config)# interface cable 4/0 Router(config-if)#</pre>                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 7</b> | <p><b>cable dhcp-giaddr policy</b> [<b>host</b>   <b>stb</b>   <b>mta</b>   <b>ps</b>  <b>profile name</b>] <i>giaddr</i></p> <p><b>Example:</b></p> <pre>Router(config-if)# cable dhcp-giaddr policy mta 172.1.1.10 Router(config-if)#</pre> | <p>Sets the DHCP GIADDR field for DHCP request packets to the primary address for cable modems, and the secondary address for CPE devices. This enables the use of separate address pools for different clients.</p> <ul style="list-style-type: none"> <li>• <b>host</b>—Specifies the GIADDR for hosts.</li> <li>• <b>mta</b>—Specifies the GIADDR for MTAs.</li> <li>• <b>ps</b>—Specifies the GIADDR for PSs.</li> <li>• <b>stb</b>—Specifies the GIADDR for STBs.</li> <li>• <b>profile name</b> Specifies DHCP profile as control policy.</li> <li>• <i>giaddr</i>—IP addresses of the secondary interface of the bundle interface.</li> </ul> <p><b>Note</b> The <b>cable dhcp-giaddr</b> command also supports the <b>primary</b> option. The <b>primary</b> option forces all device types to use only the primary interface IP address as GIADDR and not rotate through the secondary address if the primary address fails.</p>      |
| <b>Step 8</b> | <p><b>cable helper-address</b> <i>address</i> [<b>cable-modem</b>   <b>host</b>   <b>mta</b>   <b>stb</b>] <b>profile name</b>]</p> <p><b>Example:</b></p> <pre>Router(config-if)# cable helper-address 10.10.10.13 Router(config-if)#</pre>  | <p>(Optional) Enables load-balancing of DHCP requests from cable modems and CPE devices by specifying different DHCP servers according to the cable interface or subinterface. You can also specify separate servers for cable modems and CPE devices.</p> <ul style="list-style-type: none"> <li>• <i>address</i> = IP address of a DHCP server to which UDP broadcast packets will be sent via unicast packets.</li> <li>• <b>cable-modem</b> = Specifies this server should only accept cable modem packets (optional).</li> <li>• <b>host</b> = Specifies this server should only accept CPE device packets (optional).</li> <li>• <b>mta</b>—(Optional) Specifies this server should only accept MTA packets .</li> <li>• <b>stb</b> —(Optional) Specifies this server should only accept STB packets .</li> <li>• <b>profile name</b>—(Optional) Specifies that only UDP broadcasts with specific DHCP profile are forwarded.</li> </ul> |

|                | Command or Action                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------|----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                      | <p><b>Note</b> If you do not specify an option, the helper-address will support all cable devices, and the associated DHCP server will accept DHCP packets from all cable device classes.</p> <p><b>Note</b> If you specify only one option, the other types of devices (cable modem, host, mta, or stb) will not be able to connect with a DHCP server. You must specify each desired option in a separate command</p> <p><b>Tip</b> Repeat this command to specify more than one helper address on each cable interface. You can specify more than 16 helper addresses, but the Cisco IOS software uses only the first 16 valid addresses.</p> <p><b>Tip</b> If you configure different helper addresses on different sub-bundles within a bundle, the cable modem may not come online. We recommend that you use the same helper address on all sub-bundles within a bundle.</p> <p><b>Note</b> The <b>ip helper-address</b> command performs a similar function to <b>cable helper-address</b>, but it should be used on non-cable interfaces. The <b>cable helper-address</b> command should be used on cable interfaces because it is optimized for the operation of DHCP requests on DOCSIS networks.</p> |
| <b>Step 9</b>  | <p><b>cable dhcp-giaddr policy</b></p> <p><b>Example:</b></p> <pre>Router(config-if)# cable dhcp-giaddr policy</pre> | Selects the control policy, so the primary address is used for cable modems and the secondary addresses are used for hosts and other customer premises equipment (CPE) devices. This setting is typically used when the CMs on the interface are configured for routing mode, so that the cable modems and hosts can use IP addresses on different subnets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 10</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Router(config-if)# exit Router(config)#</pre>                         | Exits interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 11</b> | <p><b>exit</b></p> <p><b>Example:</b></p>                                                                            | Exits global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## How to Configure ToD, and TFTP Services

See the following configuration tasks required to configure time-of-day service, and TFTP service on a Cisco CMTS:

## Configuration Examples

This section provides examples for the following configurations:

### ToD Server Example

The following example shows a typical ToD server configuration:

```
service udp-small-servers max-servers no-limit
cable time-server
```

These are the only commands required to enable the ToD server.

### TFTP Server Example

The following lines are an excerpt from a configuration that includes a TFTP server. Change the files listed with the **tftp-server** command to match the specific files that are on your system.

```
! Enable the user of unlimited small servers
service udp-small-servers max-servers no-limit
!
...
! Enable the TFTP server and specify the files that can be
! downloaded along with their aliases
tftp-server disk0:gold.cm alias gold.cm
tftp-server disk0:silver.cm alias silver.cm
tftp-server disk0:bronze.cm alias bronze.cm
tftp-server disk0:ubr924-k8y5-mz.bin alias ubr924-codefile
tftp-server disk0:ubr925-k9v9y5-mz.bin alias ubr925-codefile
```

## Feature Information for the DHCP, ToD, and TFTP Services for the CMTS Routers

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfmng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

*Table 144: Feature Information for Downstream Interface Configuration*

| Feature Name                 | Releases                 | Feature Information                                                                                            |
|------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------|
| DHCP, ToD, and TFTP services | Cisco IOS XE Fuji 16.7.1 | This feature was integrated into Cisco IOS XE Fuji 16.7.1 on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 54

# Virtual Interface Bundling

---

Virtual Interface Bundling allows supports combining multiple cable interfaces in a Cisco cBR series router into a single logical bundle, so as to conserve IP address space and simplify network management.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Information About Virtual Interface Bundling

This section contains the following:

### Overview of Virtual Interface Bundling

**Note** All cable bundles are automatically converted and configured to virtual interface bundles. Any standalone cable interfaces must be manually configured to be in a virtual bundle to operate properly.

Virtual interface bundling supports the following:

- Virtual interface bundling uses *bundle interface* and *bundle members* instead of primary or secondary interfaces.
- A virtual bundle interface is virtually defined, as with IP loopback addresses.
- Virtual interface bundling supports bundle information in multiple **show** commands.

- The CISCO-DOCS-EXT-MIB is updated for cable helper-address and IPv6 DHCP relay configurations.

Virtual interface bundling prevents loss of connectivity on physical interfaces should there be a failure, problematic online insertion and removal (OIR) of one line card in the bundle, or erroneous removal of configuration on the primary interface.

Virtual interface bundling supports and governs the following Layer 3 settings for the bundle member interfaces:

- IP address
- IP helper-address
- source-verify and lease-timer functions
- cable dhcp-giaddr (The giaddr field is set to the IP address of the DHCP client.)
- Protocol Independent Multicast (PIM)
- Access control lists (ACLs)
- Sub-interfaces
- IPv6
- 1982 bytes layer 3 MTU.

---

**Note** In case customer wants to test 1982 bytes MTU by issuing a ping from CMTS to DOCSIS 3.1 modem, **cable mtu-override** command needs to be configured. After the test, please remove this configuration using **no cable mtu-override** command. By default, there is no cable mtu-override configured in bundle interface.

---

---

**Note** This virtual interface for the bundle should always remain on (enabled with **no shutdown**).

---

## Guidelines for Virtual Interface Bundling

The following guidelines describe virtual interface bundling:

- Initial configuration of the first virtual bundle *member* automatically creates a virtual bundle interface.
- All cable bundles are automatically converted and configured to be in a virtual bundle after loading the software image.
- Standalone cable interfaces must be manually configured to be in a virtual bundle to operate properly.
- The virtual bundle interface accumulates the counters from members; counters on member links are not cleared when they are added to the bundle. If a bundle-only counter is desired, clear the bundle counter on the members before adding them to the bundle, or before loading the image.
- This feature supports a maximum of 40 virtual interface bundles, with the numeric range from 1 to 255.

- The virtual bundle interface remains configured unless specifically deleted, even if all members in the bundle are deleted.
- This feature supports subinterfaces on the virtual bundle interface.
- *Bundle-aware* configurations are supported on the virtual bundle interface.
- *Bundle-unaware* configurations are supported on each bundle member.
- While creating the virtual bundle interface, if the bundle interface existed in earlier Cisco IOS releases, then the earlier cable configurations re-appear after upgrade.
- When using sub-bundle, all layer 3 configurations must be configured on sub-bundle, instead of main bundle.

## Virtual Interface Bundle-aware and Bundle-unaware Support

Virtual interface bundling uses two configurations: the virtual *bundle* itself, and the interfaces in that virtual bundle, known as *bundle members*. The virtual interface bundle and bundle members are either aware of the bundle, or unaware of the bundle, as follows.

- Bundle-aware features are maintained on the virtual *bundle*. These include:
  - IP Address
  - IP helper, cable helper
  - Dhcp-giaddr
  - Sub-interface
  - Source verify
  - Lease-query
  - Address Resolution Protocol (Cable ARP filtering, which also bundles cable interfaces, and Proxy ARP)
  - Cable match
  - Access Control Lists (ACLs)
  - Protocol Independent Multicast (PIM)
  - Cable Intercept
- Bundle-unaware features are maintained on the *bundle members*. These include:
  - DS/US configurations
  - HCCP redundancy
  - Load balancing
  - DMIC, tftp-enforce, shared-secret
  - Spectrum management
  - Admission control
  - Intercept

# Configuring Virtual Interface Bundling

To enable virtual interface bundling, and to reconfigure interface information on the Cisco CMTS as required, you first configure the virtual interface bundle, then add additional bundle members for the specified virtual bundle. Perform these steps on each interface, as needed for all virtual interface bundles.

## Procedure

|        | Command or Action                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                        |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                                                                                                           | Enters global configuration mode.                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>interface bundle <i>n</i></b><br><b>Example:</b><br><pre>Router(config-if)# interface bundle 1</pre>                                                                                                         | Adds the selected interface to the virtual bundle. If this is the first interface on which the virtual bundle is configured, this command enables the bundle on the specified interface.<br><br>As many as 40 virtual interface bundles can be configured on the Cisco CMTS. Numeric identifiers may range from 1 to 255. |
| Step 4 | <b>ip address <i>address mask</i></b><br><b>Example:</b><br><pre>Router(config-if)# ip address 7.7.7.7 255.255.255.0</pre>                                                                                      | Use as needed after Cisco IOS upgrade.<br><br>Configures the IP address for the specified interface and virtual bundle.                                                                                                                                                                                                   |
| Step 5 | <b>cable helper-address <i>address</i> [<i>cable-modem</i>   <i>host</i>   <i>mta</i>   <i>ps</i>   <i>stb</i>]</b><br><b>Example:</b><br><pre>Router(config-if)# cable helper-address 10.10.10.13</pre>        | (Optional) Specifies the IPv4 DHCP server address.                                                                                                                                                                                                                                                                        |
| Step 6 | <b>cable dhcp-giaddr {<i>primary</i>   <i>policy</i> [<i>host</i>   <i>stb</i>   <i>mta</i>   <i>ps</i>   <i>strict</i>]}</b><br><b>Example:</b><br><pre>Router(config-if)# cable dhcp-giaddr policy host</pre> | Sets the DHCP GIADDR field for DHCP request packets.                                                                                                                                                                                                                                                                      |
| Step 7 | <b>cable source-verify dhcp</b><br><b>Example:</b><br><pre>Router(config-if)# cable source-verify dhcp</pre>                                                                                                    | (Optional) Ensures that the Cisco CMTS allows network access only to those IP addresses that DHCP servers issued to devices on this cable interface. The Cisco CMTS examines the DHCP packets that pass through the cable                                                                                                 |

|                | Command or Action                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                              | interfaces to build a database of which IP addresses are valid on which interface. Drops traffic from all devices with unknown IP addresses, but the Cisco CMTS also sends a query to the DHCP servers for any information about the device. If a DHCP server informs the Cisco CMTS that the device has a valid IP address, the CMTS then allows the device on the network. |
| <b>Step 8</b>  | <b>no cable arp</b><br><b>Example:</b><br>Router(config-if)# <b>no cable arp</b>                             | (Optional) Blocks the static IPv4 CPE from coming online. Also blocks Address Resolution Protocol (ARP) process destined to devices on the cable network.<br><br><b>Note</b> Use this command, together with the <b>cable source-verify dhcp</b> command, to block certain types of scanning attacks that attempt to cause denial of service (DoS) on the Cisco CMTS.        |
| <b>Step 9</b>  | <b>exit</b><br><b>Example:</b><br>Router(config-if)# <b>exit</b>                                             | Exits the interface configuration mode and enters global configuration mode.                                                                                                                                                                                                                                                                                                 |
| <b>Step 10</b> | <b>interface cable slot /subslot/port</b><br><b>Example:</b><br>Router(config)# <b>interface cable 3/0/0</b> | Enters interface configuration mode for the selected interface, on which virtual interface bundling is to be enabled.                                                                                                                                                                                                                                                        |
| <b>Step 11</b> | <b>cable bundle n</b><br><b>Example:</b><br>Router(config-if)# <b>cable bundle 1</b>                         | Configures a cable interface to belong to an interface bundle, where <i>n</i> is the bundle number.                                                                                                                                                                                                                                                                          |
| <b>Step 12</b> | <b>no cable upstream n shut</b><br><b>Example:</b><br>Router(config-if)# <b>no cable upstream 4 shut</b>     | Use as needed after Cisco IOS upgrade.<br><br>The cable interface must be enabled using the no shutdown command for the specified cable interface.<br><br><i>n</i> —Specifies the cable interface to enable for the virtual bundle.                                                                                                                                          |
| <b>Step 13</b> | <b>end</b><br><b>Example:</b><br>Router(config-if)# <b>end</b>                                               | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                             |

### What to do next

To remove a virtual bundle from the interface, use the **no interface bundle** command in interface configuration mode, where *n* specifies the bundle identifier:

**no interface bundle *n***

If you remove a member from a bundle, the bundle remains on the interface (even if empty) until the bundle itself is specifically removed.

For more information on configuring IPv6 parameters for bundle interface, see *IPv6 on Cable* feature guide.

## Verifying the Virtual Interface Bundling Configuration

- **show ip interface brief**—Displays the summary of interfaces.

Following is a sample output of this command:

```
Router# show ip interface brief
```

| Interface        | IP-Address       | OK?        | Method        | Status                | Protocol  |
|------------------|------------------|------------|---------------|-----------------------|-----------|
| Cable3/0/0       | Bundle1          | YES        | unset         | up                    | up        |
| GigabitEthernet0 | 10.86.3.175      | YES        | NVRAM         | administratively down | down      |
| <b>Bundle1</b>   | <b>100.1.2.1</b> | <b>YES</b> | <b>manual</b> | <b>up</b>             | <b>up</b> |
| <b>Bundle2</b>   | <b>100.1.3.1</b> | <b>YES</b> | <b>NVRAM</b>  | <b>up</b>             | <b>up</b> |
| Dti4/1/0         | unassigned       | YES        | unset         | administratively down | down      |
| Dti5/1/0         | unassigned       | YES        | unset         | administratively down | down      |
| Dti4/1/1         | unassigned       | YES        | unset         | administratively down | down      |
| Dti5/1/1         | unassigned       | YES        | unset         | administratively down | down      |
| Loopback1        | 1.2.3.4          | YES        | NVRAM         | up                    | up        |
| Tunnel0          | unassigned       | YES        | unset         | up                    | up        |

- **show running-config interface bundle *n***—Displays the information about the specified bundle.

Following is a sample output of this command:

```
Router# show running-config interface Bundle 1
```

```
Current configuration : 696 bytes
!
interface Bundle2
 ip address 100.1.3.1 255.255.255.0
 no cable nd
 cable arp filter request-send 3 2
 cable arp filter reply-accept 3 2

 ipv6 dhcp relay source-interface Bundle2
 arp timeout 2147483
```

- **show ip interface brief | include bundle**—Displays the bundle interface information.

Following is a sample output of this command:

```
Router# show ip interface brief | include Bundle

Bundle1 unassigned YES unset up up
Bundle1.1 100.1.2.1 YES NVRAM up up
Bundle2 100.1.3.1 YES NVRAM up up
```

- **show running-config interface bundle *n.n***—Displays the subinterface information for the specified bundle.

Following is a sample output of this command:

```
Router# show running-config interface bundle 1.1

Current configuration : 1415 bytes

## Feature Information for Virtual Interface Bundling

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 146: Feature Information for Virtual Interface Bundling**

| Feature Name               | Releases                 | Feature Information                                                                                            |
|----------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------|
| Virtual interface bundling | Cisco IOS XE Fuji 16.7.1 | This feature was integrated into Cisco IOS XE Fuji 16.7.1 on the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 55

# IPv6 on Cable

Cisco cBR series Converged Broadband Router supports full IPv6 functionality.

The IPv6 feature support available in the Cisco IOS software and for Cisco CMTS routers is extensive. This document provides a comprehensive overview of all of the IPv6 features supported on the Cisco CMTS routers, and their restrictions.

However, the details of every feature are not covered in this document. The areas of IPv6 protocol support for the Cisco CMTS routers discussed in this document are classified by platform-independence or by platform-specific feature support.

- Platform-independent IPv6 features—Describes IPv6 features that are supported in the Cisco IOS software for several other Cisco platforms, and which generally do not have any platform-specific behavior or configuration differences on the Cisco CMTS routers.
- Documentation about the restrictions for these platform-independent features can be found in the Restrictions for IPv6 on Cable.
- Detailed information about these features, including conceptual and task-based configuration information, is documented outside of this feature and in the Cisco IOS software documentation. Detailed information about the location of this related documentation in the Cisco IOS software documentation is described in the Feature Information for IPv6 on Cable.

Platform-specific IPv6 features—Describes IPv6 features that are specific to the cable technology area and that only apply to the supported Cisco CMTS routers. The cable-specific IPv6 feature support includes new or modified cable features supporting IPv6, and any transparent support of the IPv6 protocol in existing (legacy) cable features on the CMTS router platforms.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

# Restrictions for IPv6 on Cable

## Multicast Restrictions

IPv6 multicast has the following behavior restrictions on the Cisco CMTS routers:

- ICMP redirects are not sent to the originating host if the packet is destined for another CPE behind the same CM. All CPE-to-CPE traffic is processed by the Cisco CMTS router.
- IPv6 multicast forwarding is not supported in Parallel Express Forwarding (PXF), therefore, the IPv6 multicast forwarding performance is limited by the Router Processor (RP).

The following areas of IPv6 multicast are not supported by the Cisco CMTS routers:

- Address family support for Multiprotocol Border Gateway Protocol (MBGP)
- Bidirectional Protocol Independent Multicast (PIM)
- Bootstrap router (BSR)
- DOCSIS 3.0 encrypted multicast
- Explicit tracking of receivers
- IPv6 multicast echo
- Multicast Forwarding Information Base (MFIB) display enhancements
- Multicast use authentication and profile support
- PIM embedded rendezvous point
- Protocol Independent Multicast sparse mode (PIM-SM) accept register feature
- Reverse path forwarding (RPF) flooding of bootstrap router (BSR) packets
- Routable address hello option
- Source Specific Multicast (SSM) mapping for Multicast Listener Device (MLD) version 1 SSM

## QoS Restrictions

In Cisco IOS-XE Release 16.5.1, the following fields are supported for the IPv6 downstream classification:

- IPv6 dest addr
- ipv6 src addr
- IPv6 next header
- IPv6 traffic class

---

**Note** IPv6 flow label field is not supported.

---

The following areas of DOCSIS QoS are not supported by the Cisco CMTS routers:

- Upstream IPv6 Type of Service (ToS) overwrite
- Downstream IPv6 classification

---

**Note** ToS overwrite, DOCSIS classification, and Modular QoS CLI (MQC) on Gigabit Ethernet are supported.

---

## Information About IPv6 on Cable

This section includes the following topics:

### Features Supported

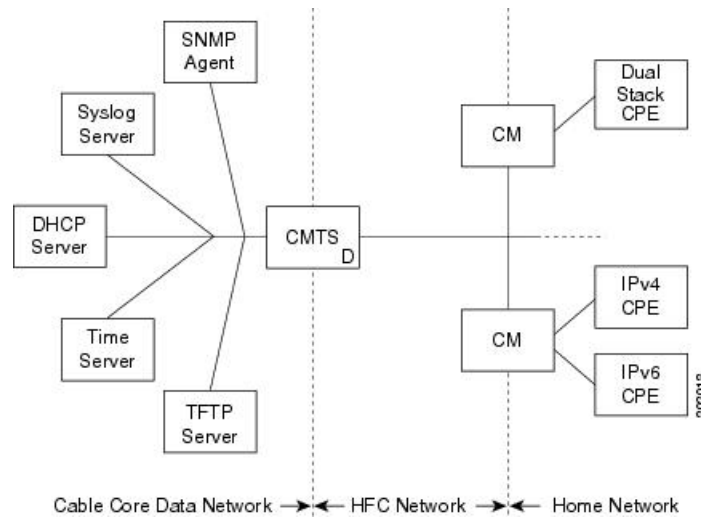

The following features are supported on the Cisco CMTS routers:

- Source verification of IPv6 packets in PXF
- ACL support for PXF
- ToS overwrite
- DOCSIS classification
- Modular QoS CLI (MQC) on Gigabit Ethernet
- IPv6 DOCSIS RP and LC HA and DCC
- MAC tapping of IPv6 packets
- Equal cost route load balancing of IPv6 packets destined to the backhaul
- IPv6 over IPv4 GRE tunnels
- Assignment of different prefixes to CM and CPE
- DHCPv6 over MPLS-VPN
- DHCPv6 relay prefix delegation VRF awareness
- Assignment of multiple IAPDs in a single advertise for each CPE.
- Assignment of multiple IA\_NA and IAPD combinations to multiple CPEs behind a CM.
- The default maximum number of IA\_NA and IAPD combinations for each cable modem is 16, including link-local addresses.
- IPv6 Downstream ToS overwrite.
- DHCPv6 Client Link-Layer Address Option (RFC 6939).
- Voice over IPv6. PacketCable Multimedia needs to be enabled before using this feature. For more information, see [http://www.cisco.com/c/en/us/td/docs/cable/cbr/configuration/guide/b\\_pktcbl\\_pktcblmm/packetcable\\_and\\_packetcable\\_multimedia.html](http://www.cisco.com/c/en/us/td/docs/cable/cbr/configuration/guide/b_pktcbl_pktcblmm/packetcable_and_packetcable_multimedia.html).

## Overview of the DOCSIS 3.0 Network Model Supporting IPv6

Figure below illustrates the network model described by the *DOCSIS 3.0 MAC and Upper Layer Protocols Interface Specification*.

Figure 26: DOCSIS 3.0 Network Model

In this model, the different devices support the following functions and services:

- Customer premises equipment (CPE)—Supports IPv4, IPv6, or dual stack operation.

**Note** Cisco cBR routers support CPE devices provisioned for dual stack operation.

- Cable modem (CM)—Functions as a bridging device and supports IPv4, IPv6, or dual stack operation.
- Cable modem termination system (CMTS) router—Works with the CM over the hybrid fiber coaxial cable (HFC) network to provide IPv4 and IPv6 network connectivity to the provisioning servers and the core data network behind the CMTS router.

The CMTS router supports IPv6 address assignment, routing, and forwarding of IPv6 multicast and unicast packets.

**Note** The Cisco cBR router supports only a single DHCPv6 IPv6 address per client cable modem or CPE. This restriction also applies to DHCPv6 Prefix Delegation prefixes. The reason for blocking more than one DHCPv6 address or prefix for a client is because the end-to-end network requires Source Address Selection (SAS) and all nodes in the end-to-end network may not support the correct SAS. Moreover, the SAS specification (RFC 3484) is being revised by the IETF to define the correct SAS behavior.

- Simple Network Management Protocol (SNMP) agent—Provides management tools to configure and query devices on the network.
- Syslog server—Collects messages from the CM to support its functions.
- Dynamic Host Control Protocol (DHCP) server—The DOCSIS 3.0 network model supports both DHCPv4 and DHCPv6 servers to control the assignment of IP addresses.
- Time server—Provides the current time to the CM.

- Trivial File Transport Protocol (TFTP) server—Provides the CM configuration file.

## Overview of Cable Modem IPv6 Address Provisioning

Prior to cable modem registration with a CMTS router, the CMTS router sends a MAC Domain Descriptor (MDD) message to provide information to the cable modem about its supported IP provisioning mode. You configure the CMTS router provisioning mode using the **cable ip-init** interface configuration command. For more information, see the [Implementing IPv6 Addressing and Basic Connectivity for Cable Interfaces and Bundles](#), on page 824.

The MDD contains an IP initialization parameters type length value (TLV) that defines the IP version, management and alternate provisioning mode, and pre-registration downstream service ID (DSID) that is used by cable modems that are capable of downstream traffic filtering.

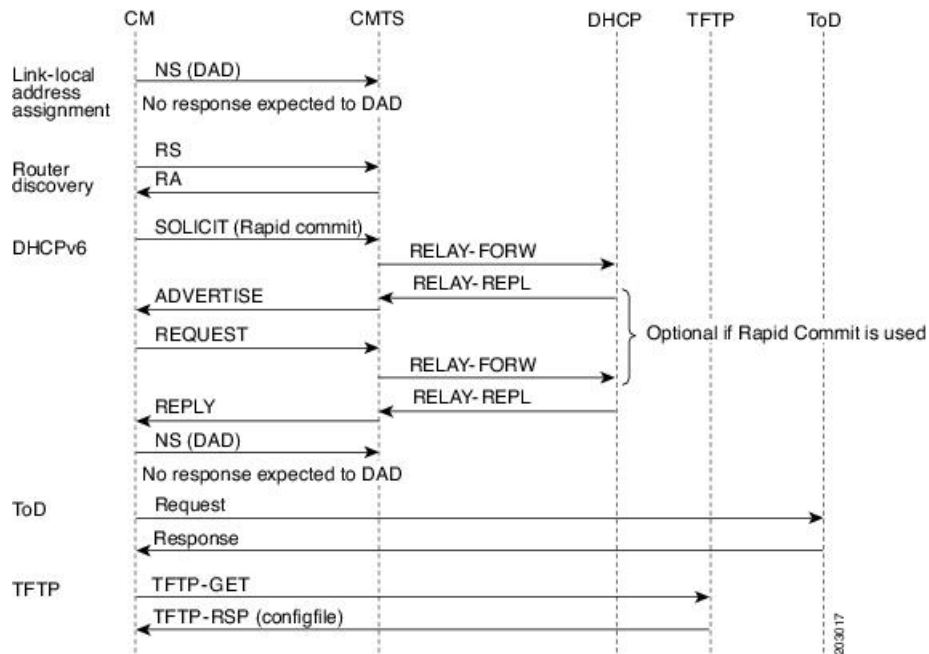

**Note** The Cisco CMTS routers do not support alternate provisioning mode or pre-registration DSID.

To support the MULPIv3.0 I04 or later version of the *DOCSIS 3.0 MAC and Upper Layer Protocols Interface Specification*, the cable modem must attempt IPv6 address acquisition first.

Figure below illustrates the message flow between a cable modem, the CMTS router, and the DHCP server when the cable modem is requesting an IPv6 address.

**Figure 27: Message Flow for CM Provisioning of DHCP IPv6 Address Assignment**

1. Link-local address assignment—The cable modem sends a Neighbor Solicit (NS) message with its link-local address (LLA) to the CMTS router, which starts the duplicate address detection (DAD) process for that LLA. The cable modem expects no response to the NS message.
2. Router discovery—The cable modem listens to the downstream to detect periodical Router Advertise (RA) messages. When an RA message is detected, the cable modem uses the data in the RA message to

configure the default route. If an RA is not detected in a specified period, the cable modem sends a Router Solicit (RS) message to find the router on the link (all nodes multicast). The CMTS router responds with a Router Advertise (RA) message with the M and O bits set to 1 to instruct the CM to perform stateful address configuration.

---

**Note** Cisco CMTS routers do not support SLAAC address assignment.

---

- DHCPv6—The cable modem sends a DHCPv6 Solicit message to the CMTS router to request an IPv6 address. The CMTS router relays this message to the DHCPv6 servers. The DHCPv6 servers send an Advertise message indicating the server's availability.

If the Rapid-Commit option is not used by the cable modem, then the cable modem responds to the Advertise message of the server with a Request message to select the server that the CMTS router relays to the DHCPv6 server. If the Rapid-Commit option is used, then multiple DHCPv6 servers that could assign different addresses to the same CPE must not be used.

The cable modem starts the DAD process to verify the uniqueness of the IPv6 address that the DHCPv6 server assigns to it.

- TFTP and Time of Day (ToD)—Once the CM establishes IP connectivity, it sends a request to the TFTP server to download a configuration file and requests the current time from the ToD server to complete its boot process.

## Overview of IPv6 Dual Stack CPE Support on the CMTS

Most operating systems (OS) deployed at homes support dual stack operation. Cisco CMTS supports dual stack, which is both IPv4 and IPv6 addressing on the CPE.

## Overview of IPv6 over Subinterfaces

Cisco CMTS supports IPv6 over bundle subinterfaces. To configure IPv6 on bundle subinterfaces, see the [Implementing IPv6 Addressing and Basic Connectivity for Cable Interfaces and Bundles, on page 824](#) section. For a CMTS bundle configuration example, see the [Example: IPv6 over Subinterfaces, on page 839](#) section.

To enable IPv6 on subinterfaces, configure IPv6 on bundle subinterfaces and not the bundle. Reset the CMs after the subinterface is configured.

---

**Note** MPLS VPN over subinterfaces for IPv6 is not supported.

---

## Overview of High Availability on IPv6

Cisco cBR Series routers support IPv6 HA for the Supervisor card.

---

**Note** IPv6 DOCSIS HA and HCCP is supported on the Cisco CMTS routers.

---

The IPv6 HA feature support in Cisco CMTS routers covers the following capabilities:

- DOCSIS PRE HA
- DOCSIS line card HA
- Dynamic Channel Change (DCC)

## DOCSIS PRE HA

The DOCSIS PRE HA has the following behavior restrictions and prerequisites on the Cisco CMTS routers:

- The CMs and CPEs should not go offline after a PRE switchover.
- The data structures of the IPv6 CM and CPE should be synchronized to the standby PRE before the PRE switchover. Both dynamic and bulk synchronization is supported.
- Single stack, dual stack, and APM are supported for the CM.
- Single stack and dual stack provisioning modes are supported on the CPE.
- After a PRE switchover, the IPv6 neighbor entries are rebuilt by Neighbor Discovery (ND) messages on the standby PRE, and the IPv6 routes are rebuilt after converging the routing protocol.

## DOCSIS Line Card HA

The DOCSIS line card HA has the following behavior restrictions and prerequisites on the Cisco CMTS routers:

- The data structures of the IPv6 CM and CPE should be synchronized to the standby line card before the line card switchover. Both dynamic and bulk synchronization is supported.
- The CMs and CPEs should not fall offline after a line card switches over and reverts; the CMs and CPEs should behave the same as before the switchover.
- The DOCSIS line card HA supports both 4+1 and 7+1 redundancy.
- Traffic outages in IPv6 may be longer because traffic recovery occurs only after converging the routing protocol.

## Dynamic Channel Change

The Dynamic Channel Change (DCC) feature is supported on Cisco CMTS routers.

---

**Note** The behavior of the DCC for single stack IPv6 CM and CPE, or dual stack CM and CPE is the same as that of a single stack IPv4 CM and CPE.

---

The IPv6 and IPv4 DCC functionality has the following behavior restrictions and prerequisites on the Cisco CMTS routers:

### Narrowband Cable Modem

- If the source and destination MAC domains of the CM are on the same line card, DCC initialization techniques 0, 1, 2, 3, and 4 are used to move the CM and its associated CPE from one upstream or downstream to another; or move the CM and CPE from one upstream and downstream combination to another.
- If the source and destination MAC domains of the CM are on different line cards, you can use only the DCC initialization technique 0 to move the CM and its associated CPE across line cards.

**Wideband Cable Modem**

- If the source and destination MAC domains of the CM are on the same line card, DCC initialization techniques 0, 1, 2, 3, and 4 are used to move the CM and its associated CPE from one upstream to another.
- If the primary downstream of a CM is changed after DCC, you can use only the DCC initialization technique 0 to move the CM and its associated CPE across line cards.

## Overview of IPv6 VPN over MPLS

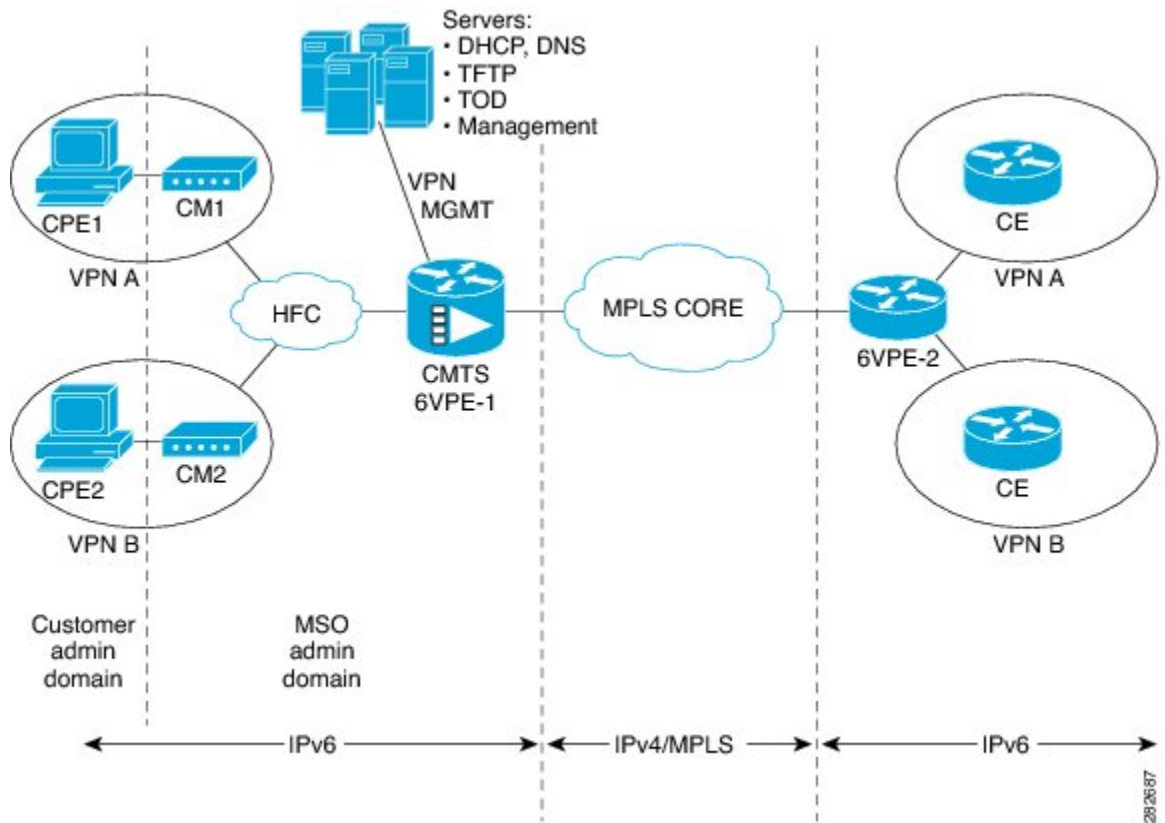

The Multiprotocol Label Switching (MPLS) VPN feature represents an implementation of the provider edge (PE) based VPN model. This document describes the IPv6 VPN over MPLS (6VPE) feature.

The 6VPE feature allows Service Providers to provide an IPv6 VPN service that does not require an upgrade or reconfiguration of the PE routers in the IPv4 MPLS Core. The resulting IPv6 VPN service has a configuration and operation which is virtually identical to the current IPv4 VPN service.

In principle, there is no difference between IPv4 and IPv6 VPNs. In both IPv4 and IPv6, the multiprotocol BGP is the core of the MPLS VPN for IPv6 (VPNv6) architecture. It is used to distribute IPv6 routes over the service provider backbone using the same procedures to work with overlapping addresses, redistribution policies, and scalability issues.

Figure below illustrates the 6PE/6VPE reference architecture diagram.

**Figure 28: 6PE/6VPE Reference Architecture**

## Cable Monitor

The Cable Monitor and Intercept features for Cisco CMTS routers provide a software solution for monitoring and intercepting traffic coming from a cable network. These features give service providers Lawful Intercept capabilities.

For more information, see the Cable Monitor and Intercept Features for the Cisco CMTS Routers guide.

## Overview of IPv6 CPE Router Support on the Cisco CMTS

The IPv6 CPE router support is provided on the Cisco CMTS. The IPv6 CPE router is a node primarily for home or small office use that connects the end-user network to a service provider network. It is also referred to as the home router.

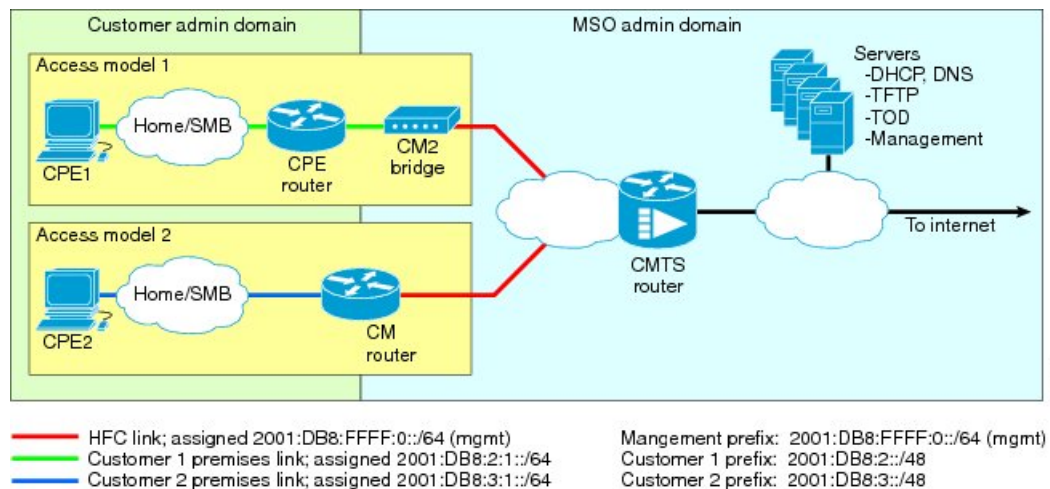

The IPv6 CPE router is responsible for implementing IPv6 routing; that is, the IPv6 CPE router looks up the IPv6 destination address in its routing table and decides to which interface the packet should be sent.

The IPv6 CPE router performs the following functions:

- Provisions its WAN interface automatically.
- Acquires IP address space for provisioning of its LAN interfaces.
- Fetches other configuration information from the service provider network.

Figure below illustrates the CPE router reference architecture diagram between the CPE router, the CMTS, and the DHCPv6 server (CNR) when the CM is requesting an IPv6 address.

**Figure 29: IPv6 CPE Router Reference Architecture**

Routers span customer and MSO administrative domains

As part of the IPv6 CPE Router Support feature, the following enhancements are introduced:

- Support to IPv6 router devices.
- IPv6 Prefix Delegation (PD) High Availability.
- Prefix awareness support in IPv6 cable source-verify, Cable DOCSIS filters code, and packet intercepts.

## Support for IPv6 Prefix Stability on the CMTS

IPv6 prefix stability is supported on the Cisco CMTS as specified in DOCSIS 3.0 MULPI CM-SP-MULPIv3.0-I15-110210 standard. The IPv6 prefix stability allows an IPv6 home router to move from one Cisco CMTS to another while retaining the same prefix.

The multiple service operators (MSOs) can use this feature to allow their business customers (with IPv6 routers) to retain the same IPv6 prefix during a node split.

## Configurable DHCPv6 Relay Address

The DHCPv6 Cisco IOS relay agent on the Cisco CMTS router sends relay-forward messages from a source address to all configured relay destinations. The source address is either an IPv6 address provisioned on the network interface or a Cisco CMTS WAN IPv6 address. The relay destination can be a unicast address of a server, another relay agent, or a multicast address. The relay-forward messages contain specific DHCPv6 link-addresses.

A DHCP relay agent is used to relay messages between the client and server. A client locates a DHCP server using a reserved, link-scoped multicast address.

### DHCPv6 Client Link-Layer Address Option (RFC 6939)

Cisco IOS-XE Releases support DHCPv6 Client Link-Layer Address Option (RFC 6939). It defines an optional mechanism and the related DHCPv6 option to allow first-hop DHCPv6 relay agents (relay agents that are connected to the same link as the client) to provide the client's link-layer address in the DHCPv6 messages being sent towards the server.

The format of the DHCPv6 Client Link-Layer Address option is shown below.

| Name            | Description                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| option-code     | OPTION_CLIENT_LINKLAYER_ADDR (79)                                                                                            |
| option-length   | 2 + length of MAC address                                                                                                    |
| link-layer type | CPE or CM MAC address type. The link-layer type MUST be a valid hardware type assigned by the IANA, as described in RFC0826. |

| Name               | Description                   |
|--------------------|-------------------------------|
| link-layer address | MAC address of the CPE or CM. |

**Note** RFC6939 is enabled by default. It can not be enabled/disabled by any CLI command.

To configure DHCPv6 Relay Address on the Cisco CMTS bundle subinterfaces, see the [Configuring DHCPv6 Relay Agent, on page 835](#) section.

For more information about the DHCPv6 client, server, and relay functions, see the “Implementing DHCP for IPv6” chapter in the [IPv6 Implementation Guide, Cisco IOS XE Release 3S](#).

## Support for Multiple IAPDs in a Single Advertise

Assignment of multiple IA\_NA and IAPD to CPEs behind a CM is supported on Cisco CMTS routers. This feature includes support for link-local addresses and IA\_NA and IAPD. However, a CM can be assigned only one IA\_NA. This IA\_NA can be either static or DHCP-assigned.

The CPEs behind the CM can request for multiple DHCPv6 IA\_NAs and IAPDs. Each CPE is assigned multiple IA\_NAs and IAPDs in a single Advertise/Reply message. Each CPE request for IA\_NA and IAPD is treated as a separate Advertise/Reply message.

## IPv6 Neighbor Discovery Gleaning

The IPv6 Neighbor Discovery (ND) Gleaning feature enables Cisco CMTS routers to automatically recover lost IPv6 CPE addresses and update the CPE records in the Cisco CMTS subscriber database. The Cisco CMTS router gleans only the solicited neighbor advertise (NA) messages transmitted in the upstream direction. IPv6 ND gleaning is similar to Address Resolution Protocol (ARP) gleaning for IPv4 CPE recovery.

The IPv6 ND Gleaning feature is configured by default on Cisco CMTS routers. To disable this feature, use the **no** form of the **cable nd** command in bundle interface configuration mode. The **cable nd** command adds a CPE (host behind a cable modem) to the Cisco CMTS subscriber database. This command does not impact the IPv6 ND protocol operation on the router.

**Note** The IPv6 ND Gleaning feature does not support gleaning of NA messages transmitted in the downstream direction.

## How to Configure IPv6 on Cable

This section includes the following tasks:

### Configuring IPv6 Switching Services

The CMTS routers support forwarding of unicast and multicast IPv6 traffic using either Cisco Express Forwarding for IPv6 (CEFv6) or distributed CEFv6 (dCEFv6):

- CEFv6—All CMTS platforms
- dCEFv6—Cisco uBR10012 universal broadband router only

The CMTS routers also support Unicast Reverse Path Forwarding (RPF), as long as you enable Cisco Express Forwarding switching or distributed Cisco Express Forwarding switching globally on the router. There is no need to configure the input interface for Cisco Express Forwarding switching. As long as Cisco Express Forwarding is running on the router, individual interfaces can be configured with other switching modes.

To configure forwarding of IPv6 traffic using Cisco Express Forwarding or distributed Cisco Express Forwarding (supported on the Cisco uBR10012 universal broadband router only) on the CMTS routers, you must configure forwarding of IPv6 unicast datagrams using the **ipv6 unicast-routing** global configuration command, and you must configure an IPv6 address on the bundle interface using the **ipv6 address** command.

The **show ipv6 cef platform** command is supported on the Cisco CMTS platform. You can use the **show ipv6 cef platform** command for debugging purposes.

### Before you begin

- You must enable Cisco Express Forwarding for IPv4 globally on the router by using the **ip cef** or **ip cef distributed** command before configuring Cisco Express Forwarding v6 or distributed Cisco Express Forwarding v6.

**Note** The **ip cef** command is enabled by default on all Cisco CMTS routers. Therefore, you only must configure the command if it has been disabled. However, you must explicitly configure the **ip cef distributed** command on a Cisco uBR10012 universal broadband router if you want to run distributed CEF switching services for IPv4 or IPv6.

- You must configure forwarding of IPv6 unicast datagrams using the **ipv6 unicast-routing** global configuration command.
- You must configure IPv6 addressing on the cable bundle interface.
- CEF switching is required for Unicast RPF to work.

### Procedure

|        | Command or Action                                                          | Purpose                                                        |
|--------|----------------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> enable                         | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Router# configure terminal | Enters global configuration mode.                              |
| Step 3 | Do one of the following:                                                   | Enables Cisco Express Forwarding.                              |

|               | Command or Action                                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                         |

| <b>Step 4</b> | <p>Do one of the following:</p> <ul style="list-style-type: none"> <li>• <b>ipv6 cef</b></li> <li>• <b>ipv6 cef distributed</b></li> </ul> <p><b>Example:</b></p> <pre>Router(config)# ipv6 cef</pre> <p>or</p> <pre>Router(config)# ipv6 cef distributed</pre> | <p>Enables Cisco Express Forwarding v6.</p> <p>or</p> <p>Enables distributed Cisco Express Forwarding v6 for IPv6 datagrams.</p> <p><b>Note</b> For CMTS routers, distributed Cisco Express Forwarding v6 is supported only on a Cisco uBR10012 universal broadband router.</p> |
| <b>Step 5</b> | <p><b>ipv6 unicast-routing</b></p> <p><b>Example:</b></p> <pre>Router(config)# ipv6 unicast-routing</pre>                                                                                                                                                       | <p>Enables the forwarding of IPv6 unicast datagrams.</p>                                                                                                                                                                                                                        |

#### What to do next

- (Optional) Enable IPv6 multicast routing using the **ipv6 multicast-routing** command in global configuration mode and configure other multicast features.

## Implementing IPv6 Addressing and Basic Connectivity for Cable Interfaces and Bundles

### Configuring the Cable Virtual Bundle Interface

The only required IPv6 configuration on a cable line card interface is the IP provisioning mode. The remainder of the IPv6 features are configured at the virtual bundle interface, which is then associated with a particular cable line card interface to establish its configuration.

Most of the IPv6 features that are supported in interface configuration mode (both cable-specific as well as platform-independent IPv6 features) are configured at a cable bundle interface.

The Cisco CMTS routers support IPv6 routing on the bundle interface and map both IPv6 unicast and multicast addresses into the cable bundle forwarding table, for packet forwarding.

Each bundle interface has a unique link-local address (LLA) to support link-local traffic when IPv6 is enabled. Cisco CMTS routers can support a maximum of 40 active bundle interfaces, which also translates to a maximum of 40 active IPv6-enabled bundle interfaces.

IPv6 commands can be configured on multiple bundle subinterfaces.

### Before you begin

The **cable ipv6 source-verify** and **cable nd** commands are not compatible with each other in Cisco IOS release 12.2(33)SCE and later. You must disable IPv6 ND gleaning using the **no** form of the **cable nd** command before using the **cable ipv6 source-verify** command to ensure that only DHCPv6 and SAV-based CPEs can send traffic on the router.

**Restriction** All multicast traffic is flooded onto bundle member interfaces.

### Procedure

|               | Command or Action                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Router> enable                                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# configure terminal                                                                      | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 3</b> | <b>interface bundle n</b><br><b>Example:</b><br><br>Router(config)# <b>interface bundle 1</b>                                                       | Specifies the cable bundle interface and enters interface configuration mode, where <i>n</i> specifies the number of the bundle interface.                                                                                                                                                                                                                                                                      |
| <b>Step 4</b> | <b>ipv6 address ipv6-prefix /prefix-length [eui-64 ]</b><br><b>Example:</b><br><br>Router(config-if)# <b>ipv6 address 2001:DB8::/32 eui-64</b>      | Specifies an IPv6 network assigned to the interface and enables IPv6 processing on the interface. The <b>ipv6 address eui-64</b> command configures site-local and global IPv6 addresses with an interface identifier (ID) in the low-order 64 bits of the IPv6 address. You need to specify only the 64-bit network prefix for the address; the last 64 bits are automatically computed from the interface ID. |
| <b>Step 5</b> | <b>ipv6 address ipv6-prefix /prefix-length link-local</b><br><b>Example:</b><br><br>Router(config-if)# <b>ipv6 address 2001:DB8::/32 link-local</b> | (Optional) Specifies an IPv6 address assigned to the interface and enables IPv6 processing on the interface. The <b>ipv6 address link-local</b> command configures a link-local address on the interface that is used instead of the link-local address that is automatically configured, when IPv6 is enabled on the interface (using the <b>ipv6 enable</b> command).                                         |
| <b>Step 6</b> | <b>ipv6 enable</b><br><b>Example:</b><br><br>Router(config-if)# <b>ipv6 enable</b>                                                                  | Automatically configures an IPv6 link-local address on the interface while also enabling the interface for IPv6 processing. The link-local address can be used only to communicate with nodes on the same link.                                                                                                                                                                                                 |

|               | Command or Action                                                                                 | Purpose                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 7</b> | cable ipv6 source-verify<br><b>Example:</b><br>Router(config-if)# <b>cable ipv6 source-verify</b> | (Optional) Enables source verification of MAC address-MD-SID-IPv6 address binding packets received by a cable interface upstream on Cisco CMTS routers. |

**What to do next**

- Configure the desired platform-independent IPv6 features on the bundle interface, such as Neighbor Discovery and DHCPv6 features.
- Configure the IP provisioning mode and bundle on the cable interface.

**Configuring the IP Provisioning Mode and Bundle on the Cable Interface**

The CMTS routers allow you to configure cable interfaces to support cable modems provisioned for both IPv4 and IPv6 addressing support (known as “dual stack”), only IPv4 addressing, or only IPv6 addressing. Prior to cable modem registration, the CMTS router sends its supported provisioning mode to the cable modem in the MDD message.

In addition to configuring the provisioning mode on the cable interface, you must also associate the cable interface with a cable bundle. You perform most of the other IPv6 feature configuration at the bundle interface.

**Note** This section describes only the commands associated with establishing IPv6 support on a CMTS router. Other cable interface commands that apply but are optional are not shown, such as to configure upstream and downstream features.

**Before you begin**

Configuration of a bundle interface is required.

**Procedure**

|               | Command or Action                                                                                                               | Purpose                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Router> enable                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                            |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Router# configure terminal                                                      | Enters global configuration mode.                                                                                                                                         |
| <b>Step 3</b> | <b>interface cable</b> {slot / port   slot / subslot /port }<br><b>Example:</b><br>Router(config)# <b>interface cable</b> 5/0/1 | Specifies the cable interface line card, where:<br><br>The valid values for these arguments are dependent on your CMTS router and cable interface line card. Refer to the |

|               | Command or Action                                                                                                            | Purpose                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                              | hardware documentation for your router chassis and cable interface line card for supported slot and port numbering.                     |
| <b>Step 4</b> | <b>cable ip-init {apm   dual-stack   ipv4   ipv6}</b><br><b>Example:</b><br><pre>Router(config-if)# cable ip-init ipv6</pre> | Specifies the IP provisioning mode supported by the cable interface, where:                                                             |
| <b>Step 5</b> | <b>cable bundlen</b><br><b>Example:</b><br><pre>Router(config)# cable bundle 1</pre>                                         | Associates the cable interface with a configured virtual bundle interface, where <i>n</i> specifies the number of the bundle interface. |

#### What to do next

- Proceed to configuring any other cable interface features that you want to support, such as upstream and downstream features. For more information about the other cable interface features, refer to the *Cisco IOS CMTS Cable Software Configuration Guide*.
- Proceed to configure other optional IPv6 cable features.

## Configuring IPv6 Cable Filter Groups

The Cisco CMTS router supports IPv6 cable filter group capability with IPv6 filter options.

## Configuring IPv6 Cable Filter Groups

The Cisco CMTS router supports IPv6 cable filter group capability with IPv6 filter options.

### Cable Filter Groups and the DOCSIS Subscriber Management MIB

Cable subscriber management is a DOCSIS 1.1 specification, which can be established using the following configuration methods:

- CMTS router configuration (via CLI)
- SNMP configuration
- DOCSIS 1.1 configuration file (TLVs 35, 36, and 37)

This section describes the IPv6 cable filter group feature support of the packet filtering portion of the DOCSIS Subscriber Management MIB (DOCS-SUBMGMT-MIB) using configuration commands on the CMTS routers. This IPv6 cable filter group support extends filter classifiers with IPv6 addressing options for CM and CPE traffic, but is independent of DOCSIS IPv6 classifiers, which are used to match packets to service flows.

Configuration of IPv6 cable filter groups on the CMTS routers is supported according to the following guidelines:

- A cable filter group consists of a set of **cable filter group** commands that share the same group ID.
- Separate indexes can be used to define different sets of filters for the same group ID. This can be used to define both IPv4 and IPv6 filters to the same filter group.
- CMs can be associated with one upstream and one downstream filter group.

- Upstream traffic—All traffic coming from CMs is evaluated against the assigned upstream filter group that is configured by the **cable submgmt default filter-group cm upstream** command.
- Downstream traffic—All traffic going to CMs is evaluated against the assigned downstream filter group that is configured by the **cable submgmt default filter-group cm downstream** command.
- CPEs can be associated with one upstream and one downstream filter group.
  - Upstream traffic—All traffic coming from CPEs is evaluated against the assigned upstream filter group that is configured by the **cable submgmt default filter-group cpe upstream** command.
  - Downstream traffic—All traffic going to CPEs is evaluated against the assigned downstream filter group that is configured by the **cable submgmt default filter-group cpe downstream** command.

**Note** Because TLVs 35, 36, and 37 do not apply to DOCSIS 1.0 CM configuration files, the only way to enable cable subscriber management for a DOCSIS 1.0 CM is to configure it explicitly on the Cisco CMTS router and activate it by using the **cable submgmt default active** global configuration command.

### Before you begin

You must create the cable filter group before you assign it to a CM or CPE upstream or downstream.

### Restriction

- Chained IPv6 headers are not supported.
- An individual filter group index cannot be configured to support both IPv4 and IPv6 versions at the same time. If you need to support IPv4 and IPv6 filters for the same filter group, then you must use a separate index number with the same filter group ID, and configure one index as **ip-version ipv4**, and the other index as **ip-version ipv6**.
- Only a single upstream and a single downstream filter group can be assigned for CM traffic.
- Only a single upstream and a single downstream filter group can be assigned to CPEs attached to a CM such that all CPEs behind a CM share a common filter group.
- For the filter group to work for CMs, a CM must re-register after the CMTS router is configured for the filter group.
- If parallel eXpress forwarding (PXF) is configured on the Cisco uBR10012 router, either the **cable filter group** commands or the interface ACL (**ip access-list**) command can be configured.
- If you do not provision TLVs 35, 36, and 37 in the DOCSIS CM configuration file, then you must activate the functionality by specifying the **cable submgmt default active** global configuration command on the CMTS router.

### Procedure

|        | Command or Action                                  | Purpose                                                        |
|--------|----------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Router> enable | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                                                                                                                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 3</b> | <b>cable filter group</b> <i>group-id</i><br><b>index</b> <i>index-num</i> <b>dest-port</b> <i>port-num</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 dest-port 69</pre>                         | (Optional) Specifies the TCP/UDP destination port number that should be matched. The valid range is from 0 to 65535. The default value matches all TCP/UDP port numbers (IPv4 and IPv6 filters).                                                                                                                                                                                                 |
| <b>Step 4</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>ip-proto</b><br><i>proto-type</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 ip-proto 17</pre>                         | (Optional) Specifies the IP protocol type number that should be matched. The valid range is from 0 to 256, with a default value of 256 that matches all protocols (IPv4 and IPv6 filters).<br><br>Some commonly used values are:                                                                                                                                                                 |
| <b>Step 5</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>ip-tos</b><br><i>tos-mask tos-value</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 ip-tos 0xff 0x80</pre>              | (Optional) Specifies a ToS mask and value to be matched (IPv4 and IPv6 filters):<br><br>The <i>tos-mask</i> is logically ANDed with the <i>tos-value</i> and compared to the result of ANDing the <i>tos-mask</i> with the actual ToS value of the packet. The filter considers it a match if the two values are the same.<br><br>The default values for both parameters matches all ToS values. |
| <b>Step 6</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>ip-version</b><br><b>ipv6</b><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 ip-version ipv6</pre>                         | Specifies that this filter group is an IPv6 filter group.                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 7</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i><br><b>match-action</b> { <b>accept</b>   <b>drop</b> }<br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 match-action drop</pre> | (Optional) Specifies the action that should be taken for packets that match this filter (IPv4 and IPv6 filters):                                                                                                                                                                                                                                                                                 |
| <b>Step 8</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>src-port</b><br><i>port-num</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 src-port 50</pre>                           | (Optional) Specifies the TCP/UDP source port number that should be matched. The valid range is from 0 to 65535. The default value matches all TCP/UDP port numbers (IPv4 and IPv6 filters).                                                                                                                                                                                                      |

|                | Command or Action                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                   |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 9</b>  | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>status</b> { <b>active</b>   <b>inactive</b> }<br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 status inactive</pre>        | (Optional) Enables or disables the filter (IPv4 and IPv6 filters):<br><b>Note</b> You must create a filter group using at least one of the other options before you can use this command to enable or disable the filter. |
| <b>Step 10</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>tcp-flags</b> <i>flags-mask</i> <i>flags-value</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 tcp-flags 0 0</pre>      | (Optional) Specifies the TCP flag mask and value to be matched (IPv4 and IPv6 filters):                                                                                                                                   |
| <b>Step 11</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>v6-dest-address</b> <i>ipv6-address</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 v6-dest-address 2001:DB8::/32</pre> | (Optional) Specifies the IPv6 destination address that should be matched using the format X:X:X:X::X (IPv6 filters only).                                                                                                 |
| <b>Step 12</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>v6-dest-pfxlen</b> <i>prefix-length</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 v6-dest-pfxlen 64</pre>             | (Optional) Specifies the length of the network portion of the IPv6 destination address. The valid range is from 0 to 128.                                                                                                 |
| <b>Step 13</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>v6-src-address</b> <i>ipv6-address</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 v6-src-address 2001:DB8::/32</pre>   | (Optional) Specifies the IPv6 source address that should be matched using the format X:X:X:X::X (IPv6 filters only).                                                                                                      |
| <b>Step 14</b> | <b>cable filter group</b> <i>group-id</i> <b>index</b> <i>index-num</i> <b>v6-src-pfxlen</b> <i>prefix-length</i><br><b>Example:</b><br><pre>Router(config)# cable filter group 1 index 1 v6-src-pfxlen 48</pre>               | (Optional) Specifies the length of the network portion of the IPv6 source address. The valid range is from 0 to 128 (IPv6 filters only).                                                                                  |
| <b>Step 15</b> | <b>cable submgmt default filter-group</b> { <b>cm</b>   <b>cpe</b> } { <b>downstream</b>   <b>upstream</b> } <i>group-id</i><br><b>Example:</b><br><pre>Router(config)# cable submgmt default filter-group cm upstream 1</pre> | Applies a defined filter group (by specifying its <i>group-id</i> ) to either a CM or its CPE devices, for downstream or upstream traffic.                                                                                |

|                | Command or Action                                                                                                     | Purpose                                                                                                                                                                                                                                          |
|----------------|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 16</b> | <b>cable submgmt default active</b><br><br><b>Example:</b><br><br>Router(config)# <b>cable submgmt default active</b> | (Required if you do not provision TLVs 35, 36, and 37 in the DOCSIS 1.1 CM configuration file)<br><br>Enables filters and allows the CMTS to manage the CPE devices for a particular CM (sets the docsSubMgtCpeActiveDefault attribute to TRUE). |

### Example

The following example shows how to create an IPv6 filter group with ID 254 and an index number of 128. The **ip-version ipv6** keywords must be configured to create the IPv6 filter group; otherwise, the default is an IPv4 filter group:

```
configure terminal
cable filter group 254
 index 128 v6-src-address 2001:DB8::/32
cable filter group 254
 index 128 v6-src-pfxlen 48
cable filter group 254
 index 128 v6-dest-address 2001:DB8::/32
cable filter group 254
 index 128 v6-dest-pfxlen 64
cable filter group 254
 index 128 ip-version ipv6
cable filter group 254
 index 128 match-action drop
cable submgmt default filter-group cm upstream 254
```

This group filters CM upstream traffic and drops any packets with an IPv6 source address of 2001:33::20B:BFFF:FEA9:741F (with network prefix of 128) destined for an IPv6 address of 2001:DB8::/32 (with network prefix of 128).

All of the **cable filter group** commands are associated by their group ID of 254 (and index of 128), and the **cable submgmt default filter-group** command applies the corresponding filter group ID of 254 to CM upstream traffic.

To monitor your cable filter group configuration, use forms of the **show cable filter** command as shown in the following examples. In these output examples, the output from the **show cable filter**, **show cable filter group 254**, and **show cable filter group 254 index 128** commands all display the same information because there is currently only a single filter group and index defined.

**Note** The “Use Verbose” string appears in the output area of the SrcAddr/mask and DestAddr/Mask fields suggesting use of the **show cable filter group verbose** form of the command to display the complete IPv6 address.

```
Router# show cable filter
Filter SrcAddr/Mask DestAddr/Mask Prot ToS SPort DPort TCP Action Status
Grp Id v6 Flags
254 128Y Use Verbose
 Use Verbose
 drop active
```

```

Router# show cable filter group 254
Filter SrcAddr/Mask DestAddr/Mask Prot ToS SPort DPort TCP Action Status
Grp Id v6 Flags
254 128Y Use Verbose Use Verbose
Router# show cable filter group 254 index 128
Filter SrcAddr/Mask DestAddr/Mask Prot ToS SPort DPort TCP Action Status
Grp Id v6 Flags
254 128Y Use Verbose Use Verbose
Router# show cable filter group 254 index 128 verbose
Filter Group : 254
Filter Index : 128
Filter Version : IPv6
Matches : 0
 Source IPv6 address : 2001:DB8::/32
 Destination IPv6 address : 2001:DB8::/32
 Match action : drop
 Status : active

```

## Troubleshooting Tips

You should configure the **cable filter group** commands prior to applying a filter group using the **cable submgmt default filter-group** command. Failure to do so results in the following message, and an association to a filter group that is undefined:

```

Router(config)# cable submgmt default filter-group cm upstream 100
Default value set to a nonexistent filter-group 100.

```

## Configuring IPv6 Domain Name Service

Cisco IOS releases support the domain name service (DNS) capability for devices using IPv6 addressing on the Cisco CMTS routers.

DNS simplifies the identification of cable devices by associating a hostname with what can often be a complex 128-bit IPv6 address. The hostname can then be used in place of the IPv6 address within the CMTS router CLI that supports use of hostnames.

There are two separate DNS caches supported on a CMTS router—an IOS DNS cache and a cable-specific DNS cache that stores IPv6 addresses learned by the CMTS router for CMs and CPEs.

In this phase of the IPv6 DNS service on cable, the DNS server is queried for domain name information as needed when you use the **show cable modem domain-name** command. When you use this command, the following actions take place:

1. The CMTS router checks whether CMs are online. If a CM is online, the CMTS router uses the corresponding IPv6 address assigned to the CM and looks up its domain name from the IOS DNS cache.
2. If no match is found, the CMTS router sends a DNS-QUERY message with the IPv6 address of the CM to the DNS server, which tries to resolve the domain name.
3. When the DNS reply is received, the CMTS router stores the domain name in the IOS DNS cache for each IPv6 address.
4. The CMTS router also stores the fully-qualified domain name (FQDN) that is replied by the DNS server in the cable-specific DNS cache.

---

**Note** Running the **no ip domain lookup** command turns off the DNS resolution.

---

The following platform-independent Cisco IOS-xe software commands are supported using host names by the CMTS router for IPv6 DNS on cable:

- **connect**
- **ping ipv6**
- **show hosts**
- **telnet**
- **traceroute**

### Before you begin

- A DNS server must be configured.
- You must identify and assign the host names to the IPv6 addresses. If you are using the Cisco DNS server, use the **ip host** global configuration command to map hostnames to IP addresses.
- You must configure the DNS server using the **ip name-server** global configuration command before use of DNS host names (or domains) are available in the supported commands.
- The **show cable modem domain-name** command must be run first on the Route Processor (RP) of the CMTS router before any domain name can be used as part of a cable command.

---

### Restriction

- DNS for cable devices using IPv4 addressing is not supported.
  - Due to column size limitations within the command-line interface (CLI), the domain name display is limited to 32 characters. Therefore, the entire domain name cannot always be seen in CMTS router command output.
  - Only those cable devices where IPv6 address learning takes place are supported, such as acquiring an IPv6 address through DHCPv6 or the IPv6 (ND) process.
  - The cable-specific DNS cache is only updated when you use the **show cable modem domain-name** command on the Route Processor (RP). A DNS-QUERY can only be sent on the RP using this command, therefore the DNS cache cannot update if you use the **show cable modem domain-name** command on a line card console. The output is displayed on the RP only.
  - The cable-specific DNS cache does not store partially qualified domain names, only FQDNs are stored.
  - The cable-specific DNS cache is not associated with the timeouts that apply to the IOS DNS cache. Therefore, a cable-specific DNS cache entry is not removed when an IOS DNS cache timeout occurs for that device. The cable-specific DNS cache is only updated when you use the **show cable modem domain-name** command.
  - The CMTS router supports storage of only one domain name per IPv6 address in the cable-specific DNS cache.
  - Domain names for the link local address are not supported.
  - The **no ip domain-name** command disables DNS lookup.
-

## Procedure

|               | Command or Action                                                                                                                                           | Purpose                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Router> enable                                                                                                          | Enables privileged EXEC mode. Enter your password if prompted.                                                 |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Router# configure terminal                                                                                  | Enters global configuration mode.                                                                              |
| <b>Step 3</b> | <b>ip name-server [vrf vrf-name] server-address1 [server-address2...server-address6]</b><br><b>Example:</b><br>Router(config)# ip name-server 2001:DB8::/32 | Specifies the address of one or more name servers to use for name and address resolution.                      |
| <b>Step 4</b> | <b>exit</b><br><b>Example:</b><br>Router(config)# exit                                                                                                      | Leaves global configuration mode and enters privileged EXEC mode.                                              |
| <b>Step 5</b> | <b>show cable modem domain-name</b><br><b>Example:</b><br>Router# show cable modem domain-name                                                              | Updates the cable-specific DNS cache and displays the domain name for all CMs and the CPE devices behind a CM. |

## Configuring IPv6 Source Verification

Typically, the IPv6 source verification feature is enabled on a cable bundle interface. From there, the cable interface is associated with the virtual bundle interface to acquire its configuration.

When you enable IPv6 source verification on a cable line card interface, the source verification routine verifies the MAC address-MD-SID-IP binding of the packet. If the source verification succeeds, the packet is forwarded. If the verification fails, the packet is dropped.

When a CM is operating as a bridge modem device, then the CMTS router verifies all the IPv6 addresses related to that CM and the CPEs behind that CM.

The **cable ipv6 source-verify** command controls only the source verification of IPv6 packets. For IPv4-based source verification, use the **cable source-verify** command, which also supports different options.

For more information about how to configure IPv6 source verification on a bundle interface, see the [Configuring the Cable Virtual Bundle Interface, on page 824](#).

### Restrictions

Source verification of IPv6 packets occurs only on packets in the process-switched path of the Route Processor (RP).

## Configuring IPv6 VPN over MPLS

The Cisco CMTS routers support the IPv6 VPN over MPLS (6VPE) feature. Implementing this feature includes the following configuration tasks.

- Configuring a VRF instance for IPv6
- Binding a VRF to an interface
- Creating a subinterface
- Configuring a static route for PE-to-CE-routing
- Configuring eBGP PE-to-CE routing sessions
- Configuring the IPv6 VPN address family for iBGP
- Configuring route reflectors for improved scalability
- Configuring Internet access

For detailed information about the configuration examples, see [Configuration Examples for IPv6 on Cable, on page 839](#).

---

**Note** The IPv6 address of the sub-bundle interface (to which the CM is connected) is used in the DHCPv6 relay packet of the CPE DHCPv6 request. If the DHCPv6 packet has to go from one VRF interface to another, the IPv6 address of each VRF interface should be configured on the Cisco CMTS to establish connectivity.

---

## Configuring DHCPv6 Relay Agent

The Cisco CMTS router supports DHCPv6 relay agent to forward relay-forward messages from a specific source address to client relay destinations.

Perform the steps given below to enable the DHCPv6 relay agent function and specify relay destination addresses on an interface.

### Before you begin

The relay-forward messages should contain specific source IPv6 address. This is required because the firewall deployed between the Cisco CMTS DHCPv6 relay agent and the DHCPv6 server expects only one source address for one Cisco CMTS bundle interface.

---

**Restriction** If you change one or more parameters of the **ipv6 dhcp relay destination** command, you have to disable the command using the **no** form, and execute the command again with changed parameters.

---

## Procedure

|               | Command or Action                                                                                                                                                                                                                                                                          | Purpose                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Router> enable                                                                                                                                                                                                                                     | Enables privileged EXEC mode. Enter your password if prompted.                                                           |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# configure terminal                                                                                                                                                                                                             | Enters global configuration mode.                                                                                        |
| <b>Step 3</b> | <b>interface type number</b><br><b>Example:</b><br><br>Router(config)# <b>interface ethernet 4/2</b>                                                                                                                                                                                       | Specifies an interface type and number, and places the router in interface configuration mode.                           |
| <b>Step 4</b> | <b>ipv6 dhcp relay destination ipv6-address[ interface] [link-address link-address ] [ source-address source-address]</b><br><b>Example:</b><br><br>Router(config-if) <b>ipv6 dhcp relay destination 2001:db8:1234::1 ethernet 4/2 link-address 2001:db8::1 source-address 2001:db8::2</b> | Specifies a destination address to which client packets are forwarded and enables DHCPv6 relay service on the interface. |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br><br>Router(config-if) <b>end</b>                                                                                                                                                                                                                          | Exits interface configuration mode and enters privileged EXEC mode.                                                      |

## Configuring IPv6 Source Address and Link Address

In some network deployments, there is a firewall between CNR servers and CMTS router. The firewall only allows packets from certain addresses to transmit to CMTS router.

To allow the DHCPv6 message to be sent to CNR server with specific source address, user needs to configure the source address of the relayed forwarded DHCPv6 message in the following 3 ways:

1. In the global configuration mode, use the command **ipv6 dhcp-relay source-interface interface-type interface-number**
2. In the interface configuration mode, use the command **ipv6 dhcp relay source-interface interface-type interface-number**
3. In the interface configuration mode, use the command **ipv6 dhcp relay destination ipv6-address[interface] [link-address link-address ] [source-address source-address]**

If the user does not have any of the above configuration, the DHCPv6 message will be relay forwarded with default source-address, which will be calculated based on relay destination address.

If any one of above is configured, the source-address of the DHCPv6 message will be based on that configuration.

If more than one configuration above is configured, the overriding rule is that more specific configuration wins, i.e., 3>2>1.

## Configurable DOCSIS CMTS Capabilities DHCPv6 Field

According to DOCSIS 3.1 specification, CMTS must support DOCSIS 3.0 cable modems and features. To support the backward compatibility of DOCSIS versions, the DHCPv6 vendor option must change from 30 to 31.

You can now upgrade to any DOCSIS version using the **cable docsis-ver [major version | minor version]** command.

The default value of the command is **cable docsis-ver 3 1**.

## Disabling IPv6 ND Gleaning

You must disable IPv6 ND gleaning before configuring IPv6 source verification using DHCPv6 leasequery.

### Procedure

|        | Command or Action                                                                                           | Purpose                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><br>Router> enable                                                      | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                            |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><br>Router# configure terminal                              | Enters global configuration mode.                                                                                                                                         |
| Step 3 | <b>interfacebundle</b> <i>bundle-no</i><br><b>Example:</b><br><br>Router(config)# <b>interface bundle 1</b> | Specifies a bundle interface number and enters bundle interface configuration mode.<br><br>• <i>bundle-no</i> —Bundle interface number. The valid range is from 1 to 255. |
| Step 4 | <b>no cable nd</b><br><b>Example:</b><br><br>Router(config-if) <b>no cable nd</b>                           | Disables IPv6 ND gleaning on the Cisco CMTS router.                                                                                                                       |
| Step 5 | <b>end</b><br><b>Example:</b>                                                                               | Returns to privileged EXEC mode.                                                                                                                                          |

|  | Command or Action            | Purpose |
|--|------------------------------|---------|
|  | Router(config-if) <b>end</b> |         |

## How to Verify IPv6 Dual Stack CPE Support

This section describes how to use **show** commands to verify the configuration of the IPv6 Dual Stack CPE Support on the CMTS feature.

### Procedure

|               | Command or Action                                                                                                                                                                                                                                       | Purpose                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                                                                                                               | Enables privileged EXEC mode. Enter your password if prompted.                                                                  |
| <b>Step 2</b> | <b>show cable modem [ip-address   mac-address ] ipv6[ cpe   prefix   registered   unregistered]</b><br><b>Example:</b><br>Router# <b>show cable modem ipv6 registered</b><br><b>Example:</b><br>Router# <b>show cable modem 0019.474a.c14a ipv6 cpe</b> | Displays IPv6 information for specified CMs and CPEs behind a CM on a Cisco CMTS router. You can specify the following options: |
| <b>Step 3</b> | <b>show cable modem [ip-address   mac-address] registered</b><br><b>Example:</b><br>Router# <b>show cable modem 0019.474e.e4DF registered</b>                                                                                                           | Displays a list of the CMs that have registered with the Cisco CMTS. You can specify the following options:                     |
| <b>Step 4</b> | <b>show cable modem {ip-address   mac-address} cpe</b><br><b>Example:</b><br>Router# <b>show cable modem 0019.474a.c14a cpe</b>                                                                                                                         | Displays the CPE devices accessing the cable interface through a particular CM. You can specify the following options:          |

## Examples

Use the **show cable modem ipv6** command to display the IPv6 portion of a dual stack CPE and use the **show cable modem cpe** command to display the IPv4 mode of a dual stack CPE. Both **show cable modem ipv6 registered** and **show cable modem registered** commands display CPE count as one for a dual stack CPE.

The following example shows the output of the **show cable modem ipv6** command:

```
Router# show cable modem ipv6 registered
Interface Prim Online CPE IP Address MAC Address
```

```

 Sid State
C4/0/U2 1 online 0 ---
C4/0/U2 3 online(pt) 1 2001:420:3800:809:EDA4:350C:2F75:4779 0019.474a.c18c
Router# show cable modem 0019.474a.c14a ipv6 cpe
MAC Address IP Address Domain Name
0005.0052.2c1d 2001:420:3800:809:48F7:3C33:B774:9185

```

The following example shows the output of the **show cable modem ipv6** command:

```

Router# show cable modem
 0023.bed9.4c8e ipv6 cpe
Load for five secs: 0%/0%; one minute: 1%; five minutes: 1%
Time source is hardware calendar, *06:37:20.439 UTC Thu Aug 2 2012
MAC Address IP Address
0023.bed9.4c91 2001:40:3:4:200:5EB7:BB6:C759
2001:40:3:4:210:D73B:7A50:2D05

```

The following example shows the output of the **show cable modem registered** command:

```

Router# show cable modem registered
Interface Prim Online Timing Rec QoS CPE IP address MAC address
 Sid State Offset Power
C4/0/U2 3 online 1022 0.00 2 1 50.3.37.12 0019.474a.c14a

```

The following example shows the output of the **show cable modem cpe** command:

```

Router# show cable modem 0019.474a.c14a cpe
IP address MAC address Dual IP
50.3.37.3 0005.0052.2c1d Y

```

## Configuration Examples for IPv6 on Cable

This section includes the following examples:

### Example: IPv6 over Subinterfaces

The following example shows the CMTS bundle configuration that can be used with subinterfaces:

```

Router# show cable modem ipv6
Device Type: B - CM Bridge, R - CM Router
IP Assignment Method: D - DHCP
MAC Address Type Interface Mac State D/IP IP Address
0019.474a.c18c B/D C4/0/U2 online Y 2001:420:3800:809:4C7A:D518:91
C6:8A18
Router# show run interface bundle2
Building configuration...
Current configuration : 138 bytes
!
interface Bundle2
 no ip address
 cable arp filter request-send 3 2
 cable arp filter reply-accept 3 2
 no cable ip-multicast-echo
end
Router#

show run interface bundle2.1

```

```

Building configuration...
Current configuration : 382 bytes
!
interface Bundle2.1
 ip address 50.3.37.1 255.255.255.0
 no cable ip-multicast-echo
 cable helper-address 10.10.0.12
 ipv6 address 2001:DB8::/32
 ipv6 enable
 ipv6 nd prefix default no-advertise
 ipv6 nd managed-config-flag
 ipv6 nd other-config-flag
 ipv6 nd ra interval msec 2000
 ipv6 dhcp relay destination 2001:420:3800:800:203:BAFF:FE11:B644
 arp timeout 240
end

```

## Example: Basic IPv6 Cable Filter Groups

The following example shows the configuration of an IPv6 filter group that drops traffic from a specific IPv6 host (with source address 2001:DB8::1/48) behind a cable router to an IPv6 host on the network (with destination address 2001:DB8::5/64):

```

configure terminal
!
! Specify the filter group criteria using a common group ID
!
cable filter group 254 index 128 v6-src-address 2001:DB8::1
cable filter group 254 index 128 v6-src-pfxlen 128
cable filter group 254 index 128 v6-dest-address 2001:DB8::5
cable filter group 254 index 128 v6-dest-pfxlen 128
!
! Specify that the filter group is IP version 6
!
cable filter group 254 index 128 ip-version ipv6
!
! Specify the drop action for matching packets
!
cable filter group 254 index 128 match-action drop
!
! Apply the filter group with ID 254 to all CM upstream traffic
!
cable submgmt default filter-group cm upstream 254

```

## Example: Complete Cable Configuration with IPv6

The following example shows a complete cable configuration example; it also displays the configuration of multiple cable filter groups using both IPv4 and IPv6 and separate indexes to associate the filter definitions with the same group ID.

```

Router# show running-config
Building configuration...
Current configuration : 15010 bytes
!

## Example: BGP Configuration for 6VPE

The following example shows a sample BGP configuration on CMTS 6VPE.

```

Router# router bgp 1
no synchronization
bgp log-neighbor-changes
neighbor 11.1.1.5 remote-as 1
neighbor 11.1.1.5 update-source Loopback1
no auto-summary
!
address-family vpnv6 --- Enable vpnv6 AF
 neighbor 11.1.1.5 activate --- Activate neighbor 6VPE-2
 neighbor 11.1.1.5 send-community extended
exit-address-family
!
address-family ipv6 vrf vrf_mgmt
 redistribute connected ---- Publish directly connected route
 redistribute static
 no synchronization
exit-address-family
!
address-family ipv6 vrf vrfa --- Enable IPv6 vrf AF for each VRF
 redistribute connected
 no synchronization
exit-address-family
!
address-family ipv6 vrf vrfb --- Enable IPv6 vrf AF for each VRF
 redistribute connected
 no synchronization

```

```
exit-address-family
!
```

## Example: Subinterface Configuration for 6VPE

The following example shows how to define a subinterface on virtual bundle interface 1.

When configuring IPv6 VPNs, you must configure the first subinterface created as a part of the management VRF. In the following example, Bundle 1.10 is the first sub-interface, which is configured into management VRF. Make sure the CNR server is reachable in management VRF.

```
interface Bundle1.10 --- Management VRF
 vrf forwarding vrf_mgmt
 cable dhcp-giaddr primary
 ipv6 address 2001:40:3:110::1/64
 ipv6 enable
 ipv6 nd managed-config-flag
 ipv6 nd other-config-flag
 ipv6 dhcp relay destination 2001:10:74:129::2
interface Bundle1.11 --- VRF A
 vrf forwarding vrfa
 cable dhcp-giaddr primary
 ipv6 address 2001:40:3:111::1/64
 ipv6 enable
 ipv6 dhcp relay destination 2001:10:74:129::2
interface Bundle1.12 --- VRFB
 vrf forwarding vrfb
 cable dhcp-giaddr primary
 ipv6 address 2001:40:3:112::1/64
 ipv6 enable
 ipv6 dhcp relay destination 2001:10:74:129::2
```

## Example: Cable Interface Bundling

The following example shows how to bundle a group of physical interfaces.

```
int C5/0/4 and int c5/0/3 are bundled.
int c5/0/4
cable bundle 1
int c5/0/3
cable bundle 1
```

## Example: VRF Configuration for 6VPE

The following example shows how to create VRFs for each VPN.

```
vrf definition vrf_mgmt
 rd 1:1
 !
 address-family ipv4
 route-target export 1:1
 route-target import 1:1
 route-target import 2:2
 route-target import 2:1
 exit-address-family
 !
 address-family ipv6
```

```

route-target export 1:1
route-target import 1:1
route-target import 2:1 -- import route of vrfa
route-target import 2:2 -- import route of vrfb
exit-address-family

```

## Verifying IPv6 on Cable

This section explains how to verify IPv6 on cable configuration and it contains the following topics:

### Verifying IPv6 VRF Configuration

To verify the IPv6 VRF configuration, use the `show vrf ipv6` command in privileged EXEC mode.

```

Router# show vrf ipv6 vrfa
 Name Default RD Protocols Interfaces
 vrfa 2:1 ipv4,ipv6 Bu1.11
Router# show vrf ipv6 interfaces
Interface VRF Protocol Address

Bu1.10 vrf_mgmt up 2001:40:3:110::1
Fa0/0/0 vrf_mgmt up 2001:20:4:1::38
Bu1.11 vrfa up 2001:40:3:111::1
Bu1.12 vrfb up 2001:40:3:112::1
CMTS#

```

### Verifying IPv6 BGP Status

To verify the IPv6 BGP status, use the `show ip bgp` command in privileged EXEC mode.

```

Router# show ip bgp vpnv6 unicast all neighbors

BGP neighbor is 11.1.1.5, remote AS 1, internal link
 BGP version 4, remote router ID 11.1.1.5
 Session state = Established, up for 00:35:52
 Last read 00:00:37, last write 00:00:14, hold time is 180, keepalive interval is 60 seconds

 BGP multisession with 2 sessions (2 established), first up for 00:40:07
 Neighbor sessions:
 2 active, is multisession capable
 Neighbor capabilities:
 Route refresh: advertised and received(new) on session 1, 2
 Address family IPv4 Unicast: advertised and received
 Address family VPNv6 Unicast: advertised and received

```

### Verifying MPLS Forwarding Table

To verify the output of the MPLS forwarding table, use the `show mpls forwarding-table` command in the privileged EXEC mode.

```

Router# show mpls forwarding-table

Local Outgoing Prefix Bytes Label Outgoing Next Hop
Label Label or VC or Tunnel Id Switched interface
.....
19 No Label 2001:40:3:110::/64[V] \
vrf_mgmt ---Route in
 0
 aggregate/vrf_mgmt
21 No Label 2001:40:3:111::/64[V] \
vrfa ---Route in
 0
 aggregate/vrfa
22 No Label 2001:40:3:112::/64[V] \
vrfb ---Route in
 0
 aggregate/vrfb
.....

```

## Verifying IPv6 Cable Modem and its Host State

To verify IPv6 addresses and connected host states of cable modems and CPEs, use the **show interface cable modem** command in the privileged EXEC mode:

```

Router# show interface cable 7/0/0 modem ipv6
SID Type State IPv6 Address M MAC address
11 CM online 2001:420:3800:809:3519:5F9C:B96A:D31 D 0025.2e2d.743a
11 CPE unknown 2001:420:3800:809:3DB2:8A6C:115F:41D8 D 0011.2544.f33b

```

## Verifying Multiple IAPDs in a Single Advertise

To verify the multiple IPv6 prefixes assigned to devices on a network, use the **show cable modem ipv6 prefix** command in privileged EXEC mode:

```

Router# show cable modem ipv6 prefix
Load for five secs: 1%/0%; one minute: 1%; five minutes: 1%
Time source is hardware calendar, *06:36:53.075 UTC Thu Aug 2 2012
Device Type: B - CM Bridge, R - CM Router
IP Assignment Method: D - DHCP
MAC Address Type IPv6 prefix
0023.bed9.4c91 R/D 2001:40:1012::/64
 R/D 2001:40:2012:1::/64
0000.002e.074c R/D 2001:40:1012:8::/64
 R/D 2001:40:2012:1D::/64
0000.002e.074b R/D 2001:40:1012:23::/64
 R/D 2001:40:2012:1C::/64
0000.002e.074a R/D 2001:40:1012:22::/64
 R/D 2001:40:2012:1B::/64

```

To verify the multiple IPv6 prefixes assigned to CPEs behind a CM with a specific MAC address, use the **show cable modem mac-address ipv6 prefix** command in privileged EXEC mode:

```

Router# show cable modem 0023.bed9.4c8e ipv6 prefix
Load for five secs: 0%/0%; one minute: 1%; five minutes: 1%
Time source is hardware calendar, *06:37:22.335 UTC Thu Aug 2 2012
Device Type: B - CM Bridge, R - CM Router
IP Assignment Method: D - DHCP
MAC Address Type IPv6 prefix
0023.bed9.4c91 R/D 2001:40:1012::/64
 R/D 2001:40:2012:1::/64

```

To verify the IPv6 information of CPEs behind a CM with a specific MAC address, use the `show cable modem mac-address ipv6 cpe` command in privileged EXEC mode:

```
Router# show cable modem 0023.bed9.4c8e ipv6 cpe
Load for five secs: 0%/0%; one minute: 1%; five minutes: 1%
Time source is hardware calendar, *06:37:20.439 UTC Thu Aug 2 2012
MAC Address IP Address
0023.bed9.4c91 2001:40:3:4:200:5EB7:BB6:C759
 2001:40:3:4:210:D73B:7A50:2D05
```

## Supported MIBs

### CISCO-DOCS-EXT-MIB

The CISCO-DOCS-EXT-MIB contains objects that support extensions to the Data-over-Cable Service Interface Specifications (DOCSIS) interface MIB, DOCS-IF-MIB.

- `CdxBundleIpHelperEntry`—Provides a list of cable helper entries on the bundle and sub-bundle interfaces.
- `CdxBundleIPv6DHCPRelayEntry`—Contains the IPv6 DHCP relay option, IPv6 DHCP relay source-interface details, and IPv6 DHCP relay trust configuration on a bundle and sub-bundle interface.
- `CdxBundleIPv6DHCPRelayDestEntry`—Contains a list of IPv6 DHCP relay destination entries on the cable bundle and sub-bundle interfaces.

## Feature Information for IPv6 on Cable

Use Cisco Feature Navigator to find information about the platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to the <https://cfnng.cisco.com/> link. An account on the Cisco.com page is not required.

**Note** The following table lists the software release in which a given feature is introduced. Unless noted otherwise, subsequent releases of that software release train also support that feature.

**Table 148: Feature Information for Downstream Interface Configuration**

| Feature Name                                       | Releases                    | Feature Information                                                                |
|----------------------------------------------------|-----------------------------|------------------------------------------------------------------------------------|
| Configurable DOCSIS CMTS Capabilities DHCPv6 Field | Cisco IOS XE Fuji 16.7.1    | This feature was introduced on the Cisco cBR Series Converged Broadband Routers.   |
| IPv6 on cable                                      | Cisco IOS XE Everest 16.6.1 | This feature was integrated into the Cisco cBR Series Converged Broadband Routers. |

## CHAPTER 56

# Cable DHCP Leasequery

---

This document describes the Dynamic Host Configuration Protocol (DHCP) Leasequery feature on the Cisco cable modem termination system (CMTS) router.

### Finding Feature Information

Your software release may not support all the features that are documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. The Feature Information Table at the end of this document provides information about the documented features and lists the releases in which each feature is supported.

## Prerequisites for Cable DHCP Leasequery

- You must configure a cable interface with the **cable source-verify dhcp** command and the **no cable arp** command before the Cisco CMTS router can enable DHCP Leasequery. Lease queries are sent to the DHCP server or to a configured alternate server.

To divert DHCP Leasequeries to a specific server, you must use the cable **source-verify dhcp server** ipaddress command and the **no cable arp** command before the Cisco CMTS router is enabled for DHCP Leasequery. Only one alternate server may be configured.

- You must configure the **ipv6 route** command when IPv6 Customer Premise Equipment (CPE) routers are deployed on the Cisco CMTS router.

## Restrictions for Cable DHCP Leasequery

- Leasequeries are sent to the DHCP server unless an alternate server is configured.
- Only one alternate server can be configured.
- Users are responsible for the synchronization of the DHCP server and the configured alternate server.

- If the configured alternate server fails, leasequery requests are *not* returned to the DHCP server.
- Only one IA\_IADDR is supported per client. If the leasequery returns multiple results, only the IA\_ADDR matching the query is added to the Cisco CMTS subscriber database.
- The Cisco CMTS will not verify the source of the IPv6 link-local address of a CPE.

## Information About Cable DHCP Leasequery

Problems can occur when viruses, denial of service (DoS) attacks, and theft-of-service attacks begin scanning a range of IP addresses, in an attempt to find unused addresses. When the Cisco CMTS router is verifying unknown IP addresses, this type of scanning generates a large volume of DHCP leasequeries, which can result in the following problems:

- High CPU utilization on the Cisco CMTS router PRE card.
- High utilization on the DHCP servers, resulting in a slow response time or no response at all.
- Packets can be dropped by the Cisco CMTS router or DHCP server (or configured alternate server).
- Lack of available bandwidth for other customers on the cable interface.

To prevent such a large volume of leasequery requests on cable interfaces, you can enable filtering of these requests on upstream interfaces, downstream interfaces, or both. When the Cable DHCP Leasequery feature is enabled, the Cisco CMTS allows only a certain number of DHCP leasequery requests for each service ID (SID) on an interface within the configured interval time period. If an SID generates more Leasequeries than the maximum, the router drops the excess number of requests until the next interval period begins.

You can configure both the number of allowable DHCP leasequery requests and the interval time period, so as to match the capabilities of your DHCP server (or configured alternate server) and cable network.

To configure the Cisco CMTS router to send DHCP leasequery requests to the DHCP server, use the **cable source-verify dhcp** and **no cable arp** commands. Unknown IP addresses that are found in packets for customer premises equipment (CPE) devices that use the cable modems on the cable interface are verified. The DHCP server returns a DHCP ACK message with the DHCP relay information and lease information of the CPE device that has been assigned this IP address, if any.

When **cable source-verify dhcp** and **no cable arp** commands are configured, DHCP leasequery is sent for downstream packets to verify unknown IP addresses within the IP address range configured on the cable bundle interface.

For DHCP leasequery to work in the downstream direction, the Cisco Network Registrar (CNR) should be made aware of the DHCP Option 82. This is required to make the CMTS map the CPE IP address to the correct CM. To do this, configure the **ip dhcp relay information option** command on the bundle interface to insert service class relay agent option into the DHCP DISCOVER messages. When the configuration is in place, during DHCP DISCOVER the values of DHCP Option 82 is cached by the CNR and is returned to the CMTS on any subsequent DHCP leasequery for that IP address.

To configure the Cisco CMTS router to divert DHCP leasequery requests to a server other than the DHCP server, use the **cable source-verify dhcp server ipaddress** and **no cable arp** commands.

The Cisco CMTS supports two types of DHCP leasequery implementation, Cisco standard compliant DHCP leasequery and RFC 4388 standard compliant DHCP leasequery. These two standards differ mostly in the identifiers used to query or respond to the DHCP Server. You can choose between these two implementations depending on which standard is supported on your DHCP Server.

Use the **ip dhcp compatibility lease-query client {cisco | standard}** command to configure the Cisco CMTS in either Cisco mode or RFC 4388 standard mode.

## DHCP MAC Address Exclusion List

This feature enables the ability to exclude trusted MAC addresses from the standard DHCP source verification checks for the Cisco CMTS. The DHCP MAC Address Exclusion List feature enables packets from trusted MAC addresses to pass when otherwise packets would be rejected with standard DHCP source verification. This feature overrides the cable source-verify command on the Cisco CMTS for the specified MAC address, yet maintains overall support for standard and enabled DHCP source verification processes. This feature is supported on the Performance Routing Engine 1 (PRE1), PRE2, and PRE4 modules on the Cisco cBR router chassis.

To enable packets from trusted source MAC addresses in DHCP to pass without source verification checks, use the cable trust command in global configuration mode. To remove a trusted MAC address from the MAC exclusion list, use the no form of this command. Removing a MAC address from the exclusion list subjects all packets from that source to standard DHCP source verification.

For more information on the cable trust command, see the [Cisco IOS CMTS Cable Command Reference Guide](#).

## Unitary DHCPv6 Leasequery

This feature supports unitary DHCPv6 leasequery protocol (RFC 5007) on the Cisco CMTS routers for upstream IPv6 source verification. This protocol verifies the authenticity of the IPv6 CPE behind a home or small office cable deployment.

If the IPv6 source verification fails on the router and the **cable ipv6 source-verify dhcp** and **no cable nd** commands are configured on the bundle interface or subinterface, the Cisco CMTS triggers a unitary DHCPv6 leasequery to the Cisco Network Registrar (CNR). If a valid leasequery response is received from the CNR, the Cisco CMTS adds the CPE to its subscriber database and allows future traffic for the CPE.

The primary use of the unitary DHCPv6 leasequery protocol on the Cisco CMTS router is to recover lost CPE data including the Prefix Delegation (PD) route. The IPv6 CPE data can be lost from the Cisco CMTS in several ways. For example, PD route loss can occur during a Cisco CMTS reload.

The unitary DHCPv6 leasequery protocol also supports the following:

- DHCPv6 leasequery protocol.
- Rogue client database for failed source-verify clients.
- DHCPv6 leasequery filters.
- DHCPv6 leasequeries to a specific DHCPv6 server.

## How to Configure Filtering of Cable DHCP Leasequery Requests

Use the following procedures to configure the filtering of DHCP Leasequery requests on the Cisco CMTS downstreams and upstreams:

### Enabling DHCP Leasequery Filtering on Downstreams

Use the following procedure to start filtering DHCP leasequeries on all downstreams of a cable interface.

## Procedure

|               | Command or Action                                                                                                                                                                                     | Purpose                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Router> <b>enable</b>                                                                                                                                         | Enables privileged EXEC mode.<br><br>• Enter your password if prompted.                                                                             |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# <b>configure terminal</b>                                                                                                                 | Enters global configuration mode.                                                                                                                   |
| <b>Step 3</b> | <b>cable source-verify leasequery-filter downstream</b><br><i>threshold interval</i><br><b>Example:</b><br><br>Router(config)# <b>cable source-verify</b><br><b>leasequery-filter downstream 5 10</b> | Enables leasequery filtering on all downstreams on the specified bundle interface, using the specified <i>threshold</i> and <i>interval</i> values. |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br><br>Router(config)# <b>end</b>                                                                                                                                       | Exits configuration mode and returns to privileged EXEC mode.                                                                                       |

## Enabling DHCP Leasequery Filtering on Upstreams

Use the following procedure to start filtering DHCP Leasequeries on all upstreams on a bundle interface.

## Procedure

|               | Command or Action                                                                     | Purpose                                                                 |
|---------------|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Router> <b>enable</b>                         | Enables privileged EXEC mode.<br><br>• Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Router# <b>configure terminal</b> | Enters global configuration mode.                                       |
| <b>Step 3</b> | <b>interface bundle</b> <i>bundle-no</i><br><b>Example:</b>                           | Enters interface configuration mode for the specified bundle interface. |

|               | Command or Action                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Router(config)# <b>interface bundle 1</b>                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 4</b> | <b>cable source-verify leasequery-filter upstream <i>threshold interval</i></b><br><b>Example:</b><br>Router(config-if)# <b>cable source-verify leasequery-filter upstream 2 5</b> | Enables leasequery filtering on all upstreams on the specified bundle interface, using the specified <i>threshold</i> and <i>interval</i> values.<br><br><b>Note</b> The <b>cable source-verify leasequery-filter upstream</b> command can only be configured under bundle interface.<br><br><b>Note</b> Repeat step 3 and step 4 to enable the filtering of DHCP Leasequeries on the upstreams for other bundle interfaces. Primary and secondary interfaces in a cable bundle must be configured separately. |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Router(config-if)# <b>end</b>                                                                                                                     | Exits interface configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Configuring Unitary DHCPv6 Leasequery Filtering

Use the following procedure to configure the Cisco CMTS router to send Leasequeries to a DHCP server to verify the authenticity of the IPv6 CPE. You can also enable filtering of these requests to prevent large volumes of Leasequery requests on the bundle interfaces. Similarly, the number of allowable Leasequery requests and the interval time period can also be configured.

**Note** When the leasequery timer expires, only the IPv4 static CPE is automatically removed from the host database.

### Before you begin

- Disable the IPv6 Neighbor Discovery (ND) Gleaning feature using the **no** form of the **cable nd** command in bundle interface configuration mode before configuring the unitary DHCPv6 leasequery protocol. For details on IPv6 ND gleaning, see [IPv6 on Cable](#) feature guide.
- Configure the **cable ipv6 source-verify dhcp** command under the Cisco CMTS bundle or bundle subinterface to enable the unitary DHCPv6 leasequery protocol.
- Use the **cable ipv6 source-verify dhcp [server *ipv6-address*]** command for a single DHCP server.
- Use the **cable ipv6 source-verify dhcp** command without any keywords for multiple DHCP servers.

### Procedure

|               | Command or Action | Purpose                       |
|---------------|-------------------|-------------------------------|
| <b>Step 1</b> | <b>enable</b>     | Enables privileged EXEC mode. |

|               | Command or Action                                                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <b>Example:</b><br><br>Router> <b>enable</b>                                                                                                                                                                                                                                      | <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                   |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br><br>Router# <b>configure terminal</b>                                                                                                                                                                                         | Enters global configuration mode.                                                                                                                                                                                                                      |
| <b>Step 3</b> | <b>interface bundle <i>bundle-no</i></b><br><br><b>Example:</b><br><br>Router(config)# <b>interface bundle 1</b>                                                                                                                                                                  | Enters interface configuration mode for the specified bundle interface.                                                                                                                                                                                |
| <b>Step 4</b> | <b>cable ipv6 source-verify</b> or <b>cable ipv6 source-verify dhcp</b><br>[server ipv6-address]<br><br><b>Example:</b><br><br>Router(config-if)# <b>cable ipv6 source-verify</b><br>or<br>Router(config-if)# <b>cable ipv6 source-verify dhcp</b><br><b>server 2001:DB8:1::1</b> | Enables leasequery filtering on the specified bundle interface and verifies the IP address with multiple DHCPv6 servers. or Enables leasequery filtering on the specified bundle interface and verifies the IP address with a specified DHCPv6 server. |
| <b>Step 5</b> | <b>cable ipv6 source-verify leasetimer <i>value</i></b><br><br><b>Example:</b><br><br>Router(config-if)# <b>cable ipv6 source-verify</b><br><b>leasetimer 200</b>                                                                                                                 | Enables leasequery timer on the specified bundle interface, for the Cisco CMTS to check its internal CPE database for IPv6 addresses whose lease time has expired.                                                                                     |
| <b>Step 6</b> | <b>cable ipv6 source-verify leasequery-filter <i>threshold interval</i></b><br><br><b>Example:</b><br><br>Router(config-if)# <b>cable ipv6 source-verify</b><br><b>leasetimer 5 10</b>                                                                                            | Enables filtering of the IPv6 leasequery requests.                                                                                                                                                                                                     |
| <b>Step 7</b> | <b>end</b><br><br><b>Example:</b><br><br>Router(config-if)# <b>end</b>                                                                                                                                                                                                            | Exits interface configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                |

## Enabling DHCPv6 Leasequery Filtering on Downstreams

Use the following procedure to start filtering DHCP Leasequeries on all downstreams of a cable interface.

### Procedure

|               | Command or Action                                                                                                                                                                                      | Purpose                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Router> <b>enable</b>                                                                                                                                              | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                    |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                                                                      | Enters global configuration mode.                                                                                                     |
| <b>Step 3</b> | <b>cable ipv6 source-verify leasequery-filter downstream<br/>           threshold interval</b><br><b>Example:</b><br>Router(config-if)# <b>cable ipv6 source-verify<br/>           leasetimer 5 10</b> | Enables leasequery filtering on all downstreams on the specified bundle interface, using the specified threshold and interval values: |
