Configuring Multicast VPN

The Multicast VPN (MVPN) feature provides the ability to support multicast over a Layer 3 Virtual Private Network (VPN). As enterprises extend the reach of their multicast applications, service providers can accommodate these enterprises over their Multiprotocol Label Switching (MPLS) core network. IP multicast is used to stream video, voice, and data to an MPLS VPN network core.

Historically, point-to-point tunnels were the only way to connect through a service provider network. Although such tunneled networks tend to have scalability issues, they represented the only means of passing IP multicast traffic through a VPN.

Because Layer 3 VPNs support only unicast traffic connectivity, deploying in conjunction with a Layer 3 VPN allows service providers to offer both unicast and multicast connectivity to Layer 3 VPN customers.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Multicast VPN

- Before performing the tasks in this module, you should be familiar with the concepts described in the “IP Multicast Technology Overview” module.
- The tasks in this module assume that IP multicasting has been enabled and that the Protocol Independent Multicast (PIM) interfaces have been configured using the tasks described in the “Configuring Basic IP Multicast” module.

Restrictions for Configuring Multicast VPN

- The update source interface for the Border Gateway Protocol (BGP) peerings must be the same for all BGP peerings configured on the router in order for the default multicast distribution tree (MDT) to be configured properly. If you use a loopback address for BGP peering, then PIM sparse mode must be enabled on the loopback address.
- The **ip mroute-cache** command must be enabled on the loopback interface used as the BGP peering interface in order for distributed multicast switching to function on the platforms that support it. The **no ip mroute-cache** command must not be present on these interfaces.
- MVPN does not support multiple BGP peering update sources.
- Data MDTs are not created for VPN routing and forwarding instance (VRF) PIM dense mode multicast streams because of the flood and prune nature of dense mode multicast flows and the resulting periodic bring-up and tear-down of such data MDTs.
- Multiple BGP update sources are not supported and configuring them can break MVPN reverse path forwarding (RPF) checking. The source IP address of the MVPN tunnels is determined by the highest IP address used for the BGP peering update source. If this IP address is not the IP address used as the BGP peering address with the remote provider edge (PE) router, MVPN will not function properly.

Information About Configuring Multicast VPN

Multicast VPN Operation

MVPN IP allows a service provider to configure and support multicast traffic in an MPLS VPN environment. This feature supports routing and forwarding of multicast packets for each individual VRF instance, and it also provides a mechanism to transport VPN multicast packets across the service provider backbone.

A VPN is network connectivity across a shared infrastructure, such as an Internet service provider (ISP). Its function is to provide the same policies and performance as a private network, at a reduced cost of ownership, thus creating many opportunities for cost savings through operations and infrastructure.

An MVPN allows an enterprise to transparently interconnect its private network across the network backbone of a service provider. The use of an MVPN to interconnect an enterprise network in this way does not change the way that enterprise network is administered, nor does it change general enterprise connectivity.

Benefits of Multicast VPN

- Provides a scalable method to dynamically send information to multiple locations.
- Provides high-speed information delivery.
- Provides connectivity through a shared infrastructure.

Multicast VPN Routing and Forwarding and Multicast Domains

MVPN introduces multicast routing information to the VPN routing and forwarding table. When a provider edge (PE) router receives multicast data or control packets from a customer edge (CE) router, forwarding is performed according to the information in the Multicast VPN routing and forwarding instance (MVRF). MVPN does not use label switching.

A set of MVRFs that can send multicast traffic to each other constitutes a multicast domain. For example, the multicast domain for a customer that wanted to send certain types of multicast traffic to all global employees would consist of all CE routers associated with that enterprise.

Multicast Distribution Trees

MVPN establishes a static default MDT for each multicast domain. The default MDT defines the path used by PE routers to send multicast data and control messages to every other PE router in the multicast domain.

If Source Specific Multicast (SSM) is used as the core multicast routing protocol, then the multicast IP addresses used for the default and data multicast distribution tree (MDT) must be configured within the SSM range on all PE routers.

MVPN also supports the dynamic creation of MDTs for high-bandwidth transmission. Data MDTs are a feature unique to Cisco IOS software. Data MDTs are intended for high-bandwidth sources such as full-motion video inside the VPN to ensure optimal traffic forwarding in the MPLS VPN core. The threshold at which the data MDT is created can be configured on a per-router or a per-VRF basis. When the multicast transmission exceeds the defined threshold, the sending PE router creates the data MDT and sends a User Datagram Protocol (UDP) message, which contains information about the data MDT to all routers on the default MDT. The statistics to determine whether a multicast stream has exceeded the data MDT threshold are examined once every second. After a PE router sends the UDP message, it waits 3 more seconds before switching over; 13 seconds is the worst case switchover time and 3 seconds is the best case.

Data MDTs are created only for (S, G) multicast route entries within the VRF multicast routing table. They are not created for (*, G) entries regardless of the value of the individual source data rate.

In the following example, a service provider has a multicast customer with offices in San Jose, New York, and Dallas. A one-way multicast presentation is occurring in San Jose. The service provider network supports all three sites associated with this customer, in addition to the Houston site of a different enterprise customer.

The default MDT for the enterprise customer consists of provider routers P1, P2, and P3 and their associated PE routers. PE4 is not part of the default MDT, because it is associated with a different

customer. The figure shows that no data flows along the default MDT, because no one outside of San Jose has joined the multicast.

Figure 1 Default Multicast Distribution Tree Overview

An employee in New York joins the multicast session. The PE router associated with the New York site sends a join request that flows across the default MDT for the multicast domain of the customer. PE1, the

PE router associated with the multicast session source, receives the request. The figure depicts that the PE router forwards the request to the CE router associated with the multicast source (CE1a).

Figure 2 *Initializing the Data MDT*

The CE router (CE1a) begins to send the multicast data to the associated PE router (PE1), which sends the multicast data along the default MDT. Immediately sending the multicast data, PE1 recognizes that the multicast data exceeds the bandwidth threshold for which a data MDT should be created. Therefore, PE1 creates a data MDT, sends a message to all routers using the default MDT that contains information about the data MDT, and, three seconds later, begins sending the multicast data for that particular stream using the data MDT. Only PE2 has interested receivers for this source, so only PE2 will join the data MDT and receive traffic on it.

PE routers maintain a PIM relationship with other PE routers over the default MDT and a PIM relationship with its directly attached PE routers.

Multicast Tunnel Interface

An MVRF, which is created per multicast domain, requires the router to create a tunnel interface from which all MVRF traffic is sourced. A multicast tunnel interface is an interface the MVRF uses to access the multicast domain. It can be thought of as a conduit that connects an MVRF and the global MVRF. One tunnel interface is created per MVRF.

Multicast Distributed Switching Support for Multicast VPN

Multicast distributed switching (MDS) is supported for MVPN on the Cisco 7500 series routers. When MDS is configured, ensure that all interfaces enabled for IP multicast have MDS enabled correctly--verify that no interface has the **no ip mroute-cache** command configured (including loopback interfaces).

MDT Address Family in BGP for Multicast VPN

The **mdt** keyword has been added to the **address-family ipv4** command to configure an MDT address-family session. MDT address-family sessions are used to pass the source PE address and MDT group address to PIM using Border Gateway Protocol (BGP) MDT Subaddress Family Identifier (SAFI) updates.

- [BGP Advertisement Methods for Multicast VPN Support, page 6](#)
- [Automigration to the MDT SAFI, page 8](#)
- [Guidelines for Configuring the MDT SAFI, page 8](#)
- [Guidelines for Upgrading a Network to Support the MDT SAFI, page 8](#)
- [Supported Policy, page 9](#)

BGP Advertisement Methods for Multicast VPN Support

In a single autonomous system, if the default MDT for an MVPN is using PIM sparse mode (PIM-SM) with a rendezvous point (RP), then PIM is able to establish adjacencies over the Multicast Tunnel Interface (MTI) because the source PE and receiver PE discover each other through the RP. In this scenario, the local PE (the source PE) sends register messages to the RP, which then builds a shortest-path tree (SPT) toward the source PE. The remote PE, which acts as a receiver for the MDT multicast group, then sends (*, G) joins toward the RP and joins the distribution tree for that group.

However, if the default MDT group is configured in a PIM Source Specific Multicast (PIM-SSM) environment rather than a PIM-SM environment, the receiver PE needs information about the source PE and the default MDT group. This information is used to send (S, G) joins toward the source PE to build a distribution tree from the source PE (without the need for an RP). The source PE address and default MDT group address are sent using BGP.

The table lists the BGP advertisement methods for sending the source PE address and the default MDT group that are available (by Cisco IOS release).

Table 1 *BGP Advertisement Methods for MVPN*

Cisco IOS Release	BGP Advertisement Method
<ul style="list-style-type: none"> • Release 12.0(29)S • Release 12.2(33)SRA1 • Release 12.2(31)SB2 • Release 12.2(33)SXH 	Extended Communities

Cisco IOS Release	BGP Advertisement Method
<ul style="list-style-type: none"> • Release 12.0(29)S and later 12.0S releases • Release 12.2(31)SB2 and later 12.2SB releases • Release 12.2(33)SRA and later 12.2SR releases • Release 12.2(33)SXH and later 12.2SX releases 	BGP address family MDT SAFI
<ul style="list-style-type: none"> • BGP Extended Community, page 7 • BGP MDT SAFI, page 7 	

BGP Extended Community

When BGP extended communities are used, the PE loopback (source address) information is sent as a VPNv4 prefix using Route Distinguisher (RD) Type 2 (to distinguish it from unicast VPNv4 prefixes). The MDT group address is carried in a BGP extended community. Using a combination of the embedded source in the VPNv4 address and the group in the extended community, PE routers in the same MVRF instance can establish SSM trees to each other.

Note

Prior to the introduction of MDT SAFI support, the BGP extended community attribute was used as an interim solution to advertise the IP address of the source PE and default MDT group before IETF standardization. A BGP extended community attribute in an MVPN environment, however, has certain limitations: it cannot be used in inter-AS scenarios (because the attribute is nontransitive), and it uses RD Type 2 (which is not a supported standard).

BGP MDT SAFI

In Cisco IOS software releases that support the MDT SAFI, the source PE address and the MDT group address are passed to PIM using BGP MDT SAFI updates. The RD type has changed to RD type 0 and BGP determines the best path for the MDT updates before passing the information to PIM.

Note

To prevent backwards-compatibility issues, BGP allows the communication of the older style updates with peers that are unable to understand the MDT SAFI address family.

In Cisco IOS software releases that support the MDT SAFI, the MDT SAFI address family needs to be explicitly configured for BGP neighbors using the **address-family ipv4 mdt** command. Neighbors that do not support the MDT SAFI still need to be enabled for the MDT SAFI in the local BGP configuration. Prior to the introduction of the MDT SAFI, additional BGP configuration from the VPNv4 unicast configuration was not needed to support MVPN.

Because the new MDT SAFI does not use BGP route-target extended communities, the regular extended community methods to filter these updates no longer apply. As a result, the **match mdt-group** route-map configuration command has been added to filter on the MDT group address using Access Control Lists (ACLs). These route maps can be applied--inbound or outbound--to the IPv4 MDT address-family neighbor configuration.

Automigration to the MDT SAFI

In Cisco IOS Release 12.0(30)S3, automigration to the MDT SAFI functionality was introduced to ease the migration to the MDT SAFI. This functionality was integrated into Cisco IOS Releases 12.2(33)SRA1, 12.2(31)SB2, and 12.2(33)SXH. When migrating a Cisco IOS release to the MDT SAFI, existing VPNv4 neighbors will be automatically configured for the MDT SAFI upon bootup based on the presence of an existing default MDT configuration (that is, pre-MDT SAFI configurations will be automatically converted to an MDT SAFI configuration upon bootup). In addition, when a default MDT configuration exists and a VPNv4 neighbor in BGP is configured, a similar neighbor in the IPv4 MDT address family will be automatically configured.

Note

Because there is no VRF configuration on route reflectors (RRs), automigration to the MDT SAFI will not be triggered on RRs. The MDT SAFI configuration, thus, will need to be manually configured on RRs. Having a uniform MDT transmission method will reduce processing time on the routers (because MDT SAFI conversion is not necessary).

Guidelines for Configuring the MDT SAFI

- We recommend that you configure the MDT SAFI on all routers that participate in the MVPN. Even though the benefits of the MDT SAFI are for SSM tree building, the MDT SAFI must also be configured when using MVPN with the default MDT group for PIM-SM. From the multicast point of view, the MDT SAFI is not required for MVPN to work within a PIM-SM core. However, in certain scenarios, the new address family must be configured in order to create the MTI. Without this notification, the MTI would not be created and MVPN would not function (even with PIM-SM).
- For backward compatible sessions, extended communities must be enabled on all MDT SAFI peers. In a pure MDT SAFI environment there is no need to configure extended communities explicitly for MVPN. However, extended communities will be needed for VPNv4 interior BGP (iBGP) sessions to relay the route-target. In a hybrid (MDT SAFI and pre-MDT SAFI) environment, extended communities must be configured to send the embedded source in the VPNv4 address and the MDT group address to MDT SAFI neighbors.

Guidelines for Upgrading a Network to Support the MDT SAFI

When moving from a pre-MDT SAFI to an MDT SAFI environment, the upmost care should be taken to minimize the impact to the MVPN service. The unicast service will not be affected, other than the outage due to the reload and recovery. To upgrade a network to support the MDT SAFI, we recommend that you perform the following steps:

- 1 Upgrade the PEs in the MVPN to a Cisco IOS release that supports the MDT SAFI. Upon bootup, the PE configurations will be automigrated to the MDT SAFI. For more information about the automigration to the MDT SAFI functionality, see the [Automigration to the MDT SAFI, page 8](#) section.
- 2 After the PEs have been upgraded, upgrade the RRs and enable the MDT SAFI for all peers providing MVPN service. Enabling or disabling the MDT SAFI will reset the BGP peer relationship for all address families; thus, a loss of routing information may occur.

**Note**

In the case of a multihomed BGP RR scenario, one of the RRs must be upgraded and configured last. The upgraded PEs will use this RR to relay MDT advertisements while the other RRs are being upgraded.

Supported Policy

The following policy configuration parameters are supported under the MDT SAFI:

- Mandatory attributes and well-known attributes, such as the AS-path, multiexit discriminator (MED), BGP local-pref, and next hop attributes.
- Standard communities, community lists, and route maps.

How to Configure Multicast VPN

- [Configuring a Default MDT Group for a VRF](#), page 9
- [Configuring the MDT Address Family in BGP for Multicast VPN](#), page 10
- [Configuring the Data Multicast Group](#), page 13
- [Configuring Multicast Routes and Information](#), page 14
- [Verifying Information for the MDT Default Group](#), page 15

Configuring a Default MDT Group for a VRF

Perform this task to configure a default MDT group for a VRF.

The default MDT group must be the same group configured on all routers that belong to the same VPN. The source IP address will be the address used to source the BGP sessions.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip multicast-routing**
4. **ip multicast-routing vrf** *vrf-name*
5. **ip vrf** *vrf-name*
6. **mdt default** *group-address*

DETAILED STEPS

Command or Action	Purpose
Step 1 enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

Command or Action	Purpose
Step 2 <code>configure terminal</code> Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3 <code>ip multicast-routing</code> Example: <pre>Router(config)# ip multicast-routing</pre>	Enables multicast routing.
Step 4 <code>ip multicast-routing vrf vrf-name</code> Example: <pre>Router(config)# ip multicast-routing vrf vrf1</pre>	Supports the MVPN VRF instance.
Step 5 <code>ip vrf vrf-name</code> Example: <pre>Router(config)# ip vrf vrf1</pre>	Enters VRF configuration mode and defines the VPN routing instance by assigning a VRF name.
Step 6 <code>mdt default group-address</code> Example: <pre>Router(config-vrf)# mdt default 232.0.0.1</pre>	Configures the multicast group address range for data MDT groups for a VRF. <ul style="list-style-type: none"> • A tunnel interface is created as a result of this command. • By default, the destination address of the tunnel header is the <i>group-address</i> argument.

Configuring the MDT Address Family in BGP for Multicast VPN

Perform this task to configure an MDT address family session on PE routers to establish MDT peering sessions for MVPN.

Before MVPN peering can be established through an MDT address family, MPLS and Cisco Express Forwarding (CEF) must be configured in the BGP network and multiprotocol BGP on PE routers that provide VPN services to CE routers.

Note

The following policy configuration parameters are not supported:

- Route-originator attribute
- Network Layer Reachability Information (NLRI) prefix filtering (prefix lists, distribute lists)
- Extended community attributes (route target and site of origin)

>

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp** *as-number*
4. **address-family ipv4 mdt**
5. **neighbor** *neighbor-address* **activate**
6. **neighbor** *neighbor-address* **send-community** [**both** | **extended** | **standard**]
7. **exit**
8. **address-family vpnv4**
9. **neighbor** *neighbor-address* **activate**
10. **neighbor** *neighbor-address* **send-community** [**both** | **extended** | **standard**]
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
Step 3	<p>router bgp <i>as-number</i></p> <p>Example:</p> <pre>Router(config)# router bgp 65535</pre>	<p>Enters router configuration mode and creates a BGP routing process.</p>

Command or Action	Purpose
<p>Step 4 <code>address-family ipv4 mdt</code></p> <p>Example:</p> <pre>Router(config-router)# address-family ipv4 mdt</pre>	<p>Enters address family configuration mode to create an IP MDT address family session.</p>
<p>Step 5 <code>neighbor neighbor-address activate</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	<p>Enables the MDT address family for this neighbor.</p>
<p>Step 6 <code>neighbor neighbor-address send-community [both extended standard]</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 send-community extended</pre>	<p>Enables community and (or) extended community exchange with the specified neighbor.</p>
<p>Step 7 <code>exit</code></p> <p>Example:</p> <pre>Router(config-router-af)# exit</pre>	<p>Exits address family configuration mode and returns to router configuration mode.</p>
<p>Step 8 <code>address-family vpnv4</code></p> <p>Example:</p> <pre>Router(config-router)# address-family vpnv4</pre>	<p>Enters address family configuration mode to create a VPNv4 address family session.</p>
<p>Step 9 <code>neighbor neighbor-address activate</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	<p>Enables the VPNv4 address family for this neighbor.</p>
<p>Step 10 <code>neighbor neighbor-address send-community [both extended standard]</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 send-community extended</pre>	<p>Enables community and (or) extended community exchange with the specified neighbor.</p>

Command or Action	Purpose
Step 11 <code>end</code> Example: <code>Router(config-router-af)# end</code>	Exits address family configuration mode and enters privileged EXEC mode.

Configuring the Data Multicast Group

Perform this task to configure a data MDT group.

A data MDT group can include a maximum of 256 multicast groups per VPN per VRF per PE router. Multicast groups used to create the data MDT group are dynamically chosen from a pool of configured IP addresses.

- Before configuring a default MDT group, the VPN must be configured for multicast routing as described in the [Configuring a Default MDT Group for a VRF, page 9](#).
- All access lists needed when using the tasks in this module should be configured prior to beginning the configuration task. For information about how to configure an access list, see the “Creating an IP Access List and Applying It to an Interface” module.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip vrf vrf-name`
4. `mdt data group-address-range wildcard-bits [threshold kb/s] [list access-list]`
5. `mdt log-reuse`
6. `exit`

DETAILED STEPS

Command or Action	Purpose
Step 1 <code>enable</code> Example: <code>Router> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2 <code>configure terminal</code> Example: <code>Router# configure terminal</code>	Enters global configuration mode.

Command or Action	Purpose
<p>Step 3 <code>ip vrf vrf-name</code></p> <p>Example:</p> <pre>Router(config)# ip vrf vrf1</pre>	<p>Enters VRF configuration mode and defines the VPN routing instance by assigning a VRF name.</p>
<p>Step 4 <code>mdt data group-address-range wildcard-bits [threshold kb/s] [list access-list]</code></p> <p>Example:</p> <pre>Router(config-vrf)# mdt data 239.192.20.32 0.0.0.15 threshold 1</pre>	<p>Specifies a range of addresses to be used in the data MDT pool.</p> <ul style="list-style-type: none"> For the <i>group-address-range</i> and <i>wildcard-bits</i> arguments, specify a multicast group address range. The range is from 224.0.0.1 to 239.255.255.255. Because the range of addresses used in the data MDT pool are multicast group addresses (Class D addresses), there is no concept of a subnet; therefore, you can use all addresses in the mask (wildcard) range that you specify for the <i>wildcard-bits</i> argument. The threshold is in kb/s. The range is from 1 through 4294967. Use the optional list keyword and <i>access-list</i> argument to define the (S, G) MVPN entries to be used in a data MDT pool, which would further limit the creation of a data MDT pool to the particular (S, G) MVPN entries defined in the access list specified for the <i>access-list</i> argument
<p>Step 5 <code>mdt log-reuse</code></p> <p>Example:</p> <pre>Router(config-vrf)# mdt log-reuse</pre>	<p>(Optional) Enables the recording of data MDT reuse and generates a syslog message when a data MDT has been reused.</p>
<p>Step 6 <code>exit</code></p> <p>Example:</p> <pre>Router(config-vrf)# exit</pre>	<p>Returns to global configuration mode.</p>

Configuring Multicast Routes and Information

Perform this task to limit the number of multicast routes that can be added in a router.

- Before configuring a default MDT group, the VPN must be configured for multicast routing as described in the [Configuring a Default MDT Group for a VRF](#), page 9.
- All access lists needed when using the tasks in this module should be configured prior to beginning the configuration task. For information about how to configure an access list, see the “Creating an IP Access List and Applying It to an Interface” module.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip multicast vrf *vrf-name* route-limit *limit* [*threshold*]**
4. **ip multicast mroute-filter *access-list***

DETAILED STEPS

Command or Action	Purpose
Step 1 enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2 configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3 ip multicast vrf <i>vrf-name</i> route-limit <i>limit</i> [<i>threshold</i>] Example: <pre>Router(config)# ip multicast vrf cisco route-limit 200000 20000</pre>	Sets the mroute limit and the threshold parameters.
Step 4 ip multicast mroute-filter <i>access-list</i> Example: <pre>Router(config)# ip multicast mroute-filter 4</pre>	Filters the multicast router information request packets for all sources specified in the access list.

Verifying Information for the MDT Default Group

Perform this task to verify information about the MDT default group.

SUMMARY STEPS

1. **enable**
2. **show ip msdp [vrf *vrf-name*] peer [*peer-address* | *peer-name*]**
3. **show ip msdp [vrf *vrf-name*] summary**
4. **show ip pim [vrf *vrf-name*] mdt bgp**
5. **show ip pim [vrf *vrf-name*] mdt send**
6. **show ip pim mdt history**

DETAILED STEPS

Step 1

enable

Enables privileged EXEC mode.

- Enter your password if prompted.

Router> **enable**

Step 2

show ip msdp [vrf vrf-name] peer [peer-address | peer-name]

Enter the **show ip msdp peer** command to verify detailed information about MSDP peer 224.135.250.116:

Example:

```
Router# show ip msdp peer 224.135.250.116

MSDP Peer 224.135.250.116 (rtp5-rpl.cisco.com), AS 109 (configured AS)
Description:
Connection status:
  State: Up, Resets: 9, Connection source: Loopback2 (228.69.199.17)
  Uptime(Downtime): 1d10h, Messages sent/received: 436765/429062
  Output messages discarded: 0
  Connection and counters cleared 1w2d ago
SA Filtering:
  Input (S,G) filter: none, route-map: none
  Input RP filter: none, route-map: none
  Output (S,G) filter: none, route-map: none
  Output RP filter: none, route-map: none
SA-Requests:
  Input filter: none
  Sending SA-Requests to peer: disabled
Peer ttl threshold: 0
SAs learned from this peer: 32, SAs limit: 500
Input queue size: 0, Output queue size: 0
```

Step 3

show ip msdp [vrf vrf-name] summary

Enter the **show ip msdp summary** command to display MSDP peer status:

Example:

```
Router# show ip msdp summary

MSDP Peer Status Summary
Peer Address      AS      State   Uptime/  Reset SA   Peer Name
                  AS      State   Downtime Count Count
224.135.250.116  109    Up      1d10h   9      111  rtp5-rpl
*144.228.240.253 1239   Up      14:24:00 5      4010 sl-rp-stk
172.16.253.19    109    Up      12:36:17 5      10   rtp4-rpl
172.16.170.110   109    Up      1d11h   9      12   ams-rpl
```

Step 4

show ip pim [vrf vrf-name] mdt bgp

To display information about and to verify information about the BGP advertisement of the RD for the MDT default group, use the **show ip pim mdt bgp** command in privileged EXEC mode:

Example:

```
Router# show ip pim mdt bgp
```

```
MDT-default group 232.2.1.4
rid:1.1.1.1 next_hop:1.1.1.1
```

Step 5**show ip pim [vrf vrf-name] mdt send**

To display detailed information about and to verify information regarding the MDT data group, perform the following steps.

Enter the **show ip pim mdt send** command to show the MDT advertisements that a specified router has made:

Example:

```
Router# show ip pim mdt send

MDT-data send list for VRF:vpn8
  (source, group)                MDT-data group    ref_count
(10.100.8.10, 225.1.8.1)         232.2.8.0         1
(10.100.8.10, 225.1.8.2)         232.2.8.1         1
(10.100.8.10, 225.1.8.3)         232.2.8.2         1
(10.100.8.10, 225.1.8.4)         232.2.8.3         1
(10.100.8.10, 225.1.8.5)         232.2.8.4         1
(10.100.8.10, 225.1.8.6)         232.2.8.5         1
(10.100.8.10, 225.1.8.7)         232.2.8.6         1
(10.100.8.10, 225.1.8.8)         232.2.8.7         1
(10.100.8.10, 225.1.8.9)         232.2.8.8         1
(10.100.8.10, 225.1.8.10)        232.2.8.9         1
```

Step 6**show ip pim mdt history**

Enter the **show ip pim mdt history** command to display the data MDTs that have been reused during the past configured interval.

Example:

```
Router# show ip pim vrf vrf1 mdt history interval 20

MDT-data send history for VRF - vrf1 for the past 20 minutes
MDT-data group      Number of reuse
  10.9.9.8           3
  10.9.9.9           2
```

Configuration Examples for Multicast VPN

- [Configuring MVPN and SSM Example, page 18](#)
- [Enabling a VPN for Multicast Routing Example, page 18](#)
- [Configuring the MDT Address Family in BGP for Multicast VPN Example, page 18](#)
- [Configuring the Multicast Group Address Range for Data MDT Groups Example, page 18](#)
- [Limiting the Number of Multicast Routes Example, page 19](#)

Configuring MVPN and SSM Example

In the following example, PIM-SSM is configured in the backbone. Therefore, the default and data MDT groups are configured within the SSM range of IP addresses. Inside the VPN, PIM-SM is configured and only Auto-RP announcements are accepted.

```
ip vrf vrfl
 rd 1:1
  route-target export 1:1
  route-target import 1:1
  mdt default 232.0.0.1
  mdt data 232.0.1.0 0.0.0.255 threshold 500 list 101
!
ip pim ssm default
ip pim vrf vrfl accept-rp auto-rp
```

Enabling a VPN for Multicast Routing Example

In the following example, multicast routing is enabled with a VPN routing instance named vrfl:

```
ip multicast-routing vrfl
```

Configuring the MDT Address Family in BGP for Multicast VPN Example

In the following example, an MDT address family session is configured on a PE router to establish MDT peering sessions for MVPN.

```
!
ip vrf test
 rd 55:2222
  route-target export 55:2222
  route-target import 55:2222
  mdt default 232.0.0.1
!
ip multicast-routing
ip multicast-routing vrf test
!
router bgp 55
.
.
.
!
address-family vpnv4
 neighbor 192.168.1.1 activate
 neighbor 192.168.1.1 send-community both
!
address-family ipv4 mdt
 neighbor 192.168.1.1 activate
 neighbor 192.168.1.1 send-community both
!
```

Configuring the Multicast Group Address Range for Data MDT Groups Example

In the following example, the VPN routing instance is assigned a VRF named blue. The MDT default group for a VPN VRF is 239.1.1.1, and the multicast group address range for MDT groups is 239.1.2.0 with wildcard bits of 0.0.0.3:

```
ip vrf blue
```

```
rd 55:1111
route-target both 55:1111
mdt default 239.1.1.1
mdt data 239.1.2.0 0.0.0.3
end
```

Limiting the Number of Multicast Routes Example

In the following example, the number of multicast routes that can be added in to a multicast routing table is set to 200,000 and the threshold value of the number of mroutes that will cause a warning message to occur is set to 20,000:

```
!
ip multicast-routing distributed
ip multicast-routing vrf cisco distributed
ip multicast cache-headers
ip multicast route-limit 200000 20000
ip multicast vrf cisco route-limit 200000 20000
no mpls traffic-eng auto-bw timers frequency 0
!
```

Feature Information for Configuring Multicast VPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 2 **Feature Information for Configuring Multicast VPN**

Feature Name	Releases	Feature Information
Multicast VPN--IP Multicast Support of MPLS VPNs	12.0(23)S 12.2(13)T 12.2(14)S 12.0(25)S1 12.0(26)S 12.0(32)SY 12.2(18)SXE 15.0(1)S	The Multicast VPN feature provides the ability to support multicast over a Layer 3 Virtual Private Network (VPN). As enterprises extend the reach of their multicast applications, service providers can accommodate these enterprises over their Multiprotocol Label Switching (MPLS) core network. IP multicast is used to stream video, voice, and data to an MPLS VPN network core. In Cisco IOS Release 12.2(18)SXE, support for this feature on the Cisco Catalyst 6000 Series Switches was added.

Configuring Multicast VPN Inter-AS Support

The Multicast VPN Inter-AS Support feature enables Multicast Distribution Trees (MDTs) used for Multicast VPNs (MVPNs) to span multiple autonomous systems. Benefits include increased multicast coverage to customers that require multicast to span multiple service providers in a Multiprotocol Label Switching (MPLS) Layer 3 Virtual Private Network (VPN) service with the flexibility to support all options described in RFC 4364. Additionally, the Multicast VPN Inter-AS Support feature can be used to consolidate an existing MVPN service with another MVPN service, such as the case with a company merger or acquisition.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Multicast VPN Inter-AS Support

- You understand IP multicast concepts and configuration tasks.
- You understand MVPN concepts and configuration tasks.
- You understand Border Gateway Protocol (BGP) concepts and configuration tasks.
- You understand MPLS Layer 3 VPN concepts and configuration tasks.

Restrictions for Configuring Multicast VPN Inter-AS Support

The Multicast VPN Inter-AS Support feature requires that all routers in the core be configured for Protocol Independent Multicast (PIM) Source Specific Multicast (SSM). Protocol Independent Multicast sparse mode (PIM-SM) and bidirectional PIM (bidir-PIM) are not supported.

Information About Multicast VPN Inter-AS Support

- [Benefits of MVPN Inter-AS Support, page 24](#)
- [MVPN Inter-AS Support Implementation Requirements, page 24](#)
- [MVPN Inter-AS Support Solution for Options B and C, page 27](#)
- [MVPN Inter-AS MDT Establishment for Option B, page 31](#)
- [MVPN Inter-AS MDT Establishment for Option C, page 36](#)

MVPN Inter-AS Support Overview

As a general concept, MVPN inter-AS support enables service providers to provide multicast connectivity to VPN sites that span multiple autonomous systems. There are two types of MVPN inter-AS deployment scenarios:

- Single provider inter-AS--A service provider whose internal network consists of multiple autonomous systems.
- Intraprovider inter-AS--Multiple service providers that need to coordinate their networks to provide inter-AS support.

The extensions added to support the Multicast VPN Inter-AS Support feature enable MDTs used for MVPNs to span multiple autonomous systems.

Benefits of MVPN Inter-AS Support

The MVPN Inter-AS Support feature provides the following benefits to service providers:

- Increased multicast coverage to customers that require multicast to span multiple services providers in an MPLS Layer 3 VPN service with the flexibility to support all options described in RFC 4364.
- The ability to consolidate an existing MVPN service with another MVPN service, such as the case with a company merger or acquisition.

MVPN Inter-AS Support Implementation Requirements

The Multicast VPN Inter-AS Support feature was implemented in the software in accordance to the following requirements:

- To achieve parity with unicast inter-AS support, the software must support the following inter-AS options for MVPN (as defined in RFC 4364):
 - Option A--Back-to-back VPN routing and forwarding (VRF) instances at the Autonomous System Border Router (ASBR) provider edge (PE) routers

The Option A model assumes direct connectivity between PE routers of different autonomous systems. The PE routers are attached by multiple physical or logical interfaces, each of which is associated with a given VPN (through a VRF instance). Each PE router, therefore, treats the adjacent PE router like a customer edge (CE) router, and the standard Layer 3 MPLS VPN mechanisms are used for route redistribution with each autonomous system; that is, the PEs use exterior BGP (eBGP) to distribute unlabeled IPv4 addresses to each other.

**Note**

Option A allows service providers to isolate each autonomous system from the other, which provides better control over routing exchanges and security between the two networks. Option A, however, is considered the least scalable of all the inter-AS connectivity options.

- ◦ Option B--VPNv4 route exchange between ASBRs

In the Option B model, the PE routers use interior BGP (iBGP) to redistribute labeled VPNv4 routes either to an ASBR or to a route reflector of which an ASBR is a client. ASBRs then use multiprotocol eBGP (MP-eBGP) to advertise VPNv4 routes into the local autonomous system.

MP-eBGP provides the functionality to advertise VPNv4 prefix and label information across the service provider boundaries. The advertising ASBR router replaces the two-level label stack (which it uses to reach the originating PE router and VPN destination in the local autonomous system) with a locally allocated label before advertising the VPNv4 route. This replacement is necessary because the next-hop attribute of all routes advertised between the two service providers is reset to the ASBR router's peering address, so the ASBR router becomes the termination point of the label-switched path (LSP) for the advertised routes. To preserve the LSP between ingress and egress PE routers, the ASBR router must allocate a local label that may be used to identify the label stack of the route within the local VPN network. This newly allocated label is set on packets sent toward the prefix from the adjacent service provider.

**Note**

Option B enables service providers to isolate both autonomous systems with the added advantage that it scales to a higher degree than Option A.

- ◦ Option C--Exchange of VPNv4 routes between route reflectors (RRs) using multihop eBGP peering sessions

The Option C model combines MP-eBGP exchange of VPNv4 routes between RR of different autonomous systems with the next hops for these routes exchanged between corresponding ASBR routers. In the Option C model, VPNv4 routes are neither maintained nor distributed by the ASBRs. ASBRs must maintain labeled IPv4 /32 routes to the PE routers within its autonomous system and use eBGP to distribute these routes to other autonomous systems. ASBRs in any transit autonomous systems will also have to use eBGP to pass along the labeled /32 routes. The result is the creation of a LSP from the ingress PE router to the egress PE router.

Because RRs of different autonomous systems will not be directly connected, multihop functionality is required to allow for the establishment of the MP-eBGP peering sessions. The exchange of next hops is necessary because the RRs do not reset the next-hop attribute of the VPNv4 routes when advertising them to adjacent autonomous systems because they do not want to attract the traffic for the destinations that they advertise. They are not the original endpoint--just a relay station between the source and receiver PEs. The PE router next-hop addresses for the VPNv4 routes, thus, are exchanged between ASBR routers. The exchange of these addresses between autonomous systems can be accomplished by redistributing the PE router /32 addresses between the autonomous systems or by using BGP label distribution.

**Note**

Option C normally is deployed only when each autonomous system belongs to the same overall authority, such as a global Layer 3 MPLS VPN service provider with autonomous systems in different regions of the world. Option B is equally suited for this purpose and is also deployed in networks where autonomy between different regions is desired.

- The Cisco software must support inter-AS MDTs. An inter-AS MDT is an MDT that extends across autonomous system boundaries. In the context of MVPN, because MVPN packets are encapsulated when being forwarded between ASBRs, an inter-AS MDT is needed (for Option B and Option C) to extend the MDT across the boundaries of the autonomous system.
- [Limitations That Prevented Option B and Option C Support, page 26](#)
- [MVPN Inter-AS Support for Option A, page 26](#)

Limitations That Prevented Option B and Option C Support

Prior to the extensions introduced in association with the Multicast VPN Inter-AS Support feature, limitations existed that prevented MVPN inter-AS support for Option B and Option C. These limitations were related to the following areas:

- Supporting reverse path forwarding (RPF) for inter-AS sources (applicable mainly to Option B)
 - When a PE router sends a PIM join (source PE address, MDT group address) for the default MDT, each P router in the path between the source and the destination PE routers must perform an RPF check on the source. Because Interior Gateway Protocol (IGP) routes (which would include the routes to source PE routers in remote autonomous systems) are not leaked across autonomous systems, the P routers in the receiving autonomous system were unable to perform an RPF check.
 - When a PIM join is received in an MVPN, an IP lookup is performed in the VRF to find the next hop toward the destination. This destination must be a PIM neighbor that can be reached through the MDT tunnel interface. However, because ASBRs change the next hop of the originating PE router for a given MDT group, the originating source address would be lost, and the RPF check at the PE router would fail.

**Note**

In typical Option C inter-AS deployments, the limitation related to supporting RPF for MVPN inter-AS support was not applicable because the RRs store all VPNv4 routes.

- Supporting an inter-AS MDT (applicable to Option B and Option C)
 - The default MDT relies on the ability of the PE routers to join the default multicast group. The source of the group is the originating PE router address used for MP-BGP peering. Prior to the extensions introduced in association with the Multicast VPN Inter-AS Support feature, this address could not be reached between autonomous systems because IGP routes could not be distributed across the autonomous systems. The default MDT for inter-AS MVPN, thus, could not be established.

MVPN Inter-AS Support for Option A

The limitations that prevented support for MVPN inter-AS support Options B and C have never applied to Option A for the following reasons:

- For Option A, native IP forwarding is used by the PE routers between autonomous systems; therefore, Option A does not require support for inter-AS MDTs.
- For Option A, the MDT is limited to one autonomous system; therefore, the issues associated with managing MDT group addresses between autonomous systems and RPF for inter-AS sources never applied to Option A.

**Note**

Because Option A requires that one physical or logical interface be configured for each VRF, Option A is considered the least scalable MVPN inter-AS solution.

MVPN Inter-AS Support Solution for Options B and C

The following extensions introduced in association with the MVPN Inter-AS Support feature resolve the MVPN inter-AS protocol limitations related to supporting RPF and inter-AS MDTs in Option B and C deployments:

- BGP connector attribute in MP-BGP--This attribute helps preserve the identity of a PE router originating a VPNv4 prefix. This BGP extension helps solve the challenge of supporting RPF to sources in a remote autonomous system.
- BGP MDT Subaddress Family Identifier (SAFI)--This identifier helps ASBRs RPF to source PEs in a remote autonomous systems. The BGP MDT SAFI also helps ASBRs and receiver PEs insert the RPF Vector needed to build an inter-AS MDT to source PEs in remote autonomous systems.
- [BGP Connector Attribute, page 27](#)
- [BGP MDT SAFI Updates for MVPN Inter-AS Support, page 28](#)
- [PIM RPF Vector, page 29](#)
- [MDT Address Family in BGP for Multicast VPN Inter-AS Support, page 30](#)

BGP Connector Attribute

In an adjacent autonomous system, a PE router that wants to join a particular source of the default MDT for a given MVPN must know the originator's address of the source PE router. This presents some challenges for Option B inter-AS deployments because the originator next hop for VPNv4 routes is rewritten at one or more points in the network. To solve this limitation, each VPNv4 route must carry a new attribute (the BGP connector attribute) that defines the route's originator.

The BGP connector attribute is a transitive attribute that stores the PE router that originated a VPNv4 prefix. In a local autonomous system, the BGP connector attribute is the same as the next hop attribute. When advertised to other ASBRs in VPNv4 advertisements (as is the case in Option B), the value of the BGP connector attribute is preserved even after the next hop attribute is rewritten by ASBRs. The BGP connector attribute is a critical component of the MVPN inter-AS solution, helping to enable RPF to sources in remote autonomous systems.

**Note**

The BGP connector attribute also helps ASBRs and receiver PEs insert the RPF Vector needed to build the inter-AS MDT for source PEs in remote autonomous systems. For more information about RPF Vectors, see the [PIM RPF Vector](#), page 29 section.

The format of the BGP connector attribute is shown in the figure.

Figure 3 *BGP Connector Attribute*

Type (2 Octets)
Length (2 Octets)
Value (Variable)
Type is the Type of the data contained in this TLV. Length is the Length of the Value portion in the TLV. Value is a variable length field defined by the AFI/SAFI carried in this tuple, which would be used by the AFI/SAFI in this tuple.

231214

BGP MDT SAFI Updates for MVPN Inter-AS Support

The BGP MDT SAFI is specifically designed to carry the address of the source PE router to which a PIM join should be sent for the MDT group contained in the PIM join. The format of the Network Layer Reachability Information (NLRI) carried in this SAFI is {RD:PE-IP-address}. The BGP MDT SAFI is capable of being advertised across autonomous system boundaries. Each MDT group is carried in the MP_REACH attribute using the format shown in the figure.

Figure 4 *MDT SAFI Format*

RD:IPv4 Address (12 Octets)
MDT Group Address (4 Octets)
RD: Route distinguisher of the VRF to which the MDT attribute belongs. IPv4 Address: IPv4 address of the originating PE router. MDT Group Address: Group address of the MDT group that a given VRF is associated with.

231215

When RRs and MP-eBGP peerings are used, the advertisement of the BGP MDT SAFI is independent of the advertisement of VPNv4 routes. BGP MDT SAFI advertisements, however, are processed and filtered like VPNv4 advertisements.

ASBRs store the path advertised in BGP MDT SAFI updates in a separate table. How the BGP MDT SAFI is advertised determines the RPF path to the PE router that originated the advertisement.

PEs also store the BGP MDT SAFI update in a separate table. PE routers use the information contained in the BGP MDT SAFI to determine the ASBR that is the exit router to the source PE router in an adjacent autonomous system.

PIM RPF Vector

Normally, in an MVPN environment, PIM sends join messages containing the IP address of upstream PE routers that are sources of a given MDT group. To be able to perform RPF checks, however, P routers must have IPv4 reachability to source PE routers in remote autonomous systems. This behavior is not the case with inter-AS Options B and C because the autonomous systems do not exchange any of their IGP routes, including those of their local PE routers. However, P routers do have reachability to the BGP next hop of the BGP MDT update received with the BGP MDT SAFI updates at the PE routers. Therefore, if the PE routers add the remote PE router IP address (as received within the BGP MDT SAFI) and the BGP next-hop address of this address within the PIM join, the P routers can perform an RPF check on the BGP next-hop address rather than the original PE router address, which, in turn, allows the P router to forward the join toward the ASBR that injected the MDT SAFI updates for a remote autonomous system. This functionality is generally referred to as the *PIM RPF Vector*; the actual vector that is inserted into PIM joins is referred to as the *RPF Vector* or the *Proxy Vector*. The PIM RPF Vector, therefore, enables P routers to determine the exit ASBR to a source PE router in a remote autonomous system. Having received the join that contains a RPF Vector, an ASBR can then determine that the next-hop address is in fact itself and can perform an RPF check based on the originating PE router address carried in the PIM join.

When configured on PE routers using the `ip multicast rpf proxy vector` command, the RPF Vector is encoded as a part of the source address in PIM join and prune messages. The RPF Vector is the IGP next hop for PIM RPF neighbor in PIM join and prune messages, which is typically the exit ASBR router to a prefix in a remote autonomous system.

The format of this PIM RPF Vector encoding in PIM join and prune messages is shown in the figure.

Figure 5 PIM RPF Vector Encoded in PIM Join and Prune Messages

Note

RPF Vectors can be used natively in an IP environment (that is, in a non-VPN environment). For more information about the use of RPF Vectors in a native environment, see RFC 5496, [The Reverse Path Forwarding \(RPF\) Vector TLV](#).

- [Originators of an RPF Vector, page 29](#)
- [Recipients of an RPF Vector, page 30](#)
- [ASBR Receipt of an RPF Vector, page 30](#)
- [Interoperability with RPF Vector, page 30](#)

Originators of an RPF Vector

Whether or not a PE router originates an RPF Vector is determined by configuration; that is, the `ip multicast rpf proxy vector` command must be configured on all PE routers in order for an RPF Vector to

be originated. The PE router that originates an RPF Vector always performs an RPF lookup on the source. When a PE router performs an RPF lookup on a source, the PE router learns the origin of an RPF Vector in one of the following ways:

- In an MVPN network environment, the RPF Vector is learned from BGP MDT SAFI updates.
- In a native IP network environment, the RPF Vector is learned from either IP unicast routing (AFI=1, SAFI=1) or IP multicast reverse-path information (AFI=1, SAFI=2).

**Note**

For more information about the use of RPF Vectors in a native environment, see RFC 5496, [The Reverse Path Forwarding \(RPF\) Vector TLV](#).

**Note**

Routers that understand the RPF Vector format advertise the RPF Vector in PIM hello messages.

Recipients of an RPF Vector

When a router receives a PIM join that contains an RPF Vector, that router stores the RPF Vector so that it can generate a PIM join to the exit ASBR router. P routers, thus, learn the RPF Vector from PIM joins. The RPF Vector is advertised to all P routers in the core. If multiple RPF Vectors are received by a router, the RPF Vector with the lower originator address is used. When the RPF Vector is present, it takes priority; as a result, RPF checks are triggered periodically to readvertise RPF Vectors upstream. If a router receives an RPF Vector that references a local interface (typically an ASBR), the RPF Vector is discarded and a normal RPF lookup is performed.

ASBR Receipt of an RPF Vector

When an ASBR receives an RPF Vector, it typically references a local interface (most likely a loopback interface); in which case, the RPF Vector is discarded and a normal RPF lookup is performed. If the RD type is 2, the ASBR performs an RPF lookup in the BGP MDT table that is built from the BGP MDT SAFI updates; this type of RPF lookup uses both the RD and the source PE address contained in the PIM join.

Interoperability with RPF Vector

A new PIM hello option is introduced along with the PIM RPF Vector extension to determine if the upstream router is capable of parsing the new encoding. An RPF Vector is included in PIM messages only when all PIM neighbors on an RPF interface support it.

MDT Address Family in BGP for Multicast VPN Inter-AS Support

The **mdt** keyword has been added to the **address-family ipv4** command to configure an MDT address-family session.

- [Supported Policy](#), page 30
- [Guidelines for Configuring MDT Address Family Sessions on PE Routers for MVPN Inter-AS Support](#), page 31

Supported Policy

The following policy configuration parameters are supported under the BGP MDT SAFI:

- Mandatory attributes and well-known attributes, such as the AS-path, multi-exit discriminator MED, BGP local-preference, and next hop attributes.
- Standard communities, community-lists, and route-maps.

Guidelines for Configuring MDT Address Family Sessions on PE Routers for MVPN Inter-AS Support

When configuring routers for MVPN inter-AS support, follow these guidelines:

- For MVPN inter-AS Option A, BGP MDT address-family peering sessions are not required between the PE routers because native IP forwarding is used by the PE routers. For option A, BGP MDT peering sessions are only required for intra-AS VPN peering sessions.
- For MVPN inter-AS Option B, BGP MDT address-family peering sessions are only required between the PEs and ASBRs. In the Option B inter-AS case where PE routers use iBGP to redistribute labeled VPNv4 routes to RRs of which ASBRs are clients, then BGP MDT address-family peering sessions are required between the PEs, ASBRs, and RRs.
- For MVPN inter-AS Option C, BGP MDT address-family peering sessions are only required between the PEs and RRs.

MVPN Inter-AS MDT Establishment for Option B

This section describes the sequence of events that leads to the establishment of an inter-AS MDT between the autonomous systems in the sample inter-AS Option B topology illustrated in the following figure. For this topology, assume that all the routers have been configured properly to support all extensions associated with the Multicast VPN Inter-AS Support feature.

Figure 6 MVPN Inter-AS Support Option B Sample Topology

The following sequence of events occur to establish an MDT default tree rooted at PE1B in this inter-AS MVPN Option B topology:

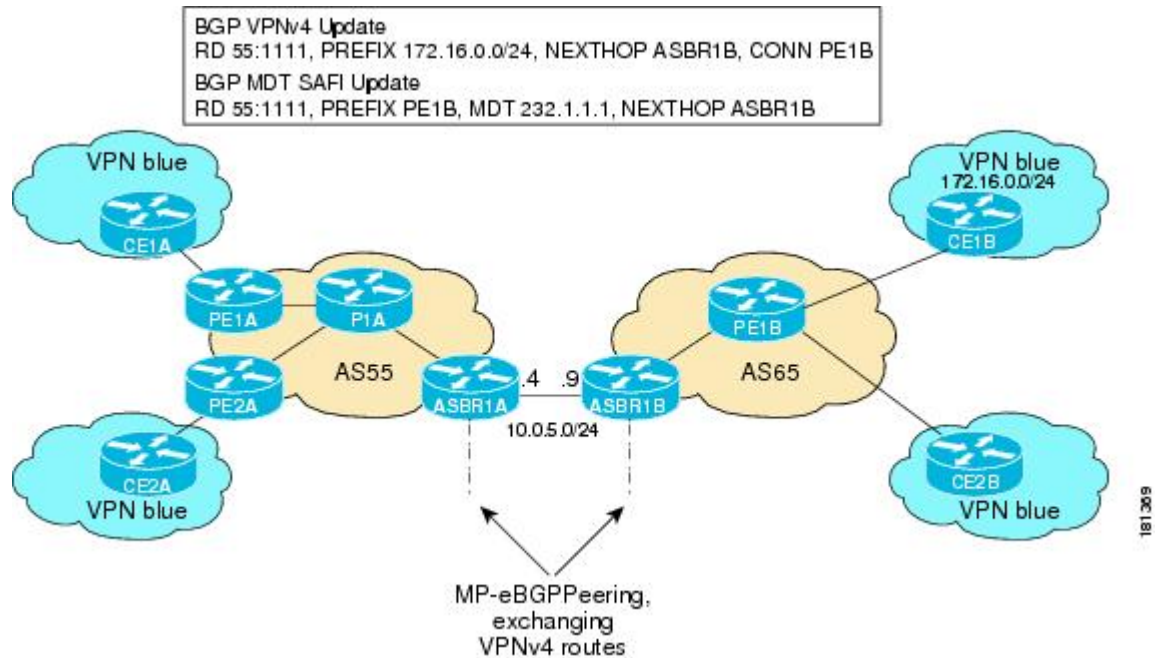

- As illustrated in the following figure, PE1B advertises the default MDT information for VPN blue using the BGP MDT SAFI with itself (PE1B) as the next hop.

Figure 7 BGP Updates from PE1B to ASBR1B

- As illustrated in the following figure, ASBR1B receives the MDT SAFI information and, in turn, advertises this information to ASBR1A with itself (ASBR1B) as the next hop.

Figure 8 BGP Updates from ASBR1B to ASBR1A

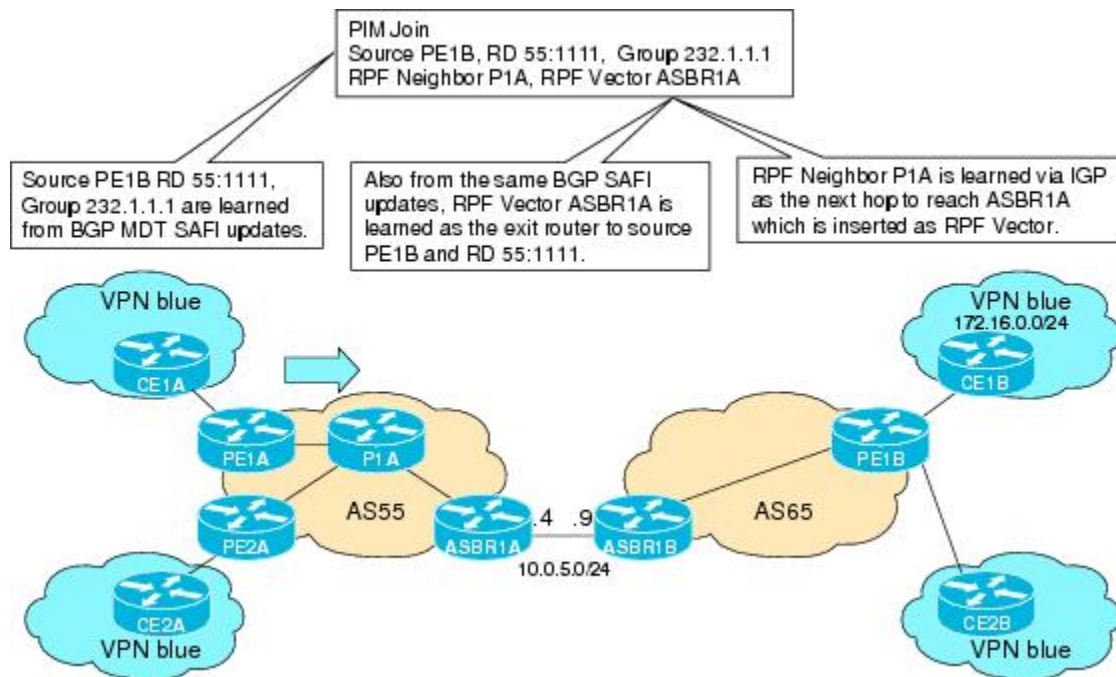

- As illustrated in the following figure, ASBR1A advertises the MDT SAFI to PE1A with itself (ASBR1A) as the next hop.

Figure 9 BGP Updates from ASBR1A to PE1A

- As illustrated in the following figure, PE1A learns the source PE router, the RD, and the default MDT group address from BGP MDT SAFI updates. In addition, from the same BGP MDT SAFI updates, PE1A learns that the RPF Vector, ASBR1A, is the exit router to source PE1B RD 55:1111. PE1A learns that P1A is an RPF neighbor through an IGP. PE1A then inserts the RPF Vector into the PIM join and sends the PIM join that is destined for source PE1B to P1A.

Figure 10 SSM Default PIM Join from PE1A to P1A

- As illustrated in the following figure, source PE1B is not reachable on P1A, but the RPF Vector ASBR1A is reachable, and the next hop is ASBR1A, as learned from the IGP running in the core. P1A then forwards the PIM join to ASBR1A.

Figure 11 SSM Default MDT PIM Join from P1A to ASBR1A

- As illustrated in the following figure, the RPF Vector, ASBR1A, is contained in the PIM join sent from P1A to ASBR1A. When ASBR1A receives the RPF Vector, it learns that it is the exit router for source PE1B with RD 55:1111. Source PE1B is not reachable on ASBR1A, but source PE1B, RD 55:1111, and group 232.1.1.1 are known from the BGP MDT SAFI updates. The RPF neighbor P1A is learned

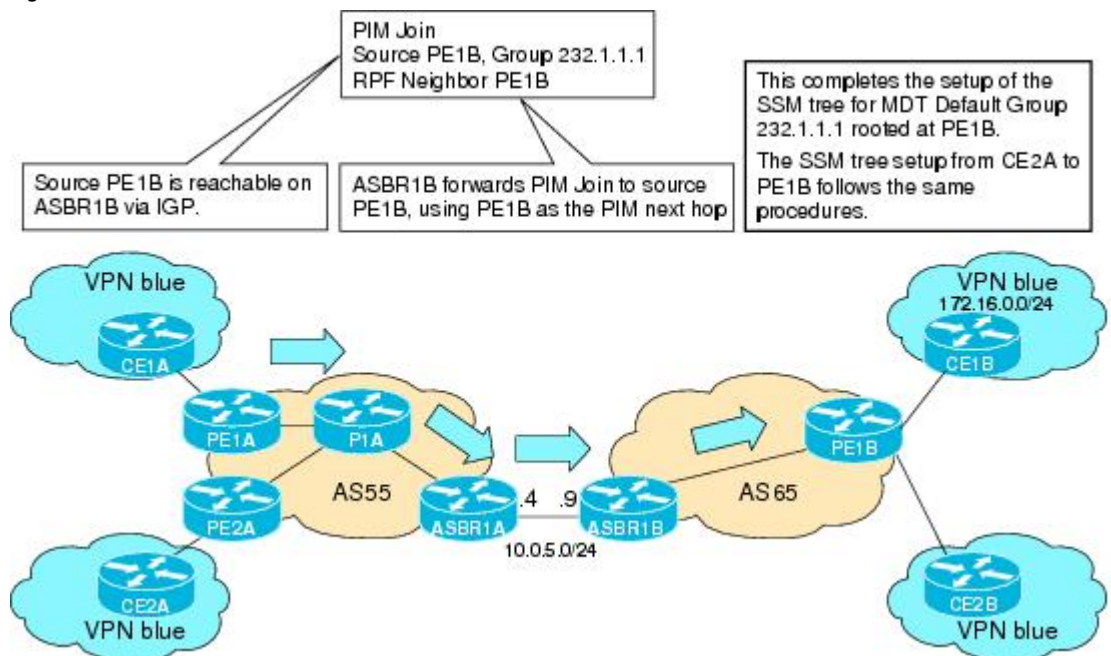

from the IGP running in the core as the next hop to reach ASBR1A, which is inserted as the RPF Vector. ASBR1A then forwards the PIM join for source PE1B to ASBR1B.

Figure 12 SSM Default MDT PIM Join from ASBR1A to ASBR1B

1 As illustrated in the following figure, source PE1B is reachable on ASBR1B through the IGP running in AS65. ASBR1B forwards the PIM join to source PE1B, using PE1B as the next hop. At this point, the setup of the SSM tree for MDT default group 232.1.1.1 rooted at PE1B is complete. The SSM MDT default group rooted at PE1B, thus, has been established. The SSM trees for the MDT default groups rooted at PE1A and PE2A follow the same procedures.

Figure 13 SSM Default MDT PIM Join from ASBR1B to PE1B

MVPN Inter-AS MDT Establishment for Option C

This section describes the sequence of events that leads to the establishment of an inter-AS MDT between the autonomous systems in the sample inter-AS Option C topology illustrated in the following figure. For this topology, assume that all the routers have been configured properly to support all features associated with the Multicast VPN Inter-AS Support feature.

Figure 14 MVPN Inter-AS Support Option C Sample Topology

The following sequence of events occur to establish an MDT default tree rooted at PE1B in this inter-AS MVPN Option C topology:

- 1 As illustrated in the following figure, PE1B advertises the default MDT information for VPN blue to RR1B within the BGP MDT SAFI.

Figure 15 BGP MDT SAFI Update from PE1B to RR1B

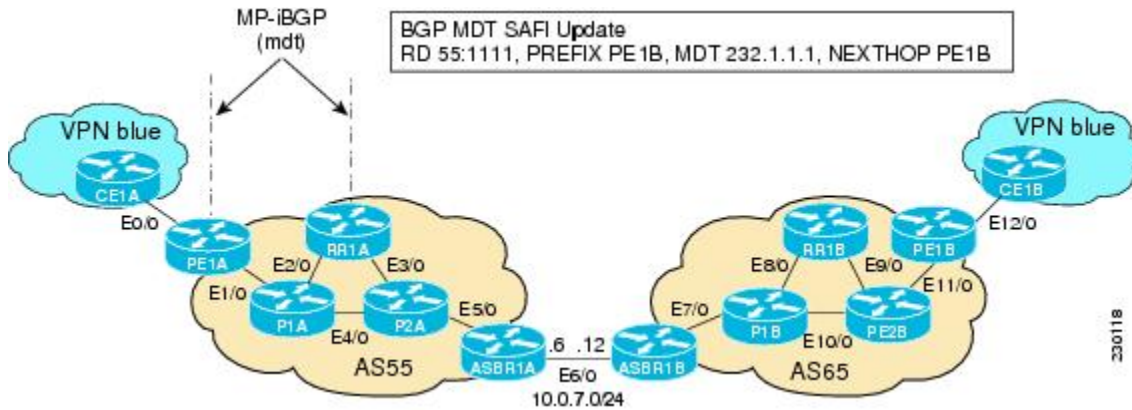

- 1 As illustrated in the following figure, RR1B receives the MDT SAFI information, and, in turn, advertises this information to RR1A.

Figure 16 BGP MDT SAFI Update from RR1B to RR1A

- 1 As illustrated in the following figure, RR1A receives the MDT SAFI information, and, in turn, advertises this information to PE1A.

Figure 17 BGP MDT SAFI Update from RR1A to PE1A

- 1 As illustrated in the following figure, PE1A sends a PIM join with the Proxy Vector that identifies ASBR1A as the exit router to reach source PE1B with RD 55:1111 and Default MDT 232.1.1.1. The Proxy Vector provides P1A and P2A a hint on how to reach PE1B in the absence of a route to reach

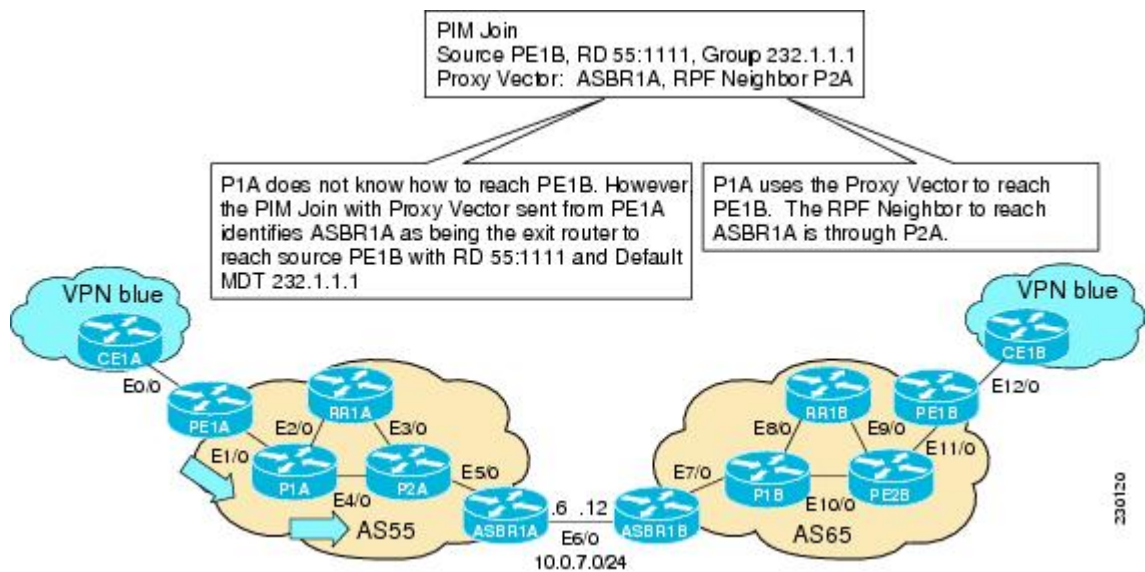

PE1B. Source PE1B is reachable through RPF neighbor P1A through BGP IPv4 learned updates on PE1A.

Figure 18 PIM SSM Join for Default MDT with Proxy Vector from PE1A to P1A

- As illustrated in the following figure, P1A does not know how to reach PE1B. However, the PIM join with the Proxy Vector sent from PE1A identifies ASBR1A as being the exit router to reach source PE1B with RD 55:1111 and Default MDT 232.1.1.1. P1A uses the Proxy Vector to reach PE1B. The RPF neighbor to reach ASBR1A is through P2A. P1A, thus, forwards the PIM SSM join to P2A.

Figure 19 PIM SSM Join for Default MDT with Proxy Vector from P1A to P2A

- As illustrated in the following figure, P2A does not know how to reach PE1B. However, the PIM join with the Proxy Vector sent from P1A identifies ASBR1A as being the exit router to reach source PE1B

with RD 55:1111 and Default MDT 232.1.1.1. P2A uses the Proxy Vector, ASBR1A, to reach PE1B. The RPF neighbor to reach ASBR1B is through ASBR1A (that is, itself).

Figure 20 PIM SSM Join for Default MDT with Proxy Vector from P2A to ASBR1A

- As illustrated in the following figure, ASBR1A receives a PIM join with Proxy Vector from P2A. ASBR1A realizes that the Proxy Vector is itself and sends a regular PIM join towards PE1B with an RPF neighbor of ASBR1B. The PIM joins continue hop-by-hop building the SSM Default MDT until PE1B is finally reached following standard PIM procedures.

Figure 21 PIM SSM Join for Default MDT with Proxy Vector from ASBR1A to PE1B

How to Configure Multicast VPN Inter-AS Support

- [Configuring the MDT Address Family in BGP for Multicast VPN Inter-AS Support, page 40](#)
- [Displaying Information About IPv4 MDT Sessions in BGP, page 42](#)
- [Clearing IPv4 MDT Peering Sessions in BGP, page 43](#)
- [Configuring a PE Router to Send BGP MDT Updates to Build the Default MDT for MVPN Inter-AS Support - Option B, page 44](#)
- [Configuring a PE Router to Send BGP MDT Updates to Build the Default MDT for MVPN Inter-AS Support - Option C, page 47](#)
- [Verifying the Establishment of Inter-AS MDTs in Option B and Option C Deployments, page 49](#)

Configuring the MDT Address Family in BGP for Multicast VPN Inter-AS Support

Perform this task to configure an MDT address family session on PE routers to establish MDT peering sessions for MVPN. The **mdt** keyword has been added to the **address-family ipv4** command to configure an MDT address-family session.

- [Supported Policy, page 40](#)
- [Guidelines for Configuring MDT Address Family Sessions on PE Routers for MVPN Inter-AS Support, page 40](#)

Supported Policy

The following policy configuration parameters are supported under the BGP MDT SAFI:

- Mandatory attributes and well-known attributes, such as the AS-path, multiexit discriminator (MED), BGP local preference, and next hop attributes.
- Standard communities, community lists, and route maps.

Guidelines for Configuring MDT Address Family Sessions on PE Routers for MVPN Inter-AS Support

When configuring routers for MVPN inter-AS support, follow these guidelines:

- For MVPN inter-AS Option A, BGP MDT address-family peering sessions are not required between the PE routers because native IP forwarding is used by the PE routers. For option A, BGP MDT peering sessions are only required for intra-AS VPN peering sessions.
- For MVPN inter-AS Option B, BGP MDT address-family peering sessions are only required between the PEs and ASBRs. In the Option B inter-AS case where PE routers use iBGP to redistribute labeled VPNv4 routes to RRs of which ASBRs are clients, then BGP MDT address-family peering sessions are required between the PEs, ASBRs, and RRs.
- For MVPN inter-AS Option C, BGP MDT address-family peering sessions are only required between the PEs and RRs.

Before inter-AS VPN peering can be established through an MDT address family, MPLS and Cisco Express Forwarding (CEF) must be configured in the BGP network and multiprotocol BGP on PE routers that provide VPN services to CE routers.

Note

The following policy configuration parameters are not supported:

- Route-originator attribute
- NLRI prefix filtering (prefix lists, distribute lists)
- Extended community attributes (route target and site of origin)

>

SUMMARY STEPS

1. enable
2. configure terminal
3. router bgp *as-number*
4. address-family ipv4 mdt
5. neighbor *neighbor-address* activate
6. end

DETAILED STEPS

Command or Action	Purpose
<p>Step 1 enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
<p>Step 2 configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
<p>Step 3 router bgp <i>as-number</i></p> <p>Example:</p> <pre>Router(config)# router bgp 65535</pre>	<p>Enters router configuration mode and creates a BGP routing process.</p>
<p>Step 4 address-family ipv4 mdt</p> <p>Example:</p> <pre>Router(config-router)# address-family ipv4 mdt</pre>	<p>Enters address family configuration mode to create an IP MDT address family session.</p>

Command or Action	Purpose
Step 5 <code>neighbor neighbor-address activate</code> Example: <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	Enables the MDT address family for this neighbor.
Step 6 <code>end</code> Example: <pre>Router(config-router-af)# end</pre>	Exits address family configuration mode and enters privileged EXEC mode.

Displaying Information About IPv4 MDT Sessions in BGP

Perform this optional task to display information about IPv4 MDT sessions in BGP.

SUMMARY STEPS

1. `enable`
2. `show ip bgp ipv4 mdt {all | rd | vrf vrf-name}`

DETAILED STEPS

Step 1

`enable`

Use this command to enable privileged EXEC mode.

- Enter your password if prompted.

Example:

```
Router> enable
```

Step 2

`show ip bgp ipv4 mdt {all | rd | vrf vrf-name}`

Use this command to display IPv4 MDT sessions in the IPv4 BGP routing table.

The following is sample output from the `show ip bgp ipv4 mdt` command with the `all` keyword:

Example:

```
Router# show ip bgp ipv4 mdt all
BGP table version is 2, local router ID is 10.1.0.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
               Network        Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 55:1111 (default for vrf blue)
```

```
*> 10.5.5.5/32      10.1.0.1      55      0 23 24 25 54 ?
* 10.9.9.9/32      0.0.0.0      0 ?
```

Clearing IPv4 MDT Peering Sessions in BGP

Perform this optional task to reset IPv4 MDT address-family sessions using the **mdt** keyword in one of the various forms of the **clear ip bgp** command. Due to the complexity of some of the keywords available for the **clear ip bgp** command, some of the keywords are documented as separate commands.

SUMMARY STEPS

1. **enable**
2. Do one of the following:
 - **clear ip bgp ipv4 mdt** *as-number* [**in**[*prefix-filter*]] [**out**] [**soft** [**in**[*prefix-filter*] | **out**]]
 -
 - **clear ip bgp ipv4 mdt peer-group** *peer-group-name* [**in** [*prefix-filter*]] [**out**] [**soft** [*in*[*prefix-filter*] | **out**]]
 -
 - **clear ip bgp ipv4 mdt update-group** [*index-group* | *neighbor-address*]

DETAILED STEPS

Command or Action	Purpose
Step 1 enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

Command or Action	Purpose
<p>Step 2 Do one of the following:</p> <ul style="list-style-type: none"> • clear ip bgp ipv4 mdt <i>as-number</i> [in[<i>prefix-filter</i>]] [out] [soft [in[<i>prefix-filter</i>] out]] • • clear ip bgp ipv4 mdt peer-group <i>peer-group-name</i> [in [<i>prefix-filter</i>]] [out] [soft [in[<i>prefix-filter</i>] out]] • • clear ip bgp ipv4 mdt update-group [<i>index-group</i> <i>neighbor-address</i>] <p>Example:</p> <pre>Router# clear ip bgp ipv4 mdt 65700</pre> <p>Example:</p> <p>Example:</p> <pre>Router# clear ip bgp ipv4 mdt peer-group test soft in</pre> <p>Example:</p> <pre>Router# clear ip bgp ipv4 mdt update-group 3</pre>	<p>(Optional) Resets IPv4 MDT address-family sessions.</p> <ul style="list-style-type: none"> • Specifying the clear ip bgp ipv4 mdt command with the <i>as-number</i> argument resets IPv4 MDT address-family sessions associated with the specified autonomous system. • The example for this form of the clear ip bgp ipv4 mdt command shows how to initiate a hard reset for all IPv4 MDT address-family sessions in the autonomous system numbered 65700. <p>or</p> <ul style="list-style-type: none"> • Specifying the clear ip bgp ipv4 mdt command with the peer-group keyword resets IPv4 MDT address-family sessions for all members of a BGP peer group. • The example for this form of the clear ip bgp ipv4 mdt command shows how to initiate a soft reset for inbound MDT address-family sessions with members of the peer group test. Outbound sessions are unaffected. <p>or</p> <ul style="list-style-type: none"> • Specifying the clear ip bgp ipv4 mdt command with the update-group keyword resets IPv4 MDT address-family sessions for all the members of a BGP update group. • The example for this form of the clear ip bgp ipv4 mdt command shows how to reset for all members of the update group 3.

Configuring a PE Router to Send BGP MDT Updates to Build the Default MDT for MVPN Inter-AS Support - Option B

Perform this task to configure PE routers in an Option B deployment to support the extensions necessary (BGP connector attribute, BGP MDT SAFI, and RPF Vector) to send BGP MDT updates to build the default MDT for MVPN inter-AS support.

SUMMARY STEPS

1. enable
2. configure terminal
3. router bgp *as-number*
4. neighbor *ip-address* remote-as *as-number*
5. address-family ipv4 mdt
6. neighbor *neighbor-address* activate
7. neighbor *neighbor-address* next-hop-self
8. exit
9. address-family vpnv4
10. neighbor *neighbor-address* activate
11. neighbor *neighbor-address* send-community extended
12. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
Step 3	<p>router bgp <i>as-number</i></p> <p>Example:</p> <pre>Router(config)# router bgp 101</pre>	<p>Enters router configuration mode for the specified routing process.</p>
Step 4	<p>neighbor <i>ip-address</i> remote-as <i>as-number</i></p> <p>Example:</p> <pre>Router(config-router)# neighbor 192.168.1.1 remote-as 45000</pre>	<p>Adds the IP address of the neighbor in the specified autonomous system to the IPv4 multiprotocol BGP neighbor table of the local router.</p>

Command or Action	Purpose
<p>Step 5 <code>address-family ipv4 mdt</code></p> <p>Example:</p> <pre>Router(config-router)# address-family ipv4 mdt</pre>	<p>Enters address family configuration mode to create an IPv4 MDT address family session.</p>
<p>Step 6 <code>neighbor neighbor-address activate</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	<p>Enables the MDT address family for this neighbor.</p>
<p>Step 7 <code>neighbor neighbor-address next-hop-self</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 next-hop-self</pre>	<p>Disables next hop processing of BGP updates on the router.</p>
<p>Step 8 <code>exit</code></p> <p>Example:</p> <pre>Router(config-router-af)# exit</pre>	<p>Exits address family configuration mode and returns to router configuration mode.</p>
<p>Step 9 <code>address-family vpnv4</code></p> <p>Example:</p> <pre>Router(config-router)# address-family vpnv4</pre>	<p>Enters address family configuration mode to create a VPNv4 address family session.</p>
<p>Step 10 <code>neighbor neighbor-address activate</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	<p>Enables the VPNv4 address family for this neighbor.</p>
<p>Step 11 <code>neighbor neighbor-address send-community extended</code></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 send-community extended</pre>	<p>Enables the standard and extended community attributes to be sent to this neighbor.</p>

Command or Action	Purpose
<p>Step 12 <code>end</code></p> <p>Example:</p> <pre>Router(config-router-af)# end</pre>	<p>Exits address family configuration mode and returns to privileged EXEC mode.</p>

Configuring a PE Router to Send BGP MDT Updates to Build the Default MDT for MVPN Inter-AS Support - Option C

Perform this task to configure PE routers in an Option B deployment to support the extensions necessary (BGP connector attribute, BGP MDT SAFI, and RPF Vector) to send BGP MDT updates to build the default MDT for MVPN inter-AS support.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `router bgp as-number`
4. `neighbor ip-address remote-as as-number`
5. `address-family ipv4 mdt`
6. `neighbor neighbor-address activate`
7. `neighbor neighbor-address send-community extended`
8. `exit`
9. `address-family vpv4`
10. `neighbor neighbor-address activate`
11. `neighbor neighbor-address send-community extended`
12. `end`

DETAILED STEPS

Command or Action	Purpose
<p>Step 1 <code>enable</code></p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
<p>Step 2 <code>configure terminal</code></p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>

	Command or Action	Purpose
Step 3	<p>router <i>bgp as-number</i></p> <p>Example:</p> <pre>Router(config)# router bgp 101</pre>	Enters router configuration mode for the specified routing process.
Step 4	<p>neighbor <i>ip-address remote-as as-number</i></p> <p>Example:</p> <pre>Router(config-router)# neighbor 192.168.1.1 remote-as 45000</pre>	Adds the IP address of the neighbor in the specified autonomous system to the IPv4 multiprotocol BGP neighbor table of the local router.
Step 5	<p>address-family <i>ipv4 mdt</i></p> <p>Example:</p> <pre>Router(config-router)# address-family ipv4 mdt</pre>	Enters address family configuration mode to create an IPv4 MDT address family session.
Step 6	<p>neighbor <i>neighbor-address activate</i></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	Enables the MDT address family for this neighbor.
Step 7	<p>neighbor <i>neighbor-address send-community extended</i></p> <p>Example:</p> <pre>Router(config-router-af)# neighbor 192.168.1.1 send-community extended</pre>	Enables the standard and extended community attributes to be sent to this neighbor.
Step 8	<p>exit</p> <p>Example:</p> <pre>Router(config-router-af)# exit</pre>	Exits address family configuration mode and returns to router configuration mode.
Step 9	<p>address-family <i>vpn4</i></p> <p>Example:</p> <pre>Router(config-router)# address-family vpn4</pre>	Enters address family configuration mode to create a VPNv4 address family session.

	Command or Action	Purpose
Step 10	neighbor <i>neighbor-address</i> activate Example: <pre>Router(config-router-af)# neighbor 192.168.1.1 activate</pre>	Enables the VPNv4 address family for this neighbor.
Step 11	neighbor <i>neighbor-address</i> send-community extended Example: <pre>Router(config-router-af)# neighbor 192.168.1.1 send- community extended</pre>	Enables the standard and extended community attributes to be sent to this neighbor.
Step 12	end Example: <pre>Router(config-router-af)# end</pre>	Exits address family configuration mode and returns to privileged EXEC mode.

Verifying the Establishment of Inter-AS MDTs in Option B and Option C Deployments

Perform this optional task to verify the establishment of Inter-AS MDTs in Option B and Option C MVPN inter-AS deployments.

Note

The steps in this optional task can be performed in any order. All steps in this task are optional.

SUMMARY STEPS

1. **enable**
2. **show ip mroute proxy**
3. **show ip pim** [*vrf vrf-name*] **neighbor** [*interface-type interface-number*]
4. **show ip rpf** [*vrf vrf-name*] {*route-distinguisher* | *source-address* [*group-address*] [**rd** *route-distinguisher*]} [**metric**]
5. **show ip pim** [*vrf vrf-name*] **mdt bgp**

DETAILED STEPS

Step 1

enable

Use this command to enable privileged EXEC mode.

- Enter your password if prompted.

Example:

```
Router> enable
```

Step 2**show ip mroute proxy**

Use this command to display information about RPF Vectors received on a multicast router.

- The information displayed in the output of this command can be used to determine if an RPF Vector proxy is received on a core router.

The following is sample output from the **show ip mroute proxy** command:

Example:

```
Router# show ip mroute proxy
```

```
(192.168.0.8, 232.1.1.1)
Proxy          Assigner      Origin      Uptime/Expire
55:1111/192.168.0.4  10.0.3.1    PIM         00:03:29/00:02:06
55:1111/192.168.0.4  10.0.3.2    PIM         00:17:47/00:02:06
```

Step 3**show ip pim [vrf vrf-name] neighbor [interface-type interface-number]**

Use this command to display the PIM neighbors discovered by PIMv1 router query messages or PIMv2 hello messages.

The P flag indicates that the neighbor has announced (through PIM hello messages) its capability to handle RPF Vectors in PIM join messages. All software versions that support the PIM RPF Vector feature announce this PIM hello option. An RPF Vector is only included in PIM messages when all PIM neighbors on an RPF interface support it.

The following is sample output from the **show ip pim neighbor** command:

Example:

```
Router# show ip pim neighbor
PIM Neighbor Table
Mode: B - Bidir Capable, DR - Designated Router, N - Default DR Priority,
      S - State Refresh Capable
Neighbor      Interface          Uptime/Expires   Ver   DR
Address
10.0.0.1      GigabitEthernet10/2  00:01:29/00:01:15 v2    1 / S
10.0.0.3      GigabitEthernet10/3  00:01:15/00:01:28 v2    1 / DR S P
```

Step 4**show ip rpf [vrf vrf-name] {route-distinguisher | source-address [group-address] [rd route-distinguisher]} [metric]**

Use this command to display information about how IP multicast routing does RPF.

The following is sample output from the **show ip rpf** command:

Example:

```
Router# show ip rpf 10.7.0.7 232.1.1.1 rd 55:1111
```

```
RPF information for ? (10.7.0.7)
RPF interface: GigabitEthernet2/2
RPF neighbor: ? (10.0.1.3)
RPF route/mask: 10.5.0.5/32
RPF type: unicast (UNKNOWN)
RPF recursion count: 0
Doing distance-preferred lookups across tables
```

```
BGP lookup of 55:1111/10.7.0.7 next_hop: 10.5.0.5
PROXY vector: 10.5.0.5
```

Step 5**show ip pim [vrf vrf-name] mdt bgp**

Use this command to display information about the BGP advertisement of RDs for the MDT default group.

The following is sample output from the **show ip pim mdt bgp** command:

Example:

```
Router# show ip pim mdt bgp
MDT (Route Distinguisher + IPv4)
MDT group 232.1.1.1
 55:1111:192.168.0.2
 55:1111:192.168.0.8
```

Router ID	Next Hop
192.168.0.2	192.168.0.2
192.168.0.4	192.168.0.4

Configuration Examples for Multicast VPN Inter-AS Support

- [Configuring an IPv4 MDT Address-Family Session for Multicast VPN Inter-AS Support Example, page 51](#)

Configuring an IPv4 MDT Address-Family Session for Multicast VPN Inter-AS Support Example

The following examples shows how to configure a router to support an IPv4 MDT address-family session with the BGP neighbor at 10.1.1.2:

```
router bgp 1
 address-family ipv4 mdt
 neighbor 10.1.1.2 activate
```

Configuring a PE Router to Send BGP MDT Updates to Build the Default MDT for MVPN Inter-AS Support

The following example shows how to configure a PE router to support the extensions necessary (BGP connector attribute, BGP MDT SAFI, and RPF Vector) to send BGP MDT updates to build the default

MDT for MVPN inter-AS support in an Option B deployment. Only the relevant configuration is shown in this example.

```

```

Configuring Back-to-Back ASBR PEs - Option A Example

The following example shows how to configure support for MVPN inter-AS support Option A. This configuration example is based on the sample inter-AS network Option A topology illustrated in the figure.

In this configuration example, PE3A in AS1 is attached directly to PE3B in AS2. The two PE routers are attached by physical interfaces, one physical interface for each of the VPNs (VPN blue and VPN green) whose routes need to be passed from AS1 to AS2, and vice versa. Each PE will treat the other as if it were a CE router; that is, the PEs associate each interface with a VRF and use eBGP to distribute unlabeled IPv4 addresses to each other. Intermediate System-to-Intermediate System (IS-IS) is being used for the BGP peerings in both autonomous systems, and Routing Information Protocol (RIP) is being used on the PE routers that face the CE routers to dynamically learn the routes from the VRFs and advertise them as VPNv4 routes to the remote PE routers. RIP is also being used between the ASBRs to set up the eBGP peerings between PE3A and PE3B.

Note

For Option A, any IGP can be used to exchange the IPv4 routes for the loopback interfaces.

Figure 22 *Topology for MVPN Inter-AS Support Option A Configuration Example*

181300

The table provides information about the topology used for the Option A configuration example presented in this section.

Table 3 *Topology Information for MVPN Inter-AS Option A Configuration Example*

PE Router	VPN	RD	AS Number	Loopback0 Interface	Default MDT (PIM-SSM)
PE1A	green	55:1111	1	10.1.1.1/32	232.1.1.1
PE2A	blue	55:1111	1	10.1.1.2/32	232.1.1.1
PE3A	blue/green	55:1111	1	10.1.1.3/32	232.1.1.1

Configuring the Exchange of VPNv4 Routes Directly Between ASBRs - Option B Example

The following example shows how to configure MVPN inter-AS support in an Option B deployment. This configuration is based on the sample inter-AS topology illustrated in the figure.

In this configuration example, PE1A and PE2A are configured to use iBGP to redistribute labeled VPNv4 routes to each other and to ASBR1A, and PE1B is configured to redistribute labeled VPNv4 routes to ASBR1B. ASBR1A and ASBR1B are configured to use eBGP to exchange those labeled VPNv4 routes to each other.

Figure 23 Topology for MVPN Inter-AS Support Option B Configuration Example

The table provides information about the topology used for this particular Option B configuration example.

Table 4 *Topology Information for MVPN Inter-AS Support Option B Configuration Example*

PE or ASBR Router	AS Number	Loopback0 Interfaces	Default MDT (PIM-SSM)
PE1A	55	192.168.0.1/32	232.1.1.1
PE2A	55	192.168.0.2/32	232.1.1.1

The following is sample output from the **show ip pim mdt bgp** command for PE1A, PE2A, and PE1B. The sample output displays information about the BGP advertisement of RDs for the MDT default group

232.1.1.1. The output displays the MDT default groups advertised, the RDs and source addresses of sources sending to the MDT default groups, the BGP router ID of the advertising routers, and the BGP next hop address contained in the advertisements.

```

PE1A# show ip pim mdt bgp
MDT (Route Distinguisher + IPv4)          Router ID      Next Hop
  MDT group 232.1.1.1
    55:1111:192.168.0.2                    192.168.0.2   192.168.0.2
    55:1111:192.168.0.8                    192.168.0.4   192.168.0.4
PE2A# show ip pim mdt bgp
MDT (Route Distinguisher + IPv4)          Router ID      Next Hop
  MDT group 232.1.1.1
    55:1111:192.168.0.1                    192.168.0.1   192.168.0.1
    55:1111:192.168.0.8                    192.168.0.4   192.168.0.4
PE1B# show ip pim mdt bgp

  MDT group 232.1.1.1
    55:1111:192.168.0.1                    192.168.0.9   192.168.0.9
    55:1111:192.168.0.2                    192.168.0.9   192.168.0.9

```

The following are sample outputs from the **show ip mroute proxy** command for PE1A, PE2A, and PE1B. The output displays information about the RPF Vectors learned by each PE router in this configuration example. The RPF Vector is the exit address of the ASBR router through which PIM messages are sent to reach inter-AS sources. The “Proxy” field displays the RPF Vectors learned by the PE routers. Each RPF Vector listed under the “Proxy” field is prepended by the RD associated with the RPF Vector. Because the PE routers are the assigners of the RPF Vector (that is, the PE routers insert the RPF Vector into PIM joins), 0.0.0.0 is the address displayed under the “Assigner” field in all the sample outputs. Finally, because PE routers learn the RPF Vector from BGP MDT SAFI updates, BGP MDT is displayed as the origin under the “Origin” field in all the outputs.

```

PE1A# show ip mroute proxy
(192.168.0.8, 232.1.1.1)
  Proxy          Assigner      Origin      Uptime/Expire
  55:1111/192.168.0.4  0.0.0.0    BGP MDT    00:13:07/stopped
PE2A# show ip mroute proxy
(192.168.0.8, 232.1.1.1)
  Proxy          Assigner      Origin      Uptime/Expire
  55:1111/192.168.0.4  0.0.0.0    BGP MDT    00:14:28/stopped
PE1B# show ip mroute proxy
(192.168.0.1, 232.1.1.1)
  Proxy          Assigner      Origin      Uptime/Expire
  55:1111/192.168.0.9  0.0.0.0    BGP MDT    00:35:19/stopped
(192.168.0.2, 232.1.1.1)
  Proxy          Assigner      Origin      Uptime/Expire
  55:1111/192.168.0.9  0.0.0.0    BGP MDT    00:35:49/stopped

```

The following is sample output from the **show ip mroute proxy** command from P1A. Because P routers learn the RPF Vector from the PIM joins sent from PE routers, the IP addresses of PE1A (10.0.3.1) and PE2A (10.0.3.2) are displayed under the “Assigner” field in the output for P1A. Because P1A learns the RPF Vector from encodings in the PIM join message, PIM is displayed as the origin under the “Origin” field.

```

P1A# show ip mroute proxy
(192.168.0.8, 232.1.1.1)
  Proxy          Assigner      Origin      Uptime/Expire
  55:1111/192.168.0.4  10.0.3.1    PIM        00:03:29/00:02:06
  55:1111/192.168.0.4  10.0.3.2    PIM        00:17:47/00:02:06

```

The following is sample output from the **show ip mroute proxy** command for ASBR1A and ASBR1B. If a router receives an RPF Vector that references a local interface (which occurs in an Option B deployment when an ASBR receives a RPF Vector owned by a local interface), the router discards the RPF Vector and performs a normal RPF lookup using information that the router learned from BGP MDT SAFI updates. In the output for all ASBR routers, under the “Proxy” field, the word “local” is displayed instead of the RPF

Vector because ASBR1A and ASBR1B are using local interfaces to perform RPF lookups for PIM joins with RPF Vectors that reference one of their local interfaces. The “Assigner” field displays the RPF address that sent the PIM join to the ASBR. Because the ASBRs learn the RPF Vectors from the PIM joins (the RPF Vectors that are subsequently discarded), PIM is displayed as the origin under the “Origin” field.

```
ASBR1A# show ip mroute proxy
(192.168.0.1, 232.1.1.1)
  Proxy          Assigner          Origin          Uptime/Expire
  55:1111/local  10.0.5.9          PIM             00:18:19/00:02:46
(192.168.0.2, 232.1.1.1)
  Proxy          Assigner          Origin          Uptime/Expire
  55:1111/local  10.0.5.9          PIM             00:18:50/00:02:24
(192.168.0.8, 232.1.1.1)
  Proxy          Assigner          Origin          Uptime/Expire
  55:1111/local  10.0.4.3          PIM             00:18:49/00:02:19
ASBR1B# show ip mroute proxy
(192.168.0.1, 232.1.1.1)
  Proxy          Assigner          Origin          Uptime/Expire
  55:1111/local  10.0.7.8          PIM             00:37:39/00:02:44
(192.168.0.2, 232.1.1.1)
  Proxy          Assigner          Origin          Uptime/Expire
  55:1111/local  10.0.7.8          PIM             00:38:10/00:02:19
(192.168.0.8, 232.1.1.1)
  Proxy          Assigner          Origin          Uptime/Expire
  55:1111/local  10.0.5.4          PIM             00:38:09/00:02:19
```

The following is sample output from the **show ip mroute** command for PE1A, PE2A, P1A, ASBR1A, ASBR1B, and PE1B. The sample outputs show the global table for the MDT default group 232.1.1.1. The output from this command confirms that all three PE routers (PE1A, PE2A, and PE1B) have joined the default MDT.

Configuring the Exchange of VPNv4 Routes Between RRs Using Multihop MP-EBGP

The following example shows how to configure support for MVPN inter-AS option C. This configuration is based on the sample inter-AS topology illustrated in the figure.

In the configuration example, MP-eBGP is used to exchange VPNv4 routes between RRs of different autonomous systems with the next hops for these routes exchanged between corresponding ASBR routers.

Because the RRs in the two autonomous systems are not directly connected, multihop functionality is required to allow them to establish MP-eBGP peering sessions. The PE router next-hop addresses for the VPNv4 routes are exchanged between ASBR routers. In this configuration example, the exchange of these addresses between autonomous systems is established using IPv4 BGP label distribution, which enables the ASBRs to distribute IPv4 routes with MPLS labels.

Figure 24 Topology for MVPN Inter-AS Support Option C Configuration Example

The table provides information about the topology used for this inter-AS MVPN Option C configuration example.

Table 5 Topology Information for MVPN Inter-AS Support Option C Configuration Example

PE, RR, or ASBR Router	AS Number	Loopback0 Interfaces	Default MDT (PIM-SSM)
PE1A	55	10.254.254.2/32	232.1.1.1
RR1A	55	10.252.252.4/32	232.1.1.1

The following is sample output from the **show ip pim mdt bgp** command for PE1A and PE2A. The sample output displays information about the BGP advertisement of RDs for MDT default groups. The output displays the MDT default groups advertised, the RDs and source addresses of sources sending to the MDT default groups, the BGP router ID of the advertising routers, and the BGP next hop address contained in the advertisements.

```

PE1A# show ip pim mdt bgp
MDT (Route Distinguisher + IPv4)          Router ID      Next Hop
MDT group 232.1.1.1                        10.252.252.4  10.254.254.8
  55:1111:10.254.254.8

```

```

PE1B# show ip pim mdt bgp
MDT (Route Distinguisher + IPv4)          Router ID      Next Hop
MDT group 232.1.1.1
55:1111:10.254.254.2                      10.252.252.10 10.254.254.2

```

The following is sample output from the **show ip mroute proxy** command from P1A, P2A, P1B, and P2B. Because P routers learn the RPF Vector from encodings in the PIM join message, PIM is displayed as the origin under the “Origin” field.

```

P1A# show ip mroute proxy
(10.254.254.8, 232.1.1.1)
Proxy 10.254.254.6          Assigner 10.0.2.2  Origin PIM      Uptime/Expire
                                00:15:37/00:02:57
P2A# show ip mroute proxy
(10.254.254.8, 232.1.1.1)
Proxy 10.254.254.6          Assigner 10.0.4.3  Origin PIM      Uptime/Expire
                                00:20:41/00:02:46
P1B# show ip mroute proxy
(10.254.254.2, 232.1.1.1)
Proxy 10.254.254.12        Assigner 10.0.10.9 Origin PIM      Uptime/Expire
                                00:29:38/00:02:16
P2B# show ip mroute proxy
(10.254.254.2, 232.1.1.1)
Proxy 10.254.254.12        Assigner 10.0.12.8 Origin PIM      Uptime/Expire
                                00:29:58/00:02:09

```

The following is sample output from the **show ip mroute** command for PE1A, P1A, P2A, ASBR1A, ASBR1B, P1B, P2B, and PE1B. The sample outputs show the global table for the MDT default group 232.1.1.1. The output from this command confirms that all three PE routers (PE1A, PE2A, and PE1B) have joined the default MDT.

Feature Information for Configuring Multicast VPN Inter-AS Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 6 Feature Information for Configuring Multicast VPN Inter-AS Support

Feature Name	Releases	Feature Information
BGP Multicast Inter-AS VPN	12.0(29)S 12.2(33)SRA 12.2(31)SB2 12.2(33)SXH 12.4(20)T 15.0(1)S	<p>The BGP Multicast Inter-AS VPN feature introduces the IPv4 MDT SAFI in BGP. The MDT SAFI is a transitive multicast capable connector attribute that is defined as an IPv4 address family in BGP. The MDT SAFI is designed to support inter-AS VPN peering sessions.</p> <p>The following commands were introduced or modified by this feature: address-family ipv4 (BGP), clear bgp ipv4 mdt, show ip bgp ipv4.</p>
Multicast VPN Inter-AS Support	12.0(30)S 12.2(33)SRA 12.2(31)SB2 12.2(33)SXH 12.4(20)T 15.0(1)S	<p>The Multicast VPN Inter-AS support feature enables MDTs used for MVPNs to span multiple autonomous systems. Benefits include increased multicast coverage to customers that require multicast to span multiple service providers in an MPLS Layer 3 VPN service with the flexibility to support all options described in RFC 4364. Additionally, the Multicast VPN Inter-AS Support feature may be used to consolidate an existing MVPN service with another MVPN service, such as the case with a company merger or acquisition.</p> <p>The following commands were introduced or modified by this feature: ip multicast rpf proxy vector, and show ip mroute, show ip pim neighbor, show ip rpf.</p>

Multicast VPN MIB

The Multicast VPN MIB feature introduces the capability for Simple Network Management Protocol (SNMP) monitoring of a Multicast VPN (MVPN) using the MVPN MIB (CISCO-MVPN-MIB).

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Multicast VPN MIB

- Before performing the tasks in this module, you must configure MVPN.
- You must configure SNMP on the routers on which the MVPN MIB is to be used.

Restrictions for Multicast VPN MIB

- Currently only IPv4 is supported.
- For all MIB objects with “read-create” access privileges, currently only “read-only” access is supported.

Information About Multicast VPN MIB

- [Overview of the MVPN MIB, page 86](#)
- [MVPN Information Retrieval Using SNMP and the MVPN MIB, page 86](#)
- [MVPN MIB Objects, page 86](#)

Overview of the MVPN MIB

In an MVPN network, a provider edge (PE) router has a multicast routing table and a Protocol Independent Multicast (PIM) instance associated with every VPN routing and forwarding (VRF) table that is used to define the VPN membership of customer sites attached to the router. There is one global multicast routing table and a table per multicast VRF (MVRF) used to route multicast packets received from a customer edge (CE) router. A set of MVRFs form a multicast domain (MD) when they are connected to potential sources and receivers of multicast traffic. A distinct group address, also known as the Multicast Distribution Tree (MDT) group address, obtained from an administrative pool, is assigned to each multicast domain. MDT groups are used by PE routers to encapsulate and transport multicast traffic within an MD through multicast tunnel interfaces (MTIs).

Initially all multicast data is forwarded using preconfigured MDT default groups. When certain multicast streams exceed a configured bandwidth threshold on the PE router, the multicast data is moved to an MDT data group that is dynamically chosen from an available pool of multicast addresses.

Using the MVPN MIB, network administrators can access MVRF information from PE routers for VPN traffic across multiple CE sites in real time. SNMP operations can be performed to monitor the MVRFs on the PE routers using **get** and **set** commands entered on the network management system (NMS) workstation for which SNMP has been implemented. The NMS workstations is also known as the SNMP manager.

MVPN Information Retrieval Using SNMP and the MVPN MIB

SNMP has historically been used to collect network information. SNMP permits retrieval of critical information from network elements such as routers, switches, and workstations. The MVPN MIB uses SNMP to configure MVRF trap notifications and to gather useful MVPN information in real time.

The MVPN MIB allows MVPN data for the managed devices on your system to be retrieved by SNMP. You can specify the retrieval of MVPN information from a managed device (for example, a router) either by entering commands on that managed device or by entering SNMP commands from the NMS workstation to gather MVPN information. MVPN MIB requests for information are sent from an NMS workstation to the router using SNMP and are retrieved from the router. This information can then be stored or viewed, thus allowing MVPN information to be easily accessed and transported across a multivendor programming environment.

MVPN MIB Objects

The MVPN MIB defines managed objects that enable a network administrator to remotely monitor the following MVPN information:

- The state of the MVRFs including the name of the MVRF, whether they are active, and the number of active multicast-enabled interfaces
- MDT default group address and encapsulation information
- Next hop information used to receive Border Gateway Protocol (BGP) MDT updates for Source Specific Multicast (SSM) mode

- Traffic threshold that determines switchover to an MDT data group
- Type of MDT group being used for a given (S, G) multicast route entry that exists on each configured MVRF, source address, and group address of the multicast route entry
- Source and group address used for encapsulation
- Information on MDT data groups currently joined
- Information on MVPN-specific MDT tunnels present in the device
- Trap notifications enabled on the router

**Note**

For a complete description of the objects supported by the MVPN MIB, see the CISCO_MVPN_MIB.my file, available on Cisco.com at <http://www.cisco.com/go/mibs>.

- [MVRF Trap Notifications, page 87](#)

MVRF Trap Notifications

An MVPN router can be configured to send MVRF (ciscoMvvpnMvrfChange) trap notifications. A ciscoMvvpnMvrfChange trap notification signifies a change about an MVRF in the device. The change event can be the creation of an MVRF, the deletion of an MVRF, or an update on the default or data multicast distribution tree (MDT) configuration of an MVRF. The change event is indicated by the ciscoMvvpnGenOperStatusChange object embedded in the trap notification.

How to Configure Multicast VPN MIB

- [Configuring the Router to Send MVRF Trap Notifications, page 87](#)

Configuring the Router to Send MVRF Trap Notifications

Perform this task to configure the router to use SNMP to send MVRF trap notifications.

**Note**

Before the MVPN MIB can be used, the SNMP server for the router must be configured. To enable the SNMP server on the router, perform Steps 3 and 4. If an SNMP server is already available, omit Steps 3 and 4 and proceed to Step 5.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. Do one of the following:
 - **snmp-server community *string* ro**
 -
 - **snmp-server community *string* rw**
4. **snmp-server host { *hostname* | *ip - address* } version 2c *community - string***
5. **snmp-server enable traps mvpn**
6. **end**

DETAILED STEPS

Command or Action	Purpose
<p>Step 1 enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
<p>Step 2 configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
<p>Step 3 Do one of the following:</p> <ul style="list-style-type: none"> • snmp-server community <i>string</i> ro • • snmp-server community <i>string</i> rw <p>Example:</p> <pre>Router(config)# snmp-server community public ro</pre> <p>Example:</p> <pre>Router(config)# snmp-server community public rw</pre>	<p>Sets up the community access string to permit access to SNMP.</p> <ul style="list-style-type: none"> • The <i>string</i> argument is a community string that consists of from 1 to 32 alphanumeric characters and functions much like a password, permitting access to the SNMP protocol. Blank spaces are not permitted in the community string. • Specifying the snmp-server community command with the ro keyword configures read-only access. SNMP management stations using this string can only retrieve MIB objects. <p>or</p> <ul style="list-style-type: none"> • Specifying the snmp-server community command with the rw keyword configures read-write access. SNMP management stations using this string can retrieve and modify MIB objects.

Command or Action	Purpose
<p>Step 4 <code>snmp-server host { hostname ip - address } version 2c community - string</code></p> <p>Example:</p> <pre>Router(config)# snmp-server host 192.168.1.1 version 2c public</pre>	Specifies the recipient of an SNMP notification operation.
<p>Step 5 <code>snmp-server enable traps mvpn</code></p> <p>Example:</p> <pre>Router(config)# snmp-server enable traps mvpn</pre>	Enables the router to send MVRP trap notifications.
<p>Step 6 <code>end</code></p> <p>Example:</p> <pre>Router(config)# end</pre>	Exits the current configuration mode and returns to privileged EXEC mode.

Configuration Examples for Multicast VPN MIB

- [Configuring the Router to Send MVRP Trap Notifications Example, page 89](#)

Configuring the Router to Send MVRP Trap Notifications Example

The following example shows how to configure a router to use SNMP to send MVRP trap notifications:

```
!
snmp-server community public rw
snmp-server enable traps mvpn
snmp-server host 10.3.32.154 version 2c public
!
```
