#### Contents

## **Feature History**

The following table lists the new and modified features supported in the MPLS Basic Configuration Guide in Cisco IOS XE 17 releases.

Feature	Description
Cisco IOS XE Bengaluru 17.4.1	
Re-optimization with Tunnel Bandwidth Modification on Flex-LSP Protect Path	This feature supports Make Before Break (MBB) functionality and thus ensures there is no traffic loss when a MPLS Flex LSP tunnel runs on protect LSP (if working LSP goes down) and the tunnel bandwidth is modified. When the working LSP comes up, use the following command to manually switch from the working to protect LSP: <b>mpls traffic-eng switch tunnel</b> <i>tunnel-ID</i>

I

## Multiprotocol Label Switching (MPLS) on Cisco **Routers**

This document describes commands for configuring and monitoring Multiprotocol Label Switching (MPLS) functionality on Cisco routers and switches. This document is a companion to other feature modules describing other MPLS applications.

- Information About MPLS, on page 3
- How to Configure MPLS, on page 6

## Information About MPLS

### MPLS Overview

Multiprotocol label switching (MPLS) combines the performance and capabilities of Layer 2 (data link layer) switching with the proven scalability of Layer 3 (network layer) routing. MPLS enables service providers to meet the challenges of explosive growth in network utilization while providing the opportunity to differentiate services without sacrificing the existing network infrastructure. The MPLS architecture is flexible and can be employed in any combination of Layer 2 technologies. MPLS support is offered for all Layer 3 protocols, and scaling is possible well beyond that typically offered in today's networks.

MPLS efficiently enables the delivery of IP services over an ATM switched network. MPLS supports the creation of different routes between a source and a destination on a purely router-based Internet backbone. By incorporating MPLS into their network architecture, service providers can save money, increase revenue and productivity, provide differentiated services, and gain competitive advantages.

Note

In the Cisco IOS XE Release 16.x, the ASR 1000 routers only support fragmentation of the MPLS packets from the IP to MPLS direction.

### **Functional Description of MPLS**

Label switching is a high-performance packet forwarding technology that integrates the performance and traffic management capabilities of data link layer (Layer 2) switching with the scalability, flexibility, and performance of network layer (Layer 3) routing.

### **Label Switching Functions**

In conventional Layer 3 forwarding mechanisms, as a packet traverses the network, each router extracts all the information relevant to forwarding the packet from the Layer 3 header. This information is then used as an index for a routing table lookup to determine the next hop for the packet.

In the most common case, the only relevant field in the header is the destination address field, but in some cases, other header fields might also be relevant. As a result, the header analysis must be done independently at each router through which the packet passes. In addition, a complicated table lookup must also be done at each router.

In label switching, the analysis of the Layer 3 header is done only once. The Layer 3 header is then mapped into a fixed length, unstructured value called a *label*.

Many different headers can map to the same label, as long as those headers always result in the same choice of next hop. In effect, a label represents a *forwarding equivalence class* --that is, a set of packets which, however different they may be, are indistinguishable by the forwarding function.

The initial choice of a label need not be based exclusively on the contents of the Layer 3 packet header; for example, forwarding decisions at subsequent hops can also be based on routing policy.

Once a label is assigned, a short label header is added at the front of the Layer 3 packet. This header is carried across the network as part of the packet. At subsequent hops through each MPLS router in the network, labels are swapped and forwarding decisions are made by means of MPLS forwarding table lookup for the label carried in the packet header. Hence, the packet header does not need to be reevaluated during packet transit through the network. Because the label is of fixed length and unstructured, the MPLS forwarding table lookup process is both straightforward and fast.

### **Distribution of Label Bindings**

Each label switching router (LSR) in the network makes an independent, local decision to determine a label value to represent a forwarding equivalence class. This association is known as a label binding. Each LSR informs its neighbors of the label bindings it has made.

When a labeled packet is being sent from LSR A to the neighboring LSR B, the label value carried by the IP packet is the label value that LSR B assigned to represent the forwarding equivalence class of the packet. Thus, the label value changes as the IP packet traverses the network.

The awareness of label bindings by neighbouring routers is facilitated using the following protocols:

- Label Distribution Protocol (LDP) Enables peer LSRs in an MPLS network to exchange label binding information for supporting hop-by-hop forwarding in an MPLS network.
- Tag Distribution Protocol (TDP) Supports MPLS forwarding along normally routed paths.
- Resource Reservation Protocol (RSVP) Supports MPLS traffic engineering.
- Border Gateway Protocol (BGP) Supports MPLS virtual private networks (VPNs) .

### **Benefits of MPLS**

MPLS provides the following major benefits to service provider networks:

Scalable support for Virtual Private Networks (VPNs)--MPLS enables VPN services to be supported in service provider networks, thereby greatly accelerating Internet growth.

The use of MPLS for VPNs provides an attractive alternative to the building of VPNs by means of either ATM or Frame Relay permanent virtual circuits (PVCs) or various forms of tunneling to interconnect routers at customer sites.

Unlike the PVC VPN model, the MPLS VPN model is highly scalable and can accommodate increasing numbers of sites and customers. The MPLS VPN model also supports "any-to-any" communication among VPN sites without requiring a full mesh of PVCs or the backhauling (suboptimal routing) of traffic across the service provider network. For each MPLS VPN user, the service provider's network appears to function as a private IP backbone over which the user can reach other sites within the VPN organization, but not the sites of any other VPN organization.

From a user perspective, the MPLS VPN model enables network routing to be dramatically simplified. For example, rather than having to manage routing over a topologically complex virtual backbone composed of many PVCs, an MPLS VPN user can generally employ the service provider's backbone as the default route in communicating with all of the other VPN sites.

**Explicit routing capabilities (also called constraint-based routing or traffic engineering)**--Explicit routing employs "constraint-based routing," in which the path for a traffic flow is the shortest path that meets the resource requirements (constraints) of the traffic flow.

In MPLS traffic engineering, factors such as bandwidth requirements, media requirements, and the priority of one traffic flow versus another can be taken into account. These traffic engineering capabilities enable the administrator of a service provider network to

- · Control traffic flow in the network
- · Reduce congestion in the network
- · Make best use of network resources

Thus, the network administrator can specify the amount of traffic expected to flow between various points in the network (thereby establishing a traffic matrix), while relying on the routing system to

- Calculate the best paths for network traffic
- Set up the explicit paths to carry the traffic

**Support for IP routing on ATM switches (also called IP and ATM integration)--**MPLS enables an ATM switch to perform virtually all of the functions of an IP router. This capability of an ATM switch stems from the fact that the MPLS forwarding paradigm, namely, label swapping, is exactly the same as the forwarding paradigm provided by ATM switch hardware.

The key difference between a conventional ATM switch and an ATM label switch is the control software used by the latter to establish its virtual channel identifier (VCI) table entries. An ATM label switch uses IP routing protocols and the Tag Distribution Protocol (TDP) to establish VCI table entries.

An ATM label switch can function as a conventional ATM switch. In this dual mode, the ATM switch resources (such as VCI space and bandwidth) are partitioned between the MPLS control plane and the ATM control plane. The MPLS control plane provides IP-based services, while the ATM control plane supports ATM-oriented functions, such as circuit emulation or PVC services.

### **Restrictions for MPLS**

Cisco ASR 900 Routers with RSP3 module can push a maximum of 4 MPLS labels in the egress direction. This includes service labels (L3VPN, L2VPN, 6PE, 6VPE), RFC 3107 BGP-LU label, and IGP labels for FRR primary or backup paths. However, Flow Aware Transport (FAT) pseudowire MPLS label is not included in this 4 label limit. FAT pseudowire MPLS label if configured, can be pushed in addition to the 4 labels mentioned.

## **How to Configure MPLS**

This section explains how to perform the basic configuration required to prepare a router for MPLS switching and forwarding.

Configuration tasks for other MPLS applications are described in the feature module documentation for the application.

### **Configuring a Router for MPLS Switching**

MPLS switching on Cisco routers requires that Cisco Express Forwarding be enabled.

For more information about Cisco Express Forwarding commands, see the Cisco IOS Switching Command Reference.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip cef distributed	Enables Cisco Express Forwarding on the route
	Example:	processor card.
	Device(config)# ip cef distributed	

#### Procedure

### Verifying Configuration of MPLS Switching

To verify that Cisco Express Forwarding has been configured properly, issue the **show ip cef summary** command, which generates output similar to that shown below:

L

#### Procedure

show ip cef summary

Example:

```
Router# show ip cef summary

IP CEF with switching (Table Version 49), flags=0x0

43 routes, 0 resolve, 0 unresolved (0 old, 0 new)

43 leaves, 49 nodes, 56756 bytes, 45 inserts, 2 invalidations

2 load sharing elements, 672 bytes, 2 references

1 CEF resets, 4 revisions of existing leaves

4 in-place modifications

refcounts: 7241 leaf, 7218 node

Adjacency Table has 18 adjacencies

Router#
```

### **Configuring a Router for MPLS Forwarding**

MPLS forwarding on Cisco routers requires that forwarding of IPv4 packets be enabled.

For more information about MPLS forwarding commands, see the *Multiprotocol Label Switching Command Reference*.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<b>interface</b> type slot/subslot /port [. subinterface]	Specifies the Gigabit Ethernet interface and
	Example:	enters interface configuration mode.
	Device(config)# interface gigabitethernet 4/0/0	
Step 4	mpls ip	Enables MPLS forwarding of IPv4 packets
	Example:	along normally routed paths for the Gigabit Ethernet interface.
	<pre>Device(config-if) # mpls ip</pre>	

#### Procedure

	Command or Action	Purpose
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

#### What to do next

Configure either of the following:

- MPLS Label Distribution Protocol (LDP). For information about configuring MPLS LDP, see the MPLS Label Distribution Protocol Configuration Guide.
- Static labels. For information about configuring static labels, see MPLS Static Labels.

### Verifying Configuration of MPLS Forwarding

To verify that MPLS forwarding has been configured properly, issue the **show mpls interfaces detail** command, which generates output similar to that shown below:

#### Procedure

#### show mpls interfaces detail

#### Example:

```
Device# show mpls interfaces detail

Interface GigabitEthernet1/0/0:

IP labeling enabled (ldp)

LSP Tunnel labeling not enabled

MPLS operational

MTU = 1500

Interface POS2/0/0:

IP labeling enabled (ldp)

LSP Tunnel labeling not enabled

MPLS not operational

MTU = 4470
```

## **Feature Information for MPLS on Cisco Routers**

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to https://cfnng.cisco.com/. An account on Cisco.com is not required.

### Glossary

**BGP** --Border Gateway Protocol. The predominant interdomain routing protocol used in IP networks.

Border Gateway Protocol --See BGP.

**FIB** --Forwarding Information Base. A table that contains a copy of the forwarding information in the IP routing table.

Forwarding Information Base -- See FIB.

**label** --A short, fixed-length identifier that tells switching nodes how the data (packets or cells) should be forwarded.

**label binding** --An association between a label and a set of packets, which can be advertised to neighbors so that a label switched path can be established.

Label Distribution Protocol -- See LDP.

Label Forwarding Information Base -- See LFIB.

label imposition -- The act of putting the first label on a packet.

label switching router --See LSR.

**LDP** --Label Distribution Protocol. The protocol that supports MPLS hop-by-hop forwarding by distributing bindings between labels and network prefixes.

**LFIB** --Label Forwarding Information Base. A data structure in which destinations and incoming labels are associated with outgoing interfaces and labels.

**LSR** --label switching router. A Layer 3 router that forwards a packet based on the value of an identifier encapsulated in the packet.

MPLS --Multiprotocol Label Switching. An industry standard on which label switching is based.

**MPLS hop-by-hop forwarding** -- The forwarding of packets along normally routed paths using MPLS forwarding mechanisms.

Multiprotocol Label Switching -- See MPLS.

Resource Reservation Protocol --See RSVP.

**RIB** --Routing Information Base. A common database containing all the routing protocols running on a router.

Routing Information Base -- See RIB.

**RSVP** --Resource Reservation Protocol. A protocol for reserving network resources to provide quality of service guarantees to application flows.

**traffic engineering** -- Techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods were used.

Virtual Private Network --See VPN.

**VPN** --Virtual Private Network. A network that enables IP traffic to use tunneling to travel securely over a public TCP/IP network.

## **MPLS Transport Profile**

Note This chapter is not applicable on the ASR 900 RSP3 Module.

Multiprotocol Label Switching (MPLS) Transport Profile (TP) enables you to create tunnels that provide the transport network service layer over which IP and MPLS traffic traverses. MPLS-TP tunnels enable a transition from Synchronous Optical Networking (SONET) and Synchronous Digital Hierarchy (SDH) time-division multiplexing (TDM) technologies to packet switching to support services with high bandwidth requirements, such as video.

- Restrictions for MPLS-TP on the Cisco ASR 900 Series Routers, on page 11
- Information About MPLS-TP, on page 12
- How to Configure MPLS Transport Profile, on page 18
- Configuration Examples for MPLS Transport Profile, on page 36

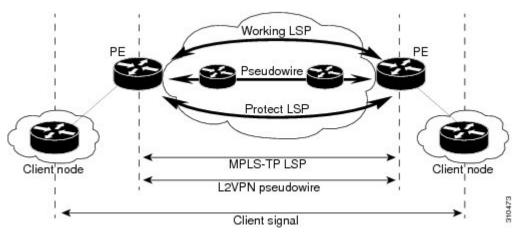

## **Restrictions for MPLS-TP on the Cisco ASR 900 Series Routers**

- Multiprotocol Label Switching Transport Profile (MPLS-TP) penultimate hop popping is *not* supported. Only ultimate hop popping is supported, because label mappings are configured at the MPLS-TP endpoints
- IPv6 addressing is not supported.
- VCCV BFD is not supported.
- Layer 2 Virtual Private Network (L2VPN) interworking is not supported.
- Local switching with Any Transport over MPLS (AToM) pseudowire as a backup is not supported.
- L2VPN pseudowire redundancy to an AToM pseudowire by one or more attachment circuits is *not* supported.
- Pseudowire ID Forward Equivalence Class (FEC) type 128 is supported, but generalized ID FEC type 129 is *not* supported
- Maximum virtual circuits (VC) supported for MPLS-TP is 2000.

## **Information About MPLS-TP**

### **How MPLS Transport Profile Works**

Multiprotocol Label Switching Transport Profile (MPLS-TP) tunnels provide the transport network service layer over which IP and MPLS traffic traverses. MPLS-TP tunnels help transition from Synchronous Optical Network/Synchronous Digital Hierarchy (SONET/SDH) and Time Division Multiplexing (TDM) technologies to packet switching to support services with high bandwidth utilization and lower cost. Transport networks are connection-oriented, statically provisioned, and have long-lived connections. Transport networks usually avoid control protocols that change identifiers (like labels). MPLS-TP tunnels provide this functionality through statically provisioned bidirectional label switched paths (LSPs), as shown in the figure below.

MPLS-TP is supported on ATM and TDM pseudowires on the Cisco router. For information, see Configuring the Pseudowire Class.

### **MPLS-TP Path Protection**

MPLS-TP label switched paths (LSPs) support 1-to-1 path protection. There are two types of LSPs: protect LSPs and working LSPs. You can configure the both types of LSPs when configuring the MPLS-TP tunnel. The working LSP is the primary LSP used to route traffic. The protect LSP acts as a backup for a working LSP. If the working LSP fails, traffic is switched to the protect LSP until the working LSP is restored, at which time forwarding reverts back to the working LSP.

### **Bidirectional LSPs**

Multiprotocol Label Switching Transport Profile (MPLS-TP) label switched paths (LSPs) are bidirectional and co-routed. They comprise of two unidirectional LSPs that are supported by the MPLS forwarding infrastructure. A TP tunnel consists of a pair of unidirectional tunnels that provide a bidirectional LSP. Each unidirectional tunnel can be optionally protected with a protect LSP that activates automatically upon failure conditions.

### **MPLS Transport Profile Static and Dynamic Multisegment Pseudowires**

Multiprotocol Label Switching Transport Profile (MPLS-TP) supports the following combinations of static and dynamic multisegment pseudowires:

- Dynamic-static
- Static-dynamic
- Static-static

### **MPLS-TP OAM Status for Static and Dynamic Multisegment Pseudowires**

With static pseudowires, status notifications can be provided by BFD over VCCV or by the static pseudowire OAM protocol. However, BFD over VCCV sends only attachment circuit status code notifications. Hop-by-hop notifications of other pseudowire status codes are not supported. Therefore, the static pseudowire OAM protocol is preferred

### **MPLS Transport Profile Links and Physical Interfaces**

Multiprotocol Label Switching Transport Profile (MPLS-TP) link numbers may be assigned to physical interfaces only. Bundled interfaces and virtual interfaces are not supported for MPLS-TP link numbers.

The MPLS-TP link creates a layer of indirection between the MPLS-TP tunnel and midpoint LSP configuration and the physical interface. The **mplstp link** command is used to associate an MPLS-TP link number with a physical interface and next-hop node. The MPLS-TP out-links can be configured only on the ethernet interfaces, with either the next hop IPv4 address or next hop mac-address specified.

Multiple tunnels and LSPs may then refer to the MPLS-TP link to indicate that they are traversing that interface. You can move the MPLS-TP link from one interface to another without reconfiguring all the MPLS-TP tunnels and LSPs that refer to the link.

Link numbers must be unique on the router or node.

### **Tunnel Midpoints**

Tunnel LSPs, whether endpoint or midpoint, use the same identifying information. However, it is entered differently.

- At the midpoint, all information for the LSP is specified with the **mpls tp lsp** command for configuring forward and reverse information for forwarding.
- At the midpoint, determining which end is source and which is destination is arbitrary. That is, if you
  are configuring a tunnel between your device and a coworker's device, then your device is the source.
  However, your coworker considers his or her device to be the source. At the midpoint, either device
  could be considered the source. At the midpoint, the forward direction is from source to destination, and
  the reverse direction is from destination to source.
- At the endpoint, the local information (source) either comes from the global device ID and global ID, or from the locally configured information using the **tp source** command.
- At the endpoint, the remote information (destination) is configured using the **tp destination** command after you enter the **interface tunnel-tp** *number* command. The **tp destination** command includes the

destination node ID, and optionally the global ID and the destination tunnel number. If you do not specify the destination tunnel number, the source tunnel number is used.

- At the endpoint, the LSP number is configured in working-lsp or protect-lsp submode. The default is 0 for the working LSP and 1 for the protect LSP.
- When configuring LSPs at midpoint devices, ensure that the configuration does not deflect traffic back to the originating node.

### **MPLS-TP Linear Protection with PSC Support**

### MPLS-TP Linear Protection with PSC Support Overview

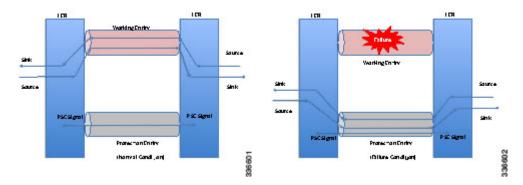

The Multiprotocol Label Switching (MPLS) Transport Profile (TP) enables you to create tunnels that provide the transport network service layer over which IP and MPLS traffic traverse.

Network survivability is the ability of a network to recover traffic deliver following failure, or degradation, of network resources. The MPLS-TP Survivability Framework (RFC-6372) describes the framework for survivability in MPLS-TP networks, focusing on mechanisms for recovering MPLS-TP label switched paths (LSPs)

Linear protection provides rapid and simple protection switching because it can operate between any pair of points within a network. Protection switching is a fully allocated survivability mechanism, meaning that the route and resources of the protection path are reserved for a selected working path or set of working paths. For a point-to-point LSPs, the protected domain is defined as two label edge routers (LERs) and the transport paths that connect them.

Protection switching in a point-to-point domain can be applied to a 1+1, 1:1, or 1:n unidirectional or bidirectional protection architecture. When used for bidirectional switching, the protection architecture must also support a Protection State Coordination (PSC) protocol. This protocol is used to help coordinate both ends of the protected domain in selecting the proper traffic flow. For example, if either endpoint detects a failure on the working transport entity, the endpoint sends a PSC message to inform the peer endpoint of the state condition. The PSC protocol decides what local action, if any, should be taken.

The following figure shows the MPLS-TP linear protection model used and the associated PSC signaling channel for state coordination.

In 1:1 bidirectional protection switching, for each direction, the source endpoint sends traffic on either a working transport entity or a protected transport entity, referred to as a data-path. If the either endpoint detects a failure on the working transport entity, that endpoint switches to send and receive traffic from the protected transport entity. Each endpoint also sends a PSC message to inform the peer endpoint of the state condition.

The PSC mechanism is necessary to coordinate the two transport entity endpoints and implement 1:1 bidirectional protection switching even for a unidirectional failure. The switching of the transport path from working path to protected path can happen because of various failure conditions (such as link down indication (LDI), remote defect indication (RDI), and link failures) or because administrator/operator intervention (such as shutdown, lockout of working/forced switch (FS), and lockout of protection).

Each endpoint LER implements a PSC architecture that consists of multiple functional blocks. They are:

- Local Trigger Logic: This receives inputs from bidirectional forwarding detection (BFD), operator commands, fault operation, administration, and maintenance (OAM) and a wait-to-restore (WTR) timer. It runs a priority logic to decide on the highest priority trigger.
- **PSC FSM:** The highest priority trigger event drives the PSC finite state machine (FSM) logic to decide what local action, if any, should be taken. These actions may include triggering path protection at the local endpoint or may simply ignore the event.
- **Remote PSC Signaling:** In addition to receiving events from local trigger logic, the PSC FSM logic also receives and processes PSC signaling messages from the remote LER. Remote messages indicate the status of the transport path from the viewpoint of the far end LER. These messages may drive state changes on the local entity.
- **PSC Message Generator:** Based on the action output from the PSC control logic, this functional block formats the PSC protocol message and transmits it to the remote endpoint of the protected domain. This message may either be the same as the previously transmitted message or change when the PSC control has changed. The messages are transmitted as an initial burst followed by a regular interval.
- Wait-to-Restore Timer: The (configurable) WTR timer is used to delay reversion to a normal state when recovering from a failure condition on the working path in revertive mode. The PSC FSM logic starts/stops the WTR timer based on internal conditions/state. When the WTR expires, it generates an event to drive the local trigger logic.
- **Remote Event Expire Timer:** The (configurable) remote-event-expire timer is used to clear the remote event after the timer is expired because of remote inactivity or fault in the protected LSP. When the remote event clear timer expires, it generates a remote event clear notification to the PSC FSM logic.

### Interoperability With Proprietary Lockout

An emulated protection (emulated automatic protection switching (APS)) switching ensures synchronization between peer entities. The emulated APS uses link down indication (LDI)message (proprietary) extensions when a lockout command is issued on the working or protected LSP. This lockout command is known as emLockout. A lockout is mutually exclusive between the working and protected LSP. In other words, when the working LSP is locked, the protected LSP cannot be locked (and vice versa).

The emLockout message is sent on the specified channel from the endpoint on the LSP where the lockout command (working/protected) is issued. Once the lockout is cleared locally, a Wait-To-Restore (WTR) timer (configurable) is started and the remote end notified. The local peer continues to remain in lockout until a clear is received from the remote peer and the WTR timer has expired and only then the LSP is considered to be no longer locked out. In certain deployments, you use a large WTR timer to emulate a non-revertive behavior. This causes the protected LSP to continue forwarding traffic even after the lockout has been removed from the working LSP.

The PSC protocol as specified in RFC-6378 is incompatible with the emulated APS implementation in certain conditions. For example, PSC implements a priority scheme whereby a lockout of protection (LoP) is at a higher priority than a forced switch (FS) issued on a working LSP. When an FS is issued and cleared, PSC

states that the switching must revert to the working LSP immediately. However, the emulated APS implementation starts a WTR timer and switches after the timer has expired.

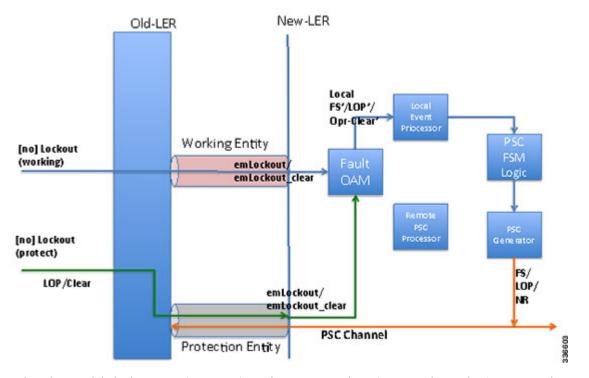

An endpoint implementing the newer PSC version may have to communicate with another endpoint implementing an older version. Because there is no mechanism to exchange the capabilities, the PSC implementation must interoperate with another peer endpoint implementing emulated APS. In this scenario, the new implementation sends both the LDI extension message (referred to as emLockout) as well as a PSC message when the lockout is issued.

### Mapping and Priority of emlockout

There are two possible setups for interoperability:

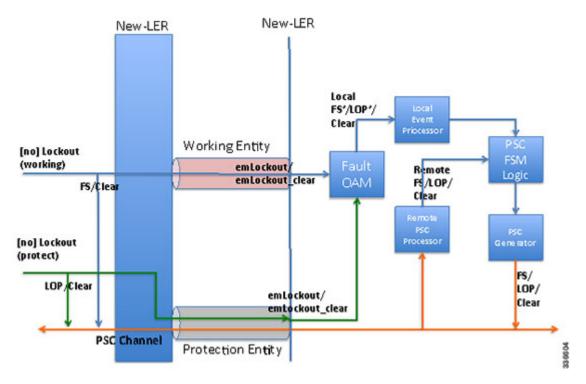

- New-old implementation.
- New-new implementation.

You can understand the mapping and priority when an emLockout is received and processed in the new-old implementation by referring to the following figure.

When the new label edge router (new-LER) receives an emLockout (or emLockout\_clear) message, the new-LER maps the message into an internal local FS'/FSc' (local FS-prime/FS-prime-clear) or LoP'/LoPc' (local LoP-prime/Lop-prime-clear) event based on the channel on which it is received. This event is prioritized by the local event processor against any persistent local operator command. The highest priority event drives the PSC FSM logic and any associated path protection logic. A new internal state is defined for FS'/FSc' events. The PSC FSM logic transmits the corresponding PSC message. This message is dropped/ignored by the old-LER.

In the new-new LER implementation shown in the following figure, each endpoint generates two messages when a lockout command is given on a working or protected LSP.

When a lockout (working) command is issued, the new-LER implementation sends an emLockout command on the working LSP and PSC(FS) on the protected LSP. The remote peer receives two commands in either order. A priority scheme for local events is modified slightly beyond what is defined in order to drive the PSC FSM to a consistent state despite the order in which the two messages are received.

In the new implementation, it is possible to override the lockout of the working LSP with the lockout of the protected LSP according to the priority scheme. This is not allowed in the existing implementation. Consider the following steps between old (O) and new (N) node setup:

Time T1: Lockout (on the working LSP) is issued on O and N. Data is switched from the working to the protected LSP.

Time T2: Lockout (on the protected LSP) is issued on O and N. The command is rejected at O (existing behavior) and accepted at N (new behavior). Data in O->N continues on the protected LSP. Data in N->O switches to the working LSP.

You must issue a clear lockout (on the working LSP) and re-issue a lockout (on the protected LSP) on the old node to restore consistency.

### WTR Synchronization

When a lockout on the working label switched path (LSP) is issued and subsequently cleared, a WTR timer (default: 10 sec, configurable) is started. When the timer expires, the data path is switched from protected to working LSP.

The PSC protocol indicates that the switch should happen immediately when a lockout (FS) is cleared.

When a new node is connected to the old node, for a period of time equal to the WTR timer value, the data path may be out-of-sync when a lockout is cleared on the working LSP. You should configure a low WTR value in order to minimize this condition.

Another issue is synchronization of the WTR value during stateful switchover (SSO). Currently, the WTR residual value is not checkpointed between the active and standby. As a result, after SSO, the new active restarts the WTR with the configured value if the protected LSP is active and the working LSP is up. As part of the PSC protocol implementation, the residual WTR is checkpointed on the standby. When the standby becomes active, the WTR is started with the residual value.

### **Priority of Inputs**

The event priority scheme for locally generated events is as follows in high to low order:

Local Events:

- 1. Opr-Clear (Operator Clear)
- 2. LoP (Lockout of Protection)
- 3. LoP'/LoP'-Clear
- 4. FS (Forced Switch)
- 5. FS'/FS'-Clear
- 6. MS (Manual-Switch)

The emLockout received on the working LSP is mapped to the local-FS'. The emLockout received on the protected LSP is mapped to the local-LoP'. The emLockout-clear received is mapped to the corresponding clear events.

The priority definition for Signal Fail (SF), Signal Degrade (SD), Manual Switch (MS), WTR, Do Not Revert (DNR), and No Request (NR) remains unchanged.

### **PSC Syslogs**

The following are the new syslogs that are introduced as part of the Linear Protection with PSC Support feature:

SYSLOG NAME	DESCRIPTION	RAW FORMAT
MPLS_TP_TUNNEL_PSC_PREEMPTION	Handle MPLS TP tunnel PSC event preemption syslog.	%MPLS-TP-5-PSCPREEMPTION: Tunnel-tp10, PSC Event: LOP:R preempted PSC Event: FS:L
MPLS_TP_TUNNEL_PSC_TYPE_MISMATCH	Handle MPLS TP tunnel type mismatch	%MPLS-PSC-5-TYPE-MISMATCH: Tunnel-tp10, type mismatch local-type: 1:1,

## How to Configure MPLS Transport Profile

### **Configuring the MPLS Label Range**

You must specify a static range of Multiprotocol Label Switching (MPLS) labels using the **mpls label range** command with the **static** keyword.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<b>mpls label range</b> <i>minimum-value</i> <i>maximum-value</i> <b>static</b> <i>minimum-static-value</i> <i>maximum-static-value</i>	Specifies a static range of MPLS labels.
	Example:	
	Device(config)# mpls label range 1001 1003 static 10000 25000	
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

#### Procedure

## **Configuring the Router ID and Global ID**

### Procedure

I

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mpls tp	Enters MPLS-TP configuration mode, from
	Example:	which you can configure MPLS-TP parameters for the device.
	Device(config)# mpls tp	

	Command or Action	Purpose
Step 4	router-id node-id	Specifies the default MPLS-TP router ID, which
	Example:	is used as the default source node ID for all MPLS-TP tunnels configured on the device.
	Device(config-mpls-tp)# router-id 10.10.10.10	
Step 5	global-id num	(Optional) Specifies the default global ID used
	<b>Example:</b> Device(config-mpls-tp)# global-id 1	for all endpoints and midpoints.
		• This command makes the router ID globally unique in a multiprovider tunnel. Otherwise, the router ID is only locally meaningful.
		• The global ID is an autonomous system number, which is a controlled number space by which providers can identify each other.
		• The router ID and global ID are also included in fault messages sent by devices from the tunnel midpoints to help isolate the location of faults.
Step 6	end	Exits MPLS-TP configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-mpls-tp)# end	

### **Configuring Bidirectional Forwarding Detection Templates**

The **bfd-template** command allows you to create a BFD template and enter BFD configuration mode. The template can be used to specify a set of BFD interval values. You invoke the template as part of the MPLS-TP tunnel. On platforms that support the BFD Hardware Offload feature and that can provide a 60-ms cutover for MPLS-TP tunnels, it is recommended to use the higher resolution timers in the BFD template.

### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	<b>bfd-template single-hop</b> <i>template-name</i> <b>Example:</b>	Creates a BFD template and enter BFD configuration mode.
	Device(config)# bfd-template single-hop mpls-bfd-1	
Step 4	interval [microseconds] {both time   min-tx time min-rx time} [multiplier multiplier-value]	Specifies a set of BFD interval values.
	Example:	
	Device(config-bfd)# interval min-tx 99 min-rx 99 multiplier 3	
Step 5	end	Exits BFD configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config-bfd)# exit	

## **Configuring Pseudowire OAM Attributes**

### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	pseudowire-static-oam class class-name	Creates a pseudowire OAM class and enters
	Example:	pseudowire OAM class configuration mode
	Device(config)# pseudowire-static-oam class oam-class1	
Step 4	timeout refresh send seconds	Specifies the OAM timeout refresh interval
	Example:	
	<pre>Device(config-st-pw-oam-class)# timeout   refresh send 20</pre>	

I

	Command or Action	Purpose
Step 5	exit	Exits pseudowire OAM configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-st-pw-oam-class)# exit	

## **Configuring the Pseudowire Class**

When you create a pseudowire class, you specify the parameters of the pseudowire, such as the use of the control word, preferred path and OAM class template.

#### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	pseudowire-class class-name	Creates a pseudowire class and enters
	Example:	pseudowire class configuration mode.
	Device(config)# pseudowire-class mpls-tp-class1	
Step 4	encapsulation mpls	Specifies the encapsulation type.
	Example:	
	Device(config-pw-class)# encapsulation mpls	
Step 5	control-word	Enables the use of the control word.
	Example:	
	Device(config-pw-class)# control-word	
Step 6	mpls label protocol [ldp   none]	Specifies the type of protocol.
	Example:	
	Device(config-pw-class)# protocol none	

	Command or Action	Purpose
Step 7	<pre>preferred-path {interface tunnel tunnel-number   peer {ip-address   host-name}} [disable-fallback]</pre>	Specifies the tunnel to use as the preferred path.
	Example:	
	Device(config-pw-class)# preferred-path interface tunnel-tp2	
Step 8	status protocol notification static class-name	Specifies the OAM class to use.
	Example:	
	Device(config-pw-class)# status protocol notification static oam-class1	
Step 9	end	Exits pseudowire class configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-pw-class)# end	

## **Configuring the Pseudowire**

I

#### Procedure

Step 1	enable
	Example:
	Device> enable
	Enables privileged EXEC mode.
	• Enter your password if prompted.
Step 2	configure terminal
	Example:
	Device# configure terminal
	Enters global configuration mode.
Step 3	interface interface-id
	Example:
	Router(config)# interface gigabitethernet 0/0/4
	Specifies the port on which to create the pseudowire and enters interface configuration mode. Valid interfaces are physical Ethernet ports.
Step 4	service instance number ethernet [name]

#### Example:

Router(config-if) # service instance 2 ethernet

Configure an EFP (service instance) and enter service instance configuration) mode.

- number-Indicates EFP identifier. Valid values are from 1 to 400
- (Optional) ethernet name—Name of a previously configured EVC. You do not need to use an EVC name in a service instance.
  - **Note** You can use service instance settings such as encapsulation, dot1q, and rewrite to configure tagging properties for a specific traffic flow within a given pseudowire session. For more information, see Ethernet Virtual Connections on the Cisco Router.

```
Step 5 mpls label local-pseudowire-label remote-pseudowire-label
```

#### Example:

Device(config-if-xconn) # mpls label 1000 1001

Configures the static pseudowire connection by defining local and remote circuit labels.

Step 6 mpls control-word

#### Example:

```
Device(config-if-xconn) # no mpls control-word
Specifies the control word.
```

 Step 7
 backup delay {enable-delay-period | never} {disable-delay-period | never}

### Example:

Device(config-if-xconn) # backup delay 0 never

Specifies how long a backup pseudowire virtual circuit (VC) should wait before resuming operation after the primary pseudowire VC goes down.

**Step 8 backup peer** peer-router-ip-addr vcid [**pw-class** pw-class-name] [**priority** value]

#### Example:

Device(config-if-xconn) # backup peer 10.0.0.2 50

Specifies a redundant peer for a pseudowire virtual circuit (VC).

Step 9 end

#### **Example:**

Device(config) # end

Exits xconn interface connection mode and returns to privileged EXEC mode.

### **Configuring the MPLS-TP Tunnel**

On the endpoint devices, create an MPLS TP tunnel and configure its parameters. See the interface tunnel-tp command for information on the parameters.

#### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface tunnel-tp number	Enters tunnel interface configuration mode.
	Example:	Tunnel numbers from 0 to 999 are supported
	Device(config) # interface tunnel-tp 1	
Step 4	description tunnel-description	(Optional) Specifies a tunnel description.
	Example:	
	Device(config-if)# description headend tunnel	
Step 5	tp tunnel-name name	Specifies the name of the MPLS-TP tunnel.
	Example:	
	Device(config-if)# tp tunnel-name tunnel 122	
Step 6	tp source node-id [global-id num]	(Optional) Specifies the tunnel source and
	Example:	endpoint.
	Device(config-if)# tp source 10.11.11.11 global-id 10	
Step 7	tp destination         node-id [tunnel-tp num[           global-id         num]]	Specifies the destination node of the tunnel.
	Example:	
	Device(config-if)# tp destination 10.10.10.10	

	Command or Action	Purpose
Step 8	bfd bfd-template	Specifies the BFD template.
	Example:	
	Device(config-if)# bfd mpls-bfd-1	
Step 9	working-lsp	Specifies a working LSP, also known as the
	Example:	primary LSP.
	Device(config-if)# working-lsp	
Step 10	in-label num	Specifies the in-label number.
	Example:	
	Device(config-if-working)# in-label 20000	
Step 11	out-label num out-link num	Specifies the out-label number and out-link
	Example:	
	Device(config-if-working)# out-label 20000 out-link	
Step 12	exit	Exits working LSP interface configuration
	Example:	mode and returns to interface configuration mode.
	<pre>Device(config-if-working)# exit</pre>	
Step 13	protect-lsp	Specifies a backup for a working LSP.
	Example:	
	Device(config-if)# protect-lsp	
Step 14	in-label num	Specifies the in label.
	Example:	
	Device(config-if-protect)# in-label 20000	
Step 15	out-label num out-link num	Specifies the out label and out link.
	Example:	
	Device(config-if-protect)# out-label 113 out-link	
Step 16	end	Exits the interface configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-if-protect)# end	

## **Configuring MPLS-TP LSPs at Midpoints**

**Note** When configuring LSPs at midpoint devices, ensure that the configuration does not deflect traffic back to the originating node.

#### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mpls tp lsp sourcenode-id [global-id num]tunnel-tp num lsp {lsp-num   protect  working} destination node-id [global-id num]tunnel-tp num	Enables MPLS-TP midpoint connectivity and enters MPLS TP LSP configuration mode.
	Example:	
	Device(config)# mpls tp lsp source 10.10.10.10 global-id 10 tunnel-tp 1 lsp protect destination 10.11.11.11 global-id 10 tunnel-tp 1	
Step 4	forward-lsp	Enters MPLS-TP LSP forward LSP configuration mode.
	Example:	
	<pre>Device(config-mpls-tp-lsp)# forward-lsp</pre>	
Step 5	in-label num out-label num out-link num	Specifies the in label, out label, and out link numbers.
	Example:	
	Device(config-mpls-tp-lsp-forw)# in-label 2000 out-label 2100 out-link 41	
Step 6	exit	Exits MPLS-TP LSP forward LSP configuration
	Example:	mode.
	<pre>Device(config-mpls-tp-lsp-forw)# exit</pre>	
Step 7	reverse-lsp	Enters MPLS-TP LSP reverse LSP
	Example:	configuration mode.

	Command or Action	Purpose
	Device(config-mpls-tp-lsp)# reverse-lsp	
Step 8	in-label num out-label num out-link num	Specifies the in-label, out-label, and out-link numbers.
	Example:	
	Device(config-mpls-tp-lsp-rev)# in-label 22000 out-label 20000 out-link 44	
Step 9 end Example:	end	Exits the MPLS TP LSP configuration mode and returns to privileged EXEC mode.
	Example:	
	Device(config-mpls-tp-lsp-rev)# end	

## **Configuring MPLS-TP Links and Physical Interfaces**

MPLS-TP link numbers may be assigned to physical interfaces only. Bundled interfaces and virtual interfaces are not supported for MPLS-TP link numbers.

### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface type number	Specifies the interface and enters interface
	Example:	configuration mode.
	Device(config)# interface ethernet 1/0	
Step 4	ip address ip-address mask	Assigns an IP address to the interface.
	Example:	
	Device(config-if)# ip address 10.10.10.10 255.255.255.0	
Step 5	<pre>mpls tp link link-num{ipv4 ip-address tx-mac mac-address}</pre>	Associates an MPLS-TP link number with a physical interface and next-hop node. On
	Example:	point-to-point interfaces or Ethernet interfaces designated as point-to-point using the <b>medium</b>

	Command or Action	Purpose	
	Device(config-if)# mpls tp link 1 ipv4 10.0.0.2	<b>p2p</b> command, the next-hop can be implicit, so the <b>mpls tp link</b> command just associates a link number to the interface.	
		Multiple tunnels and LSPs can refer to the MPLS-TP link to indicate they are traversing that interface. You can move the MPLS-TP link from one interface to another without reconfiguring all the MPLS-TP tunnels and LSPs that refer to the link.	
		Link numbers must be unique on the device or node.	
Step 6	end	Exits interface configuration mode and returns	
	Example:	to privileged EXEC mode.	
	Device(config-if)# end		

## **Configuring MPLS-TP Linear Protection with PSC Support**

The **psc** command allows you to configure MPLS-TP linear protection with PSC support. PSC is disabled by default. However, it can be enabled by issuing the **psc** command.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mpls tp	Enters Multiprotocol Label Switching (MPLS)
	Example:	Transport Profile (TP) global mode.
	Device(config)# mpls tp	
Step 4	psc	Enables the PSC Protocol.
	Example:	
	Device(config-mpls-tp)# psc	

#### Procedure

	Command or Action	Purpose	
Step 5	psc fast refresh interval time-in-msec	Configures the fast refresh interval for PSC messages.	
	<pre>Example: Device(config-mpls-tp)# psc fast refresh interval 2000</pre>	• The default is 1000 ms with a jitter of 50	
Step 6	psc slow refresh interval time-in-msec	Configures the slow refresh interval for PSC	
	<pre>Example: Device(config-mpls-tp)# psc slow refresh interval 10</pre>	<ul> <li>messages.</li> <li>The default is 5 sec. The range is from 5 secs to 86400 secs (24 hours).</li> </ul>	
Step 7	psc remote refresh interval time-in-sec	Configures the remote-event expiration timer	
	message-count num	• By default, this timer is disabled. The	
	<pre>Example: Device(config-mpls-tp)# psc remote refresh interval 20 message-count 15</pre>	remote refresh interval range is from 86400 sec (24 hours). The message co is from 5 to 1000. If you do not speci the message count value, it is set to 5 which is the default.	
Step 8	exit	Exits MPLS TP global mode.	
	Example:		
	Device(config-mpls-tp)# exit		
Step 9	interface tunnel-tp number	Creates an MPLS-TP tunnel called <i>number</i>	
	Example:	and enters TP interface tunnel mode.	
	Device(config)# interface tunnel-tp 1		
Step 10	psc	Enables PSC.	
	Example:	By default, PSC is disabled.	
	Device(config-if)# psc		
Step 11	emulated-lockout	Enables the sending of emLockout on	
	Example:	working/protected transport entities if the <b>lockout</b> command is issued on each	
	Device(config-if)# emulated-lockout	working/protected transport entity respectively By default, the sending of emLockout is disabled.	
Step 12	working-lsp	Enters working LSP mode on a TP tunnel	
	Example:	interface.	
	Device(config-if)# working-lsp		

I

	Command or Action	Purpose	
Step 13	<pre>manual-switch Example: Device(config-if-working)# manual-switch</pre>	Issues a local manual switch condition on a working label switched path (LSP). This car be configured only in working LSP mode or a TP tunnel interface.	
Step 14	exit Example:	Exits working LSP mode.	
	<pre>Device(config-if-working)# exit</pre>		
Step 15	exit	Exits TP interface tunnel mode.	
	Example:		
	Device(config-if)# exit		

# Configuring Static-to-Static Multisegment Pseudowires for MPLS-TP

#### Procedure

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	l2 vfi name point-to-point	Creates a point-to-point Layer 2 virtual	
	Example:	forwarding interface (VFI) and enters VFI configuration mode.	
	Device(config)# 12 vfi atom point-to-point		
Step 4	bridge-domainbridge-id	Configures the bridge domain service instance.	
	Example:	• bridge-id—Bridge domain identifier. The	
	Device)config)# bridge-domain 400	valid values are from 1 to 4000.	
Step 5	neighbor <i>ip-address vc-id</i> {encapsulation	Sets up an emulated VC. Specify the IP	
	<b>mpls</b>   <b>pw-class</b> <i>pw-class-name</i> }	address, the VC ID of the remote device, and the pseudowire class to use for the emulated	
	Example:	VC.	
	Device(config-vfi)# neighbor 10.111.111.111 123 pw-class atom		

	Command or Action	Purpose	
		Note Only two neighbor commands are allowed for each Layer 2 VFI point-to-point command.	
Step 6	<b>mpls label</b> local-pseudowire-label remote-pseudowire-label	Configures the static pseudowire connection by defining local and remote circuit labels.	
	Example:		
	Device(config-vfi)# mpls label 10000 25000		
Step 7	mpls control-word	Specifies the control word.	
	Example:		
	Device(config-vfi)# mpls control-word		
Step 8	<b>neighbor</b> <i>ip-address vc-id</i> { <b>encapsulation mpls</b>   <b>pw-class</b> <i>pw-class-name</i> }	Sets up an emulated VC. Specify the IP address, the VC ID of the remote device, a	
	Example:	the pseudowire class to use for the emulated VC.	
	Device(config-vfi)# neighbor 10.10.10.11 123 pw-class atom		
Step 9	<b>mpls label</b> local-pseudowire-label remote-pseudowire-label	Configures the static pseudowire connection by defining local and remote circuit labels.	
	Example:		
	Device(config-vfi)# mpls label 11000 11001		
Step 10	mpls control-word	Specifies the control word.	
	Example:		
	Example:		
	Device(config-vfi)# mpls control-word		
Step 11	end	Exits VFI configuration mode and returns to	
	Example:	privileged EXEC mode.	
	Device(config)# end		

## **Configuring Static-to-Dynamic Multisegment Pseudowires for MPLS-TP**

When you configure static-to-dynamic pseudowires, you configure the static pseudowire class with the protocol none command, create a dynamic pseudowire class, and then invoke those pseudowire classes with the neighbor commands.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	pseudowire-class class-name	Creates a pseudowire class and enters	
	Example:	pseudowire class configuration mode.	
	Device(config)# pseudowire-class mpls-tp-class1		
Step 4	encapsulation mpls	Specifies the encapsulation type.	
	Example:		
	Device(config-pw-class)# encapsulation mpls		
Step 5	control-word	Enables the use of the control word.	
	Example:		
	Device(config-pw-class)# control-word		
Step 6	mpls label protocol [ldp   none]	Specifies the type of protocol.	
	Example:		
	Device(config-pw-class) # <b>protocol none</b>		
Step 7	exit	Exits pseudowire class configuration mode	
	Example:	and returns to global configuration mode.	
	Device(config-pw-class)# exit		
Step 8	pseudowire-class class-name	Creates a pseudowire class and enters	
	Example:	pseudowire class configuration mode.	
	Device(config)# pseudowire-class mpls-tp-class1		
Step 9	encapsulation mpls	Specifies the encapsulation type.	
	Example:		

#### Procedure

	Command or Action	Purpose		
	Device(config-pw-class)# encapsulation mpls			
Step 10	exit	Exits pseudowire class configuration mode		
	Example:	and returns to global configuration mode.		
	Device(config-pw-class)# exit			
Step 11	12 vfi name point-to-point	Creates a point-to-point Layer 2 virtual		
	Example:	forwarding interface (VFI) and enters VFI configuration mode.		
	Device(config)# 12 vfi atom point-to-point			
Step 12	<b>neighbor</b> <i>ip-address vc-id</i> { <b>encapsulation</b> <b>mpls</b>   <b>pw-class</b> <i>pw-class-name</i> }	Sets up an emulated VC and enters VFI neighbor configuration mode.		
	Example:	Note: Only two <b>neighbor</b> commands are allowed for each <b>l2 vfi</b>		
	Device(config-vfi)# neighbor 10.111.111.111 123 pw-class atom	point-to-point command.		
Step 13	neighbor <i>ip-address vc-id</i> {encapsulation	Sets up an emulated VC.		
	<pre>mpls   pw-class pw-class-name } Example:</pre>	Note Only two <b>neighbor</b> commands are allowed for each <b>l2 vfi point-to-point</b>		
	Device(config-vfi-neighbor)# neighbor 10.111.111.111 123 pw-class atom	command.		
Step 14	mpls label local-pseudowire-label	Configures the static pseudowire connection		
	remote-pseudowire-label	by defining local and remote circuit labels.		
	Example:			
	Device(config-vfi-neighbor)# mpls label 10000 25000			
Step 15	mpls control-word	Specifies the control word.		
	Example:			
	Device(config-vfi-neighbor)# mpls control-word			
Step 16	local interface pseudowire-type	Specifies the pseudowire type.		
	Example:			
	Device(config-vfi-neighbor)# local interface 4			

	Command or Action	Purpose
Step 17	Do one of the following: • tlv [type-name] type-value length [dec   hexstr   str] value • tlv template template-name	Specifies the TLV parameters or invokes a previously configured TLV template.
	Example:	
	Device(config-vfi-neighbor)# tlv statictemp 2 4 hexstr 1	
Step 18	end	Ends the session.
	Example:	
	Device(config-vfi-neighbor)# end	

# Configuring a Template with Pseudowire Type-Length-Value Parameters

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	tlv [type-name] type-value length [dec   hexstr   str] value	Specifies the TLV parameters.	
	Example:		
	Device(config-pw-tlv-template)# tlv statictemp 2 4 hexstr 1		
Step 4	end	Exits pseudowire TLV template configuration	
	Example:	mode and returns to privileged EXEC mode.	
	Device(config-pw-tlv-template)# end		

#### Procedure

## Verifying the MPLS-TP Configuration

Use the following commands to verify and help troubleshoot your MPLS-TP configuration:

- debug mpls tp—Enables the logging of MPLS-TP error messages.
- logging (MPLS-TP)—Displays configuration or state change logging messages.
- show bfd neighbors mpls-tp—Displays the BFD state, which must be up in order for the endpoint LSPs to be up.
- show mpls l2transport static-oam l2transport static-oam—Displays MPLS-TP messages related to pseudowires.
- **show mpls tp tunnel-tp** *number* **detail**—Displays the number and details of the tunnels that are not functioning.
- show mpls tp tunnel-tp lsps—Displays the status of the LSPs, and helps you ensure that both LSPs are up and working from a tunnel endpoint.
- traceroute mpls tp and ping mpls tp—Helps you identify connectivity issues along the MPLS-TP tunnel path.

## **Configuration Examples for MPLS Transport Profile**

### Example: Configuring MPLS-TP Linear Protection with PSC Support

The following example enters MPLS TP global mode and enables the PSC Protocol.

```
Device> enable
Device# configure terminal
Device(config)# mpls tp
Device(config-mpls-tp)# psc
```

The following example configures the fast refresh interval for PSC messages. The interval value is 2000 seconds.

Device(config-mpls-tp)# psc fast refresh interval 2000

The following example configures the slow refresh interval for PSC messages. The interval value is 10 seconds.

Device(config-mpls-tp) # psc slow refresh interval 10

The following example configures the remote event expiration timer with a refresh interval value of 20 seconds with a message count of 15.

Device (config-mpls-tp) # psc remote refresh interval 20 message-count 15

The following example exits MPLS TP global mode, creates a TP interface tunnel, and enables PSC.

```
Device(config-mpls-tp)# exit
Decice(config) interface tunnel-tp 1
Device(config-if)# psc
```

The following example enables the sending of emLockout on working/protected transport entities, enters working LSP mode on a TP tunnel interface, and issues a local manual switch condition on a working LSP.

```
Device(config-if)# emulated-lockout
Device(config-if)# working-lsp
Device(config-if-working)# manual-switch
```

## **Example: Verifying MPLS-TP Linear Protection with PSC Support**

The following example displays a summary of the MPLS-TP settings.

Device# show mpls tp summary

The following example provides information about the MPLS-TP link number database.

```
Device# show mpls tp link-numbers
```

### Example: Troubleshooting MPLS-TP Linear Protection with PSC Support

The following example enables debugging for all PSC packets that are sent and received.

Device# debug mpls tp psc packet The following example enables debugging for all kinds of PSC events.

Device# debug mpls tp psc event The following example clears the counters for PSC signaling messages based on the tunnel number.

Device# clear mpls tp 1 psc counter

The following example clears the remote event for PSC based on the tunnel number.

Device# clear mpls tp tunnel-tp 1 psc remote-event

# **MPLS Multilink PPP Support**

Note This chapter is not applicable on the ASR 900 RSP3 Module for the Cisco IOS XE Release 3.16.

The MPLS Multilink PPP Support feature ensures that MPLS Layer 3 Virtual Private Networks (VPNs) with quality of service (QoS) can be enabled for bundled links. This feature supports Multiprotocol Label Switching (MPLS) over Multilink PPP (MLP) links in the edge (provider edge [PE]-to-customer edge [CE]) or in the MPLS core (PE-to-PE and PE-to-provider [P] device).

Service providers that use relatively low-speed links can use MLP to spread traffic across them in their MPLS networks. Link fragmentation and interleaving (LFI) should be deployed in the CE-to-PE link for efficiency, where traffic uses a lower link bandwidth (less than 768 kbps). The MPLS Multilink PPP Support feature can reduce the number of Interior Gateway Protocol (IGP) adjacencies and facilitate load sharing of traffic.

- Prerequisites for MPLS Multilink PPP Support, on page 39
- Restrictions for MPLS Multilink PPP Support, on page 39
- Information About MPLS Multilink PPP Support, on page 40
- How to Configure MPLS Multilink PPP Support, on page 44
- Configuration Examples for MPLS Multilink PPP Support, on page 52

## Prerequisites for MPLS Multilink PPP Support

• Multiprotocol Label Switching (MPLS) must be enabled on provider edge (PE) and provider (P) devices

# **Restrictions for MPLS Multilink PPP Support**

- Only 168 multilink bundles can be created per the OC-3 interface module on the router.
- The maximum number of members per multilink bundle is 16.
- Links in multilink bundles must be on the same interface module.
- On the 8 T1/E1, a maximum of 8 bundles can be supported.
- On the 16T1/E1, a maximum of 16 bundles can be supported.

• On the 32 T1/E1, a maximum of 32 bundles can be supported.

For information on how to configure, Protocol-Field-Compression (PFC) and Address-and-Control-Field-Compression (AFC), see *Configuring PPP and Multilink PPP on the Cisco ASR 903 Router*.

# **Information About MPLS Multilink PPP Support**

### **MPLS Layer 3 Virtual Private Network Features Supported for Multilink PPP**

The table below lists Multiprotocol Label Switching (MPLS) Layer 3 Virtual Private Network (VPN) features supported for Multilink PPP (MLP) and indicates if the feature is supported on customer edge-to-provider edge (CE-to-PE) links, PE-to-provider (P) links, and Carrier Supporting Carrier (CSC) CE-to-PE links.

MPLS L3 VPN Feature	CE-to-PE Links	PE-to-P Links	CSC CE-to-PE Links
Static routes	Supported	Not supported	Not supported
External Border Gateway Protocol (eBGP)	Supported	Not applicable to this configuration	Supported
Intermediate System-to-Intermediate System (IS-IS)	Not supported	Supported	Not supported
Open Shortest Path First (OSPF)	Supported	Supported	Not supported
Enhanced Interior Gateway Routing Protocol (EIGRP)	Supported	Supported	Not supported
Interprovider interautonomous (Inter-AS) VPNs (with Label Distribution Protocol [LDP])	Not applicable to this configuration	Supported (MLP between Autonomous System Boundary Routers [ASBRs])	Not applicable to this configuration
Inter-AS VPNs with IPv4 Label Distribution	Not applicable to this configuration	Supported (MLP between ASBRs)	Not applicable to this configuration
CSC VPNs (with LDP)	Not supported	Not applicable to this configuration	Supported
CSC VPNs with IPv4 label distribution	Supported	Not applicable to this configuration	Supported
External and internal BGP (eiBGP) Multipath	Not supported	Not supported	Not applicable to this configuration
Internal BGP (iBGP) Multipath	Not applicable to this configuration	Not supported	Not applicable to this configuration

#### Table 1: MPLS Layer 3 VPN Features Supported for MLP

Μ	IPLS L3 VPN Feature	CE-to-PE Links	PE-to-P Links	CSC CE-to-PE Links
el	BGP Multipath	Not supported	Not supported	Not supported

## **MPLS Quality of Service Features Supported for Multilink PPP**

The table below lists the Multiprotocol Label Switching (MPLS) quality of service (QoS) features supported for Multilink PPP (MLP) and indicates if the feature is supported on customer edge-to-provider edge (CE-to-PE) links, PE-to-provider (P) links, and Carrier Supporting Carrier (CSC) CE-to-PE links.

Table 2: MPLS QoS Features Supported for MLP

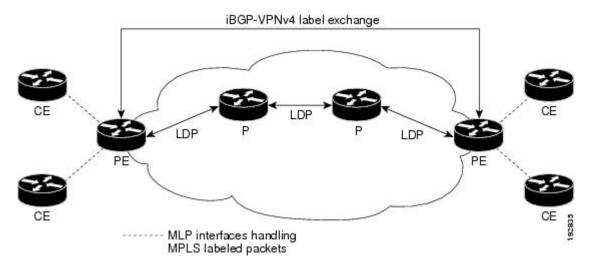

MPLS QoS Feature	CE-to-PE Links	PE-to-P Links	CSC CE-to-PE Links
Default copy of IP Precedence to EXP bits and the reverse	Supported	Not supported	Not supported
Set MPLS EXP bits using the modular QoS Command-Line Interface (MQC)	Supported	Supported	Supported
Matching on MPLS EXP using MQC	Supported	Supported	Supported
Low Latency Queueing (LLQ)/Class-Based Weighted Fair Queueing (CBWFQ) support	Supported	Supported	Supported
Weighted Random Early Detection (WRED) based on EXP bits using MQC	Supported	Supported	Supported
Policer with EXP bit-marking using MQC-3 action	Supported	Supported	Supported
Support for EXP bits in MPLS accounting	Supported	Supported	Supported

## **MPLS Multilink PPP Support and PE-to-CE Links**

The figure below shows a typical Multiprotocol Label Switching (MPLS) network in which the provider edge (PE) device is responsible for label imposition (at ingress) and disposition (at egress) of the MPLS traffic.

In this topology, Multilink PPP (MLP) is deployed on the PE-to-customer edge (CE) links. The Virtual Private Network (VPN) routing and forwarding instance (VRF) interface is in a multilink bundle. There is no MPLS interaction with MLP; all packets coming into the MLP bundle are IP packets.

Figure 1: MLP and Traditional PE-to-CE Links

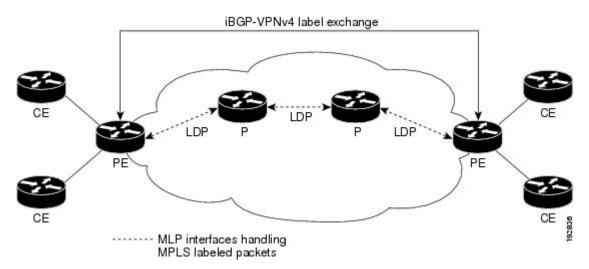

The PE-to-CE routing protocols that are supported for the MPLS Multilink PPP Support feature are external Border Gateway Protocol (eBGP), Open Shortest Path First (OSPF), and Enhanced Interior Gateway Routing Protocol (EIGRP). Static routes are also supported between the CE and PE devices.

Quality of service (QoS) features that are supported for the MPLS Multilink PPP Support feature on CE-to-PE links are link fragmentation and interleaving (LFI), compressed Real-Time Transport Protocol (cRTP), policing, marking, and classification.

## **MPLS Multilink PPP Support and Core Links**

The figure below shows a sample topology in which Multiprotocol Label Switching (MPLS) is deployed over Multilink PPP (MLP) on provider edge-to-provider (PE-to-P) and P-to-P links. Enabling MPLS on MLP for PE-to-P links is similar to enabling MPLS on MLP for P-to-P links.

#### Figure 2: MLP on PE-to-P and P-to-P Links

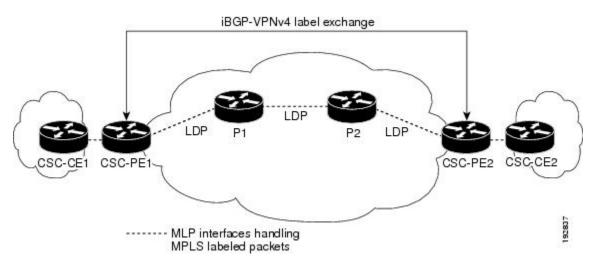

You employ MLP in the PE-to-P or P-to-P links primarily so that you can reduce the number of Interior Gateway Protocol (IGP) adjacencies and facilitate the load sharing of traffic.

In addition to requiring MLP on the PE-to-P links, the MPLS Multilink PPP Support feature requires the configuration of an IGP routing protocol and the Label Distribution Protocol (LDP).

## **MPLS Multilink PPP Support in a CSC Network**

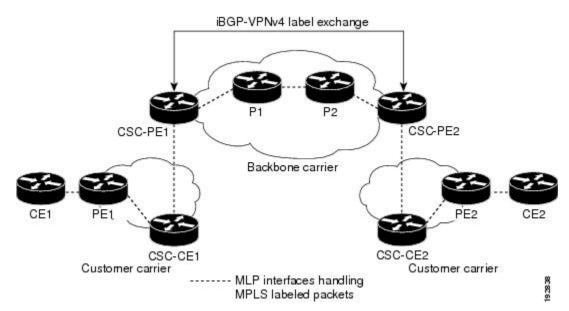

The figure below shows a typical Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) Carrier Supporting Carrier (CSC) network where Multilink PPP (MLP) is configured on the CSC customer edge (CE)-to-provider edge (PE) links.

Figure 3: MLP on CSC CE-to-PE Links with MPLS VPN Carrier Supporting Carrier

The MPLS Multilink PPP Support feature supports MLP between CSC-CE and CSC-PE links with the Label Distribution Protocol (LDP) or with external Border Gateway Protocol (eBGP) IPv4 label distribution. This feature also supports link fragmentation and interleaving (LFI) for an MPLS VPN CSC configuration. The figure below shows all MLP links that this feature supports for CSC configurations.

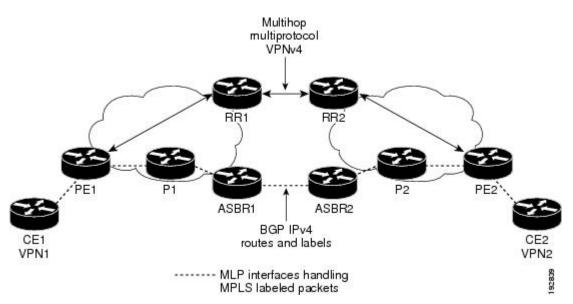

#### Figure 4: MLP Supported Links with MPLS VPN Carrier Supporting Carrier

## **MPLS Multilink PPP Support in an Interautonomous System**

The figure below shows a typical Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) interautonomous system (Inter-AS) network where Multilink PPP (MLP) is configured on the provider edge-to-customer edge (PE-to-CE) links.

Figure 5: MLP on ASBR-to-PE Links in an MPLS VPN Inter-AS Network

The MPLS Multilink PPP Support feature supports MLP between Autonomous System Boundary Router (ASBR) links for Inter-AS VPNs with Label Distribution Protocol (LDP) and with external Border Gateway Protocol (eBGP) IPv4 label distribution.

# How to Configure MPLS Multilink PPP Support

The tasks in this section can be performed on customer edge-to-provider edge (CE-to-PE) links, PE-to-provider (P) links, P-to-P links, and Carrier Supporting Carrier (CSC) CE-to-PE links.

### **Creating a Multilink Bundle**

Perform this task to create a multilink bundle for the MPLS Multilink PPP Support feature. This multilink bundle can reduce the number of Interior Gateway Protocol (IGP) adjacencies and facilitate load sharing of traffic.

#### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface multilink group-number	Creates a multilink bundle and enters multilink interface configuration mode.
	<pre>Example: Device(config)# interface multilink 1</pre>	• The <i>group-number</i> argument is the number of the multilink bundle (a nonzero number).
Step 4	ip address address mask [secondary]	Sets a primary or secondary IP address for an interface.
	Example:	• The <i>address</i> argument is the IP address.
	Device(config-if)# ip address 10.0.0.0 255.255.0.0	• The <i>mask</i> argument is the mask for the associated IP subnet.
		• The <b>secondary</b> keyword specifies that the configured address is a secondary IP address. If this keyword is omitted, the configured address is the primary IP address.
		This command is used to assign an IP address to the multilink interface.
Step 5	encapsulation encapsulation-type	Sets the encapsulation method as PPP to be used by the interface.
	Example:	
	Device(config-if)# encapsulation ppp	• The <i>encapsulation-type</i> argument specifies the encapsulation type.
Step 6	ppp multilink	Enables MLP on an interface.
	Example:	
	Device(config-if)# ppp multilink	
Step 7	mpls ip	Enables label switching on the interface.
	Example:	
	Device(config-if)# mpls ip	
Step 8	end	Returns to privileged EXEC mode.
	Example:	

# Assigning an Interface to a Multilink Bundle

#### Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	controller {t1   e1} slot/port	Configures a T1 or E1 controller and enters
	Example:	<ul><li>controller configuration mode.</li><li>The t1 keyword indicates a T1 line card</li></ul>
	Device# controller t1 0/0/1	• The <b>e1</b> keyword indicates an E1 line card.
		• The <i>slot/port</i> arguments are the backplan slot number and port number on the interface. Refer to your hardware installation manual for the specific slot numbers and port numbers.
Step 4	<b>channel-group</b> <i>channel-number</i> <b>timeslots</b> <i>fulltimeslots</i>	Defines the time slots that belong to each T1 or E1 circuit.
	Example: Device(config-controller)# channel-group 1 timeslots 1-24	• The <i>channel-number</i> argument is the channel-group number. When a T1 data line is configured, channel-group number can be values from 1 to 24. When an E1 data line is configured, channel-group numbers can be values from 1 to 31.
		• The <b>timeslots</b> <i>fulltimeslots</i> keyword and argument specifies time slots. For a T1 controller, the time slot is 1-24. For an E1 controller the time slot is 1-31.
Step 5	exit	Returns to global configuration mode.
	Example:	
	Device(config-controller)# exit	

	Command or Action	Purpose
Step 6	interface serial slot/subslot / port : channel-group Example:	Configures a serial interface for a Cisco 7500 series router with channelized T1 or E1 and enters interface configuration mode.
	Device(config)# interface serial 0/0/1:1	• The <i>slot</i> argument indicates the slot number. Refer to the appropriate hardware manual for slot and port information.
		• The <i>/port</i> argument indicates the port number. Refer to the appropriate hardware manual for slot and port information.
		• The <i>:channel-group</i> argument indicates the channel group number. Cisco 7500 series routers specify the channel group number in the range of 0 to 4 defined with the <b>channel-group</b> controller configuration command.
Step 7	ip route-cache [cef   distributed]	Controls the use of switching methods for forwarding IP packets.
	Example:	
	<pre>Device(config-if)# ip route-cache cef</pre>	• The <b>cef</b> keyword enables Cisco Express Forwarding operation on an interface after Cisco Express Forwarding operation was disabled.
		• The <b>distributed</b> keyword enables distributed switching on the interface.
Step 8	no ip address	Removes any specified IP address.
	Example:	
	Device(config-if)# no ip address	
Step 9	keepalive [period [retries]]	Enables keepalive packets and specifies the
	<b>Example:</b> Device(config-if)# keepalive	number of times that the Cisco software tries to send keepalive packets without a response before bringing down the interface or before bringing the tunnel protocol down for a
		specific interface.
		• The <i>period</i> argument is an integer value, in seconds, greater than 0. The default is 10.
		• The <i>retries</i> argument specifies the number of times that the device continues to send keepalive packets without a response before bringing the interface down. Enter

I

	Command or Action	Purpose
		an integer value greater than 1 and less than 255. If you do not enter a value, the value that was previously set is used; if no value was specified previously, the default of 5 is used.
		If you are using this command with a tunnel interface, the command specifies the number of times that the device continues to send keepalive packets without a response before bringing the tunnel interface protocol down.
Step 10	encapsulation encapsulation-type	Sets the encapsulation method used by the interface.
	Example:	
	Device(config-if)# encapsulation ppp	• The <i>encapsulation-type</i> argument specifies the encapsulation type. The example specifies PPP encapsulation.
Step 11	ppp multilink group group-number	Restricts a physical link to join only one
	Example:	designated multilink group interface.
	Device(config-if)# ppp multilink group 1	• The <i>group-number</i> argument is the number of the multilink bundle (a nonzero number).
Step 12	ppp multilink	Enables MLP on the interface.
	Example:	
	Device(config-if)# ppp multilink	
Step 13	ppp authentication chap	(Optional) Enables Challenge Handshake
	Example:	Authentication Protocol (CHAP) authentication on the serial interface.
	Device(config-if) # ppp authentication chap	
Step 14	end	Returns to privileged EXEC mode.
	Example:	
	Device(config-if)# end	
	1	1

# Verifying the Multilink PPP Configuration

Procedure

Step 1 enable

Enables privileged EXEC mode. Enter your password if prompted.

#### Example:

Device> **enable** Device#

#### **Step 2** show ip interface brief

Verifies logical and physical Multilink PPP (MLP) interfaces.

#### **Example:**

Device# show ip interface brief

Locolrface	IP-Address	OK? Method Status	Prot
GigabitEthernet1/0/0	10.3.62.106	YES NVRAM up	up
GigabitEthernet0/0/1	unassigned	YES NVRAM administratively down	down
GigabitEthernet0/0/0	unassigned	YES NVRAM administratively down	down
GigabitEthernet0/0/1	unassigned	YES NVRAM administratively down	down
GigabitEthernet0/0/2	unassigned	YES NVRAM administratively down	down
GigabitEthernet0/1/0	unassigned	YES NVRAM administratively down	down
GigabitEthernet0/1/1	unassigned	YES NVRAM administratively down	down
GigabitEthernet0/1/2	unassigned	YES NVRAM administratively down	down
Serial0/1/0:1	unassigned	YES NVRAM administratively down	down
Serial0/1/0:2	unassigned	YES NVRAM administratively down	down
Serial0/1/1:1	unassigned	YES NVRAM up	up
Serial0/1/1:2	unassigned	YES NVRAM up	down
Serial0/1/3:1	unassigned	YES NVRAM up	up
Serial0/1/3:2	unassigned	YES NVRAM up	up
Multilink6	10.30.0.2	YES NVRAM up	up
Multilink8	unassigned	YES NVRAM administratively down	down
Multilink10	10.34.0.2	YES NVRAM up	up
Loopback0	10.0.0.1	YES NVRAM up	up

#### **Step 3** show ppp multilink

Verifies that you have created a multilink bundle.

#### Example:

```
Device# show ppp multilink
```

```
Multilink1, bundle name is group 1
Bundle is Distributed
0 lost fragments, 0 reordered, 0 unassigned, sequence 0x0/0x0 rcvd/sent
0 discarded, 0 lost received, 1/255 load
Member links: 4 active, 0 inactive (max no set, min not set)
Serial0/0/0/:1
Serial0/0/0/:2
Serial0/0/0/:3
Serial0/0/0/:4
```

#### **Step 4 show ppp multilink interface** *interface-bundle*

Displays information about a specific MLP interface.

Example:

Device# show ppp multilink interface multilink6

```
Multilink6, bundle name is router
Bundle up for 00:42:46, 1/255 load
```

#### **Step 5 show interface** *type number*

Displays information about serial interfaces in your configuration.

#### Example:

```
Device# show interface serial 0/1/3:1
```

```
Serial0/1/3:1 is up, line protocol is up
 Hardware is Multichannel T1
 MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec,

     1 carrier transitions no alarm present
  Timeslot(s) Used:2, subrate: 64Kb/s, transmit delay is 0 flags
  Transmit queue length 26
```

You can also use the **show interface** command to display information about the multilink interface:

#### Example:

Device# show interface multilink6 Multilink6 is up, line protocol is up Hardware is multilink group interface Internet address is 10.30.0.2/8 MTU 1500 bytes, BW 128 Kbit, DLY 100000 usec, reliability 255/255, txload 1/255, rxload 1/255 Encapsulation PPP, LCP Open, multilink Open Open: CDPCP, IPCP, TAGCP, loopback not set DTR is pulsed for 2 seconds on reset Last input 00:00:00, output never, output hang never Last clearing of "show interface" counters 00:48:43 Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0 Queueing strategy: fifo Output queue: 0/40 (size/max) 30 second input rate 0 bits/sec, 0 packets/sec 30 second output rate 0 bits/sec, 0 packets/sec 1340 packets input, 102245 bytes, 0 no buffer Received 0 broadcasts, 0 runts, 0 giants, 0 throttles 0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort 1283 packets output, 101350 bytes, 0 underruns 0 output errors, 0 collisions, 1 interface resets 0 output buffer failures, 0 output buffers swapped out 0 carrier transitions

#### **Step 6** show mpls forwarding-table

Displays contents of the Multiprotocol Label Switching (MPLS) Label Forwarding Information Base (LFIB). Look for information on multilink interfaces associated with a point2point next hop.

#### Example:

Device# show mpls forwarding-table

Local	Outgoing	Prefix	Bytes tag	Outgoing	Next Hop
tag	tag or VC	or Tunnel Id	switched	interface	
16	Untagged	10.30.0.1/32	0	Mu 6	point2point
17	Pop tag	10.0.0.3/32	0	Mu 6	point2point
18	Untagged	10.0.0.9/32[V]	0	Mu10	point2point
19	Untagged	10.0.0.11/32[V]	6890	Mu10	point2point
20	Untagged	10.32.0.0/8[V]	530	Mu10	point2point
21	Aggregate	10.34.0.0/8[V]	0		
22	Untagged	10.34.0.1/32[V]	0	Mu10	point2point

Use the **show ip bgp vpnv4** command to display VPN address information from the Border Gateway Protocol (BGP) table.

#### Example:

Device# show ip bgp vpnv4 all summary

BGP router identifier 10.0.0.1, local AS number 100 BGP table version is 21, main routing table version 21 10 network entries using 1210 bytes of memory 10 path entries using 640 bytes of memory 2 BGP path attribute entries using 120 bytes of memory 1 BGP extended community entries using 24 bytes of memory 0 BGP route-map cache entries using 0 bytes of memory 0 BGP filter-list cache entries using 0 bytes of memory

	BGP using 1994 total bytes of memory BGP activity 10/0 prefixes, 10/0 paths, scan interval 5 secs 10.0.0.3 4 100 MsgRc52 MsgSe52 TblV21 0 0 00:46:35 State/P5xRcd		
Step 7	exit		
	Returns to user EXEC mode.		
	Example:		
	Device# <b>exit</b> Device>		

# **Configuration Examples for MPLS Multilink PPP Support**

### Sample MPLS Multilink PPP Support Configurations

The following examples show sample configurations on a Carrier Supporting Carrier (CSC) network. The configuration of MLP on an interface is the same for provider edge-to-customer edge (PE-to-CE) links, PE-to-provider (P) links, and P-to-P links.

#### Example: Configuring Multilink PPP on an MPLS CSC PE Device

The following example shows how to configure for Multiprotocol Label Switching (MPLS) Carrier Supporting Carrier (CSC) provider edge (PE) device.

```
1
mpls label protocol ldp
ip cef
ip vrf vpn2
rd 200:1
route-target export 200:1
route-target import 200:1
1
controller T1 0/0/1
framing esf
clock source internal
linecode b8zs
channel-group 1 timeslots 1-24
interface Serial0/0:1
no ip address
encapsulation ppp
ppp multilink
ppp multilink group 1
interface Multilink1
 ip vrf forwarding vpn2
ip address 10.35.0.2 255.0.0.0
no peer neighbor-route
load-interval 30
ppp multilink
```

```
ppp multilink interleave
ppp multilink group 1
mpls ip

neighbor 10.35.0.1 advertisement-interval 5
 no auto-summary
no synchronization
 exit-address-family
```

## **Example: Creating a Multilink Bundle**

The following example shows how to create a multilink bundle for the MPLS Multilink PPP Support feature:

```
Device(config)# interface multilink 1
Device(config-if)# ip address 10.0.0.0 10.255.255.255
Device(config-if)# encapsulation ppp
Device(config-if)# ppp chap hostname group 1
Device(config-if)# ppp multilink
Device(config-if)# ppp multilink group 1
Device(config-if)# mpls ip
Device(config-if)# mpls label protocol ldp
```

### Example: Assigning an Interface to a Multilink Bundle

The following example shows how to create four multilink interfaces with Cisco Express Forwarding switching and Multilink PPP (MLP) enabled. Each of the newly created interfaces is added to a multilink bundle.

```
interface multilink1
ip address 10.0.0.0 10.255.255.255
ppp chap hostname group 1
ppp multilink
```

ppp multilink group 1 mpls ip mpls label protocol ldp interface serial 0/0/0/:1 no ip address encapsulation ppp ip route-cache cef no keepalive ppp multilink ppp multilink group 1 no ip address encapsulation ppp ip route-cache cef no keepalive ppp chap hostname group 1 ppp multilink ppp multilink group 1 no ip address encapsulation ppp ip route-cache cef no keepalive ppp chap hostname group 1

ppp multilink ppp multilink group 1

no ip address encapsulation ppp ip route-cache cef no keepalive ppp chap hostname group 1 ppp multilink ppp multilink group 1

# **MPLS LSP Ping, Traceroute, and AToM VCCV**

As Multiprotocol Label Switching (MPLS) deployments increase and the traffic types they carry increase, the ability of service providers to monitor label switched paths (LSPs) and quickly isolate MPLS forwarding problems is critical to their ability to offer services. The MPLS LSP Ping, Traceroute, and AToM VCCV feature helps them mitigate these challenges.

The MPLS LSP Ping, Traceroute, and AToM VCCV feature can detect when an LSP fails to deliver user traffic.

- You can use MPLS LSP Ping to test LSP connectivity for IPv4 Label Distribution Protocol (LDP) prefixes, traffic engineering (TE) Forwarding Equivalence Classes (FECs), and AToM FECs.
- You can use MPLS LSP Traceroute to trace the LSPs for IPv4 LDP prefixes and TE tunnel FECs.
- Any Transport over MPLS Virtual Circuit Connection Verification (AToM VCCV) allows you to use MPLS LSP Ping to test the pseudowire (PW) section of an AToM virtual circuit (VC).

Internet Control Message Protocol (ICMP) ping and trace are often used to help diagnose the root cause when a forwarding failure occurs. The MPLS LSP Ping, Traceroute, and AToM VCCV feature extends this diagnostic and troubleshooting ability to the MPLS network and aids in the identification of inconsistencies between the IP and MPLS forwarding tables, inconsistencies in the MPLS control and data plane, and problems with the reply path.

The MPLS LSP Ping, Traceroute, and AToM VCCV feature uses MPLS echo request and reply packets to test LSPs. The Cisco implementation of MPLS echo request and echo reply are based on the Internet Engineering Task Force (IETF) Internet-Draft *Detecting MPLS Data Plane Failures*.

- Prerequisites for MPLS LSP Ping, Traceroute, and AToM VCCV, on page 55
- Restrictions for MPLS LSP Ping, Traceroute, and AToM VCCV, on page 56
- Information About MPLS LSP Ping, Traceroute, and AToM VCCV, on page 56

# Prerequisites for MPLS LSP Ping, Traceroute, and AToM VCCV

Before you use the MPLS LSP Ping, Traceroute, and AToM VCCV feature, you should:

- Determine the baseline behavior of your Multiprotocol Label Switching (MPLS) network. For example:
  - What is the expected MPLS experimental (EXP) treatment?
  - What is the expected maximum size packet or maximum transmission unit (MTU) of the label switched path?

- What is the topology? What are the expected label switched paths? How many links in the label switching path (LSP)? Trace the paths of the label switched packets including the paths for load balancing.
- Understand how to use MPLS and MPLS applications, including traffic engineering, Any Transport over MPLS (AToM), and Label Distribution Protocol (LDP). You need to
  - Know how LDP is configured
  - Understand AToM concepts
  - Be able to troubleshoot a TE tunnel
- Understand label switching, forwarding, and load balancing.

## **Restrictions for MPLS LSP Ping, Traceroute, and AToM VCCV**

- You cannot use MPLS LSP Traceroute to trace the path taken by Any Transport over Multiprotocol Label Switching (AToM) packets. MPLS LSP Traceroute is not supported for AToM. (MPLS LSP Ping is supported for AToM.) However, you can use MPLS LSP Traceroute to troubleshoot the Interior Gateway Protocol (IGP) LSP that is used by AToM.
- You cannot use MPLS LSP Ping or Traceroute to validate or trace MPLS Virtual Private Networks (VPNs).
- You cannot use MPLS LSP Traceroute to troubleshoot label switching paths (LSPs) that employ time-to-live (TTL) hiding.

## Information About MPLS LSP Ping, Traceroute, and AToM VCCV

### **MPLS LSP Ping Operation**

MPLS LSP Ping uses Multiprotocol Label Switching (MPLS) echo request and reply packets to validate a label switched path (LSP). Both an MPLS echo request and an MPLS echo reply are User Datagram Protocol (UDP) packets with source and destination ports set to 3503.

The MPLS echo request packet is sent to a target device through the use of the appropriate label stack associated with the LSP to be validated. Use of the label stack causes the packet to be switched inband of the LSP (that is, forwarded over the LSP itself). The destination IP address of the MPLS echo request packet is different from the address used to select the label stack. The destination address of the UDP packet is defined as a 127.x. *y*. *z* /8 address. This prevents the IP packet from being IP switched to its destination if the LSP is broken.

An MPLS echo reply is sent in response to an MPLS echo request. It is sent as an IP packet and forwarded using IP, MPLS, or a combination of both types of switching. The source address of the MPLS echo reply packet is an address from the device generating the echo reply. The destination address is the source address of the MPLS echo request packet.

The figure below shows the echo request and echo reply paths for MPLS LSP Ping.

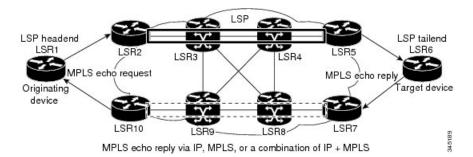

Figure 6: MPLS LSP Ping Echo Request and Echo Reply Paths

If you initiate an MPLS LSP Ping request at LSR1 to a Forwarding Equivalence Class (FEC), at LSR6, you get the results shown in the table below .

Step	Device	Action
1.	LSR1	Initiates an MPLS LSP Ping request for an FEC at the target device LSR6 and sends an MPLS echo request to LSR2.
1.	LSR2 Receives and forwards the MPLS echo request packet through transit devices L and LSR4 to the penultimate device LSR5.	
1.	LSR5	Receives the MPLS echo request, pops the MPLS label, and forwards the packet to LSR6 as an IP packet.
1.	LSR6	Receives the IP packet, processes the MPLS echo request, and sends an MPLS echo reply to LSR1 through an alternate route.
1.	LSR7 to LSR10	Receive and forward the MPLS echo reply back toward LSR1, the originating device.
1.	LSR1	Receives the MPLS echo reply in response to the MPLS echo request.

Table 3: MPLS LSP Ping Example

You can use MPLS LSP Ping to validate IPv4 Label Distribution Protocol (LDP), Any Transport over MPLS (AToM), and IPv4 Resource Reservation Protocol (RSVP) FECs by using appropriate keywords and arguments with the command:

```
ping mpls {ipv4
```

destination-address destination-mask
 | pseudowire

ipv4-address vc-id

| traffic-eng

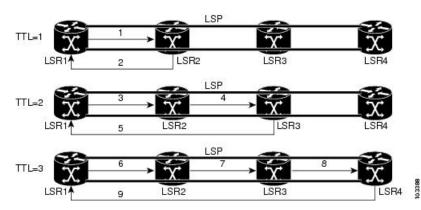

tunnel-interface tunnel-number
}

## **MPLS LSP Traceroute Operation**

MPLS LSP Traceroute also uses Multiprotocol Label Switching (MPLS) echo request and reply packets to validate a label switched path (LSP). The echo request and echo reply are User Datagram Protocol (UDP) packets with source and destination ports set to 3503.

The MPLS LSP Traceroute feature uses time-to-live (TTL) settings to force expiration of the TTL along an LSP. MPLS LSP Traceroute incrementally increases the TTL value in its MPLS echo requests (TTL = 1, 2, 3, 4, ...) to discover the downstream mapping of each successive hop. The success of the LSP traceroute depends on the transit device processing the MPLS echo request when it receives a labeled packet with a TTL of 1. On Cisco devices, when the TTL expires, the packet is sent to the Route Processor (RP) for processing. The transit device returns an MPLS echo reply containing information about the transit hop in response to the TTL-expired MPLS packet.

The figure below shows an MPLS LSP Traceroute example with an LSP from LSR1 to LSR4.

If you enter an LSP traceroute to a Forwarding Equivalence Class (FEC) at LSR4 from LSR1, you get the results shown in the table below.

#### Table 4: MPLS LSP Traceroute Example

Step	Device	MPLS Packet Type and Description	Device Action
1.	LSR1	MPLS echo request—With a target FEC pointing to LSR4 and to a downstream mapping.	<ul><li>Sets the TTL of the label stack to 1.</li><li>Sends the request to LSR2.</li></ul>
1.	LSR2	MPLS echo reply.	<ul> <li>Receives packet with TTL = 1.</li> <li>Processes the UDP packet as an MPLS echo request.</li> <li>Finds a downstream mapping, replies to LSR1 with its own downstream mapping based on the incoming label, and sends a reply.</li> </ul>
1.	LSR1	MPLS echo request—With the same target FEC and the downstream mapping received in the echo reply from LSR2.	<ul><li>Sets the TTL of the label stack to 2.</li><li>Sends the request to LSR2.</li></ul>

Step	Device	MPLS Packet Type and Description	Device Action
1.	LSR2	MPLS echo request.	Receives packet with $TTL = 2$ .
			• Decrements the TTL.
			• Forwards the echo request to LSR3.
1.	LSR3	MPLS reply packet.	Receives packet with TTL = 1.
			• Processes the UDP packet as an MPLS echo request.
			• Finds a downstream mapping and replies to LSR1 with its own downstream mapping based on the incoming label.
1.	LSR1	MPLS echo request—With the same target	• Sets the TTL of the packet to 3.
		FEC and the downstream mapping received in the echo reply from LSR3.	• Sends the request to LSR2.
1.	LSR2	MPLS echo request.	Receives packet with TTL = 3.
			• Decrements the TTL.
			• Forwards the echo request to LSR3.
1.	LSR3	MPLS echo request.	Receives packet with TTL = 2
			• Decrements the TTL.
			• Forwards the echo request to LSR4.
1.	LSR4	MPLS echo reply.	Receives packet with TTL = 1.
			• Processes the UDP packet as an MPLS echo request.
			• Finds a downstream mapping and also finds that the device is the egress device for the target FEC.
			• Replies to LSR1.

You can use MPLS LSP Traceroute to validate IPv4 Label Distribution Protocol (LDP) and IPv4 RSVP FECs by using appropriate keywords and arguments with the **trace mpls** command:

trace mpls ipv4 {destination-address destination-mask | traffic-eng
tunnel-interface tunnel-number}

By default, the TTL is set to 30. Therefore, the traceroute output always contains 30 lines, even if an LSP problem exists. This might mean duplicate entries in the output, should an LSP problem occur. The device address of the last point that the trace reaches is repeated until the output is 30 lines. You can ignore the duplicate entries. The following example shows that the trace encountered an LSP problem at the device that has an IP address of 10.6.1.6:

```
Device# traceroute mpls ipv4 10.6.7.4/32
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
```

'.' - timeout, 'U' - unreachable, 'R' - downstream router but not target Type escape sequence to abort. 0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0] R 1 10.6.1.5 MRU 4470 [Labels: 21 Exp: 0] 2 ms R 2 10.6.1.6 4 ms <---- Router address repeated for 2nd to 30th TTL. R 3 10.6.1.6 1 ms R 4 10.6.1.6 1 ms R 5 10.6.1.6 3 ms R 6 10.6.1.6 4 ms R 7 10.6.1.6 1 ms R 8 10.6.1.6 2 ms R 9 10.6.1.6 3 ms R 10 10.6.1.6 4 ms R 11 10.6.1.6 1 ms R 12 10.6.1.6 2 ms R 13 10.6.1.6 4 ms R 14 10.6.1.6 5 ms R 15 10.6.1.6 2 ms R 16 10.6.1.6 3 ms R 17 10.6.1.6 4 ms R 18 10.6.1.6 2 ms R 19 10.6.1.6 3 ms R 20 10.6.1.6 4 ms R 21 10.6.1.6 1 ms R 22 10.6.1.6 2 ms R 23 10.6.1.6 3 ms R 24 10.6.1.6 4 ms R 25 10.6.1.6 1 ms R 26 10.6.1.6 3 ms R 27 10.6.1.6 4 ms R 28 10.6.1.6 1 ms R 29 10.6.1.6 2 ms R 30 10.6.1.6 3 ms <---- TTL 30.

If you know the maximum number of hops in your network, you can set the TTL to a smaller value with the **trace mpls ttl** *maximum-time-to-live* command. The following example shows the same **traceroute** command as the previous example, except that this time the TTL is set to 5.

```
Device# traceroute mpls ipv4 10.6.7.4/32 ttl 5
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
                '.' - timeout, 'U' - unreachable,
                'R' - downstream router but not target
Type escape sequence to abort.
                0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4474 [No Label] 3 ms
R 2 10.6.1.6 4 ms
R 3 10.6.1.6 1 ms
R 4 10.6.1.6 3 ms
R 5 10.6.1.6 4 ms
```

### Any Transport over MPLS Virtual Circuit Connection Verification

AToM Virtual Circuit Connection Verification (AToM VCCV) allows the sending of control packets inband of an AToM pseudowire (PW) from the originating provider edge (PE) device. The transmission is intercepted at the destination PE device, instead of being forwarded to the customer edge (CE) device. This capability allows you to use MPLS LSP Ping to test the PW section of AToM virtual circuits (VCs).

AToM VCCV consists of the following:

- · A signaled component in which the AToM VCCV capabilities are advertised during VC label signaling
- A switching component that causes the AToM VC payload to be treated as a control packet

#### **AToM VCCV Signaling**

One of the steps involved in Any Transport over Multiprotocol Label Switching (AToM) virtual circuit (VC) setup is the signaling of VC labels and AToM Virtual Circuit Connection Verification (VCCV) capabilities between AToM VC endpoints. The device uses an optional parameter, defined in the Internet Draft *draft-ieft-pwe3-vccv-01.txt*, to communicate the AToM VCCV disposition capabilities of each endpoint.

The AToM VCCV disposition capabilities are categorized as follows:

- Applications—MPLS LSP Ping and Internet Control Message Protocol (ICMP) Ping are applications that AToM VCCV supports to send packets inband of an AToM PW for control purposes.
- Switching modes—Type 1 and Type 2 are switching modes that AToM VCCV uses for differentiating between control and data traffic.

The table below describes AToM VCCV Type 1 and Type 2 switching modes.

Switching Mode	Description
Type 1	Uses a Protocol ID (PID) field in the AToM control word to identify an AToM VCCV packet.
Type 2	Uses an MPLS Router Alert Label above the VC label to identify an AToM VCCV packet.

#### Selection of AToM VCCV Switching Types

Cisco devices always use Type 1 switching, if available, when they send MPLS LSP Ping packets over an Any Transport over Multiprotocol Label Switching (AToM) virtual circuit (VC) control channel. Type 2 switching accommodates those VC types and implementations that do not support or interpret the AToM control word.

The table below shows the AToM Virtual Circuit Connection Verification (VCCV) switching mode advertised and the switching mode selected by the AToM VC.

Type Advertised	Type Selected	
AToM VCCV not supported	-	
Type 1 AToM VCCV switching	Type 1 AToM VCCV switching	
Type 2 AToM VCCV switching	Type 2 AToM VCCV switching	
Type 1 and Type 2 AToM VCCV switching	Type 1 AToM VCCV switching	

An AToM VC advertises its AToM VCCV disposition capabilities in both directions: that is, from the originating device (PE1) to the destination device (PE2), and from PE2 to PE1.

In some instances, AToM VCs might use different switching types if the two endpoints have different AToM VCCV capabilities. If PE1 supports Type 1 and Type 2 AToM VCCV switching and PE2 supports only Type 2 AToM VCCV switching, there are two consequences:

• LSP ping packets sent from PE1 to PE2 are encapsulated with Type 2 switching.

LSP ping packets sent from PE2 to PE1 use Type 1 switching.

You can determine the AToM VCCV capabilities advertised to and received from the peer by entering the **show mpls l2transport binding** command at the PE device. For example:

```
Device# show mpls l2transport binding
Destination Address: 10.131.191.252, VC ID: 333
Local Label: 16
Cbit: 1, VC Type: FastEthernet, GroupID: 0
MTU: 1500, Interface Desc: n/a
VCCV Capabilities: Type 1, Type 2
Remote Label: 19
Cbit: 1, VC Type: FastEthernet, GroupID: 0
MTU: 1500, Interface Desc: n/a
VCCV Capabilities: Type 1
```

### **Command Options for ping mpls and trace mpls**

MPLS LSP Ping and Traceroute command options are specified as keywords and arguments on the **ping mpls** and **trace mpls** commands.

The **ping mpls** command provides the options displayed in the command syntax below:

```
ping mpls ipv4{destination-address/destination-mask [destination address-start
address-end increment] [ttl time-to-live] | pseudowire ipv4-address
vc-id vc-id [destination address-start address-end increment] |
traffic-eng tunnel-interface tunnel-number [ttl time-to-live]} [source
source-address] [repeat count] [timeout seconds][{size
packet-size} | {sweep minimum maximum size-Increment}] [pad pattern]
[reply mode {ipv4|router-alert}] [interval msec]
[exp exp-bits] [verbose]
```

The **trace mpls** command provides the options displayed in the command syntax below:

```
trace mpls {ipv4 destination-address/destination-mask [destination
address-start [address-end [address-increment]]] | traffic-eng tunnel tunnel-interface-number}
[source source-address] [timeout seconds] [reply mode reply-mode]
[ttl maximum-time-to-live] [exp exp-bits]
```

#### Selection of FECs for Validation

A label switched path (LSP) is formed by labels. Devices learn labels through the Label Distribution Protocol (LDP), traffic engineering (TE), Any Transport over Multiprotocol Label Switching (AToM), or other MPLS applications. You can use MPLS LSP Ping and Traceroute to validate an LSP used for forwarding traffic for a given Forwarding Equivalence Class (FEC). The table below lists the keywords and arguments for the **ping mpls** and **traceroute mpls** commands that allow the selection of an LSP for validation.

FEC Type	ping mpls Keyword and Argument	traceroute mpls Keyword and Argument	
LDP IPv4 prefix	<b>ipv4</b> destination-address destination-mask	ipv4 destination-address destination-mask	
MPLS TE tunnel	traffic-eng tunnel-interface tunnel-numberNoteMPLS TE Tunnel is not applicable on the ASR 900 RSP3 Module for the Cisco IOS XE Release 3.16.	<ul> <li>traffic-eng tunnel-interface tunnel-number</li> <li>Note MPLS TE Tunnel is not applicable on the ASR 900 RSP3 Module for the Cisco IOS XE Release 3.16.</li> </ul>	
AToM VC	pseudowire ipv4-address vc-id vc-id	MPLS LSP Traceroute does not support the AToM tunnel LSP type for this release.	

Table 7: Selection of LSPs for Validation

### **Reply Mode Options for MPLS LSP Ping and Traceroute**

The reply mode is used to control how the responding device replies to a Multiprotocol Label Switching (MPLS) echo request sent by an MPLS LSP Ping or MPLS LSP Traceroute command. The table below describes the reply mode options.

Option	Description
ipv4	Reply with an IPv4 User Datagram Protocol (UDP) packet (default). This is the most common reply mode selected for use with an MPLS LSP Ping and Traceroute command when you want to periodically poll the integrity of a label switched path (LSP).
	With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request.
	If the headend device fails to receive a reply, select the router-alert option, "Reply with an IPv4 UDP packet with a router alert."
	The responding device sets the IP precedence of the reply packet to 6.
	You implement this option using the <b>reply mode ipv4</b> keywords.
router-alert	Reply with an IPv4 UDP packet with a device alert. This reply mode adds the router alert option to the IP header. This forces the packet to be special handled by the Cisco device at each intermediate hop as it moves back to the destination.
	This reply mode is more expensive, so use the router-alert option only if you are unable to get a reply with the ipv4 option, "Reply with an IPv4 UDP packet."
	You implement this option using the <b>reply mode router-alert</b> keywords

The reply with an IPv4 UDP packet implies that the device should send an IPv4 UDP packet in reply to an MPLS echo request. If you select the ipv4 reply mode, you do not have explicit control over whether the packet uses IP or MPLS hops to reach the originator of the MPLS echo request. This is the mode that you would normally use to test and verify LSPs.

The reply with an IPv4 UDP packet that contains a device alert forces the packet to go back to the destination and be processed by the Route Processor (RP) process switching at each intermediate hop. This bypasses

hardware/line card forwarding table inconsistencies. You should select this option when the originating (headend) devices fail to receive a reply to the MPLS echo request.

You can instruct the replying device to send an echo reply with the IP router alert option by using one of the following commands:

```
ping mpls
 {ipv4 destination-address/destination-mask | pseudowire ipv4-address
 vc-idvc-id | traffic-engtunnel-interface tunnel-number}
reply mode router-alert
Or
trace mpls
 {ipv4destination-address/destination-mask
 | traffic-eng tunnel-interface tunnel-number
 } reply mode router-alert
```

However, the reply with a router alert adds overhead to the process of getting a reply back to the originating device. This method is more expensive to process than a reply without a router alert and should be used only if there are reply failures. That is, the reply with a router alert label should only be used for MPLS LSP Ping or MPLS LSP Traceroute when the originating (headend) device fails to receive a reply to an MPLS echo request.

#### **Reply Mode Options for MPLS LSP Ping and Traceroute**

The reply mode is used to control how the responding device replies to a Multiprotocol Label Switching (MPLS) echo request sent by an MPLS LSP Ping or MPLS LSP Traceroute command. The table below describes the reply mode options.

Table J. ne	φιγινιούε Οριιοί	ις ισι α πεεμυπαπιά	Device

Table O Panly Made Ontions for a Peananding Davias

Option	Description
ipv4	Reply with an IPv4 User Datagram Protocol (UDP) packet (default). This is the most common reply mode selected for use with an MPLS LSP Ping and Traceroute command when you want to periodically poll the integrity of a label switched path (LSP).
	With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request.
	If the headend device fails to receive a reply, select the router-alert option, "Reply with an IPv4 UDP packet with a router alert."
	The responding device sets the IP precedence of the reply packet to 6.
	You implement this option using the <b>reply mode ipv4</b> keywords.
router-alert	Reply with an IPv4 UDP packet with a device alert. This reply mode adds the router alert option to the IP header. This forces the packet to be special handled by the Cisco device at each intermediate hop as it moves back to the destination.
	This reply mode is more expensive, so use the router-alert option only if you are unable to get a reply with the ipv4 option, "Reply with an IPv4 UDP packet."
	You implement this option using the <b>reply mode router-alert</b> keywords

The reply with an IPv4 UDP packet implies that the device should send an IPv4 UDP packet in reply to an MPLS echo request. If you select the ipv4 reply mode, you do not have explicit control over whether the packet uses IP or MPLS hops to reach the originator of the MPLS echo request. This is the mode that you would normally use to test and verify LSPs.

The reply with an IPv4 UDP packet that contains a device alert forces the packet to go back to the destination and be processed by the Route Processor (RP) process switching at each intermediate hop. This bypasses hardware/line card forwarding table inconsistencies. You should select this option when the originating (headend) devices fail to receive a reply to the MPLS echo request.

You can instruct the replying device to send an echo reply with the IP router alert option by using one of the following commands:

```
ping mpls
{ipv4 destination-address/destination-mask | pseudowire ipv4-address
vc-idvc-id | traffic-engtunnel-interface tunnel-number}
reply mode router-alert
Or
trace mpls
{ipv4destination-address/destination-mask
| traffic-eng tunnel-interface tunnel-number
} reply mode router-alert
```

However, the reply with a router alert adds overhead to the process of getting a reply back to the originating device. This method is more expensive to process than a reply without a router alert and should be used only if there are reply failures. That is, the reply with a router alert label should only be used for MPLS LSP Ping or MPLS LSP Traceroute when the originating (headend) device fails to receive a reply to an MPLS echo request.

### Packet Handling Along Return Path with an IP MPLS Router Alert

When an IP packet that contains an IP router alert option in its IP header or a Multiprotocol Label Switching (MPLS) packet with a router alert label as its outermost label arrives at a device, the device punts (redirects) the packet to the Route Processor (RP) process level for handling. This allows these packets to bypass the forwarding failures in hardware routing tables. The table below describes how IP and MPLS packets with an IP router alert option are handled by the device switching path processes.

Table 10: Switching Path Process Handling of IP and MPLS Router Alert Packets

Incoming Packet	Normal Switching Action	Process Switching Action	Outgoing Packet	
	A rRouter alert option in the IP header causes the packet to be punted to the process switching path.	Forwards the packet as is.	IP packet—Router alert option in IP header.	
	A router alert option in theIP header causes the packet to be punted to the process switching path.	Adds a router alert as the outermost label and forwards as an MPLS packet.	MPLS packet— Outermost label contains a router alert.	

Incoming Packet	Normal Switching Action	Process Switching Action	Outgoing Packet
packet—Outermostlabel, the packet is punted to the processlabel contains alabel contains aswitching path.to		Removes the outermost router alert label, adds an IP router alert option to the IP header, and forwards as an IP packet.	IP packet—Router alert option in IP header.
	If the router alert label is the outermost label, the packet is punted to the process switching path.	Preserves the outermost router alert label and forwards the MPLS packet.	1

### **Other MPLS LSP Ping and Traceroute Command Options**

The table below describes other MPLS LSP Ping and Traceroute command options that can be specified as keywords or arguments with the **ping mpls** command, or with both the **ping mpls** and **trace mpls** commands. Options available to use only on the **ping mpls** command are indicated as such.

Table 11: Other MPLS LSP Ping and Traceroute and AToM VCCV Options

Option	Description	
Datagram size	Size of the packet with the label stack imposed. Specified with the <b>size</b> <i>packet-size</i> keyword and argument. The default size is 100.	
	For use with the MPLS LSP Ping feature only.	
Padding	Padding (the pad time-length-value [TLV]) is used as required to fill the datagram so that the MPLS echo request (User Datagram Protocol [UDP] packet with a label stack) is the size specified. Specify with the <b>pad</b> <i>pattern</i> keyword and argument. For use with the MPLS LSP Ping feature only.	
Sweep size range	ge Parameter that enables you to send a number of packets of different sizes, ranging from a start size to an end size. This parameter is similar to the Internet Control Message Protocol (ICMP) ping sweep parameter. The lower boundary on the sweep range variable depending on the label switched path (LSP) type. You can specify a sweep size range when you use the <b>ping mpls</b> command. Use the <b>sweep</b> minimum maximum size-increment keyword and arguments.	
	For use with the MPLS LSP Ping feature only.	
Repeat count	Number of times to resend the same packet. The default is 5 times. You can specify a repeat count when you use the <b>ping mpls</b> command. Use the <b>repeat</b> <i>count</i> keyword and argument.	
	For use with the MPLS LSP Ping feature only.	
MPLS echo request source addressRoutable address of the sender. The default address is loopback0. This address as the destination address in the Multiprotocol Label Switching (MPLS) echo Use the source source-address keyword and argument.		
	For use with the MPLS LSP Ping and Traceroute features.	

Option	Description
UDP destination address	A valid 127/8 address. You have the option to specify a single <i>x.y.z</i> or a range of numbers between 0.0.0 and <i>x.y.z</i> , where <i>x.y.z</i> are numbers between 0 and 255 and correspond to 127. <i>x.y.z</i> . Use the <b>destination</b> { <i>address</i>   <i>address-start address-end increment</i> } keyword and arguments.
	The MPLS echo request destination address in the UDP packet is not used to forward the MPLS packet to the destination device. The label stack that is used to forward the echo request routes the MPLS packet to the destination device. The 127/8 address guarantees that the packets are routed to the localhost (the default loopback address of the device processing the address) if the UDP packet destination address is used for forwarding.
	In addition, the destination address is used to affect load balancing when the destination address of the IP payload is used for load balancing.
	For use with IPv4 and Any Transport over MPLS (AToM) Forwarding Equivalence Classes (FECs) with the MPLS LSP Ping feature and with IPv4 FECs with the MPLS LSP Traceroute feature.
Time-to-live (TTL)	A parameter you can set that indicates the maximum number of hops a packet should take to reach its destination. The time-to-live (TTL) field in a packet is decremented by 1 each time it travels through a device.
	For MPLS LSP Ping, the TTL is a value after which the packet is discarded and an MPLS echo reply is sent back to the originating device. Use the <b>ttl</b> <i>time-to-live</i> keyword and argument.
	For MPLS LSP Traceroute, the TTL is a maximum time to live and is used to discover the number of downstream hops to the destination device. MPLS LSP Traceroute incrementally increases the TTL value in its MPLS echo requests (TTL = 1, 2, 3, 4,) to accomplish this. Use the <b>ttl</b> <i>time-to-live</i> keyword and argument.
Timeouts	A parameter you can specify to control the timeout in seconds for an MPLS request packet. The range is from 0 to 3600 seconds. The default is 2.
	Set with the <b>timeout</b> seconds keyword and argument.
	For use with the MPLS LSP Ping and Traceroute features.
Intervals	A parameter you can specify to set the time in milliseconds between successive MPLS echo requests. The default is 0.
	Set with the <b>interval</b> <i>msec</i> keyword and argument.
Experimental bits	Three experimental bits in an MPLS header used to specify precedence for the MPLS echo reply. (The bits are commonly called EXP bits.) The range is from 0 to 7, and the default is 0.
	Specify with the <b>exp</b> <i>exp</i> - <i>bits</i> keyword and argument.
	For use with the MPLS LSP Ping and Traceroute features.

Option	Description
Verbose	Option that provides additional information for the MPLS echo replysource address and return codes. For the MPLS LSP Ping feature, this option is implemented with the <b>verbose</b> keyword.
	For use with the MPLS LSP Ping feature only.

MPLS LSP Ping options described in the table above can be implemented by using the following syntax:

```
ping mpls
```

```
{ipv4 destination-address destination-mask [destination address-start address-end increment]
  [ttl time-to-live] | pseudowire ipv4-address
  vc-id vc-id
  [destination address-start address-end increment] | traffic-eng tunnel-interface
  tunnel-number
  [ttl time-to-live] }
  [source source-address] [repeat count]
  [{size packet-size} | {sweep minimum maximum size-Increment}]
  [pad pattern]
  [timeout seconds] [intervalmsec]
  [exp exp-bits] [verbose
```

MPLS LSP Traceroute options described in the table below can be implemented by the use of the following syntax:

```
trace mpls
{ipv4 destination-address destination-mask
[destination address-start address-end address-increment] | traffic-eng tunnel-interface
tunnel-number}
[source source-address] [timeout seconds]
[ttl maximum-time-to-live]
[exp exp-bits]
```

### **Option Interactions and Loops**

Usage examples for the MPLS LSP Ping and Traceroute and AToM VCCV feature in this and subsequent sections are based on the sample topology shown in the figure below.

#### Figure 8: Sample Topology for Configuration Examples

10.131.191.253	10.131.191.25	52 10.131.191	.251	10.131.159	.251 10.	131.159.252	10.131.159.253
FE2	2.0/0 F	E0/0/0 FE0/0/0	FE1/0/0 F FE1/1/0 F	E1/0/0	FE0/0/0 FE0/0/0 FE0/1/0 FE0/1/0	FE2	
CE1	10.0.0.1 P	E1	P1	LSP P	2	PE2 1	0.0.0.2 CE2

The interaction of some MPLS LSP Ping and Traceroute and AToM VCCV options can cause loops. See the following topic for a description of the loops you might encounter with the **ping mpls** and **trace mpls** commands:

### Possible Loops with MPLS LSP Ping

With the MPLS LSP Ping feature, loops can occur if you use the repeat count option, the sweep size range option, or the User Datagram Protocol (UDP) destination address range option.

```
ping mpls
{ipv4 destination-address/destination-mask
[destination address-start address-end increment] | pseudowire ipv4-address
vc-id vc-id
[destination address-start address-end increment] |
traffic-eng tunnel-interface tunnel-number}
[repeat count]
[sweep minimum maximum size-increment]
```

Following is an example of how a loop operates if you use the following keywords and arguments on the **ping mpls** command:

```
Device# ping mpls
ipv4
10.131.159.251/32 destination 127.0.0.1 127.0.0.1 0.0.0.1 repeat 2
sweep 1450 1475 25
Sending 2, [1450..1500]-byte MPLS Echos to 10.131.159.251/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
Destination address 127.0.0.1
1
1
Destination address 127.0.0.1
!
!
Destination address 127.0.0.1
1
1
Destination address 127.0.0.1
1
!
```

An **mpls ping** command is sent for each packet size range for each destination address until the end address is reached. For this example, the loop continues in the same manner until the destination address, 127.0.0.1, is reached. The sequence continues until the number is reached that you specified with the **repeat** *count* keyword and argument. For this example, the repeat count is 2. The MPLS LSP Ping loop sequence is as follows:

```
repeat = 1
  destination address 1 (address-start
)
   for (size from sweep
minimum
to maximum
, counting by size-increment
     send an lsp ping
 destination address 2 (address-start
 +
address-
increment
)
   for (size from sweep
minimum
to maximum
, counting by size-increment
)
      send an lsp ping
```

```
destination address 3 (address-start
+
address-
increment
+
address-
increment
)
    for (size from sweep
minimum
to maximum
, counting by size-increment
)
    send an lsp ping
.
.
.
until destination address = address-end
.
.
until repeat = count
```

### Possible Loop with MPLS LSP Traceroute

With the MPLS LSP Traceroute feature, loops can occur if you use the User Datagram Protocol (UDP) destination address range option and the time-to-live option.

```
trace mpls
{ipv4
destination-address destination-mask
[destination
address-start
address-end
address-increment
] | traffic-eng
tunnel-interface
tunnel-number
[ttl
maximum-
time-to-live
]
```

Here is an example of how a loop operates if you use the following keywords and arguments on the **trace mpls** command:

```
Device# trace mpls
ipv4
10.131.159.251/32 destination 127.0.0.1 127.0.0.1 1 ttl 5
Tracing MPLS Label Switched Path to 10.131.159.251/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
        '.' - timeout, 'U' - unreachable,
        'R - downstream router but not target
Type escape sequence to abort.
Destination address 127.0.0.1
        0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.225 40 ms
```

```
Destination address 127.0.0.2

0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]

R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms

! 2 10.131.159.225 40 ms

Destination address 127.0.0.3

0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]

R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms

! 2 10.131.159.225 48 ms
```

An **mpls trace** command is sent for each TTL from 1 to the maximum TTL (**ttl** *maximum-time-to-live* keyword and argument) for each destination address until the address specified with the destination *end-address* argument is reached. For this example, the maximum TTL is 5 and the end destination address is 127.0.0.1. The MPLS LSP Traceroute loop sequence is as follows:

```
destination address 1 (address-start
)
 for (ttl
from 1 to maximum-time-to-live
    send an lsp trace
destination address 2 (address-start
 + address-increment
)
  for (ttl
 from 1 to maximum-time-to-live
   send an lsp trace
destination address 3 (address-start
+ address-increment
 + address-increment
)
 for (tt]
from 1 to
maximum-time-to-live)
    send an lsp trace
until destination address = address-end
```

## **MPLS Echo Request Packets Not Forwarded by IP**

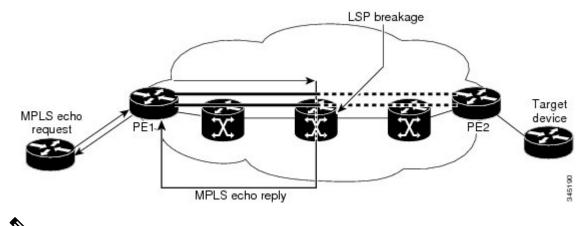

Multiprotocol Label Switching (MPLS) echo request packets sent during a label switched path (LSP) ping are never forwarded by IP. The IP header destination address field in an MPLS echo request packet is a 127.*x*.*y*.*z* /8 address. Devices should not forward packets using a 127.*x*.*y*.*z* /8 address. The 127.*x*.*y*.*z* /8 address corresponds to an address for the local host.

The use of a 127.*x* .*y* .*z* address as a destination address of the User Datagram Protocol (UDP) packet is significant in that the MPLS echo request packet fails to make it to the target device if a transit device does not label switch the LSP. This allows for the detection of LSP breakages.

- If an LSP breakage occurs at a transit device, the MPLS echo packet is not forwarded, but consumed by the device.
- If the LSP is intact, the MPLS echo packet reaches the target device and is processed by the terminal point of the LSP.

The figure below shows the path of the MPLS echo request and reply when a transit device fails to label switch a packet in an LSP.

Figure 9: Path When Transit Device Fails to Label Switch a Packet

**Note** An Any Transport over MPLS (AToM) payload does not contain usable forwarding information at a transit device because the payload might not be an IP packet. An MPLS virtual private network (VPN) packet, although an IP packet, does not contain usable forwarding information at a transit device because the destination IP address is only significant to the virtual routing and forwarding (VRF) instances at the endpoints of the MPLS network.

## Information Provided by the Device Processing LSP Ping or LSP Traceroute

The table below describes the characters that the device processing an LSP ping or LSP traceroute packet returns to the sender about the failure or success of the request.

You can also view the return code for an MPLS LSP Ping operation if you enter the **ping mpls verbose** command.

Character	Meaning
Period "."	A timeout occurs before the target device can reply.
U	The target device is unreachable.
R	The device processing the Multiprotocol Label Switching (MPLS) echo request is a downstream device but is not the destination.
Exclamation mark "!"	Replying device is an egress for the destination.
Q	Echo request was not successfully transmitted. This could be returned because of insufficient memory or more probably because no label switched path (LSP) exists that matches the Forwarding Equivalence Class (FEC) information.
С	Replying device rejected the echo request because it was malformed.

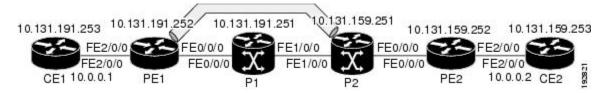

Table 12: LSP Ping and Traceroute Reply Characters

## **MTU Discovery in an LSP**

During an MPLS LSP Ping, Multiprotocol Label Switching (MPLS) echo request packets are sent with the IP packet attribute set to do not fragment. That is, the DF bit is set in the IP header of the packet. This allows you to use the MPLS echo request to test for the MTU that can be supported for the packet through the label switched path (LSP) without fragmentation.

The figure below shows a sample network with a single LSP from PE1 to PE2 formed with labels advertised by means of LDP.

Figure 10: Sample Network with LSP—Labels Advertised by LDP

You can determine the maximum receive unit (MRU) at each hop by tracing the LSP using the MPLS Traceroute feature. The MRU is the maximum size of a labeled packet that can be forwarded through an LSP. The following example shows the results of a **trace mpls** command when the LSP is formed with labels created by the Label Distribution Protocol (LDP):

You can determine the MRU for the LSP at each hop through the use of the **show forwarding detail** command:

Device# show mpls forwarding 10.131.159.252 detail

Local Outgoing Prefix Bytes tag Outgoing Next Hop tag or VC or Tunnel Id switched interface tag 10.131.159.252/32 0 22 19 Tu1 point2point MAC/Encaps=14/22, MRU=1496, Tag Stack{22 19}, via Et0/0 AABBCC009700AABBCC0098008847 000160000013000 No output feature configured

To determine the maximum sized echo request that will fit on the LSP, you can find the IP MTU by using the **show interface** *type number* command.

Device# show interface e0/0

```
FastEthernet0/0/0 is up, line protocol is up
Hardware is Lance, address is aabb.cc00.9800 (bia aabb.cc00.9800)
Internet address is 10.131.191.230/30
MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load \%55
Encapsulation ARPA, loopback not set
Keepalive set (10 sec)
ARP type: ARPA, ARP Timeout 04:00:00
Last input 00:00:01, output 00:00:01, output hang never
```

```
Last clearing of "show interface" counters never
Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
Queueing strategy: fifo
Output queue: 0/40 (size/max)
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
377795 packets input, 33969220 bytes, 0 no buffer
Received 231137 broadcasts, 0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
0 input packets with dribble condition detected
441772 packets output, 40401350 bytes, 0 underruns
0 output errors, 0 collisions, 10 interface resets
0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier
0 output buffer failures, 0 output buffers swapped out
```

The IP MTU in the **show interface** *type number* example is 1500 bytes. Subtract the number of bytes corresponding to the label stack from the MTU number. From the output of the **show mpls forwarding** command, the Tag stack consists of one label (21). Therefore, the largest MPLS echo request packet that can be sent in the LSP, shown in the figure above, is  $1500 - (2 \times 4) = 1492$ .

You can validate this by using the following **ping mpls** command:

```
Device# ping mpls ipv4 10.131.159.252/32 sweep 1492 1500 1 repeat 1
Sending 1, [1492..1500]-byte MPLS Echos to 10.131.159.252/32,
    timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
        '.' - timeout, 'U' - unreachable,
        'R' - downstream router but not target
Type escape sequence to abort.
!QQQQQQQQ
Success rate is 11 percent (1/9), round-trip min/avg/max = 40/40/40 ms
```

In this command, only packets of 1492 bytes are sent successfully, as indicated by the exclamation point (!). Packets of byte sizes 1493 to 1500 are source-quenched, as indicated by the Q.

You can pad an MPLS echo request so that a payload of a given size can be tested. The pad TLV is useful when you use the MPLS echo request to discover the MTU supportable by an LSP. MTU discovery is extremely important for applications like AToM that contain non-IP payloads that cannot be fragmented.

### LSP Network Management

To manage a Multiprotocol Label Switching (MPLS) network you must have the ability to monitor label switched paths (LSPs) and quickly isolate MPLS forwarding problems. You need ways to characterize the liveliness of an LSP and reliably detect when a label switched path fails to deliver user traffic.

You can use MPLS LSP Ping to verify the LSP that is used to transport packets destined for IPv4 Label Distribution Protocol (LDP) prefixes, traffic engineering (TE) tunnels, and Any Transport over MPLS pseudowire Forwarding Equivalence Classes (AToM PW FECs). You can use MPLS LSP Traceroute to trace LSPs that are used to carry packets destined for IPv4 LDP prefixes and TE tunnel FECs.

An MPLS echo request is sent through an LSP to validate it. A TTL expiration or LSP breakage causes the transit device to process the echo request before it gets to the intended destination and returns an MPLS echo reply that contains an explanatory reply code to the originator of the echo request.

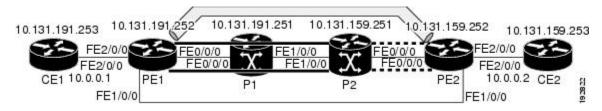

The successful echo request is processed at the egress of the LSP. The echo reply is sent via an IP path, an MPLS path, or a combination of both back to the originator of the echo request.

## ICMP ping and trace Commands and Troubleshooting

Internet Control Message Protocol (ICMP) **ping** and **trace** commands are often used to help diagnose the root cause of a failure. When a label switched path (LSP) is broken, the packet might make its way to the target device by way of IP forwarding, thus making ICMP ping and traceroute unreliable for detecting Multiprotocol Label Switching (MPLS) forwarding problems. The MPLS LSP Ping, Traceroute and ATOM VCCV feature extends this diagnostic and troubleshooting ability to the MPLS network and handles inconsistencies between the IP and MPLS forwarding tables, inconsistencies in the MPLS control and data plane, and problems with the reply path.

The figure below shows a sample topology with a Label Distribution Protocol (LDP) LSP and traffic engineering (TE) tunnel LSP.

Figure 11: Sample Topology with LDP and TE Tunnel LSPs

This section contains the following topics:

### MPLS LSP Ping and Traceroute Discovers LSP Breakage

### **Configuration for Sample Topology**

These are sample topology configurations for the troubleshooting examples in the following sections (see the figure above). There are the six sample device configurations.

### **Device CE1 Configuration**

```
version 12.0
!
hostname cel
!
enable password lab
!
interface Loopback0
ip address 10.131.191.253 255.255.255.255
no ip directed-broadcast
!
interface GigabitEthernet0/0/0
ip address 10.0.0.1 255.255.255.255
no ip directed-broadcast
no keepalive
no cdp enable
!
end
```

### **Device PE1 Configuration**

version 12.0 ! hostname pel

```
!

### Verifying That the LSP Is Set Up Correctly

A **show mpls forwarding-table** command shows that tunnel 1 is in the Multiprotocol Label Switching (MPLS) forwarding table.

Device# show mpls forwarding-table 10.131.159.252 Local Outgoing Prefix Bytes tag Outgoing Next Hop or Tunnel Id tag or VC tag switched interface 19 2.2 [T] 10.131.159.252/32 0 Tu1 point2point Forwarding through a TSP tunnel. [T] View additional tagging info with the 'detail' option

A show mpls traffic-eng tunnels tunnel 1 command entered at PE1 displays information about tunnel 1 and verifies that it is forwarding packets with an out label of 22.

```
Device# show mpls traffic-eng tunnels tunnel 1
Name: PE1_t1 (Tunnel1) Destination: 10.131.159.251
```

```
Status:

```

A **trace mpls** command issued at PE1 verifies that packets with 22 as the outermost label and 19 as the end of stack label are forwarded from PE1 to PE2.

```
Device# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
        '.' - timeout, 'U' - unreachable,
        'R' - downstream router but not target
Type escape sequence to abort.
        0 10.131.191.230 MRU 1496 [Labels: 22/19
Exp: 0/0]
R 1 10.131.159.226 MRU 1504 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
```

The MPLS LSP Traceroute to PE2 is successful, as indicated by the exclamation point (!).

### **Discovering LSP Breakage**

A Label Distribution Protocol (LDP) target-session is established between devices PE1 and P2, as shown in the output of the following **show mpls ldp discovery** command:

Device# show mpls ldp discovery Local LDP Identifier:

```
10.131.191.252:0
Discovery Sources:
Interfaces:
    GigabitEthernet0/0/0 (ldp): xmit/recv
        LDP Id: 10.131.191.251:0
    Tunnel1 (ldp): Targeted -> 10.131.159.251
Targeted Hellos:
    10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
        LDP Id: 10.131.159.252:0
10.131.191.252 -> 10.131.159.251 (ldp): active, xmit/recv
        LDP Id: 10.131.159.251:0
```

Enter the following command on the P2 device in global configuration mode:

Device# no mpls ldp discovery targeted-hello accept

The LDP configuration change causes the targeted LDP session between the headend and tailend of the traffic engineering (TE) tunnel to go down. Labels for IPv4 prefixes learned by P2 are not advertised to PE1. Thus, all IP prefixes reachable by P2 are reachable by PE1 only through IP (not MPLS). In other words, packets destined for those prefixes through Tunnel 1 at PE1 will be IP switched at P2 (which is undesirable).

The following **show mpls ldp discovery** command shows that the LDP targeted-session is down:

```
Device# show mpls ldp discovery
```

```
Local LDP Identifier:
   10.131.191.252:0
   Discovery Sources:
   Interfaces:
    GigabitEthernet0/0/0 (ldp): xmit/recv
        LDP Id: 10.131.191.251:0
    Tunnel1 (ldp): Targeted -> 10.131.159.251
Targeted Hellos:
        10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
        LDP Id: 10.131.159.252:0
        10.131.191.252 -> 10.131.159.251 (ldp): active, xmit
```

Enter the **show mpls forwarding-table** command at the PE1 device. The display shows that the outgoing packets are untagged as a result of the LDP configuration changes.

```
Device# show mpls forwarding-table 10.131.159.252
Local Outgoing
                  Prefix
                                    Bytes tag Outgoing
                                                         Next Hop
                 or Tunnel Id
      tag or VC
                                    switched interface
tag
2.2
      Untagged[T]
10.131.159.252/32 0
                            Tu1
                                        point2point
[T]
       Forwarding through a TSP tunnel.
        View additional tagging info with the 'detail' option
```

A **ping mpls** command entered at the PE1 device displays the following:

```
Device# ping mpls ipv4 10.131.159.252/32 repeat 1
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
    timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
        '.' - timeout, 'U' - unreachable,
        'R' - downstream router but not target
Type escape sequence to abort.
R
Success rate is 0 percent (0/1)
```

The **ping mpls** command fails. The R indicates that the sender of the Multiprotocol Label Switching (MPLS) echo reply had a routing entry but no MPLS Forwarding Equivalence Class (FEC). Entering the **ping mpls verbose** command displays the MPLS label switched path (LSP) echo reply sender address and the return code. You should be able to solve the problem by Telneting to the replying device and inspecting its forwarding and label tables. You might need to look at the neighboring upstream device as well, because the breakage might be on the upstream device.

```
Device# ping mpls ipv4 10.131.159.252/32 repeat 1 verbose
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
    timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
        '.' - timeout, 'U' - unreachable,
        'R' - downstream router but not target
Type escape sequence to abort.
R 10.131.159.225, return code 6
Success rate is 0 percent (0/1)
```

Alternatively, use the LSP **traceroute** command to figure out which device caused the breakage. In the following example, for subsequent values of TTL greater than 2, the same device keeps responding (10.131.159.225). This suggests that the MPLS echo request keeps getting processed by the device regardless of the TTL. Inspection of the label stack shows that P1 pops the last label and forwards the packet to P2 as an IP packet. This explains why the packet keeps getting processed by P2. MPLS echo request packets cannot be forwarded by use of the destination address in the IP header because the address is set to a 127/8 address.

```
Device# trace mpls ipv4 10.131.159.252/32 ttl 5
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
                '.' - timeout, 'U' - unreachable,
                'R' - downstream router but not target
Type escape sequence to abort.
        0 10.131.191.230 MRU 1500 [Labels: 22 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
R 2 10.131.159.225 40 ms
R 3 10.131.159.225 40 ms
R 4 10.131.159.225 40 ms
R 5 10.131.159.225 40 ms
```

### MPLS LSP Traceroute Tracks Untagged Cases

This troubleshooting section contains examples of how to use MPLS LSP Traceroute to determine potential issues with packets that are tagged as implicit null and packets that are untagged.

Untagged output interfaces at a penultimate hop do not impact the forwarding of IP packets through a label switched path (LSP) because the forwarding decision is made at the penultimate hop through use of the incoming label. The untagged case causes Any Transport over Multiprotocol Label Switching (AToM) and MPLS virtual private network (VPN) traffic to be dropped at the penultimate hop.

#### **Troubleshooting Implicit Null Cases**

In the following example, Tunnel 1 is shut down, and only a label switched path (LSP) formed with Label Distribution Protocol (LDP) labels is established. An implicit null is advertised between the P2 and PE2 devices. Entering an MPLS LSP Traceroute at the PE1 device results in the following display:

```
'R' - downstream router but not target
Type escape sequence to abort.
0 10.131.191.230 MRU 1500 [Labels: 20 Exp: 0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 80 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
```

This output shows that packets are forwarded from P2 to PE2 with an implicit-null label. Address 10.131.159.229 is configured for the P2 Fast Ethernet 0/0/0 out interface for the PE2 device.

#### **Troubleshooting Untagged Cases**

Untagged cases are valid configurations for Interior Gateway Protocol (IGP) label switched paths (LSPs) that could cause problems for Multiprotocol Label Switching (MPLS) virtual private networks (VPNs).

A **show mpls forwarding-table** command and a **show mpls ldp discovery** command issued at the P2 device show that the Label Distribution Protocol (LDP) is properly set up:

```
Device# show mpls forwarding-table 10.131.159.252
```

```
Prefix
Local Outgoing
                                    Bytes tag Outgoing
                                                           Next Hop
      tag or VC or Tunnel Id
                  or Tunnel Id switched interface
10.131.159.252/32 0 Et0/0
taσ
      Pop tag
                                                          10.131.159.230
19
Device# show mpls ldp discovery
Local LDP Identifier:
   10.131.159.251:0
   Discovery Sources:
    Interfaces:
          GigabitEthernet0/0/0 (ldp): xmit/recv
           LDP Td: 10.131.159.252:0
        FastEthernet1/0/0 (ldp): xmit/recv
           LDP Id: 10.131.191.251:0
```

The **show mpls ldp discovery** command output shows thatGigabitEthernet0/0/0, which connects PE2 to P2, is sending and receiving packets.

If a **no mpls ip** command is entered on GigabitEthernet0/0/0, this could prevent an LDP session between the P2 and PE2 devices from being established. A **show mpls ldp discovery** command entered on the PE device shows that the MPLS LDP session with the PE2 device is down:

```
Device# show mpls ldp discovery
```

```
Local LDP Identifier:
10.131.159.251:0
Discovery Sources:
Interfaces:
GigabitEthernet0/0/0 (ldp): xmit
FastEthernet1/0/0 (ldp): xmit/recv
LDP Id: 10.131.191.251:0
```

If the MPLS LDP session to PE2 goes down, the LSP to 10.131.159.252 becomes untagged, as shown by the **show mpls forwarding-table** command:

Device# show mpls forwarding-table 10.131.159.252 Local Outgoing Prefix Bytes tag Outgoing Next Hop tag tag or VC or Tunnel Id switched interface 19 Untagged 10.131.159.252/32 864 Et0/0 10.131.159.230 Untagged cases would provide an MPLS LSP Traceroute reply with packets tagged with No Label, as shown in the following display:

### MPLS LSP Ping and Traceroute Returns a Q

The Q return code always means that the packet could not be transmitted. The problem can be caused by insufficient memory, but it probably results because a label switched path (LSP) could not be found that matches the Forwarding Equivalence Class (FEC), information that was entered on the command line.

The reason that the packet was not forwarded needs to be determined. To do so, look at the Routing Information Base (RIB), the Forwarding Information Base (FIB), the Label Information Base (LIB), and the MPLS Label Forwarding Information Base (LFIB). Lack of an entry for the FEC in any one of these routing/forwarding bases would return a Q.

The table below lists commands that you can use for troubleshooting when the MPLS echo reply returns a Q.

Database	Command to View Contents
Routing Information Base	show ip route
Label Information Base and MPLS Forwarding Information Base	show mpls forwarding-table detail

#### Table 13: Troubleshooting a Q

The following example shows a **ping mpls** command where the MPLS echo request is not transmitted, as shown by the returned Qs:

```
Device# ping mpls ipv4 10.0.0.1/32
Sending 5, 100-byte MPLS Echos to 10.0.0.1/32,
    timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
        '.' - timeout, 'U' - unreachable,
        'R' - downstream router but not target
Type escape sequence to abort.
OCO202
Success rate is 0 percent (0/5)
```

A show mpls forwarding-table command and a show ip route command demonstrate that the address is not in either routing table:

```
Device# show mpls forwarding-table 10.0.0.1
Local Outgoing Prefix Bytes tag Outgoing Next Hop
tag tag or VC or Tunnel Id switched interface
Device# show ip route 10.0.0.1
% Subnet not in table
```

The MPLS echo request is not transmitted because the IPv4 address (10.0.0.1) is not found in either the LFIB or the RIB routing table.

### Load Balancing for IPv4 LDP LSPs

An Internet Control Message Protocol (ICMP) ping or trace follows one path from the originating device to the target device. Round robin load balancing of IP packets from a source device is used to discover the various output paths to the target IP address.

For MPLS LSP Ping and Traceroute, Cisco devices use the source and destination addresses in the IP header for load balancing when multiple paths exist through the network to a target device. The Cisco implementation of MPLS might check the destination address of an IP payload to accomplish load balancing (this checking depends on the platform).

To check for load balancing paths, you use the 127.*z.y.x*/8 destination address in the **ping mpls ipvr** *ip-address* address-mask **destination** address-start address-end address-increment command. The following examples show that different paths are followed to the same destination. This demonstrates that load balancing occurs between the originating device and the target device.

To ensure that the Fast Ethernet interface 1/0/0 on the PE1 device is operational, you enter the following commands on the PE1 device:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface fastethernet 1/0/0
Device(config-if)# no shutdown
Device(config-if)# end
*Dec 31 19:14:10.034: %LINK-3-UPDOWN: Interface FastEthernet1/0/0, changed state to up
*Dec 31 19:14:11.054: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet1/0/0,
changed state to upend
PE1#
*Dec 31 19:14:12.574: %SYS-5-CONFIG_I: Configured from console by console
*Dec 31 19:14:19.334: %OSFF-5-ADJCHG: Process 1, Nbr 10.131.159.252 on FastEthernet1/0/0
from LOADING to FULL, Loading Done
PE1#
```

The following **show mpls forwarding-table** command displays the possible outgoing interfaces and next hops for the prefix 10.131.159.251/32:

Device# show mpls forwarding-table 10.131.159.251

Local	Outgoing	Prefix	Bytes tag	Outgoing Next Hop
tag	tag or VC	or Tunnel Id	switched	interface
21	19	10.131.159.251/32	0	FE0/0/0 10.131.191.229
	20	10.131.159.251/32	0	FE1/0/0 10.131.159.245

The following **ping mpls** command to 10.131.159.251/32 with a destination UDP address of 127.0.0.1 shows that the path selected has a path index of 0:

```
Device# ping mpls ipv4
10.131.159.251/32 destination
127.0.0.1 repeat 1
Sending 1, 100-byte MPLS Echos to 10.131.159.251/32,
    timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
    '.' - timeout, 'U' - unreachable,
    'R' - downstream router but not target
Type escape sequence to abort.
```

Success rate is 100 percent (1/1), round-trip min/avg/max = 40/40/40 ms PE1# \*Dec 29 20:42:40.638: LSPV: Echo Request sent on IPV4 LSP, load index 2, pathindex 0 , size 100 \*Dec 29 20:42:40.638: 46 00 00 64 00 00 40 00 FF 11 9D 03 0A 83 BF FC \*Dec 29 20:42:40.638: 7F 00 00 01 94 04 00 00 0D AF 0D AF 00 4C 14 70 \*Dec 29 20:42:40.638: 00 01 00 00 01 02 00 00 1A 00 00 1C 00 00 00 01 \*Dec 29 20:42:40.638: C3 9B 10 40 A3 6C 08 D4 00 00 00 00 00 00 00 00 00 \*Dec 29 20:42:40.638: 00 01 00 09 00 01 00 05 0A 83 9F FB 20 00 03 00 \*Dec 29 20:42:40.638: 13 01 AB CD \*Dec 29 20:42:40.638: AB CD AB CD \*Dec 29 20:42:40.678: LSPV: Echo packet received: src 10.131.159.225, dst 10.131.191.252, size 74 \*Dec 29 20:42:40.678: AA BB CC 00 98 01 AA BB CC 00 FC 01 08 00 45 C0 \*Dec 29 20:42:40.678: 00 3C 32 D6 00 00 FD 11 15 37 0A 83 9F E1 0A 83 \*Dec 29 20:42:40.678: BF FC 0D AF 0D AF 00 28 D1 85 00 01 00 00 02 02 \*Dec 29 20:42:40.678: 03 00 1A 00 00 1C 00 00 01 C3 9B 10 40 A3 6C \*Dec 29 20:42:40.678: 08 D4 C3 9B 10 40 66 F5 C3 C8

The following **ping mpls** command to 10.131.159.251/32 with a destination UDP address of 127.0.0.1 shows that the path selected has a path index of 1:

```
Device# ping mpls ipv4 10.131.159.251/32 dest 127.0.0.1 repeat 1
Sending 1, 100-byte MPLS Echos to 10.131.159.251/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
Success rate is 100 percent (1/1), round-trip min/avg/max = 40/40/40 ms

*Dec 29 20:43:09.558: 95 84 C3 9B 10 5D 48 3D 50 78
```

To see the actual path chosen, you use the **debug mpls lspv packet data** command.

Note

The hashing algorithm is nondeterministic. Therefore, the selection of the *address-start*, *address-end*, and *address-increment* arguments for the **destination** keyword might not provide the expected results.

# **NSR LDP Support**

The NSR LDP Support feature allows the Label Distribution Protocol (LDP) to continue to operate across a Router Processor (RP) failure in redundant systems, without losing peer sessions. Before the introduction of nonstop routing (NSR), LDP sessions with peers reset if an RP failover (in a redundant system) or a Cisco In-Service Software Upgrade (ISSU) occurred. When peers reset, traffic is lost while the session is down. Protocol reconvergence occurs after the session is reestablished.

When NSR is enabled, RP failover and Cisco ISSU events are not visible to the peer device, and the LDP sessions that were established prior to failover do not flap. The protocol state learned from the peers persists across an RP failover or Cisco ISSU event and does not need to be relearned.

- Prerequisites for NSR LDP Support, on page 89
- Information About NSR LDP Support, on page 89
- How to Configure NSR LDP Support, on page 92
- Configuration Examples for NSR LDP Support, on page 93
- Additional References for NSR LDP Support, on page 94
- Feature Information for NSR LDP Support, on page 95

## **Prerequisites for NSR LDP Support**

The Label Distribution Protocol (LDP) must be up and running on the standby Route Processor (RP) for NSR LDP Support to work.

# **Information About NSR LDP Support**

## **Roles of the Standby Route Processor and Standby LDP**

For the NSR LDP Support feature to work, the Label Distribution Protocol (LDP) must be up and running on the standby Route Processor (RP). The LDP component running on the active RP is called the active LDP, and the LDP component running on the standby RP is called the standby LDP.

When nonstop routing (NSR) is enabled, the standby LDP runs independently from the active LDP, but with the assistance of some software components. The standby LDP maintains LDP session states and database information, ready to take over for the active LDP if the failover occurs.

Standby LDP maintains its local database by querying or receiving notifications of interface status change, configuration changes from the CLI, and checkpoints from the active LDP for other information that is not directly available on the standby RP.

To keep the protocol and session-state information synchronized with the active LDP, the standby LDP depends on TCP to replicate all LDP messages on the active RP to the standby RP. The standby LDP processes all received messages, updates its state, but does not send any responses to its neighbors.

The standby LDP performs the following tasks:

- Processes LDP configuration on startup and during steady state
- Processes active LDP checkpoints of state and session information such as LDP adjacencies, remote addresses, remote bindings, and so forth
- · Builds its database of local interfaces
- · Processes interface change events
- Receives and processes all LDP messages replicated by TCP
- · Updates remote address and label databases

After a switchover and notification that the RP has become active, the standby LDP takes over the role of the active LDP and performs the following tasks:

- Sends hello messages immediately to prevent neighbors from reaching the discovery timeout and bringing down the session
- Retransmits any protocol-level response that has not been sent by the previous active LDP
- · Readvertises label bindings
- Refreshes all forwarding entries
- Processes and responds to any LDP message from its neighbor

When the NSR LDP Support feature is disabled, the active LDP performs the following tasks:

- Stops checkpointing to the standby LDP
- · Continues to manage all existing sessions

The standby LDP performs the following tasks:

- · Cleans up all session-state information
- · Reverses to the behavior before NSR is enabled

## LDP Operating States

When the NSR LDP Support feature is enabled, the Label Distribution Protocol (LDP) operates in the following states:

### **Initial State**

In the initial state, the active Label Distribution Protocol (LDP) process sets up the standby LDP to be ready to support nonstop routing (NSR). The active LDP performs the following tasks:

- Replicates all TCP sessions used by LDP with the standby LDP
- · Synchronizes all existing session-state information with the standby LDP
- Synchronizes the LDP database with the standby LDP

LDP could be in the initial state because of one of these conditions:

- NSR is enabled
- NSR was enabled and the standby Route Processor (RP) starts up (asymmetric startup)
- System boots up and NSR is configured (symmetric startup)

### **Steady State**

In the steady state, the active and standby Label Distribution Protocol (LDP) databases are synchronized. The active and standby LDP process the same LDP messages and update their states independently. The standby LDP is ready to take over the active LDP role in a switchover event.

On the active Route Processor (RP), the active LDP performs the following tasks:

- Continues to manage all existing sessions and checkpoints any significant session event to the standby LDP (such as adjacency delete, session shutdown, timers)
- · Notifies the standby LDP of new adjacencies and neighbors

On the standby RP, the standby LDP performs these tasks:

- Processes all received messages but does not send any messages to its neighbor
- · Processes checkpoint information from the active LDP
- Manages session keepalive timers but does not bring down the session if a keepalive timer times out

### **Post Switchover**

In the post switchover state, the standby Label Distribution Protocol (LDP) process takes over the active LDP role while the active Route Processor (RP) is reloading.

### Supported NSR Scenarios

The NSR LDP Support feature is supported under the following scenarios:

• Route Processor (RP) failover or node failure

The Label Distribution Protocol (LDP) keeps the session up during an RP or node failover because the LDP adjacency and session-state information between LDP on the active and standby RPs are synchronized. As sessions are created on the active RP, new adjacencies are synchronized to the standby RP. If a standby RP is brought online after sessions are already up (asymmetric startup), LDP synchronizes the existing session-state information from the active to the standby RP.

Cisco In-Service Software Upgrade (ISSU)

LDP supports Cisco ISSU negotiation between RPs when a standby RP comes online for the MPLS LDP IGP Synchronization feature. Current Cisco ISSU negotiation is not impacted by NSR. For NSR, LDP negotiates messages specific to NSR, which are checkpointed during initial synchronization (adjacency and session-state information).

## How to Configure NSR LDP Support

## **Enabling NSR LDP Support**

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	mpls ldp nsr	Enables nonstop routing (NSR) for all Label	
	Example:	Distribution Protocol (LDP) sessions for b link and targeted.	
	Device(config) # mpls ldp nsr		
Step 4	exit	Returns to privileged EXEC mode.	
	Example:		
	Device(config)# exit		
Step 5	show mpls ldp nsr	Displays whether NSR is enabled.	
	Example:		
	Device# show mpls ldp nsr		

#### Procedure

## Troubleshooting Tips for NSR LDP Support

Use the **debug mpls ldp nsr** command to enable the display of Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) nonstop routing (NSR) debugging events for all NSR sessions or for the specified peer.

## **Configuration Examples for NSR LDP Support**

# **Feature Information for NSR LDP Support**

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Feature Name	Release	Feature Information
NSR LDP Support	IOS XE 3.5	This feature was introduced on the Cisco RSP1 Module in this release.
NSR LDP Support	IOS XE 3.13	This feature was introduced on the Cisco RSP2 Module in this release.
NSR LDP Support	IOS XE 3.16	This feature was introduced on the Cisco RSP3 Module in this release.

Table 14: Feature Information for NSR LDP Support

# **Flex LSP Overview**

Flex LSP also known as Associated Bidirectional LSPs is the combination of static bidirectional MPLS-TP and dynamic MPLS-TE. Flex LSP provides bidirectional label switched paths (LSPs) set up dynamically through Resource Reservation Protocol–Traffic Engineering (RSVP-TE). It does not support non-co routed LSPs.

Flex Label Switched Paths are LSP instances where the forward and the reverse direction paths are setup, monitored and protected independently and associated together during signaling. You use a RSVP Association object to bind the two forward and reverse LSPs together to form either a co-routed or non co-routed associated bidirectional TE tunnel.

You can associate a protecting MPLS-TE tunnel with either a working MPLS-TE LSP, protecting MPLS-TE LSP, or both. The working LSP is the primary LSP backed up by the protecting LSP. When a working LSP goes down, the protecting LSP is automatically activated. You can configure a MPLS-TE tunnel to operate without protection as well.

Effective Cisco IOS XE Release 3.18.1SP, Flex LSP supports inter-area tunnels with non co-routed mode.

## **Signaling Methods and Object Association for Flex LSPs**

This section provides an overview of the association signaling methods for the bidirectional LSPs. Two unidirectional LSPs can be bound to form an associated bidirectional LSP in the following scenarios:

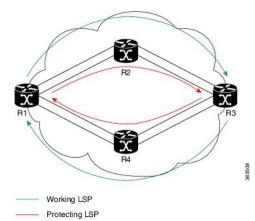

- No unidirectional LSP exists, and both must be established.
- Both unidirectional LSPs exist, but the association must be established.
- One unidirectional LSP exists, but the reverse associated LSP must be established.

## **Associated Bidirectional Non Co-routed and Co-routed LSPs**

This section provides an overview of associated bidirectional non co-routed and co-routed LSPs. Establishment of MPLS TE-LSP involves computation of a path between a head-end node to a tail-end node, signaling along the path, and modification of intermediate nodes along the path. The signaling process ensures bandwidth reservation (if signaled bandwidth is lesser than 0 and programming of forwarding entries).

Path computation is performed by the head-end nodes of both the participating LSPs using Constrained Shortest Path First (CSPF). CSPF is the 'shortest path (measured in terms of cost) that satisfies all relevant LSP TE constraints or attributes, such as required bandwidth, priority and so on.

Associated Bidirectional Non Co-routed LSPs: A non co-routed bidirectional TE LSP follows two different paths, that is, the forward direction LSP path is different than the reverse direction LSP path. Here is an illustration.

In the above topology:

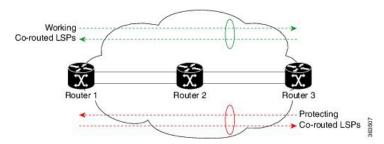

- The outer paths (in green) are working LSP pairs.
- The inner paths (in red) are protecting LSP pairs.
- Router 1 sets up working LSP to Router 3 and protecting LSP to Router 3 independently.
- Router 3 sets up working LSP to Router 1 and protecting LSP to Router 1 independently.

Non co-routed bidirectional TE LSP is available by default, and no configuration is required.

**Note** In case of non co-routed LSPs, the head-end nodes relax the constraint on having identical forward and reverse paths. Hence, depending on network state you can have identical forward and reverse paths, though the bidirectional LSP is co-routed.

Associated Bidirectional Co-routed LSPs: A co-routed bidirectional TE LSP denotes a bidirectional tunnel where the forward direction LSP and reverse direction LSP must follow the same path, for example, the same nodes and paths. Here is an illustration.

In the above topology:

- Paths at the top of the figure (in green) indicate working co-routed LSP pairs.
- Paths at the bottom of the figure (in red) indicate protecting co-routed LSP pairs.
- Router 1 sets up working LSP to Router 3 (in red) after performing bidirectional CSPF and sends reverse explicit route object (ERO) to Router 3. Node Router 3 uses the received reverse ERO to set up reverse red working LSP to Router 1.
- Router 3 sets up protecting LSP to Router 1 (in green) after performing bidirectional CSPF and sends reverse ERO to Router 1. Node Router 1 uses the received reverse ERO to set up reverse green protecting LSP to Router 3.

## **Restrictions for Flex LSP**

- Exp-null over Flex-LSP is not supported.
- Flex-LSP does not support tunnel statistics.
- VC (layer 2 VPN ckts) statistics are not supported.
- It is recommended to configure for the following timers for Flex-LSP deployments:

mpls traffic-eng reoptimize timers frequency 120

mpls traffic-eng reoptimize timers delay installation 30

mpls traffic-eng reoptimize timers delay cleanup 90

- The **no mpls ip propagate-tcl** command is not recommended with Flex-LSP. The PREC value of BFD control packet is set to "0". Therefore, packet prioritization cannot be done at midpoints and BFD flap can occur with traffic congestions.
- It is recommended to configure BFD timers as 10x3 during cable pull testing or in Flex LSP feature deployments.
- 50-msec convergence is not guaranteed for local shut.
- 50-msec convergence is not guaranteed without WRAP protection. WRAP protection is mandatory to achieve 50-msec convergence for remote failures.
- 50-msec convergence is expected with a maximum of 30 Flex-LSP tunnels that use the same egress interface.
- With scale and multiple other feature mix-ups, it is possible to see higher convergence.
- TE NSR and IGP NSR are mandatory for RSP switchover.
- Flex LSP is supported with the IPv4 template.

- The ip rsvp signalling hello command is not mandatory and it can cause a large punt during the cutover and can lead to unexpected results like BFD flapping.
- VPLS over Flex-LSP is not supported.
- Both IGP and FRR must be configured as clients for single-hop BFD when the WRAP protection is enabled; only FRR cannot be the only client that is configured at midpoint.
- Layer 3 VPN over Flex-LSP is not supported.
- It is recommended to configure 10x3 BFD timers for cable failures, to achieve 50 msec of convergence.
- Flex LSP is not supported over Port-channel in RSP3.
- It is recommended to configure 10x3 BFD timers for cable failures, to achieve 50 msec of convergence.
- Dynamic diverse paths are not supported for Flex LSP Tunnel.
- The Diverse node SRLG path option is not supported.
- The protect dynamic SRLG path is diverse from the primary path and thus the shortest path is not always chosen.
- When the constraint for the protect path of Flex-LSP tunnel does not meet, it will wait in the REQUESTED state.

### **Restrictions for Non Co-routed Inter-Area Flex LSP Tunnels**

- The dynamic path option feature for TE tunnels (**tunnel mpls traffic-eng path-option number dynamic**) is not supported for inter-area tunnels. An explicit path identifying the area border routers (ABRs) is required.
- The MPLS TE AutoRoute feature (tunnel mpls traffic-eng autoroute announce) is not supported for inter-area tunnels.
- Tunnel affinity (tunnel mpls traffic-eng affinity) is not supported for inter-area tunnels.
- Tunnel metric (tunnel mpls traffic-eng path-selection metric) is not supported for inter-area tunnels.
- BFD is not supported with non co-routed inter-area flex LSP tunnels.

## How to Configure Co-routed Flex LSPs

A co-routed bidirectional packet LSP is a combination of two LSPs (one in the forward direction and the other in reverse direction) sharing the same path between a pair of ingress and egress nodes. It is established using the extensions to RSVP-TE. This type of LSP can be used to carry any of the standard types of MPLS-based traffic, including Layer 2 VPNs and Layer 2 circuits. You can configure a single BFD session for the bidirectional LSP (that is, you do not need to configure a BFD session for each LSP in each direction). You can also configure a single standby bidirectional LSP to provide a backup for the primary bidirectional LSP.

The configuration includes the following steps:

- 1. Enable basic MPLS Traffic Engineering on hostname PE1.
- 2. Map L2VPN pseudowire to a specific FLEX LSP tunnel.

- 3. Configure Flex LSP.
- 4. Enable BFD.
- 5. Enable Wrap and Fault OAM.
- 6. Enable BDIs on a core-facing interface.

# **Configuring Co-routed Flex LSPs**

### Before you begin

- You must have symmetric source and destination TE router IDs in order for bidirectional LSPs to be associated.
- Tunnels attributes must be configured identically on both sides of co-routed bidirectional LSP.

Note Up to 250 Flex LSP tunnels are supported.

### Procedure

1. Enable basic MPLS Traffic Engineering on hostname PE1:

```
mpls traffic-eng tunnels
mpls traffic-eng fault-oam
mpls traffic-eng nsr
router ospf 100
router-id 10.1.1.1
nsr
mpls traffic-eng router-id Loopback0
mpls traffic-eng area 0
```

#### 2. Map L2VPN pseudowire to a specific Flex LSP tunnel:

```
template type pseudowire mpls-te1 (mpls-tel can be any name)
encapsulation mpls
preferred-path interface Tunnel1 disable-fallback
bandwidth 100
template type pseudowire mpls-te4
```

encapsulation mpls preferred-path interface Tunnel4 disable-fallback bandwidth 100

### 3. Configure Flex LSP:

```
interface Tunnel1
bandwidth 1000
ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 22.22.22.22
tunnel mpls traffic-eng autoroute announce
tunnel mpls traffic-eng priority 7 7
tunnel mpls traffic-eng bandwidth 1000
tunnel mpls traffic-eng path-option 1 explicit name BDI1 bandwidth 1000
tunnel mpls traffic-eng path-option protect 1 explicit name BACKUP1 bandwidth 1000
```

```
tunnel mpls traffic-eng bidirectional association id 1 source-address 11.11.11.11 global-id
1
tunnel mpls traffic-eng bidirectional association type co-routed
ip explicit-path name BDI1 enable
next-address 1.11.1.1
next-address 10.1.2.2
next-address 2.22.1.22
ip explicit-path name BACKUP1 enable
next-address 10.3.11.1.10
next-address 10.4.22.22
```

**Note** To bring up the bi-directional tunnels, association ID, source address and global ID must match on both sides of the tunnel.

#### 4. Enable BFD

```
bfd-template single-hop BFD_FLEX
interval min-tx 50 min-rx 50 multiplier 3
interface Tunnel1
tunnel mpls traffic-eng bfd encap-mode gal BFD_FLEX
```

5. Enable Wrap and Fault OAM

interface Tunnel1 tunnel mpls traffic-eng bidirectional association type co-routed fault-oam wrap-protection

6. Enable BDIs on core-facing interface:

```
interface BDI1
ip address 1.11.1.11 255.255.255.0
ip ospf 1 area 0
mpls traffic-eng tunnels
```

```
interface BDI4
ip address 1.11.4.11 255.255.255.0
ip ospf 1 area 0
mpls traffic-eng tunnels
```

```
interface GigabitEthernet0/3/1
ip address 10.3.11.11 255.255.255.0
ip ospf 1 area 0
mpls traffic-eng tunnels
```

```
interface GigabitEthernet0/3/0
service instance 1 ethernet
encapsulation dotlq 1
rewrite ingress tag pop 1 symmetric
bridge-domain 1
service instance 4 ethernet
encapsulation dotlq 4
rewrite ingress tag pop 1 symmetric
bridge-domain 4
End
```

# Note

NOTE: Since VLANs are not supported, to represent a VLAN interface, BDI must be used towards core-facing interface.

# Verifying the Co-routed Flex LSP Configuration

To verify the FLEX LSP tunnel summary, use the **show mpls traffic-eng tunnels bidirectional-associated concise** command in MPLS tunnel-te interface.

```
Router# show mpls traffic-eng tunnels summary
Signalling Summary:
   LSP Tunnels Process:
                                    running
    Passive LSP Listener:
                                    running
   RSVP Process:
                                    running
   Forwarding:
                                    enabled
   auto-tunnel:
          Disabled (0), id-range:62336-64335
   p2p
    Periodic reoptimization:
                                    every 3600 seconds, next in 2942 seconds
    Periodic FRR Promotion:
                                    Not Running
                                   every 300 seconds, next in 243 seconds
    Periodic auto-bw collection:
    SR tunnel max label push:
                                   1 labels
   P2P:
     Head: 100 interfaces,
                             0 active signalling attempts, 0 established
            87733091 activations, 87733091 deactivations
           144287155 failed activations
            0 SSO recovery attempts, 0 SSO recovered
     Midpoints: 0, Tails: 0

# **Co-routed Inter-area Flex-LSP Tunnels**

Feature Name	Release Information	Feature Description
Co-routed Inter-area Flex-LSP Tunnels	Cisco IOS XE Cupertino 17.9.1	Flex LSPs (also called Associated Bidirectional LSPs) now support inter-area, co-routed tunnels. This implementation meets the specific requirements of network operators (LSP users) to create on-demand tunnels by defining an explicit path across different areas.

Table 15: Feature History

From Cisco IOS XE Cupertino 17.9.1, co-routed inter-area flex-LSPs, also known as Associated Bidirectional LSPs, are supported. In an inter-area environment, the head-end and tail-end of a flex-LSP are in different areas. As a result, the head-end LSR is unaware of the end-to-end topology. With this implementation, you can now configure an end-to-end strict-hop explicit path, including all hops, which enables the head-end LSR discover the topology. Ensure that you configure identical explicit paths at the head-end and tail-end.

In co-routed LSPs, there is a forward LSP path and a reverse LSP path. Both paths pass through the same nodes, but in the reverse orders.

The explicit path for the MPLS tunnel refers to a set of nodes. The relationship between any two neighbouring nodes on an explicit path can be:

- Strict—The two neighboring nodes must be directly connected.
- Loose—The two neighboring nodes can have devices in between.

Co-routed inter-area flex-LSPs are configured using the end-to-end strict-hop explicit path.

Note

For the tunnel to be in the Up state, ensure that you include the complete end-to-end strict-hop explicit path in the head-end and tail-end LSRs.

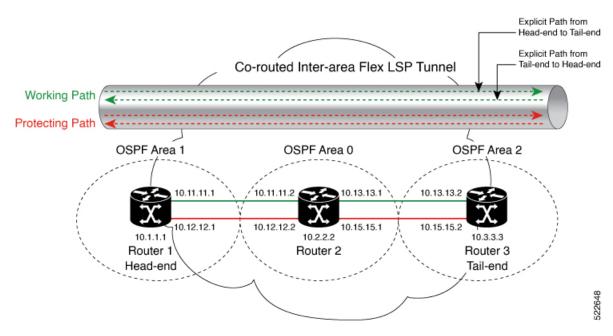

# **Restrictions for Co-Routed Inter-Area Flex LSP Tunnels**

- The dynamic path-option is not supported.
- The autoroute announce feature is not supported.
- The tunnel affinity feature is not supported.
- The **re-optimization** of tunnel paths is not supported.

# How to Configure Co-routed Inter-area Flex LSP Tunnels

For co-routed, inter-area tunnels, you configure an end-to-end strict-hop explicit path by using the MPLS TE **verbatim** path option. Ensure that you configure identical explicit path addresses in the head-end and tail-end LSRs.

In a co-routed inter-area environment, the working and protecting paths are configured on the head-end router first and then on the tail-end router. See Flex LSP Overview for more information on working and protecting paths information. This configuration example is based on the following topology:

#### **Configuration Example**

This example shows how to configure the tunnel and the explicit path on the head-end router.

### At Router 1 (head-end)

#### **Tunnel Configuration**

```
interface Tunnel2002
no shut
ip unnumbered Loopback1
load-interval 30
mpls ip
mpls label protocol ldp
tunnel mode mpls traffic-eng
tunnel destination 10.3.3.3
tunnel mpls traffic-eng priority 0 0
tunnel mpls traffic-eng path-option 1 explicit name working verbatim
tunnel mpls traffic-eng path-option protect 1 explicit name protect verbatim
tunnel mpls traffic-eng record-route
tunnel mpls traffic-eng bidirectional association id 24 source-address 10.1.1.1 global-id
10
tunnel mpls traffic-eng bidirectional association type co-routed fault-oam wrap-protection
tunnel mpls traffic-eng bfd encap-mode gal FlexBfd
```

### **Strict-hop Explicit Path Configuration**

**Note** You can only achieve the tunnel UP state by configuring the complete end-to-end hops in the explicit path as a strict-hop.

```
ip explicit-path name working enable
index 1 next-address 10.11.11.2
index 2 next-address 10.13.13.1
index 3 next-address 10.13.13.2
ip explicit-path name protect enable
index 1 next-address 10.12.12.2
```

index 2 next-address 10.15.15.1
index 3 next-address 10.15.15.2

This example shows how to configure the tunnel and the explicit path on the tail-end router.

#### At Router 3 (tail-end)

#### **Tunnel Configuration**

```
interface Tunnel2002
no shut
load-interval 30
ip unnumbered Loopback1
mpls ip
mpls label protocol ldp
tunnel mode mpls traffic-eng
tunnel destination 10.1.1.1
tunnel mpls traffic-eng priority 0 0
tunnel mpls traffic-eng path-option 1 explicit name working verbatim
tunnel mpls traffic-eng path-option protect 1 explicit name protect verbatim
tunnel mpls traffic-eng record-route
tunnel mpls traffic-eng bidirectional association id 24 source-address 10.1.1.1 global-id
10
tunnel mpls traffic-eng bidirectional association type co-routed fault-oam wrap-protection
tunnel mpls traffic-eng bfd encap-mode gal FlexBfd
```

#### **Strict-hop Explicit Path Configuration**

```
ip explicit-path name working enable
index 1 next-address 10.13.13.1
index 2 next-address 10.11.11.2
index 3 next-address 10.11.11.1
ip explicit-path name protect enable
index 1 next-address 10.15.15.1
index 2 next-address 10.12.12.2
index 3 next-address 10.12.12.1
```

# Verifying Co-routed Inter-area Flex LSP Tunnels

To verify that the flex-LSP tunnel is up:

#### At Router 1

```
Router# show mpls traffic-eng tunnels

# Flex LSP Phase 2

Flex LSP phase 2 is supported from Cisco IOS XE Everest 16.5.1. Flex LSP, also known as Associated Bidirectional Label Switched Paths (LSPs), are LSP instances where the forward and the reverse direction paths are set up, monitored, protected independently, and associated together during signaling. The RSVP Association aims to bind the forward and reverse LSPs together to form either a co-routed or a non co-routed associated bidirectional traffic engineering (TE) tunnel.

The Cisco IOS XE Everest 16.5.1 supports only co-routed Flex LSP tunnels. Flex LSP Phase 2 supports the following features:

• Shared Risk Link Groups (SRLGs) Protection – SRLGs indicate situations where links in a network share a common fiber (or a common physical attribute). If one link fails, the other links in the group may also fail. Links in this group have a shared risk.

The MPLS-TE SRLG Protection feature enhances backup tunnel path selection so that a backup tunnel avoids using links that are in the same SRLG as interfaces the backup tunnel is protecting.

- Non-revertive
- Sticky
- Hop count and Cost max limit Each path from the tunnel source node (head-end) to destination node (tail-end) has a number of characteristics, including node hop count and accumulated path cost. Node hop count is the number of nodes along a path excluding the source node.

To ensure that the selected path does not exceed the specified hop count, configure a maximum node hop count.

Each link segment along the path has an associated path cost. Accumulated path cost is the sum of the path cost of all link segments. In the co-routed tunnel case, the accumulated path cost includes both, the forward and reverse link cost. To ensure that the selected path does not exceed the specified cost value, configure a cost max limit.

- ECMP min-fill, max-fill Path calculation selects a path with the lowest accumulated path cost. Sometimes there are multiple paths from the tunnel source node to the destination node, and all these paths may have the same accumulated (and lowest) path cost. These paths are referred to as "Equal Cost Multi Path" (ECMP). In this scenario, path calculation must use other tiebreakers (such as, node hop count and path minimum bandwidth) to select one path. Max-fill is a tiebreaker method that selects, from all ECMPs, a path with the least head room, but can still accommodate the path request. This method has the effect of packing the links. Min-fill is a tiebreaker method that selects, from all ECMPs, a path with the most head room, and which has a load balance effect over time.
- Restore path option The restore path option signals a restore LSP after a double failure of both, primary and protect LSPs.

# Flex LSP SRLG and Exclude Option for Explicit Path

Use the following commands to configure SRLG on an interface:

```
Router(config)# interface Ethernet0/1
Router(config-if)# srlg gid <1-4294967295>
```

SRLG values configured on MPLS TE enabled interfaces are flooded through IGP (IS-IS or OSPF), and are used by MPLS TE in the following scenarios:

• Restrict protection path to avoid SRLGs of links in the working path.

```
Router(config) # interface Tunnel100
Router(config-if) # tunnel mpls traffic-eng path-option protect 1 diverse srlg lockdown
```

Exclude SRLG in IP Explicit Path.

```
Router(config)# ip explicit-path name EXAMPLE
Router(cfg-ip-expl-path)# exclude-srlg A.B.C.D
```

The exclude-srlg command specifies an address to get SRLGs from for exclusion.

Note

For bidirectional co-routed LSP, both ends of the tunnel must be configured with the same exclude options in explicit path. Otherwise, it is considered a configuration error.

**Note** Only 32 SRLG values can be configured on an interface. Also, MPLS TE only accepts up to 400 SRLG values configured on a system.

### Configuring Flex LSP SRLG and Exclude Option

On the MPLS-TE enabled interface:

```
interface GigabitEthernet0/3/0
srlg gid 10
srlg gid 20
srlg gid 30
srlg gid 40
srlg gid 50
ip address 102.103.1.1 255.255.255.0
ip ospf 1 area 0
negotiation auto
mpls ip
mpls traffic-eng tunnels
ip rsvp bandwidth 200000 120000 sub-pool 120000
ip rsvp signalling hello graceful-restart
```

### Enable the SRLG on the Flex LSP tunnel:

```
!
interface Tunnel1
bandwidth 100000
ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 54.4.4.4
tunnel mpls traffic-eng autoroute announce
```

```
tunnel mpls traffic-eng priority 7 7
tunnel mpls traffic-eng bandwidth 10000000
tunnel mpls traffic-eng path-option 1 explicit name SRLG
tunnel mpls traffic-eng path-option protect 1 diverse srlg lockdown
tunnel mpls traffic-eng bidirectional association id 1 source-address 52.2.2.2 global-id 1
tunnel mpls traffic-eng bidirectional association type co-routed fault-oam wrap-protection
```

#### To enable explicit path SRLG:

ip explicit-path name SRLG enable exclude-srlg 102.103.1.1

### Verifying the Flex LSP SRLG and Exclude Option

To view the SRLG values in the topology:

#### Router# show mpls traffic-eng topology 52.2.2.2

# **Flex LSP Non-Revertive 1:1 Path Protection**

Currently, MPLS-TE path protection is triggered every time a fail is detected on a working path (assuming a protect path is configured and available). Once the fail is resolved, TE switches back traffic to the working path. The process of switching back the traffic to the working path is done in a make-before-break fashion but it still does not guarantee that traffic jitter or delay is not introduced (due to different path lengths between working and protect paths). This jitter is not desirable in delay-intolerant applications like Circuit Emulation (CEM).

In Cisco IOS XE Everest 16.5.1, TE no longer switches back to the working path when the working path is restored. Instead, the protected path continues to be the working path. This behavior is achieved by configuring a specific attribute, [non-revertive], to the protecting path-options.

However, if the non-revertive option is not configured, TE switches back to the working path.

This is the sequence of actions for MPLS TE when the non-revertive protect path is configured:

- 1. Detects failure on the current path.
- 2. Switches to the protect path. The protect path now becomes the active non-revertive path (that is, the path carrying traffic).
- **3.** Signals a new path and marks it as pending. This new pending path must be diverse from the active path, only if the diverse option is configured on the protect path option.
- **4.** Re-optimizes this pending path periodically (but at the same time ensures this is diverse from the active non-revertive protect path).
- 5. Switches over to the pending path, if the active path fails [traffic is wrapped]. Marks pending path as active path. Re-signals a protect path for the new active path.
- 6. You can force traffic to a pending path by running the command **mpls traffic-eng switch non-revertive**.

In this case, the pending path becomes the current active path and the non-revertive path is re-signaled as a protect path for the new current path.

### Configuring Flex LSP Non-Revertive Path Protection

The following command is used to configure the non-revertive path protection:

```
[no] tunnel mpls traffic-eng path-option protect [preference] {diverse | explicit {identifier
[id] | name [name]} | list {identifier [id] | name [name]}} [non-revertive]
```

The following sample configuration illustrates a co-routed Flex LSP enabled with the non-revertive option:

**Note** Non-revertive must be configured on the both ends of a Flex Tunnel.

```
Router(config)# interface tunnel 1000
Router(config-if)# ip unnumbered loopback0
Router(config-if)# tunnel mode mpls traffic-eng
Router(config-if)# tunnel destination 56.6.6.6
Router(config-if)# tunnel mpls traffic-eng bidir association type co-routed fault-oam wrap
Router(config-if)# tunnel mpls traffic-eng bidir association id 1000 source 55.5.5 global
```

```
1000
Router(config-if)# tunnel mpls traffic-eng path-selection hop-limit 5
Router(config-if)# tunnel mpls traffic-eng bandwidth 200
Router(config-if)# tunnel mpls traffic-eng autoroute announce
Router (config-if)# tunnel mpls traffic-eng path-option 10 dynamic
Router(config-if)# tunnel mpls traffic-eng path-option protect 10 diverse non-revertive
lockdown
```

### Verifying Flex LSP Non-Revertive Path Protection

```
Router# show mpls traffic-eng tunnels tunnel 1000 detail
```

```
Name: Router t1000

# **Flex LSP Sticky**

Some tunnel configuration changes (for example, bandwidth) or network events (for example, link failure along the path, a higher priority LSP that preempts the current LSP, or a lockout event on a link along the path) can trigger a new LSP to be signaled. In such instances, the current LSP is switched over to the new LSP in a make-before-break manner.

If the tunnel is running on protect LSP make-before-break is not supported.

The new LSP may have a different path, and lockdown does not prevent this path change. This path change can cause packet jitter that may be unacceptable to Circuit Emulation (CEM) services.

To avoid switching over to a new LSP, a new keyword – sticky is introduced in Cisco IOS XE Everest 16.5.1.

```
tunnel mpls traffic-eng path-option 1 dynamic {lockdown {sticky}]
Router(config-if)# tunnel mpls traffic-eng path-option 1 dynamic lockdown ?
bandwidth override the bandwidth configured on the tunnel
sticky stay on the same path after change in required resources
```

You can configure lockdown as one of LSP attributes, which in turn is extended with the sticky option.

```
Router(config)#mpls traffic-eng lsp attributes EXAMPLE
Router(config-lsp-attr)#lockdown ?
   sticky stay on the same path after change in required resources
```

Note The sticky option can be configured only on the primary path option.

Once configured, the protect path option with the same path option index is also sticky. This means that either both primary and protect paths are sticky or none of them are sticky.

Use the following command in EXEC mode to manually trigger rerouting the sticky primary and protect path to override the sticky behavior:

```
mpls traffic-eng reroute {Tunnel <num>}
Router# mpls traffic-eng ?
fast-reroute fast-reroute command
reoptimize reoptimize traff-eng tunnels
reroute allow traff-eng tunnels with sticky path to reroute
setup-timer set up timer expiration
```

#### Restrictions

- A primary or protect path becomes sticky if the LSP is connected.
- If the path is for Flex LSP tunnel, the LSP must be bi-directionally connected.
- If BFD is configured, the LSP must be BFD connected.

### **Configuring Flex LSP Sticky Option**

## Ø

```
Note
```

Both ends of a Flex LSP tunnel must have the same sticky configuration.

```
interface Tunnel1000
ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 56.6.6.6
tunnel mpls traffic-eng autoroute announce
tunnel mpls traffic-eng priority 7 7
tunnel mpls traffic-eng bandwidth 200
tunnel mpls traffic-eng path-option 10 dynamic lockdown sticky
tunnel mpls traffic-eng path-option protect 10 diverse non-revertive lockdown
tunnel mpls traffic-eng bidirectional association id 1000 source-address 55.5.5.5 global-id
1000
tunnel mpls traffic-eng bidirectional association type co-routed fault-oam wrap-protection
end
```

```
Ŵ
```

Note The flex LSP sticky option also works with the primary path as an explicit path, and the protect path is dynamic.

## Verifying the Flex LSP Sticky Option

```

# Flex LSP Hop Count and Cost-Max Limit

In some scenarios, path hop count is used as an estimate of path delay between a source node and destination node.

The hop-limit is the number of nodes in the path, excluding the headend. For example, a single-hop tunnel has a headend router and a tailend router, but no mid-node routers, a two-hop tunnel has a single mid-node router and atailend router, and so on.

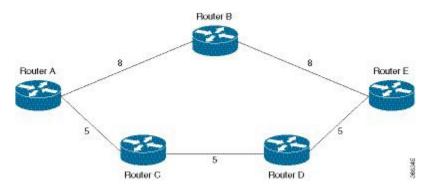

You can configure the hop-limit applicable to a specific tunnel. For example,

```
Router(config)# interface tunnel 1400
Router(config-if)# tunnel mpls traffic-eng path-selection hop-limit <1-255>
```

Consider the following simple topology with only the path cost and path hop count. The number indicated along each link segment is the link cost.

Without any hop-limit, the best path from Router A to Router E as selected by PCALC is [A, C, D, E] since this path has lower accumulated path cost than the other path [A, B, E]. If hop-limit is set to two, then the *best* path that can pass this check is [A, B, E] even though it has higher accumulated path cost.

Figure 12: Topology: Hop Count and Path Cost

## **Flex LSP Cost-Max Limit**

In some scenarios, accumulated path cost is used as an estimate for path delay between a source node and destination node. The intent is to ensure that the accumulated path cost of a chosen path is not higher than a configured limit. A cost limit check is added after the CSPF determines the best path (lowest cost path that satisfied the path request constraints) from source node to destination node, and that for path verification.

**Note** Ensure that the accumulated path cost for co-routed bidirectional LSP includes both, forward and reverse path cost.

To configure the hop-limit that is applicable to a specific tunnel, use:

```
Router(config)# interface tunnel 1400
Router(config-if)# tunnel mpls traffic-eng path-selection cost-limit <1-4294967295>
```

### Configuring Flex LSP Hop Count and Cost-Max Limit

Configure each end of the co-routed bi-directional LSP independently. Ensure that cost-limit and hop-limit on both ends are configured in the same way.

```
Router(config) # interface tunnel 1000
Router(config-if) # ip unnumbered loopback0
Router(config-if) # tunnel mode mpls traffic-eng
Router(config-if) # tunnel destination 56.6.6.6
Router(config-if) # tunnel mpls traffic-eng bidir association type co-routed fault-oam wrap
Router(config-if)# tunnel mpls traffic-eng bidir association id 1000 source 55.5.5.5 global
1000
Router(config-if) # tunnel mpls traffic-eng path-selection hop-limit 5
Router(config-if) # tunnel mpls traffic-eng bandwidth 200
Router (config-if) # tunnel mpls traffic-eng autoroute announce
Router(config-if) # tunnel mpls traffic-eng path-option 10 dynamic
Router(config) # interface tunnel 3000
Router(config-if) # ip unnumbered loopback0
Router(config-if) # tunnel mode mpls traffic-eng
Router(config-if) # tunnel destination 56.6.6.6
Router (config-if) # tunnel mpls traffic-eng bidir association type co-routed fault-oam wrap
Router(config-if) # tunnel mpls traffic-eng bidir association id 3000 source 55.5.5.5 global
3000
Router(config-if)# tunnel mpls traffic-eng path-selection cost-limit 50
Router(config-if) # tunnel mpls traffic-eng bandwidth 200
Router(config-if) # tunnel mpls traffic-eng autoroute announce
Router(config-if) # tunnel mpls traffic-eng path-option 10 dynamic
```

## **Verifying Flex LSP Hop Count and Cost-Max Limit**

Router# show mpls traffic-eng tunnels tunnel 1000 detail

Hop Limit: disabled
Cost Limit: 50
```

The accumulated path cost for co-routed bidirectional LSP includes both, forward and reverse path cost.

# Flex LSP ECMP min-fill, max-fill, random

MPLS TE chooses the least utilized path given the same accumulated path cost and hop count. However, in Cisco IOS XE Everest 16.5.1, you can steer traffic to an alternate path, depending on:

Tie-breaker 1: min-fill (choose least-utilized path)

- Smaller path cost value
- Larger path minimum bandwidth
- Smaller hop count value
- Lexicographically selects a greater path bandwidth vector (bandwidth value is sorted in ascending order)

Tie-breaker 2: max-fill (choose most-utilized path)

- Smaller path cost value
- Smaller path minimum bandwidth
- Smaller hop count value
- Lexicographically selects a smaller path bandwidth vector (bandwidth value is sorted in ascending order)

Tie-breaker 3: random

- Smaller path cost value
- · Smaller hop count value
- Randomly selects a path regardless of the path bandwidth value (as long as it satisfies the request constraints)

The key decision criterion is still path cost; the tie-breakers evaluate, in sequence, until a path is selected. The random tie-breaker does not take the available link bandwidth into consideration.

### Configuring Flex LSP ECMP min-fill and max-fill

ECMP can be configured globally or specifically to a tunnel. Tunnel specific configuration override the global tiebreaker selection. The default selection algorithm is min-fill.

For a Flex LSP co-routed tunnel, the same path-selection tiebreaker should be configured on each end of the bi-directional LSP.

#### **Global Configuration Command**

```
Router(config)# mpls traffic-eng path-selection tiebreaker ?
max-fill Use max-fill tiebreaker
```

min-fill Use min-fill tiebreaker
random Use random tiebreaker

Use the **no mpls traffic-eng path-selection tiebreaker** command to remove the global configuration.

#### **Tunnel-Specific Configuration Commands**

Configure path selection tiebreaker that is applicable to a specific tunnel. Tunnel specific configuration override global tiebreaker configuration.

```
Router(config)# interface tunnel 1400
Router(config-if)# tunnel mpls traffic-eng path-selection tiebreaker ?
max-fill Use max-fill tiebreaker
min-fill Use min-fill tiebreaker
random Use random tiebreaker
```

Use the **no tunnel mpls traffic-eng path-selection tiebreaker** command to remove the tunnel-specific configuration.

```
Router(config) # interface tunnel 2000
Router(config-if) # ip unnumbered loopback0
Router(config-if) # tunnel mode mpls traffic-eng
Router(config-if) # tunnel destination 56.6.6.6
Router (config-if) # tunnel mpls traffic-eng bidir association type co-routed fault-oam wrap
Router(config-if) # tunnel mpls traffic-eng bidir association id 2000 source 55.5.5.5 global
2000
Router(config-if) # tunnel mpls traffic-eng path-select tie min-fill
Router(config-if) # tunnel mpls traffic-eng bandwidth 5000
Router(config-if) # tunnel mpls traffic-eng autoroute announce
Router(config-if) # tunnel mpls traffic-eng path-option 10 dynamic
Router(config) # interface tunnel 2000
Router(config-if) # ip unnumbered loopback0
Router(config-if) # tunnel mode mpls traffic-eng
Router(config-if) # tunnel destination 56.6.6.6
Router (config-if) # tunnel mpls traffic-eng bidir association type co-routed fault-oam wrap
Router(config-if) # tunnel mpls traffic-eng bidir association id 2000 source 55.5.5.5 global
2000
Router (config-if) # tunnel mpls traffic-eng path-select tie max-fill
Router(config-if) # tunnel mpls traffic-eng bandwidth 5000
Router(config-if) # tunnel mpls traffic-eng autoroute announce
Router(config-if) # tunnel mpls traffic-eng path-option 10 dynamic
```

### Verifying the Flex LSP ECMP min-fill and max-fill

#### **Global Commands**

To display the current global tiebreaker value.

- If the global tiebreaker is not set, the effective tiebreaker is the default setting (min-fill).
- If the global tiebreaker is set, it is the effective tiebreaker as well.

#### Router# show mpls traffic-eng path-selection tiebreaker

#### **Tunnel-Specific Commands**

To display current tiebreaker configuration of a tunnel:

Router# show mpls traffic-end	-	=	
Tunnel Name		unnel Specific ax-fill	
Router_t1400	not set in	dx-1111	Illax-1111
To display the tiebreaker:			
Router# show mpls traffic-end	g tunnels tun	nel 2000 detail	
Name: Router_t2000 Status:		(Tunnel2000)	Destination: 56.6.6.6
Admin: up Oper: n path option 10, type dyna Lockout Info: Locked Out: No	-	-	-
Config Parameters: Bandwidth: 5000 kbps	(Clobal) Dr	ionitus 7 7 Af	finitus 0.0 (Ourrer
Metric Type: TE (default)		IOTILY: / / AI	.linity: 0x0/0xFFFF
Path-selection Tiebreake:	r:		
<b>Global: not set Tunne</b> Hop Limit: 5 Cost Limit: disabled	-		
Path-invalidation timeou AutoRoute: enabled Lock auto-bw: disabled Association Type: Single	Down: disable	d Loadshare: 5000	) [400000] bw-based
	SERVE DEGILO		

Use the **debug mpls traffic-eng path ecmp** command to display the ECMP-related debug information, such as for BWV comparison when all other tiebreakers failed to yield a selected path. Use this command in conjunction with the **debug mpls traffic-eng path spf** or **debug mpls traffic-eng path lookup** commands.

## **Restore Path Option**

The restore path option signals a restore LSP after the double failure of both, primary and protect LSPs. The restore LSP is signaled only after both, primary and protect LSPs fail or are administratively down and it is destroyed when the primary LSP comes back up. If the sticky option is configured, and both, primary and protect LSPs fail, restore LSP is destroyed when either the primary or protect LSP comes up. Also, restore LSP can be SRLG capable if it is configured.

Note

Traffic loss is expected and acceptable until the restore LSP is signaled and established.

When the primary LSP recovers, traffic is automatically switched back to the primary LSP (make-before-break scenario) and restore LSP is torn down. If the sticky option is configured in the path option, protect LSP can recover before the primary LSP. In this case, traffic reverted to the protect LSP and the restore LSP is torn down.

To enable restore LSP for a tunnel, configure the restore path option under the tunnel interface using the command:

tunnel mpls traffic-eng path-option restore <index> [dynamic | explicit]

Multiple restore path options can be configured on a tunnel. However, only the restore path option with the same index as the path option used by primary LSP is used for establishing the restore LSP. For example, after primary and protect LSPs associated with the path option index X are administratively down, restore LSP is signaled using the restore path option with index X, if it is configured. Else, no restore LSP is signaled.

Note

Restore path option is supported for unidirectional, bidirectional co-routed, or non co-routed tunnels. It is not supported for lockout, sticky, and non-revertive modes.

### **Configuring the Restore Path Option**

```
tunnel mpls traffic-eng path-option restore <index> [dynamic | explicit]
Router(config-if)# tunnel mpls traffic-eng path-option ?
    <1-1000> preference for this path option
    protect a path protection setup option
    restore a path restore setup option
```

### Verifying the Restore Path Option

The following is an example of the information displayed for the tunnel when restore LSP is carrying traffic:

```
Router# show mpls traffic-eng tunnels Tunnel 100
Name: iolA t100
                                           (Tunnel100) Destination: 192.168.1.4
  Status:

# **Re-optimization with Tunnel Bandwidth Modification on Flex-LSP Protect Path**

#### **Table 16: Feature History**

Feature Name	Release Information	Description
Re-optimization with Tunnel Bandwidth Modification on Flex-LSP Protect Path	Cisco IOS XE Bengaluru 17.4.1	This feature supports Make Before Break (MBB) functionality and thus ensures there is no traffic loss when a MPLS Flex LSP tunnel runs on protect LSP (if working LSP goes down) and the tunnel bandwidth is modified. When the working LSP comes up, use the following command to manually switch from the working to protect LSP: <b>mpls traffic-eng switch tunnel</b>
		tunnel-ID

Prior to Cisco IOS XE Bengaluru Release 17.4.1, when a MPLS Flex LSP tunnel used to run on the protect LSP (when the working LSP would go down) and the tunnel bandwidth was modified, the existing LSP was replaced by a new LSP. The new LSP reflected the tunnel bandwidth, but there was a traffic loss of two seconds. This happened because Make Before Break (MBB) functionality was only supported on the working LSP and not on the protect LSP.

Starting with Cisco IOS XE Bengaluru Release 17.4.1, the MBB functionality is supported on the protect LSP. Thus, when a working LSP goes down, the tunnel does not break and continues with the old bandwidth. You need to manually bring up the working LSP to experience the new bandwidth. When the working LSP comes up, use the following command to manually switch from the working to the protect LSP:

#### mpls traffic-eng switch tunnel tunnel-ID.

This configuration switches the traffic from protect to working. Thus, both the working and protect LSP reflect the new bandwidth. This in turn ensures no traffic loss.

# **Configuration Example: Flex LSP MBB Support on Protect Path**

### **Prerequisites of Configuration**:

- You must configure the Flex LSP tunnel as sticky and non-revertive.
- The tunnel must run on the protect LSP and not on the working LSP.

The following example shows the Flex LSP MBB on protect path configuration:

```
Router#show run interface tunnel2200
interface Tunnel2200
 ip unnumbered Loopback1
 tunnel mode mpls traffic-eng
 tunnel destination 21.21.21.21
 tunnel mpls traffic-eng path-option 1 dynamic attributes modern-plane1-sticky
 tunnel mpls traffic-eng path-option protect 1 diverse non-revertive lockdown attributes
modern-plane1-sticky
 tunnel mpls traffic-eng path-option restore 1 dynamic
tunnel mpls traffic-eng bidirectional association id 2200 source-address 2.2.0.1 global-id
2200
tunnel mpls traffic-eng bidirectional association type co-routed fault-oam wrap-protection
 tunnel mpls traffic-eng bfd encap-mode gal FlexBfd
end
Router#show run | s modern-plane1-sticky
mpls traffic-eng lsp attributes modern-plane1-sticky
lockdown sticky
Router#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
