Cisco IOS Voice Commands: A

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the Cisco IOS Master Commands List online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Library.*

aal2-profile custom

To specify custom numbers and user-to-user information (UUI) code points for ATM adaptation layer 2 (AAL2) profiles and codecs, use the **aal2-profile custom** command in global configuration mode. To disable the configuration, use the **no** form of this command.

aal2-profile custom *number number number* {**clear-channel | g711alaw | g711ulaw | g726r32 | g729br8 | g720r8 | llcc**} *packet-length minimum-UUI-codepoint maximum-UUI-codepoint*

no aal2-profile custom *number*

Syntax Description

number	AAL profile number. For more information, use the question mark (?) online help function.
clear-channel | g711alaw | g711ulaw | g726r32 | g729br8 | g720r8 | llcc	Specifies the types of codec as follows: • Clear Channel • G.711 a-law • G.711-mu-law • G.726r32 • G.729 ANNEX-B 8000 bits per second • G.729 8000 bps • Lossless Compression
packet-length	Packet length in octets. The range is from 5 to 64.
minimum-UUI-codepoint	Minimim UUI code point. The range is from 0 to 15.
maximum-UUI-codepoint	Maximum UUI code point. The range is from 0 to 15.

Command Default

One of the predefined International Telecommunication Union - Telecommunication Standardization Sector (ITU-T) profiles can be used.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines

AAL2 custom profiles are used to define additional profiles that are not present in the ITU-T specifications.

After defining a custom profile, apply that profile under a Voice over ATM (VoATM) dial peer for it to take affect using the **codec aal2-profile** command. The **codec aal2-profile** command can be used only if the session protocol is "aal2-trunk".

Examples

The following example shows how to specify custom numbers and UUI cod epoints for AAL2 profiles and codecs:

```
Router# configure terminal
Router(config)# aal2-profile custom  2 1 1 g711ulaw 6 3 3
```

aaa nas port voip

To send out the standard NAS-port attribute (RADIUS IETF Attribute 5) on voice interfaces, use the **aaa nas port voip** command in global configuration mode. To disable the command, use the **no** form of the command.

aaa nas port voip

no aaa nas port voip

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco AS5300.

Usage Guidelines This command brings back the original behavior of the Authentication, Authorization, and Accounting (AAA). NAS-Port on VoIP interfaces. By default this feature is disabled.

Examples The following example shows how to return to the original behavior of the AAA NAS-Port:

```
aaa nas port voip
```

Related Commands

Command	Description
aaa nas port extended	Replaces the NAS-port attribute with RADIUS IETF attribute 26 and displays extended field information.

aaa username

To determine the information with which to populate the username attribute for Authentication, Authorization, and Accounting (AAA). billing records, use the **aaa username** command in SIP UA configuration mode. To achieve default capabilities, use the **no** form of this command.

aaa username {**calling-number** | **proxy-auth**}

no aaa username

Syntax Description

calling-number	Uses the FROM: header in the SIP INVITE (default value). This keyword is used in most implementations.
proxy-auth	Parses the Proxy-Authorization header. Decodes the Microsoft Passport user ID (PUID) and password, and then populates the PUID into the username attribute and a "." into the password attribute. The username attribute is used for billing, and the "." is used for the password, because the user has already been authenticated before this point.

Command Default **calling-number**

Command Modes SIP UA configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco AS5300, Cisco AS5350, and the Cisco AS5400.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 in this release.
12.2(11)T	This command was integrated Cisco IOS Release 12.2(11)T and was implemented on the Cisco AS5850. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800 in this release.

Usage Guidelines Parsing the Proxy-Authorization header, decoding the PUID and password, and populating the username attribute with the PUID must be enabled through this command. If this command is not issued, the Proxy-Authorization header is ignored.

The keyword **proxy-auth** is a nonstandard implementation, and Session Initiation Protocol (SIP) gateways do not normally receive or process the Proxy-Authorization header.

Examples

The following example enables the processing of the SIP username from the Proxy-Authorization header:

```
Router(config)# sip-ua
Router(config-sip-ua)# aaa username proxy-auth
```

Related Commands

Command	Description
show call active voice	Displays sactive call information for voice calls or fax transmissions in progress.
show call history voice	Displays the voice call history table.

access-list (voice source-group)

To assign an access list to a voice source group, use the **access-list** command in voice source-group configuration mode. To delete the access list, use the **no** form of this command.

access-list *access-list-number*

no access-list *access-list-number*

Syntax Description

access-list-number	Number of an access list. The range is from 1 to 99.

Command Default

No default behavior or values

Command Modes

Voice source-group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced in voice source-group configuration mode.

Usage Guidelines

An access list defines a range of IP addresses for incoming calls that require additional scrutiny. Two related commands are used for voice source groups:

- Use the **access-list** *access-list-number* {**deny** | **permit**} *source* [*source-wildcard*] [**log**] command in global configuration mode to define the contents of the access list.
- Use the **access-list** *access-list-number* command in voice source-group configuration mode to assign the defined access list to the voice source group.

The terminating gateway uses the source IP group to identify the source of the incoming VoIP call before selecting an inbound dial peer. If the source is found in the access list, then the call is accepted or rejected, depending on how the access list is defined.

The terminating gateway uses the access list to implement call blocking. If the call is rejected, the terminating gateway returns a disconnect cause to the source. Use the **disconnect-cause** command to specify a disconnect cause to use for rejected calls.

Use the **show access-lists** privileged EXEC command to display the contents of all access lists.

Use the **show ip access-lis**t privileged EXEC command to display the contents of one access list.

Examples

The following example assigns access list 1 to voice source-group alpha. Access list 1 was defined previously using another command. An incoming source IP group call is checked against the conditions defined for access list 1 and is processed based on the permit or deny conditions of the access list.

```
Router(config)# voice source-group alpha
Router(cfg-source-grp)# access-list 1
```

Related Commands

Command	Description
carrier-id (dial peer)	Specifies the carrier as the source of incoming VoIP calls (for carrier ID routing).
disconnect-cause	Specifies a cause for blocked calls.
h323zone-id (voice source group)	Associates a zone for an incoming H.323 call.
show access-lists	Displays the contents of all access lists.
show ip access-list	Displays the contents of one access list.
translation-profile (source group)	Associates a translation profile with incoming source IP group calls.
trunk-group-label (voice source group)	Specifies the trunk group as the source of incoming VoIP calls (for trunk group label routing).
voice source-group	Initiates the source IP group profile definition.

access-policy

To require that a neighbor be explicitly configured in order for requests to be accepted, use the **access-policy** command in Annex G configuration mode. To reset the configuration to accept all requests, use the **no** form of this command.

access-policy [**neighbors-only**]

no access-policy

Syntax Description

neighbors-only	(Optional) Requires that a neighbor be configured.

Command Default

Border elements accept any and all requests if service relationships are not configured.

Command Modes

Annex G configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

Border elements accept any and all requests if service relationships are not configured. The **access-policy** command eliminates arbitrary requests from unknown border elements, and is a required prerequisite for configuring service relationships.

Examples

The following example shows how to enable the service relationship between border elements:

```
Router(config-annexg)# access-policy neighbors-only
```

Related Commands

Command	Description
call-router	Enables the Annex G border element configuration commands.
domain-name	Sets the domain name reported in service relationships.

accounting (gatekeeper)

To enable and define the gatekeeper-specific accounting method, use the **accounting** command in gatekeeper configuration mode. To disable gatekeeper-specific accounting, use the **no** form of this command.

accounting {**username h323id** | **vsa**}

no accounting

Syntax Description

username h323id	Enables H323ID in the user name field of accounting record.
vsa	Enables the vendor specific attribute accounting format.

Command Default Accounting is disabled.

Command Modes Gatekeeper configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.1(5)XM	The **vsa** keyword was added.
12.2(2)T	The **vsa** keyword was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850 universal gateway.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.3(9)T	This **username h323id** keyword was added.

Usage Guidelines To collect basic start-stop connection accounting data, the gatekeeper must be configured to support gatekeeper-specific H.323 accounting functionality. The **accounting** command enables you to send accounting data to the RADIUS server via IETF RADIUS or VSA attriibutes.

Specify a RADIUS server before using the **accounting** command.

There are three different methods of accounting. The H.323 method sends the call detail record (CDR) to the RADIUS server, the syslog method uses the system logging facility to record the CDRs, and the VSA method collects VSAs.

Examples The following example enables the gateway to report user activity to the RADIUS server in the form of connection accounting records:

```
aaa accounting connection start-stop group radius
gatekeeper
 accounting
```

The following example shows how to enable VSA accounting:

```
aaa accounting connection start-stop group radius
gatekeeper
 accounting exec vsa
```

The following example configures H.323 accounting using IETF RADIUS attributes:

```
Router(config-gk)# accounting username h323id
```

The following example configures H.323 accounting using VSA RADIUS attributes:

```
Router(config-gk)# accounting vsa
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes.
gatekeeper	Enters gatekeeper configuration mode.

accounting method

To set an accounting method at login for calls that come into a dial peer, use the **accounting method** command in voice class AAA configuration mode. To disable the accounting method set at login, use the **no** form of this command.

accounting method *MethListName* [**out-bound**]

no accounting method *MethListName* [**out-bound**]

Syntax Description

MethListName	Defines an accounting method list name.
out-bound	(Optional) Defines the outbound leg.

Command Default

When this command is not used to specify an accounting method, the system uses the **aaa accounting connection h323** command as the default. If the method list name is not specified, the outbound call leg uses the same method list name as the inbound call leg

Command Modes

Voice class AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

This command sets the accounting method for dial peers in voice class AAA configuration mode. To initially define a method list, refer to the *Cisco IOS Security Configuration Guide,* Release 12.2.

If the outbound option is specified, the outbound call leg on the dial peer uses the method list name specified in the command. If the method list name is not specified, by default, the outbound call leg uses the same method list name as the inbound call leg.

Examples

The following example sets the dp-out method for the outbound leg:

```
voice class aaa 1
 accounting method dp-out out-bound
```

Related Commands

Command	Description
aaa accounting connection h323	Defines the accounting method list H.323 with RADIUS, using **stop-only** or **start-stop** accounting options.
voice class aaa	Enables dial-peer-based VoIP AAA configurations.

accounting suppress

To disable accounting that is automatically generated by a service provider module for a specific dial peer, use the **accounting suppress** command in voice class AAA configuration mode. To allow accounting to be automatically generated, use the **no** form of this command.

accounting suppress [**in-bound** | **out-bound**]

no accounting suppress [**in-bound** | **out-bound**]

Syntax Description

in-bound	(Optional) Defines the call leg for incoming calls.
out-bound	(Optional) Defines the call leg for outbound calls.

Command Default

Accounting is automatically generated by the service provider module.

Command Modes

Voice class AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

If a call leg option is not specified by the command, accounting is disabled for both inbound and outbound calls. For accounting to be automatically generated in the service provider module, you must first configure **gw-accounting aaa** command in global configuration mode before configuring dial-peer-based accounting in voice class AAA configuration mode.

Examples

In the example below, accounting is suppressed for the incoming call leg.

```
voice class aaa 1
 accounting suppress in-bound
```

Related Commands

Command	Description
gw-accounting aaa	Enables VoIP gateway accounting.
suppress	Turns off accounting for a call leg on a POTS or VoIP dial peer. This command is used in gw-accounting aaa configuration mode.
voice class aaa	Enables dial-peer-based VoIP AAA configurations.

accounting template

To allow each dial peer to choose and send a customized accounting template to the RADIUS server, use the **accounting template** command in voice class AAA configuration mode. To disable the dial peer from choosing and sending a customized accounting template, use the **no** form of this command.

accounting template *acctTempName* [**out-bound**]

no accounting template *acctTempName* [**out-bound**]

Syntax Description

acctTempName	Defines an accounting template name.
out-bound	(Optional) Defines the outbound leg.

Command Default

The dial peer does not choose and send a customized accounting template to the RADIUS server.

Command Modes

Voice class AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

By default, non-RFC-mandatory vendor-specific attributes (VSAs) are not included in accounting records if you do not configure the accounting template. The accounting template enables you to manage accounting records at a per-VSA level. When an accounting template is used for customizing the accounting record, the VSA name release source has to be included in the template file so that it is included in the accounting record and sent to the RADIUS server.

This command overrides the **acct-template** command in gateway accounting AAA configuration mode when a customized accounting template is used.

If you use a Tool Command Language (Tcl) script, the Tcl verb **aaa accounting start** [**-t acctTempName**] takes precedence over the **accounting template** command in voice class AAA configuration mode.

Examples

The following example sets the template temp-dp for the outbound leg

```
voice class aaa 1
 accounting template temp-dp out-bound
```

Related Commands

Command	Description
acct-template	Sends a selected group of voice accounting VSAs.
voice class aaa	Enables dial-peer-based VoIP AAA configurations.

acc-qos

To define the acceptable quality of service (QoS) for any inbound and outbound call on a VoIP dial peer, use the **acc-qos** command in dial peer configuration mode. To restore the default QoS setting, use the **no** form of this command.

acc-qos {**best-effort** | **controlled-load** | **guaranteed-delay**} [**audio** | **video**]

no acc-qos

Syntax Description

best-effort	Indicates that Resource Reservation Protocol (RSVP) makes no bandwidth reservation. This is the default.
controlled-load	Indicates that RSVP guarantees a single level of preferential service, presumed to correlate to a delay boundary. The controlled load service uses admission (or capacity) control to ensure that preferential service is received even when the bandwidth is overloaded.
guaranteed-delay	Indicates that RSVP reserves bandwidth and guarantees a minimum bit rate and preferential queueing if the bandwidth reserved is not exceeded.
audio	(Optional) Configures acceptable QoS for audio traffic.
video	(Optional) Configures acceptable QoS for video traffic.

Command Default **best-effort**

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series routers.
12.1(5)T	The description of the command was modified.
12.3(4)T	The **audio** and **video** keywords were added.

Usage Guidelines This command is applicable only to VoIP dial peers.

When VoIP dial peers are used, the Cisco IOS software uses RSVP to reserve a certain amount of bandwidth so that the selected QoS can be provided by the network. Call setup is aborted if the RSVP resource reservation does not satisfy the acceptable QoS for both peers.

To select the most appropriate value for this command, you need to be familiar with the amount of traffic this connection supports and what kind of impact you are willing to have on it. The Cisco IOS software generates a trap message when the bandwidth required to provide the selected quality of service is not available.

If **audio** or **video** is not configured, the bearer capability information element (IE) is not checked against max values during SETUP.

You must use the **ip rsvp bandwidth** command to enable RSVP on an IP interface before you can specify RSVP QoS.

In order to use this command, you have to have the **req-qos** statement present.

Examples

The following example selects **guaranteed-delay** as the acceptable QoS for inbound and outbound audio calls on VoIP dial peer 10:

```
dial-peer voice 10 voip
 acc-qos guaranteed-delay
```

The following example selects **controlled-load** as the acceptable QoS for audio and video:

```
dial-peer voice 100 voip
 acc-qos controlled-load audio
 acc-qos controlled-load video
```

Related Commands

Command	Description
req-qos	Requests a particular QoS using RSVP to be used in reaching a specified dial peer in VoIP.

acct-template

To select a group of voice attributes to collect in accounting records, use the **acct-template** command in gateway accounting AAA or gateway accounting file configuration mode. To disable collection of a group of voice attributes, use the **no** form of this command.

acct-template {*template-name* | **callhistory-detail**}

no acct-template {*template-name* | **callhistory-detail**}

Syntax Description

template-name	Name of the custom accounting template.
callhistory-detail	Collects all voice vendor-specific attributes (VSAs) for accounting.

Command Default

No voice attributes are collected.

Command Modes

Gateway accounting AAA configuration (config-gw-accounting-aaa)
Gateway accounting file configuration (config-gw-accounting-file)

Command History

Release	Modification
12.2(11)T	This command was introduced.
12.4(15)XY	This command was added to gateway accounting file configuration mode.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use this command to collect only the voice attributes that are defined in an accounting template. The accounting template is a text file that you create by selecting specific attributes that are applicable to your billing needs. Use the **call accounting-template voice** command to define your accounting template before using the **acct-template** command.

The **show call accounting-template voice master** command displays all the voice attributes that can be filtered by accounting templates.

Use the **callhistory-detail** keyword to send all voice VSAs to the accounting server. For a description of supported voice VSAs, see the "VSAs Supported by Cisco Voice Products" section in the *RADIUS VSA Voice Implementation Guide*.

When you send only those VSAs defined in your accounting template, the default call-history records that are created by the service provider are automatically suppressed.

Examples

The example below uses the **acct-template** command to specify temp-global, a custom template.

```
gw-accounting aaa
 acct-template temp-global
```

Related Commands

Command	Description
call accounting-template voice	Defines a customized accounting template.
gw-accounting	Enables the method of collecting accounting data.
show call accounting-template voice	Displays attributes defined in accounting templates.

activation-key

To define an activation key that can be dialed by phone users to activate Call Back on Busy on an analog phone, use the **activation-key** command in STC application feature callback configuration mode. To return the code to its default, use the **no** form of this command.

activation-key *string*

no activation-key

Syntax Description

string	Character string that can be dialed on a telephone keypad (0-9, *, #). Length of string is one to five characters. Default: #1.

Command Default Callback activation key is #1.

Command Modes STC application feature callback configuration (config-stcapp-callback)

Command History

Release	Modification
12.4(20)YA	This command was introduced.
12.4(22)T	This command was integrated into Cisco IOS Release 12.4(22)T.

Usage Guidelines This command changes the value of the callback activation key for Call Back on Busy from the default (#1) to the specified value.

To display information about the Call Back configuration, use the **show stcapp feature codes** command.

Examples The following example shows how to change the value of the callback activation key sequence from the default (#1) to a new value (*22).

```
Router(config)# stcapp feature callback
Router(config-stcapp-callback)# activation-key *22
Router(config-stcapp-callback)#
```

The following partial output from the **show stcapp feature codes** command displays values for the call back feature:

```
Router# show stcapp feature codes

.
.
.

  stcapp feature callback
    key *1
    timeout 30
```

Related Commands

Command	Description
ringing-timeout	Defines the timeout period for Callback on Busy.
show stcapp feature codes	Displays all feature codes for FACs, FSDs, and call back.

address-family (tgrep)

To set the global address family to be used on all dial peers, use the **address-family** command in TGREP configuration mode. To change back to the default address family, use the **no** form of this command.

address family {**e164** | **decimal** | **penta-decimal**}

no address family {**e164** | **decimal** | **penta-decimal**}

Syntax Description

e164	E.164 address family.
decimal	Digital address family.
penta-decimal	Pentadecimal address family.

Command Default E.164 address family

Command Modes TGREP configuration

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines The E. 164 address family is used if the telephony network is a public telephony network. Decimal and pentadecimal options can be used to advertise private dial plans. For example, if a company wants to use TRIP in within its enterprise telephony network using five-digit extensions, then the gateway would advertise the beginning digits of the private numbers as a decimal address family. These calls cannot be sent out of the company's private telephony network because they are not E.164-compliant.

The pentadecimal family allows numbers 0 through 9 and alphabetic characters A through E and can be used in countries where letters are also carried in the called number.

Examples The following example shows that the address family for itad 1234 is set for E.164 addresses:

```
Router(config)# tgrep local-itad 1234
Router(config-tgrep)# address family e164
```

Related Commands

Command	Description
tgrep local-itad	Enters TGREP configuration mode and defines an ITAD.

address-hiding

To hide signaling and media peer addresses from endpoints other than the gateway use the **address-hidding** command in voice-service configuration mode. To allow the peer address known to all endpoints, use the **no** form of this command.

address-hiding

no address-hiding

Syntax Description There are no keywords or aruguments.

Command Default Signaling and media addresses are visable to all endpoints.

Command Modes Voice-service configuration mode

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines All SIP methods/messages should terminate at IP-to-IP gateway and re-originate with IP-to-IP gateway address, address hiding makes the peer address known only to the IP-to-IP gateway. Hiding address in flow-through mode is required for SIP-to-SIP in an IP-to-IP gateway network.

Note Distinctive ringing headers include ringing information and server address where the ring tone can be optained. These headers will be forwarded as is to the peer side even if address hiding is enabled.

Examples The following example show address-hiding being configured for all VoIP calls:

```
Router(config)# voice service voip
Router(config-voi-serv) address-hiding
```

Related Commands

Command	Description
voice service	Enters voice-service configuration mode.

advertise (annex g)

To control the types of descriptors that the border element (BE) advertises to its neighbors, use the **advertise** command in Annex G configuration mode. To reset this command to the default value, use the **no** form of this command.

advertise [**static** | **dynamic** | **all**]

no advertise

Syntax Description

static	(Optional) Only the descriptors provisioned on this BE is advertised. This is the default.
dynamic	(Optional) Only dynamically learned descriptors is advertised.
all	(Optional) Both static and dynamic descriptors is advertised.

Defaults

Static

Command Modes

Annex G configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300 universal access server, Cisco AS5350, Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850 universal gateway.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples

The following example configures a BE that advertises both static and dynamic descriptors to its neighbors:

```
Router(config)# call-router h323-annexg be20
Router(config-annexg)# advertise all
```

Related Commands

Command	Description
call-router	Enables the Annex G border element configuration commands.
show call history	Displays the routes stored in cache for the BE.
show call-router status	Displays the Annex G BE status.

advertise (tgrep)

To turn on reporting for a specified address family, use the **advertise** command in TGREP configuration mode. To turn off reporting for a specified address family, use the **no** form of this command.

advertise {**e164 | decimal | penta-decimal** }[**csr**][**ac**][**tc**][**trunk-group | carrier**]

advertise {**trunk-group | carrier**}[**csr**][**ac**][**tc**]

no advertise {**e164 | decimal | penta-decimal | trunk-group | carrier**}

Syntax Description

e164	E.164 address family.
decimal	Decimal address family
penta-decimal	Penta-decimal address family
trunk-group	Trunk group address family
carrier	Carrier code address family
csr	Call success rate
ac	Available circuits
tc	Total circuits

Command Default No attributes for address families are advertised.

Command Modes TGREP configuration

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines If you specify **e164**, **decimal** or **penta-decimal** for the address family, you can stipulate whether the related **carrier** or **trunk-group** parameters are advertised. If you stipulate **carrier** or **trunk-group** for the address family, you can stipulate that the related address family prefix is advertised. If you stipulate **carrier** or **trunk-group** for the address family, you cannot stipulate **carrier** or **trunk-group** attributes for advertising.

When the **no** version of this command is used, it turns off the advertisement of that particular address family altogether.

Examples The following example shows that the E.164 address family with call success rate, available circuits, total circuits, and trunk group attributes is being advertised for ITAD 1234:

```
Router(config)# tgrep local-itad 1234
Router(config-tgrep)# advertise e164 csr ac tc trunk-group
```

Related Commands

Command	Description
tgrep local-itad	Enters TGREP configuration mode and defines an ITAD.

alarm-trigger

To configure a T1 or E1 controller to send an alarm to the public switched telephone network (PSTN) or switch if specified T1 or E1 DS0 groups are out of service, use the **alarm-trigger** command in controller configuration mode. To configure a T1 or E1 controller not to send an alarm, use the **no** form of this command.

alarm-trigger blue *ds0-group-list*

no alarm-trigger

Syntax Description

blue	Specifies the alarm type to be sent is "blue," also known as an Alarm Indication Signal (AIS).
ds0-group-list	Specifies the DS0 group or groups to be monitored for permanent trunk connection status or busyout status.

Command Default

No alarm is sent

Command Modes

Controller configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600, Cisco 3600, and Cisco MC3810.

Usage Guidelines

Any monitored time slot can be used for either permanent trunk connections or switched connections. Permanent virtual circuits (PVCs) and switched virtual circuits (SVCs) can be combined on a T1 or E1 controller and monitored for alarm conditioning.

An alarm is sent only if all of the time slots configured for alarm conditioning on a T1 or E1 controller are out of service. If one monitored time slot remains in service or returns to service, no alarm is sent.

Examples

The following example configures T1 0 to send a blue (AIS) alarm if DS0 groups 0 and 1 are out of service:

```
controller t1 0
 alarm-trigger blue 0,1
 exit
```

Related Commands

Command	Description
busyout monitor	Configures a voice port to monitor an interface for events that would trigger a voice-port busyout.
connection trunk	Creates a permanent trunk connection (private line or tie-line) between a voice port and a PBX.
voice class permanent	Creates a voice class for a Cisco or FRF-11 permanent trunk.

alias static

To create a static entry in the local alias table, use the **alias static** command in gatekeeper configuration mode. To remove a static entry, use the **no** form of this command.

alias static *ip-signaling-addr* [*port*] **gkid** *gatekeeper-name* [**ras** *ip-ras-addr port*] [**terminal | mcu | gateway** {**h320 | h323-proxy | voip**}] [**e164** *e164-address*] [**h323id** *h323-id*]

no alias static *ip-signaling-addr* [*port*] **gkid** *gatekeeper-name* [**ras** *ip-ras-addr port*] [**terminal | mcu | gateway** {**h320 | h323-proxy | voip**}] [**e164** *e164-address*] [**h323id** *h323-id*]

Syntax Description

ip-signaling-addr	IP address of the H.323 node, used as the address to signal when establishing a call.
port	(Optional) Port number other than the endpoint Call Signaling well-known port number (1720).
gkid *gatekeeper-name*	Name of the local gatekeeper of whose zone this node is a member.
ras *ip-ras-addr*	(Optional) Node remote access server (RAS) signaling address. If omitted, the *ip-signaling-addr* parameter is used in conjunction with the RAS well-known port.
port	(Optional) Port number other than the RAS well-known port number (1719).
terminal	(Optional) Indicates that the alias refers to a terminal.
mcu	(Optional) Indicates that the alias refers to a multiple control unit (MCU).
gateway	(Optional) Indicates that the alias refers to a gateway.
h320	(Optional) Indicates that the alias refers to an H.320 node.
h323-proxy	(Optional) Indicates that the alias refers to an H.323 proxy.
voip	(Optional) Indicates that the alias refers to VoIP.
e164 *e164-address*	(Optional) Specifies the node E.164 address. This keyword and argument can be used more than once to specify as many E.164 addresses as needed. Note that there is a maximum number of 128 characters that can be entered for this address. To avoid exceeding this limit, you can enter multiple **alias static** commands with the same call signaling address and different aliases.
h323id *h323-id*	(Optional) Specifies the node H.323 alias. This keyword and argument can be used more than once to specify as many H.323 identification (ID) aliases as needed. Note that there is a maximum number of 256 characters that can be entered for this address. To avoid exceeding this limit, you can enter multiple **alias static** commands with the same call signaling address and different aliases.

Command Default No static aliases exist.

Command Modes Gatekeeper configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on the Cisco 2500 series and Cisco 3600 series.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines

The local alias table can be used to load static entries by performing as many of the commands as necessary. Aliases for the same IP address can be added in different commands, if required.

Typically, static aliases are needed to access endpoints that do not belong to a zone (that is, they are not registered with any gatekeeper) or whose gatekeeper is inaccessible.

Examples

The following example creates a static terminal alias in the local zone:

```
zone local gk.zone1.com zone1.com
alias static 192.168.8.5 gkid gk.zone1.com terminal e164 14085551212 h323id terminal1
```

allow-connections

To allow connections between specific types of endpoints in a VoIP network, use the **allow-connections** command in voice service configuration mode. To refuse specific types of connections, use the **no** form of this command.

allow-connections *from-type* **to** *to-type*

no allow-connections *from-type* **to** *to-type*

Syntax Description

from-type	Originating endpoint type. The following choices are valid: • **h323**—H.323. • **sip**—Session Interface Protocol (SIP).
to	Indicates that the argument that follows is the connection target.
to-type	Terminating endpoint type. The following choices are valid: • **h323**—H.323. • **sip**—Session Interface Protocol (SIP).

Command Default

Cisco IOS Release 12.3(4)T, Cisco IOS Release 12.3, and Earlier Releases

H.323-to-H.323 connections are enabled by default and cannot be changed, and POTS-to-any and any-to-POTS connections are disabled.

Cisco IOS Release 12.3(7)T and Later Releases

H.323-to-H.323 connections are disabled by default and can be changed, and POTS-to-any and any-to-POTS connections are enabled.

H.323-to-SIP Connections

H.323-to-SIP and SIP-to-H.323 connections are disabled by default, and POTS-to-any and any-to-POTS connections are enabled.

SIP-to-SIP Connections

SIP-to-SIP connections are disabled by default, and POTS-to-any and any-to-POTS connections are enabled.

Command Modes

Voice service configuration

Command History

Cisco IOS Release	Modification
12.2(13)T3	This command was introduced.
12.3(7)T	The default was changed.
12.3(11)T	The **sip** endpoint option was introduced for use with Cisco CallManager Express.

Cisco IOS Release	Modification
12.2(13)T3	This command was introduced.
12.4(4)T	The **sip** endpoint option was implemented for use in IP-to-IP gateway networks.
12.2(33)SB	This command was integrated into Cisco IOS Release 12.2(33)SB.
12.4(22)T	Support for IPv6 was added.
Cisco IOS XE Release 2.5	This command was integrated into Cisco IOS XE Release 2.5.

Usage Guidelines

Cisco IOS Release 12.3(4)T, Cisco IOS Release 12.3, and Earlier Releases

This command is used to allow connections between specific types of endpoints in a Cisco multiservice IP-to-IP gateway. The command is enabled by default and cannot be changed. Connections to or from POTS endpoints are not allowed. Only H.323-to-H.323 connections are allowed.

Cisco IOS Release 12.3(7)T and Later Releases

This command is used with Cisco Unified Communications Manager Express 3.1 or later systems and with the Cisco Multiservice IP-to-IP Gateway feature. In Cisco Unified Communications Manager Express, the **allow-connections** command enables the VoIP-to-VoIP connections used for hairpin call routing or routing to an H.450 tandem gateway.

Examples

The following example specifies that connections between H.323 and SIP endpoints are allowed:

```
Router(config-voi-serv)# allow-connections h323 to sip
```

The following example specifies that connections between H.323 endpoints are allowed:

```
Router(config-voi-serv)# allow-connections h323 to h323
```

The following example specifies that connections between SIP endpoints are allowed:

```
Router(config-voi-serv)# allow-connections sip to sip
```

Related Commands

Command	Description
voice service	Enters voice service configuration mode.

allow subscribe

To allow internal watchers to monitor external presentities, use the **allow subscribe** command in presence configuration mode. To disable external watching, use the **no** form of this command.

allow subscribe

no allow subscribe

Syntax Description

This command has no arguments or keywords.

Command Default

Only internal presentities can be watched when presence is enabled.

Command Modes

Presence configuration (config-presence)

Command History

Release	Modification
12.4(11)XJ	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

This command allows internal watchers to receive Busy Lamp Field (BLF) status notification for external directory numbers on a remote router connected through a SIP trunk. An external directory number must be enabled as a presentity with the **allow watch** command.

The router sends SUBSCRIBE requests through the SIP trunk to an external presence server on behalf of the internal watcher and returns presence status to the watcher. To permit the external directory numbers to be watched, you must enable the **watcher all** command on the remote router.

Examples

The following example shows how to enable internal watchers to monitor external presentities:

```
Router(config)# presence
Router(config-presence)# allow subscribe
```

Related Commands

Command	Description
allow watch	Allows a line on a phone registered to Cisco Unified CME to be watched in a presence service.
blf-speed-dial	Enables BLF monitoring for a speed-dial number on a phone registered to Cisco Unified CME.
presence	Enables presence service on the router and enters presence configuration mode.
presence call-list	Enables BLF monitoring for call lists and directories on phones registered to Cisco Unified CME.

Command	Description
presence enable	Allows incoming presence requests from SIP trunks.
server	Specifies the IP address of a presence server for sending presence requests from internal watchers to external presence entities.
show presence global	Displays configuration information about the presence service.
show presence subscription	Displays information about active presence subscriptions.
watcher all	Allows an external watcher to monitor an internal presentity.

alt-dial

To configure an alternate dial-out string for dial peers, use the **alt-dial** command in dial peer configuration mode. To delete the alternate dial-out string, use the **no** form of this command.

alt-dial *string*

no alt-dial *string*

Syntax Description

string	The alternate dial-out string.

Command Default No alternate dial-out string is configured

Command Modes Dial Peer configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.

Usage Guidelines This command applies to plain old telephone service (POTS), Voice over Frame Relay (VoFR), and Voice ATM (VoATM) dial peers.

The **alt-dial** command is used for the on-net-to-off-net alternative dialing function. The string replaces the destination-pattern string for dialing out.

Examples The following example configures an alternate dial-out string of 95550188:

```
alt-dial 95550188
```

anat

To enable Alternative Network Address Types (ANAT) on a Session Initiation Protocol (SIP) trunk, use the **anat** command in voice service voip-sip configuration mode or dial peer configuration mode. To ANAT on SIP trunks, use the **no** form of this command.

anat

no anat

Syntax Description This command has no arguments or keywords.

Command Default ANAT is enabled on SIP trunks.

Command Modes Voice service voip-sip configuration
Dial peer configuration

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines Both the Cisco IOS SIP gateway and the Cisco Unified Border Element are required to support Session Description Protocol (SDP) ANAT semantics for SIP IPv6 sessions. SDP ANAT semantics are intended to address scenarios that involve different network address families (for example, different IP versions). Media lines grouped using ANAT semantics provide alternative network addresses of different families for a single logical media stream. The entity creating a session description with an ANAT group must be ready to receive or send media over any of the grouped "m" lines.

By default, ANAT is enabled on SIP trunks. However, if the SIP gateway is configured in IPv4-only or IPv6-only mode, the gateway will not use ANAT semantics in its SDP offer.

Examples The following example enables ANAT on a SIP trunk:

```
router(conf-serv-sip)# anat
```

ani mapping

To preprogram the Numbering Plan Area (NPA), or area code, into a single Multi Frequency (MF) digit, use the **ani mapping** command in voice-port configuration mode. To disable Automatic Number Identification (ANI) mapping, use the **no** form of this command.

ani mapping *npd-value npa-number*

no ani mapping

Syntax Description

npd-value	Value of the Numbering Plan Digit (NPD). Range is 0 to 3. There is no default.
npa-number	Number (area code) of the NPA. Range is 100 to 999. There is no default value.

Command Default No default behavior or values

Command Modes Voice-port configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines The **ani mapping** command table translates the NPA into a single MF digit. The number of NPDs programmed is determined by local policy as well as by the number of NPAs that the public service answering point (PSAP) serves. Repeat this command until all NPDs are configured or until the NPD maximum range is reached.

Examples The following example shows the voice port preprogramming the NPA into a single MF digit:

```
voice-port 1/1/0
 timing digit 100
 timing inter-digit 100
 ani mapping 1 408
 signal cama KP-NPD-NXX-XXXX-ST
!
voice-port 1/1/1
 timing digit 100
 timing inter-digit 100
 ani mapping 1 408
 signal cama KP-NPD-NXX-XXXX-ST
```

Related Commands

Command	Description
signal	Specifies the type of signaling for a CAMA port.
voice–port	Enters voice-port configuration mode.

answer-address

To specify the full E.164 telephone number to be used to identify the dial peer of an incoming call, use the **answer-address** command in dial peer configuration mode. To disable the configured telephone number, use the **no** form of this command.

answer-address [**+**]*string*[**T**]

no answer-address

Syntax Description

+	(Optional) Character that indicates an E.164 standard number.
string	Series of digits that specify a pattern for the E.164 or private dialing plan telephone number. Valid entries are the digits 0 through 9, the letters A through D, and the following special characters: • The asterisk (*) and pound sign (#) that appear on standard touch-tone dial pads. • Comma (,), which inserts a pause between digits. • Period (.), which matches any entered digit (this character is used as a wildcard). • Percent sign (%), which indicates that the preceding digit occurred zero or more times; similar to the wildcard usage. • Plus sign (+), which indicates that the preceding digit occurred one or more times. **Note** The plus sign used as part of a digit string is different from the plus sign that can be used in front of a digit string to indicate that the string is an E.164 standard number. • Circumflex (^), which indicates a match to the beginning of the string. • Dollar sign ($), which matches the null string at the end of the input string. • Backslash symbol (\), which is followed by a single character, and matches that character. Can be used with a single character with no other significance (matching that character). • Question mark (?), which indicates that the preceding digit occurred zero or one time. • Brackets ([ ]), which indicate a range. A range is a sequence of characters enclosed in the brackets; only numeric characters from 0 to 9 are allowed in the range. • Parentheses (( )), which indicate a pattern and are the same as the regular expression rule.
T	(Optional) Control character that indicates that the **destination-pattern** value is a variable-length dial string. Using this control character enables the router to wait until all digits are received before routing the call.

Command Default The default value is enabled with a null string

Command Modes Dial peer voice configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on Cisco 3600 series routers.

Usage Guidelines Use the **answer-address** command to identify the origin (or dial peer) of incoming calls from the IP network. Cisco IOS software identifies the dial peers of a call in one of two ways: by identifying either the interface through which the call is received or the telephone number configured with the **answer-address** command. In the absence of a configured telephone number, the peer associated with the interface is associated with the incoming call.

For calls that come in from a plain old telephone service (POTS) interface, the **answer-address** command is not used to select an incoming dial peer. The incoming POTS dial peer is selected on the basis of the port configured for that dial peer.

There are certain areas in the world (for example, certain European countries) where valid telephone numbers can vary in length. Use the optional control character **T** to indicate that a particular **answer-address** value is a variable-length dial string. In this case, the system does not match the dialed numbers until the interdigit timeout value has expired.

Note Cisco IOS software does not check the validity of the E.164 telephone number; it accepts any series of digits as a valid number.

Examples The following example shows the E.164 telephone number 555-0104 as the dial peer of an incoming call being configured:

```
dial-peer voice 10 pots
 answer-address +5550104
```

Related Commands

Command	Description
destination-pattern	Specifies either the prefix or the full E.164 telephone number to be used for a dial peer.
port (dial peer)	Associates a dial peer with a specific port.
prefix	Specifies the prefix of the dialed digits for a dial peer.

application (dial peer)

To enable a specific application on a dial peer, use the **application** command in dial peer configuration mode. To remove the application from the dial peer, use the **no** form of this command.

application *application-name* [**out-bound**]

no application *application-name* [**out-bound**]

Syntax Description

application-name	Name of the predefined application that you wish to enable on the dial peer. See the "Usage Guidelines" section for valid application names.
out-bound	(Optional) Outbound calls are handed off to the named application. This keyword is used for store-and-forward fax applications and VoiceXML applications.

Command Default No default behavior or values

Command Modes Dial peer voice configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the Cisco 2500 series, Cisco 3600 series, and Cisco AS5300.
12.0(5)T	The SGCPAPP application was supported initially on the Cisco AS5300.
12.0(7)XK	Support for the SGCPAPP application was implemented on the Cisco MC3810 and the Cisco 3600 series (except for the Cisco 3620).
12.1(2)T	The SGCPAPP application was integrated into Cisco IOS Release 12.1(2)T.
12.1(3)T	The MGCPAPP application was implemented on the Cisco AS5300.
12.1(3)XI	The **out-bound** keyword was added for store-and-forward fax on the Cisco AS5300.
12.1(5)T	The **out-bound** keyword was integrated into Cisco IOS Release 12.1(5)T, and the command was implemented on the Cisco AS5800.
12.2(2)T	This command was implemented on the Cisco 7200 series.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(2)XN	Support for enhanced MGCP voice gateway interoperability was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(4)XM	This command was implemented on the Cisco 1751.

Release	Modification
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: The Cisco 3725 and Cisco 3745. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was integrated into Cisco CallManager Version 3.2 and implemented on the Cisco 1760 and Cisco IAD2420 series routers. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.2(13)T	The *application-name* argument was removed from the **no** form of this command.
12.2(15)T	Malicious Caller Identification (MCID) was added as a valid *application-name* argument.
12.2(15)ZJ	The session application referred to by the **default** value of the *application-name* argument was updated to include support for Open Settlement Protocol (OSP), call transfer, and call forwarding. The version of the session application referred to by **default** in Cisco IOS Release 12.2(13)T and earlier releases was renamed default.c.old.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(14)T	This command is obsolete in Cisco IOS Release 12.3(14)T. For Cisco IOS Release 12.3(14)T and later releases, use the **application** command in global configuration mode to configure applications on a dial peer.

Usage Guidelines

Use this command when configuring interactive voice response (IVR) or any of the IVR-related features to associate a predefined session application with an incoming POTS dial peer and an outgoing Multimedia Mail over IP (MMoIP) dial peer. Calls that use the incoming POTS dial peer and the outgoing MMoIP dial peer are handed off to the specified predefined session application.

Note In Cisco IOS Release 12.2(15)T and later releases, the application name default refers to the application new version of the default session application that supports OSP, call transfer, and call forwarding. The default session application in Cisco IOS Release 12.2(13)T and earlier releases has been renamed default.old.c and can still be configure for specific dial peers through the **application** command or globally configured for all inbound dial peers through the **call application global** command.

For Media Gateway Control Protocol (MGCP) and Simple Gateway Control Protocol (SGCP) networks, enter the application name in uppercase characters. For example, for MGCP networks, you would enter MGCPAPP for the *application-name* argument. The application can be applied only to POTS dial peers. Note that SGCP dial peers do not use dial-peer hunting.

Note In Cisco IOS Release 12.2, you cannot mix SGCP and non-SGCP endpoints in the same T1 controller, nor can you mix SGCP and non-SGCP endpoints in the same DS0 group.

Note MGCP scripting is not supported on the Cisco 1750 router or on Cisco 7200 series routers.

For H.323 networks, the application is defined by a Tool Command Language/interactive voice response (Tcl/IVR) filename and location. Incoming calls that use POTS dial peers and outgoing calls that use MMoIP dial peers are handed off to this application**.**

For Session Initiation Protocol (SIP) networks, use this command to associate a predefined session application. The default Tcl application (from the Cisco IOS image) for SIP is session and can be applied to both VoIP and POTS dial peers.

Examples

The following example defines an application and applies it to an outbound MMoIP dial peer for the fax on-ramp operation:

```
call application voice fax_on_vfc_onramp http://santa/username/clid_4digits_npw_3.tcl
dial-peer voice 3 mmoip
 application fax_on_vfc_onramp out-bound
 destination-pattern 57108..
 session target mailto:$d$@mail-server.cisco.com
```

The following example applies the MGCP application to a dial peer:

```
dial-peer voice 1 pots
 application MGCPAPP
```

The following example applies a predefined application to an incoming POTS dial peer:

```
dial-peer voice 100 pots
 application c4
```

The following example applies a predefined application to an outbound MMoIP dial peer for the on-ramp operation:

```
dial-peer voice 3 mmoip
  application fax_on_vfc_onramp_ap out-bound
  destination-pattern 57108..
  session target mailto:$d$@mail-server.cisco.com
```

The following example applies the predefined SIP application to a dial peer:

```
dial-peer voice 10 pots
 application session
```

For Cisco IOS Release 12.2(15)T, MCID was added as a valid *application-name* argument. The following is a sample configuration using the MCID application name:

```
call application voice mcid http://santa/username/app_mcid_dtmf.2.0.0.28.tcl
dial-peer voice 3 pots
 application mcid
 incoming called-number 222....
 direct-inward-dial
 port 1:D
```

Related Commands

Command	Description
application	Enables a specific application on a dial peer.
call application voice	Defines the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
mgcp	Starts the MGCP daemon.
sgcp	Starts and allocates resources for the SGCP daemon.
sgcp call-agent	Defines the IP address of the default SGCP call agent.

application (global)

To enter application configuration mode to configure applications, use the **application** command in global configuration mode.

application

Syntax Description

This command has no keywords or arguments.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **application** command in dial peer configuration mode.

Usage Guidelines

Use this command to enter application configuration mode. Related commands are used in application configuration mode to configure standalone applications (services) and linkable functions (packages).

Examples

The following example shows how to enter application configuration mode and configure a debit card service:

Enter application configuration mode to configure applications and services:

```
Router(config)# application
```

Load the debit card script:

```
Router(config-app)# service debitcard
tftp://server-1/tftpboot/scripts/app_debitcard.2.0.2.8.tcl
```

Configure language parameters for the debit card service:

```
Router(config-app-param)# paramspace english language en
  paramspace english index 1
  paramspace english prefix en
  paramspace english location tftp://server-1/tftpboot/scripts/au/en/
```

Related Commands

Command	Description
call application voice	Defines the name of a voice application and specify the location of the Tcl or VoiceXML document to load for this application.

arq reject-resource-low

To configure the gatekeeper to send an Admission Reject (ARJ) message to the requesting gateway if destination resources are low, use the **arq reject-resource-low** command in gatekeeper configuration mode. To disable the gatekeeper from checking resources, use the **no** form of this command.

arq reject-resource-low

no arq reject-resource-low

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.3(1)	This command was introduced.

Examples

The following example shows that the gatekeeper is configured to send an ARJ message to the requesting gateway if destination resources are low:

```
gatekeeper
 arq reject-resource-low
```

Related Commands

Command	Description
lrq reject-resource-low	Configures a gatekeeper to notify a sending gatekeeper on receipt of an LRQ message that no terminating endpoints are available.

arq reject-unknown-prefix

To enable the gatekeeper to reject admission requests (ARQs) for zone prefixes that are not configured, use the **arq reject-unknown-prefix** command in gatekeeper configuration mode. To reenable the gatekeeper to accept and process all incoming ARQs, use the **no** form of this command.

arq reject-unknown-prefix

no arq reject-unknown-prefix

Syntax Description

This command has no arguments or keywords

Command Default

The gatekeeper accepts and processes all incoming ARQs.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
11.3(6)Q,	This command was introduced.
11.3(7)NA	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines

Use the **arq reject-unknown-prefix** command to configure the gatekeeper to reject any incoming ARQs for a destination E.164 address that does not match any of the configured zone prefixes.

When an endpoint or gateway initiates an H.323 call, it sends an ARQ to its gatekeeper. The gatekeeper uses the configured list of zone prefixes to determine where to direct the call. If the called address does not match any of the known zone prefixes, the gatekeeper attempts to *hairpin* the call out through a local gateway. If you do not want your gateway to do this, then use the **arq reject-unknown-prefix** command. (The term *hairpin* is used in telephony. It means to send a call back in the direction from which it came. For example, if a call cannot be routed over IP to a gateway that is closer to the target phone, the call is typically sent back out through the local zone, back the way it came.)

This command is typically used to either restrict local gateway calls to a known set of prefixes or deliberately fail such calls so that an alternate choice on a gateway's rotary dial peer is selected.

Examples

Consider a gatekeeper configured as follows:

```
zone local gk408 cisco.com
zone remote gk415 cisco.com 172.21.139.91
zone prefix gk408 1408.......
zone prefix gk415 1415.......
```

In this example configuration, the gatekeeper manages a zone containing gateways to the 408 area code, and it knows about a peer gatekeeper that has gateways to the 415 area code. Using the **zone prefix** command, the gatekeeper is then configured with the appropriate prefixes so that calls to those area codes hop off in the optimal zone.

If the **arq request-unknown-prefix** command is not configured, the gatekeeper handles calls in the following way:

- A call to the 408 area code is routed out through a local gateway.
- A call to the 415 area code is routed to the gk415 zone, where it hops off on a local gateway.
- A call to the 212 area code is routed to a local gateway in the gk408 zone.

If the **arq reject-unknown-prefix** command is configured, the gatekeeper handles calls in the following way:

- A call to the 408 area code is routed out through a local gateway.
- A call to the 415 area code is routed to the gk415 zone, where it hops off on a local gateway.
- A call to the 212 area code is rejected because the destination address does not match any configured prefix.

Related Commands

Command	Description
zone prefix	Adds a prefix to the gatekeeper zone list.

as

To define an application server for backhaul, use the **as** command in IUA configuration mode. To disable the backhaul ability from an application server, use the **no** form of this command.

as *as-name* {*localip1* [*localip2*]} [**local-sctp-port**] [**fail-over-timer**] [**sctp-startup-rtx**] [**sctp-streams**] [**sctp-t1init**]

no as *name*

Syntax Description

as-name	Defines the protocol name (only ISDN is supported).
localip1	Defines the local IP address(es) for all the ASPs in a particular AS.
localip2	(Optional) Defines the local IP address(es) for all the ASPs in a particular application server .
local-sctp-port	(Optional) Defines a specific local Simple Control Transmission Protocol (SCTP) port rather than an ISDN Q.921 User Adaptation Layer (IUA) well-known port.
fail-over-timer	(Optional) Configures the failover timer for a particular application server .
sctp-startup-rtx	(Optional) Configures the SCTP maximum startup retransmission timer.
sctp-streams	(Optional) Configures the number of SCTP streams for a particular application server .
sctp-t1init	(Optional) Configures the SCTP T1 initiation timer.

Command Default No application server is defined.

Command Modes IUA configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and support was added for the Cisco AS5300 platform.
12.2(13)T1	This command was implemented on the Cisco AS5850.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T and implemented on the Cisco 2420, Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series; Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 network access server (NAS) platforms.

Usage Guidelines A maximum of two local IP addresses can be specified. (Note that SCTP has built-in support for multihomed machines.)

Note All of the ASPs in an application server must be removed before an application server can be unconfigured.

The default value of the SCTP streams is determined by the hardware that you have installed. The value of the failover timer is found in the **show iua as all** command output.

The number of streams to assign to a given association is implementation dependent. During the initialization of the IUA association, you need to specify the total number of streams that can be used. Each D channel is associated with a specific stream within the association. With multiple trunk group support, every interface can potentially be a separate D channel.

At startup, the IUA code checks for all the possible T1, E1, or T3 interfaces and sets the total number of inbound and outbound streams supported accordingly. In most cases, there is only a need for one association between the gateway (GW) and the Media Gateway Controller (MGC). For the rare case that you are configuring multiple AS associations to various MGCs, the overhead from the unused streams would have minimal impact. The NFAS D channels are configured for one or more interfaces, where each interface is assigned a unique stream ID.

The total number of streams for the association needs to include an additional stream for the SCTP management messages. So during startup, the IUA code adds one to the total number of interfaces (streams) found.

You have the option to manually configure the number of streams per association. In the backhaul scenario, if the number of D channel links is limited to one, allowing the number of streams to be configurable avoids the unnecessary allocation of streams in an association that is never used. For multiple associations between a GW and multiple MGCs, the configuration utility is useful in providing only the necessary number of streams per association. The overhead from the streams allocated but not used in the association is negligible.

If the number of streams is manually configured through the CLI, the IUA code cannot distinguish between a startup event, which automatically sets the streams to the number of interfaces, or if the value is set manually during runtime. If you are configuring the number of SCTP streams manually, you must add one plus the number of interfaces using the **sctp-streams** keyword. Otherwise, IUA needs to always add one for the management stream, and the total number of streams increments by one after every reload.

When you set the SCTP stream with the CLI, you cannot change the inbound and outbound stream support once the association is established with SCTP. The value takes effect when you first remove the IUA AS configuration and then configure it back as the same application server or a new one. The other option is to reload the router.

Examples

An application server and the application server process (ASP) should be configured first to allow a National ISDN-2 with Cisco extensions (NI2+) to be bound to this transport layer protocol. The application server is a logical representation of the SCTP local endpoint. The local endpoint can have more than one IP address but must use the same port number.

The following is an example of an application server configuration on a gateway. The configuration shows that an application server named as5400-3 is configured to use two local IP addresses and a port number of 2577:

```
Router(config-iua)# as as5400-3 10.1.2.34 10.1.2.35 2577
```

The following output shows that the application server (as1) is defined for backhaul:

```
AS as1 10.21.0.2 9900
```

Related Commands

Command	Description
asp	Defines an ASP for backhaul.

asp

To define an application server process (ASP) for backhaul, use the **asp** command in IUA configuration mode. To disable the ASP, use the **no** form of this command.

asp *asp-name* **as** *as-name* {*remoteip1* [*remoteip2*]} [**remote-sctp-port**] [**ip-precedence** [**sctp-keepalives**] [**sctp-max-associations**] [**sctp-path-retransmissions**] [**sctp-t3-timeout**]

no asp *asp-name*

Syntax Description

asp-name	Names the current ASP.
as	The application server to which the ASP belongs.
as-name	Name of the application server to which the ASP belongs.
remoteip1	(Optional) Designates the remote IP address for this Simple Control Transmission Protocol (SCTP) association.
remoteip2	Designates the remote IP address for this SCTP association.
remote-sctp-port	Connects to a remote SCTP port rather than the IUA well-known port.
ip-precedence	(Optional) Sets IP Precedence bits for protocol data units (PDUs). • IP precedence is expressed in the type of service (ToS) field of the **show ip sctp association parameters** output. The default type of service (ToS) value is 0. • Valid precedence values range from 0 to 7. You can also use the default IP precedence value for this address by choosing the default option.
sctp-keepalives	(Optional) Modifies the keepalive behavior of an IP address in a particular ASP. • Valid keepalive interval values range from 1000 to 60000. The default value is 500 ms (see the **show ip sctp association parameters** output under **heartbeats**).
sctp-max-associations	(Optional) Sets the SCTP maximum association retransmissions for a particular ASP. Valid values range from 2 to 20. The default is 5.
sctp-path-retransmissions	(Optional) Sets the SCTP path retransmissions for a particular ASP. Valid values range from 2 to 10. The default is 3.
sctp-t3-timeout	(Optional) Sets the SCTP T3 retransmission timeout for a particular ASP. The default value is 900 ms.

Command Default No ASP is defined.

Command Modes IUA configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and support was added for the Cisco AS5300.
12.2(11)T1	This command was implemented on the Cisco AS5850.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T and implemented on the Cisco 2420, Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series; and Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 network access server (NAS) platforms.

Usage Guidelines

This command establishes SCTP associations. There can be only a maximum of three ASPs configured per AS. IP precedence is expressed in the ToS field of **show ip sctp association parameters** output. The default ToS value is 0.

Note All of the ASPs in an application server must be removed before an application serever can be unconfigured.

You can configure the precedence value in IUA in the range of 0 to 7 for a given IP address. Within IUA, the upper three bits representing the IP precedence in the ToS byte (used in the IP header) is set based on the user input before passing down the value to SCTP. In turn, SCTP passes the ToS byte value to IP. The default value is 0 for "normal" IP precedence handling.

The *asp-name* argument specifies the name of this ASP. The **ip-precedence** keyword sets the precedence and ToS field. The *remote-ip-address* argument specifies the IP address of the remote end-point (the address of MGC, for example). The *number* argument can be any IP precedence bits in the range 1 to 255.

The **no** form of the command results in precedence bits not being explicitly set by SCTP.

In the case of a hot-standby Cisco PGW2200 pair, from the gateway (GW) perspective there is usually one ASP active and another in the INACTIVE state. The ASP_UP message is used to bring the ASP state on the GW to the INACTIVE state, followed by the ASPTM message, ASP_ACTIVE to ready the IUA link for data exchange. (Eventually the QPTM Establish Request message actually initiates the start of the D channel for the given interface.) In the event that the GW detects a failure on the active ASP, it can send a NTFY message to the standby ASP to request that it become active.

Examples

An ASP can be viewed as a local representation of an SCTP association because it specifies a remote endpoint that is in communication with an AS local endpoint. An ASP is defined for a given AS. For example, the following configuration defines a remote signaling controller *asp-name* at two IP addresses for AS as1. The remote SCTP port number is 2577:

```
Router(config-iua)# as as1 10.4.8.69, 10.4.9.69 2477
Router(config-iua)# asp asp1 as as1 10.4.8.68 10.4.9.68 2577
```

Multiple ASPs can be defined for a single AS for the purpose of redundancy, but only one ASP can be active. The ASPs are inactive and only become active after fail-over.

In the Cisco Media Gateway Controller (MGC) solution, a signaling controller is always the client that initiates the association with a gateway. During the initiation phase, you can request outbound and inbound stream numbers, but the gateway only allows a number that is at least one digit higher than the number of interfaces (T1/E1) allowed for the platform.

The following example specifies the IP precedence level on the specified IP address. This example uses IP precedence level 7, which is the maximum level allowed:

```
Router(config-iua)# asp asp1 as ip-precedence 10.1.2.345 7
```

The following example specifies the IP address to enable and disable keepalives:

```
Router(config-iua)# asp asp1 as sctp-keepalive 10.1.2.34
```

The following example specifies the keepalive interval in milliseconds. In this example, the maximum value of 60000 ms is used:

```
Router(config-iua)# asp asp1 as sctp-keepalive 10.10.10.10 60000
```

The following example specifies the IP address for the SCTP maximum association and the maximum association value. In this example, a maximum value of 20 is used:

```
Router(config-iua)# asp asp1 as sctp-max-association 10.10.10.10 20
```

The following example specifies the IP address for the SCTP path retransmission and the maximum path retransmission value. In this example, a maximum value of 20 is used:

```
Router(config-iua)# asp asp1 as sctp-path-retransmissions 10.10.10.10 10
```

The following example specifies the IP address for SCTP T3 timeout and specifies the T3 timeout value in milliseconds. In this example, the maximum value of 60000 is used:

```
Router(config-iua)# asp asp1 as sctp-t3-timeout 10.10.10.10 60000
```

Related Commands

Command	Description
as	Defines an application server for backhaul.

asserted-id

To set the privacy level and enable either P-Asserted-Identity (PAI) or P-Preferred-Identity (PPI) privacy headers in outgoing SIP requests or response messages, use the **asserted-id** command in voice service voip-sip configuration mode or on a dial peer. To remove the privacy level of either PAI or PPI, use the **no** form of this command.

asserted-id [**pai** | **ppi**]

no asserted-id

Syntax Description

pai	(Optional) Enables PAI privacy headers in outgoing SIP requests or response messages.
ppi	(Optional) Enables PPI privacy headers in outgoing SIP requests or response messages.

Command Default

The command is disabled.

Command Modes

Voice service voip-sip configuration
Dial-peer configuration

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Enter SIP configuration mode from voice-service configuration mode, as shown in the example.

If you configure the **asserted-id pai** command, the gateway builds a P-Asserted-Identity header into the common SIP stack. The **asserted-id pai** command has a priority over the Remote-Party-ID (RPID) header and removes this header from any outbound message, even if the router is configured to use the RPID header.

If you configure the **asserted-id ppi** command, the gateway builds a P-Preferred-Identity header into the common SIP stack. The **asserted-id ppi** command has a priority over the Remote-Party-ID (RPID) header and removes this header from any outbound message, even if the router is configured to use the RPID header.

Examples

The following example shows how to set the P-Asserted Identity in the privacy header:

```
router> enable
router# configure terminal
router(config)# voice service voip
router(conf-voi-serv)# sip
router(conf-serv-sip)# asserted-id pai
```

Related Commands

Command	Description
calling-info pstn-to-sip	Specifies calling information treatment for PSTN-to-SIP calls.
privacy	Sets privacy in support of RFC 3323.

associate application

To associate an application to the digital signal processor (DSP) farm profile, use the **associate application** command in DSP farm profile configuration mode. To remove the protocol, use the **no** form of this command.

associate application {**cube** | **sbc** | **sccp**} *profile-description-text*

no associate application sccp

Syntax Description

cube	Associates the Cisco Unified Border Element application to a defined profile in the DSP farm.
sbc	Associates the SBC application to a defined profile in the DSP farm.
sccp	Associates the skinny client control protocol application to a defined profile in the DSP farm.
profile-description-text	(Optional) User defined name for the associated applicaion.

Command Default No application is associated with the DSP farm profile.

Command Modes DSP farm profile configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.2(33)SB	This command was integrated into Cisco IOS Release 12.2(33)SB.
12.4(22)T	Support for IPv6 was added.
Cisco IOS XE Release 3.2S	This command was modified. The **cube** and **sbc** keywords and the *profile-description-text* argument were added.

Usage Guidelines Use the associate application command to associate an application to a predefinded DSP farm profile.

Examples The following example associates SCCP to the DSP farm profile:

```
Router(config-dspfarm-profile)# associate application sccp
```

The following example associates Cisco Unified Border Element to the DSP farm profile:

```
Router(config-dspfarm-profile)# associate application cube
```

Related Commands

Command	Description
voice-card	Enters voice card configuration mode
codec (dspfarm-profile)	Specifies the codecs supported by a DSP farm profile.
description (dspfarm-profile)	Includes a specific description about the DSP farm profile.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
maximum sessions (dspfarm-profile)	Specifies the maximum number of sessions that need to be supported by the profile.
shutdown (dspfarm-profile)	Allocates DSP farm resources and associates with the application.

associate ccm

To associate a Cisco Unified CallManager with a Cisco CallManager group and establish its priority within the group, use the **associate ccm** command in the SCCP Cisco CallManager configuration mode. To disassociate a Cisco Unified CallManager from a Cisco CallManager group, use the **no** form of this command.

associate ccm *identifier-number* **priority** *priority-number*

no associate ccm *identifier-number* **priority** *priority-number*

Syntax Description

identifier-number	Number that identifies the Cisco Unified CallManager. Range is 1 to 65535. There is no default value.
priority *priority-number*	Priority of the Cisco Unified CallManager within the Cisco CallManager group. Range is 1 to 4. There is no default value. The highest priority is 1.

Command Default

No default behavior or values

Command Modes

SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Examples

The following example associates Cisco Unified CallManager 125 with Cisco CallManager group 999 and sets the priority of the Cisco Unified CallManager within the group to 2:

```
Router(config)# sccp ccm group 999
Router(config-sccp-ccm)# associate ccm 125 priority 2
```

Related Commands

Command	Description
connect interval	Specifies the amount of time that a DSP farm profile waits before attempting to connect to a Cisco Unified CallManager when the current Cisco Unified CallManager fails to connect.
connect retries	Specifies the number of times that a DSP farm attempts to connect to a Cisco Unified CallManager when the current Cisco Unified CallManager connections fails.
sccp ccm group	Creates a Cisco CallManger group and enters SCCP Cisco CallManager configuration mode.

associate profile

To associate a digital signal processor (DSP) farm profile with a Cisco CallManager group, use the **associate profile** command in SCCP Cisco CallManager configuration mode. To disassociate a DSP farm profile from a Cisco Unified CallManager, use the **no** form of this command.

associate profile *profile-identifier* **register** *device-name*

no associate profile *profile-identifier* **register** *device-name*

Syntax Description

profile-identifier	Number that identifies the DSP farm profile. Range is 1 to 65535. There is no default value.
register *device-name*	User-specified device name in Cisco Unified CallManager. A maximum number of 15 characters can be entered for the device name.

Command Default This command is not enabled.

Command Modes SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(22)T	Support for IPv6 was added.

Usage Guidelines The device name must match the name configured in Cisco UnifiedCallManager; otherwise the profile is not registered to Cisco Unified CallManager.

Note Each profile can be associated to only one Cisco CallManager group.

Examples The following example associates DSP farm profile abgz12345 to Cisco CallManager group 999:

```
Router(config)# sccp ccm group 999
Router(conif-sccp-ccm)# associate profile 1 register abgz12345
```

Related Commands

Command	Description
bind interface	Binds an interface to a Cisco CallManager group.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
sccp ccm group	Creates a Cisco CallManager group and enters SCCP Cisco CallManager configuration mode.

associate registered-number

To associate the preloaded route and outbound proxy details with the registered number, use the **associate registered-number** command in voice service VoIP SIP configuration mode. To remove the association, use the **no** form of this command.

associate registered-number *number*

no associate registered-number

Syntax Description

number	Registered number. The number must be between 4 and 32.

Command Default The preloaded route and outbound proxy details are not associated with the registered number by default.

Command Modes Voice service VoIP SIP configuration (conf-serv-sip)

Command History

Release	Modification
15.1(2)T	This command was introduced.

Examples The following example shows how to associate a registered number in the SIP configuration mode:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# associate registered-number 5
```

Related Commands

Command	Description
voice-class sip associate registered-number	Associates preloaded route and outbound proxy details with the registered number in the dial-peer configuration level.

asymmetric payload

To configure Session Initiation Protocol (SIP) asymmetric payload support, use the **asymmetric payload** command in SIP configuration mode. To disable asymmetric payload support, use the **no** form of this command.

asymmetric payload {**dtmf** | **dynamic-codecs** | **full** | **system**}

no asymmetric payload

Syntax Description

dtmf	(Optional) Specifies that the asymmetric payload support is dual-tone multi-frequency (DTMF) only.
dynamic-codecs	(Optional) Specifies that the asymmetric payload support is for dynamic codec payloads only.
full	(Optional) Specifies that the asymmetric payload support is for both DTMF and dynamic codec payloads.
system	(Optional) Specifies that the asymmetric payload uses the global value.

Command Default This command is disabled.

Command Modes Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(15)T	This command was introduced.
Cisco IOS XE Release 3.1S	This command was integrated into Cisco IOS Release IOS XE 3.1.

Usage Guidelines Enter SIP configuration mode from voice-service configuration mode, as shown in the example.

For the Cisco UBE the SIP asymmetric payload-type is supported for audio/video codecs, DTMF, and NSE. Hence, **dtmf** and **dynamic-codecs** keywords are internally mapped to the **full** keyword to provide asymmetric payload-type support for audio/video codecs , DTMF, and NSE.

Examples The following example shows how to set up a full asymmetric payload globally on a SIP network for both DTMF and dynamic codecs:

```
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# asymmetric payload full
```

Related Commands

Command	Description
sip	Enters SIP configuration mode from voice-service VoIP configuration mode.
voice-class sip asymmetric payload	Configures SIP asymmetric payload support on a dial peer.

atm scramble-enable

To enable scrambling on E1 links, use the **atm scramble-enable** command in interface configuration mode. To disable scrambling, use the **no** form of this command.

atm scramble-enable

no atm scramble-enable

Syntax Description This command has no arguments or keywords.

Command Default By default, payload scrambling is set off

Command Modes Interface configuration

Command History

Release	Modification
12.0(5)XK	This command was introduced for ATM interface configuration on the Cisco MC3810.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.

Usage Guidelines Enable scrambling on E1 links only. On T1 links, the default binary 8-zero substitution (B8ZS) line encoding normally ensures sufficient reliability. Scrambling improves data reliability on E1 links by randomizing the ATM cell payload frames to avoid continuous nonvariable bit patterns and to improve the efficiency of the ATM cell delineation algorithms.

The scrambling setting must match that of the far end.

Examples The following example shows how to set the ATM0 E1 link to scramble payload:

```
interface atm0
 atm scramble-enable
```

atm video aesa

To set the unique ATM end-station address (AESA) for an ATM video interface that is using switched virtual circuit (SVC) mode, use the **atm video aesa** command in ATM interface configuration mode. To remove any configured address for the interface, use the **no** form of this command.

atm video aesa [**default** | *esi-address*]

no atm video aesa

Syntax Description

default	(Optional) Automatically creates a network service access point (NSAP) address for the interface, based on a prefix from the ATM switch (26 hexadecimal characters), the MAC address (12 hexadecimal characters) as the end station identifier (ESI), and a selector byte (two hexadecimal characters).
esi-address	(Optional) Defines the 12 hexadecimal characters used as the ESI. The ATM switch provides the prefix (26 hexadecimal characters), and the video selector byte provides the remaining two hexadecimal characters.

Command Default **default**

Command Modes ATM Interface configuration

Command History

Release	Modification
12.0(5)XK	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.

Usage Guidelines You cannot specify the ATM interface NSAP address in its entirety. The system creates either all of the address or part of it, depending on how you use this command.

Examples The following example shows the ATM interface NSAP address set automatically:

```
interface atm0
 atm video aesa default
```

The following example shows the ATM interface NSAP address set to a specific ESI value:

```
interface atm0/1
 atm video aesa 444444444444
```

Related Commands

Command	Description
show atm video-voice address	Displays the NSAP address for the ATM interface.

attribute acct-session-id overloaded

To overload the acct-session-id attribute with call detail records, use the **attribute acct-session-id overloaded** command in gateway accounting AAA configuration mode. To disable overloading the acct-session-id attribute with call detail records, use the **no** form of this command.

attribute acct-session-id overloaded

no attribute acct-session-id overloaded

Syntax Description

This command has no arguments or keywords.

Command Default

The acct-session-id attribute is not overloaded with call detail records.

Command Modes

Gateway accounting AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

- The **attribute acct-session-id overloaded** command replaces the **gw-accounting h323** command.
- The acct-session-id attribute is RADIUS attribute 44. For more information on this attribute, see the document *RADIUS Attribute 44 (Accounting Session ID) in Access Requests*.
- Attributes that cannot be mapped to standard RADIUS attributes are packed into the acct-session-id attribute field as ASCII strings separated by the forward slash ("/") character.
- The Accounting Session ID (acct-session-id) attribute contains the RADIUS account session ID, which is a unique identifier that links accounting records associated with the same login session for a user. This unique identifier makes it easy to match start and stop records in a log file.
- Accounting Session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded.

Examples

The following example shows the acct-session-id attribute being overloaded with call detail records:

```
gw-accounting aaa
 attribute acct-session-id overloaded
```

Related Commands

Command	Description
call accounting-template voice	Defines and loads the template file at the location defined by the URL.
gw-accounting aaa	Enables VoIP gateway accounting.

attribute h323-remote-id resolved

To resolve the h323-remote-id attribute, use the **attribute h323-remote-id resolved** command in gateway accounting AAA configuration mode. To keep the h323-remote-id attribute unresolved, use the **no** form of this command.

attribute h323-remote-id resolved

no attribute h323-remote-id resolved

Syntax Description This command has no arguments or keywords.

Command Default The h323-remote-id attribute is not resolved.

Command Modes gateway accounting aaa configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines In Cisco IOS Release 12.2(11)T, the **attribute h323-remote-id resolved** command replaces the **gw-accounting h323 resolve** command, and the h323-remote-id attribute has been added as a Cisco vendor-specific attribute (VSA). This attribute is a string that indicates the Domain Name System (DNS) name or locally defined host name of the remote gateway.

You can obtain the value of the h323-remote-id attribute by doing a DNS lookup of the h323-remote-address attribute. The h323-remote-address attribute indicates the IP address of the remote gateway.

Examples The following example sets the h323-remote-id attribute to resolved:

```
gw-accounting aaa
 attribute h323-remote-id resolved
```

Related Commands

Command	Description
gw-accounting aaa	Enables VoIP gateway accounting.

audio

To enable the incoming and outgoing IP-IP call gain/loss feature for audio volume control on the incoming dial peer and the outgoing dial peer, enter the **audio** command in dial-peer configuration mode. To disable this feature, use the **no** form of this command.

audio {**incoming** | **outgoing**} **level adjustment** *value*

no audio {**incoming** | **outgoing**} **level adjustment** *value*

Syntax Description

incoming	Enables the incoming IP-IP call volume control on either the incoming dial peer or the outgoing dial peer.
outgoing	Enables the outgoing IP-IP call volume control on either the incoming dial peer or the outgoing dial peer.
value	Range is -27 to 16.

Command Default This command is disabled by default, and there is no volume control available.

Command Modes Dial-peer configuration (config-dialpeer)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines This feature enables the adjustment of the audio volume within a Cisco Unified Border Element (Cisco UBE) call. As with codec repacketization, dissimilar networks that have different built-in loss/gain characteristics may experience connectivity problems. By adding the ability to control the loss/gain within the Cisco UBE, you can more easily connect your networks.

The DSP requires one level for each stream, so the *value* for audio incoming level-adjustment and the *value* for audio outgoing level-adjustment will be added together. If the combined values are outside of the limit the DSP can perform, the value sent to the DSP will be either the minimum (-27) or maximum (+16) supported by the DSP.

Caution For gain/loss control, be aware that adding gain in a network with echo can generate feedback loud enough to cause hearing damage. Always exercise extreme caution when configuring gain into your network.

To configure IP-IP Call Gain/Loss Control on a voice gateway, you must configure the incoming and outgoing VoIP dial peers.

Examples

The following example shows how to configure audio incoming level to 5 and the audio outgoing level to -5:

```
Router(config-dialpeer)# audio incoming level-adjustment 5
Router(config-dialpeer)# audio outgoing level-adjustment -5
```

Related Commands

Command	Description
show dial peer voice	Displays the codec setting for dial peers.

audio-prompt load

To initiate loading the selected audio file (.au), which contains the announcement prompt for the caller, from Flash memory into RAM, use the **audio-prompt load** command in privileged EXEC mode. This command does not have a **no** form.

audio-prompt load *name*

Syntax Description

name	Location of the audio file that you want to have loaded from memory, flash memory, an FTP server, an HTTP server, or an HTTPS (HTTP over Secure Socket Layer (SSL)) server.

Command Default No default behavior or values

Command Modes Privileged EXEC

Command History

Release	Modification
11.3(6)NA2	This command was introduced. **Note** With Cisco IOS Release 11.3(6)NA2, the URL pointer refers to the directory where Flash memory is stored.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751. Support for other Cisco platforms is not included in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. This command is supported on the Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.4(15)T	The *name* argument was modified to accept an HTTPS server URL.

Usage Guidelines The first time the interactive voice response (IVR) application plays a prompt, it reads it from the URL (or the specified location for the .au file, such as Flash or FTP) into RAM. Then it plays the script from RAM. An example of the sequence of events follows:

- When the first caller is asked to enter the account and personal identification numbers (PINs), the enter_account.au and enter_pin.au files are loaded into RAM from Flash memory.
- When the next call comes in, these prompts are played from the RAM copy.
- If all callers enter valid account numbers and PINs, the auth_failed.au file is not loaded from Flash memory into RAM.

The router loads the audio file only when the script initially plays that prompt after the router restarts. If the audio file is changed, you must run this privileged EXEC command to reread the file. This generates an error message if the file is not accessible or if there is a format error.

Examples

The following example shows how to load the enter_pin.au audio file from Flash memory into RAM:

```
audio-prompt load flash:enter_pin.au
```

The following example shows how to load the hello.au audio file from an HTTPS server into RAM:

```
audio-prompt load https://http-server1/audio/hello.au
```

authenticate redirecting-number

To enable a Cisco IOS voice gateway to authenticate and pass Session Initiation Protocol (SIP) credentials based on the redirecting number when available instead of the calling number of a forwarded call, use the **authenticate redirecting-number** command in voice service SIP configuration mode. To return a Cisco IOS voice gateway to the default setting so that the gateway uses only the calling number for SIP credentials, use the **no** form of this command.

authenticate redirecting-number

no authenticate redirecting-number

Syntax Description

This command has no arguments or keywords.

Command Default

The Cisco IOS voice gateway uses only the calling number of a forwarded call for SIP credentials even when the redirecting number information is available for that call.

Command Modes

Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(24)T	This command was introduced.

Usage Guidelines

When an INVITE message sent out by the gateway is challenged, it must respond with the appropriate SIP credentials before the call is established. The default global behavior for the gateway is to authenticate and pass SIP credentials based on the calling number and all dial peers on a gateway default to the global setting. However, for forwarded calls, it is sometimes more appropriate to use the redirecting number and this can be specified at either the global or dial peer level (configuring behavior for a specific dial peer supersedes the global setting).

Use the **authenticate redirecting-number** command in voice service SIP configuration mode to globally enable a Cisco IOS voice gateway to authenticate and pass SIP credentials based on the redirecting number when available. Use the **no** form of this command to configure the gateway to authenticate and pass SIP credentials based only on the calling number of forwarded calls unless otherwise configured at the dial peer level:

- Use the **voice-class sip authenticate redirecting-number** command in dial peer voice configuration mode to supersede global settings and force a specific dial peer on the gateway to authenticate and pass SIP credentials based on the redirecting number when available.
- Use the **no** form of the **voice-class sip authenticate redirecting-number** command in dial peer voice configuration mode to supersede global settings and force a specific dial peer on the gateway to authenticate and pass SIP credentials based only on the calling number regardless of the global setting.

The redirecting number is present only in the headers of forwarded calls. When this command is disabled or the redirecting number is not available (nonforwarded calls), the gateway uses the calling number for SIP credentials.

Examples

The following example shows how to globally enable a Cisco IOS voice gateway to authenticate and pass the redirecting number of a forwarded call when a SIP INVITE message is challenged:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# authenticate redirecting-number
```

Related Commands

Command	Description
voice-class sip authenticate redirecting-number	Supersedes global settings and enables a dial peer on a Cisco IOS voice gateway to authenticate and pass SIP credentials based on the redirecting number of forwarded calls.

authentication (dial peer)

To enable SIP digest authentication on an individual dial peer, use the **authentication** command in dial peer voice configuration mode. To disable SIP digest authentication, use the **no** form of this command.

authentication username *username* **password** [**0** | **7**] *password* [**realm** *realm* [**challenge**]]

no authentication username *username* [**password** [**0** | **7**] *password* [**realm** *realm* [**challenge**]]]

Syntax Description

username	Specifies the username for the user who is providing authentication.
username	A string representing the username for the user who is providing authentication. A username must be at least four characters.
password	Specifies password settings for authentication.
0	(Optional) Specifies encryption type as cleartext (no encryption). This is the default.
7	(Optional) Specifies encryption type as encrypted.
password	A string representing the password for authentication. If no encryption type is specified, the password will be cleartext format. The string must be between 4 and 128 characters.
realm	(Optional) Specifies the domain where the credentials are applicable.
realm	(Optional) A string representing the domain where the credentials are applicable.

Command Default

SIP digest authentication is disabled.

Command Modes

Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.3(8)T	This command was introduced.
15.1(3)T	This command was modified. The **challenge** keyword was added.

Usage Guidelines

The following configuration rules are applicable when enabling digest authentication:

- Only one username can be configured per dial peer. Any existing username configuration must be removed before configuring a different username.
- A maximum of five *password* or *realm* arguments can be configured for any one username.

  The *username* and *password* arguments are used to authenticate a user. An authenticating server/proxy issuing a 407/401 challenge response includes a realm in the challenge response and the user provides credentials that are valid for that realm. Because it is assumed that a maximum of five proxy servers in the signaling path can try to authenticate a given request from a user-agent client (UAC) to a user-agent server (UAS), a user can configure up to five password and realm combinations for a configured username.

Note The user provides the password in plain text but it is encrypted and saved for 401 challenge response. If the password is not saved in encrypted form, a junk password is sent and the authentication fails.

- The realm specification is optional. If omitted, the password configured for that username applies to all realms that attempt to authenticate.
- Only one password can be configured at a time for all configured realms. If a new password is configured, it overwrites any previously configured password.

  This means that only one global password (one without a specified realm) can be configured. If you configure a new password without configuring a corresponding realm, the new password overwrites the previous one.
- If a realm is configured for a previously configured username and password, that realm specification is added to that existing username and password configuration. However, once a realm is added to a username and password configuration, that username and password combination is valid only for that realm. A configured realm cannot be removed from a username and password configuration without first removing the entire configuration for that username and password—you can then reconfigure that username and password combination with or without a different realm.
- In an entry with both a password and realm, you can change either the password or realm.

Examples

The following example shows how to enable the digest authentication:

```
Router> enable
Router# configure terminal
Router(config)# dial-peer voice 1 pots
Router(config-dial-peer)# authentication username MyUser password 7 MyPassword realm
MyRealm.example.com
```

The following example shows how to remove a previously configured digest authentication:

```
Router> enable
Router# configure terminal
Router(config)# dial-peer voice 1 pots
Router(config-dial-peer)# no authentication username MyUser password MyPassword
```

Related Commands

Command	Description
authentication (SIP UA)	Enables SIP digest authentication globally.
credentials (SIP UA)	Configures a Cisco UBE to send a SIP registration message when in the UP state.
localhost	Configures global settings for substituting a DNS local hostname in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages.
registrar	Enables Cisco IOS SIP gateways to register E.164 numbers on behalf of FXS, EFXS, and SCCP phones with an external SIP proxy or SIP registrar.
voice-class sip localhost	Configures settings for substituting a DNS local hostname in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages on an individual dial peer, overriding the global setting.

authentication (SIP UA)

To enable SIP digest authentication, use the **authentication** command in SIP UA configuration mode. To disable SIP digest authentication, use the **no** form of this command.

authentication username *username* **password** [**0** | **7**] *password* [**realm** *realm*]

no authentication username *username* [**password** [**0** | **7**] *password* [**realm** *realm*]]

Syntax Description

username *username*	A string representing the username for the user who is providing authentication (must be at least four characters).
password	Specifies password settings for authentication.
0	(Optional) Specifies encryption type as cleartext (no encryption). This is the default.
7	(Optional) Specifies encryption type as encrypted.
password	A string representing the password for authentication. If no encryption type is specified, the password will be cleartext format. The string must be between 4 and 128 characters.
realm *realm*	(Optional) A string representing the domain where the credentials are applicable.

Command Default

SIP digest authentication is disabled.

Command Modes

SIP UA configuration (config-sip-ua)

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

The following configuration rules are applicable when enabling digest access authentication:

- Only one username can be configured globally in SIP UA configuration mode. Any existing username configuration must be removed before configuring a different username.
- A maximum of five *password* or *realm* arguments are allowed for a given *username* argument.

  The *username* and *password* arguments are used to authenticate a user. An authenticating server/proxy issuing a 407/401 challenge response includes a realm in the challenge response and the user provides credentials that are valid for that realm. Because it is assumed that a maximum of five proxy servers in the signaling path can try to authenticate a given request from a user-agent client (UAC) to a user-agent server (UAS), a user can configure up to five password and realm combinations for a configured username.
- The realm specification is optional. If omitted, the password configured for that username applies to all realms that attempt to authenticate.

- Only one password can be configured at a time for all configured realms. If a new password is configured, it overwrites any previously configured password.

  This means that only one global password (one without a specified realm) can be configured. If you configure a new password without configuring a corresponding realm, the new password overwrites the previous one.
- If a realm is configured for a previously configured username and password, that realm specification is added to that existing username and password configuration. However, once a realm is added to a username and password configuration, that username and password combination is valid only for that realm. A configured realm cannot be removed from a username and password configuration without first removing the entire configuration for that username and password—you can then reconfigure that username and password combination with or without a different realm.
- In an entry with both a password and realm, you can change either the password or realm.

Examples

The following example shows how to enable digest access authentication:

```
Router> enable
Router# configure terminal
Router(config)# sip-ua
Router(config-sip-ua)# authentication username MyUser password MyPassword realm
example.com
```

The following example shows how to remove a previously configured digest access authentication:

```
Router> enable
Router# configure terminal
Router(config)# sip-ua
Router(config-sip-ua)# no authentication username MyUser password MyPassword realm
example.com
```

Related Commands

Command	Description
authentication (dial peer)	Enables SIP digest authentication on an individual dial peer.
credentials (SIP UA)	Configures a Cisco UBE to send a SIP registration message when in the UP state.
localhost	Configures global settings for substituting a DNS localhost name in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages.
registrar	Enables Cisco IOS SIP gateways to register E.164 numbers on behalf of FXS, EFXS, and SCCP phones with an external SIP proxy or SIP registrar.
voice-class sip localhost	Configures settings for substituting a DNS localhost name in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages on an individual dial peer, overriding the global setting.

authentication method

To set an authentication method at login for calls that come into a dial peer, use the **authentication method** command in voice class AAA configuration mode. To disable the authentication method set at login, use the **no** form of this command.

authentication method *MethListName*

no authentication method *MethListName*

Syntax Description

MethListName	Authentication method list name.

Command Default

When this command is not used to specify a login authentication method, the system uses the **aaa authentication login h323** command as the default.

Command Modes

Voice class AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

This command is used to direct authentication requests to a RADIUS server based on dialed number information service (DNIS) or trunk grouping.

This command is used for directing dial-peer-based authentication requests. The method list must be defined during initial authentication setup.

Examples

In the example below, “dp” is the method list name used for authentication. The method list name is defined during initial authentication setup.

```
voice class aaa 1
 authentication method dp
```

Related Commands

Command	Description
aaa authentication login	Sets AAA authentication at login.
voice class aaa	Enables dial-peer-based VoIP AAA configurations.

authorization method

To set an authorization method at login for calls that are into a dial peer, use the **authorization method** command in voice class AAA configuration mode. To disable the authorization method set at login, use the **no** form of this command.

authorization method *MethListName*

no authorization method *MethListName*

Syntax Description

MethListName	Defines an authorization method list name.

Command Default

When this command is not used to specifiy a login authorization method, the system uses the **aaa authorization exec h323** command as the default.

Command Modes

Voice class AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

This command is used to direct authentication requests to a RADIUS server based on dialed number information service (DNIS) or trunk grouping.

This command is used for directing dial-peer-based authentication requests. The method list must be defined during initial authentication setup.

Examples

The following example set an authorization method of “dp”:

```
voice class aaa 1
 authorization method dp
```

Related Commands

Command	Description
aaa authorization exec	Runs authorization to determine if the user is allowed to run an EXEC shell.
voice class aaa	Enables dial-peer-based VoIP AAA configurations.

auto-config

To enable auto-configuration or to enter auto-config application configuration mode for the Skinny Client Control Protocol (SCCP) application, use the **auto-config** command in global configuration mode. To disable auto-configuration, use the **no** form of this command.

auto-config [**application sccp**]

no auto-config

Syntax Description

application sccp	(Optional) Enters auto-config application configuration mode for the SCCP application.

Command Default

Auto-configuration is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)XY	This command was introduced on the Communication Media Module for the SCCP application.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T.

Examples

The following example shows the **auto-config** command used to enter auto-configuration application configuration mode for the SCCP application and the **no shutdown** command used to enable the SCCP application for download:

```
Router(config)# auto-config application sccp
Router(auto-config-app)# no shutdown
```

Related Commands

Command	Description
shutdown (auto-config application)	Disables an auto-configuration application for download.
show auto-config	Displays the current status of auto-configuration applications.

auto-cut-through

To enable call completion when a PBX does not provide an M-lead response, use the **auto-cut-through** command in voice-port configuration mode. To disable the auto-cut-through operation, use the **no** form of this command.

auto-cut-through

no auto-cut-through

Syntax Description

This command has no arguments or keywords.

Command Default

Auto-cut-through is enabled.

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was first supported on the Cisco 2600 and Cisco 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

The **auto-cut-through** command applies to ear and mouth (E&M) voice ports only.

Examples

The following example shows enabling of call completion on a router when a PBX does not provide an M-lead response:

```
voice-port 1/0/0
 auto-cut-through
```

Related Commands

Command	Description
show voice port	Displays voice port configuration information.

Cisco IOS Voice Commands: B

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Library.*

backhaul-session-manager

To enter backhaul session manager configuration mode, use the **backhaul-session-manager** command in global configuration mode.

backhaul-session-manager

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850 platform.
12.2(8)T	This command was implemented on Cisco IAD2420. Support for the Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command is supported on the Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.

Usage Guidelines

Use the **backhaul-session-manager** command to switch to backhaul session manager configuration mode from global configuration mode. Use the **exit** command to exit backhaul session manager configuration mode and return to global configuration mode.

Examples

The following example enters backhaul session manager configuration mode:

```
Router(config)# backhaul-session-manager
Router(config-bsm)#
```

Related Commands

Command	Description
clear backhaul-session-manager group	Resets the statistics or traffic counters for a specified session group.
clear rudpv1 statistics	Clears the RUDP statistics and failure counters.

Command	Description
group	Creates a session group and associates it with a specified session set.
group auto-reset	Configures the maximum auto-reset value.
group cumulative-ack	Configures maximum cumulative acknowledgments.
group out-of-sequence	Configures maximum out-of-sequence segments that are received before an EACK is sent.
group receive	Configures maximum receive segments.
group retransmit	Configures maximum retransmits.
group timer cumulative-ack	Configures cumulative acknowledgment timeout.
group timer keepalive	Configures keepalive (or null segment) timeout.
group timer retransmit	Configures retransmission timeout.
group timer transfer	Configures state transfer timeout.
isdn bind-l3	Configures the ISDN serial interface for backhaul.
session group	Associates a transport session with a specified session group.
set	Creates a fault-tolerant or non-fault-tolerant session set with the client or server option.
show backhaul-session-manager group	Displays status, statistics, or configuration of a specified or all session groups.
show backhaul-session-manager session	Displays status, statistics, or configuration of sessions.
show backhaul-session-manager set	Displays session groups associated with a specific or all session sets.
show rudpv1	Displays RUDP statistics.

bandwidth (dial peer)

To set the maximum bandwidth on a POTS dial peer for an H.320 call, use the **bandwidth** command in dial peer configuration mode. To remove the bandwidth setting, use the **no** form of this command.

bandwidth maximum *value* [**maximum** *value*]

no bandwidth

Syntax Description

maximum *value*	Sets the maximum bandwidth for an H.320 call on a POTS dial peer. The range is 64 to 1024, entered in increments of 64 kilobits per second (kbps). The default is 64.
minimum *value*	(Optional) Sets the minimum bandwidth. Acceptable values are 64 kbps or **minimum** *value*=**maximum** *value*.

Command Default No maximum bandwidth is set.

Command Modes Dial peer configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines Use this command to set the maximum and minimum bandwidth for an H.320 POTS dial-peer. Only the maximum bandwidth is required. The value must be entered in increments of 64 kbps. The minimum bandwidth setting is optional, and the value must be either 64 kbps or equal to the maximum value setting.

Examples The following example shows configuration for POTS dial peer 200 with a maximum bandwidth of 1024 kbps:

```
dial-peer voice 200 pots
 bandwidth maximum 1024
```

The following example shows configuration for POTS dial peer 11 with a maximum bandwidth of 640 and a minimum of 64:

```
dial-peer voice 11 pots
 bandwidth maximum 640 minimum 64
```

Related Commands

Command	Description
bandwidth	Specifies the maximum aggregate bandwidth for H.323 traffic and verifies the available bandwidth of the destination gatekeeper.

bandwidth

To specify the maximum aggregate bandwidth for H.323 traffic and verify the available bandwidth of the destination gatekeeper, use the **bandwidth** command in gatekeeper configuration mode. To disable maximum aggregate bandwidth, use the **no** form of this command.

bandwidth {**interzone** | **total** | **session**} {**default** | **zone** *zone-name*} *bandwidth-size*

no bandwidth {**interzone** | **total** | **session**} {**default** | **zone** *zone-name*}

Syntax Description

interzone	Total amount of bandwidth for H.323 traffic from the zone to any other zone.
total	Total amount of bandwidth for H.323 traffic allowed in the zone.
session	Maximum bandwidth allowed for a session in the zone.
default	Default value for all zones.
zone	A particular zone.
zone-name	Name of the particular zone.
bandwidth-size	Maximum bandwidth, in kbps. For **interzone** and **total**, range : 1 to 10000000. For **session**, range:1 to 5000.

Command Default

Maximum aggregate bandwidth is unlimited by default.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on the Cisco 2500, Cisco 3600 series and the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T. The **bandwidth** command replaced the **zone bw** command.
12.1(5)XM	The **bandwidth** command was recognized without using the **zone gatekeeper** command.
12.2(2)T	The changes in Cisco IOS Release 12.1(5)XM were integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Usage Guidelines

This command, in conjunction with the **bandwidth remote** command, replaces the **zone gatekeeper** command.

To specify maximum bandwidth for traffic between one zone and any other zone, use the **default** keyword with the **interzone** keyword.

To specify maximum bandwidth for traffic within one zone or for traffic between that zone and another zone (interzone or intrazone), use the **default** keyword with the **total** keyword.

To specify maximum bandwidth for a single session within a specific zone, use the **zone** keyword with the **session** keyword.

To specify maximum bandwidth for a single session within any zone, use the **default** keyword with the **session** keyword.

Examples

The following example configures the default maximum bandwidth for traffic between one zone and another zone to 5000 kbps:

```
gatekeeper
 bandwidth interzone default 5000
```

The following example configures the default maximum bandwidth for all zones to 5000 kbps:

```
gatekeeper
 bandwidth total default 5000
```

The following example configures the default maximum bandwidth for a single session within any zone to 2000 kbps:

```
gatekeeper
 bandwidth session default 2000
```

The following example configures the default maximum bandwidth for a single session with a specific zone to 1000 kbps:

```
gatekeeper
 bandwidth session zone example 1000
```

Related Commands

Command	Description
bandwidth check-destination	Enables the gatekeeper to verify available bandwidth resources at the destination endpoint.
bandwidth remote	Specifies the total bandwidth for H.323 traffic between this gatekeeper and any other gatekeeper.
h323 interface	Defines on which port the proxy listens.
h323 t120	Enables the T.120 capabilities on the router and specifies bypass or proxy mode.

bandwidth check-destination

To enable the gatekeeper to verify available bandwidth resources at the destination endpoint, use the **bandwidth check-destination command in** gatekeeper configuration mode. To disable resource verification, use the **no** form of this command.

bandwidth check-destination

no bandwidth check-destination

Syntax Description This command has no arguments or keywords.

Command Default Resource verification is disabled by default.

Command Modes Gatekeeper configuration

Command History

Release	Modification
12.3(1)	This command was introduced.

Examples The following example activates bandwidth resource verification at the destination:

```
gatekeeper
 bandwidth check-destination
```

Related Commands

Command	Description
bandwidth	Specifies the maximum aggregate bandwidth for H.323 traffic from a zone to another zone, within a zone, or for a session in a zone.
bandwidth remote	Specifies the total bandwidth for H.323 traffic between this gatekeeper and any other gatekeeper.
h323 interface	Defines the port on which port the proxy listens.
h323 t120	Enables the T.120 capabilities on your router and specifies bypass or proxy mode.

bandwidth remote

To specify the total bandwidth for H.323 traffic between this gatekeeper and any other gatekeeper, use the **bandwidth remote** command in gatekeeper configuration mode. To disable total bandwidth specified, use the **no** form of this command.

bandwidth remote *bandwidth-size*

no bandwidth remote

Syntax Description

bandwidth-size	Maximum bandwidth, in kbps. Range: 1 to 10000000.

Command Default

Total bandwidth is unlimited by default.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Usage Guidelines

This command, with the **bandwidth** command, replaces the **zone gatekeeper** command.

Examples

The following example configures the remote maximum bandwidth to 100,000 kbps:

```
gatekeeper
 bandwidth remote 100000
```

Related Commands

Command	Description
bandwidth	Specifies the maximum aggregate bandwidth for H.323 traffic from a zone to another zone, within a zone, or for a session in a zone.
bandwidth check-destination	Enables the gatekeeper to verify available bandwidth resources at the destination endpoint.
h323 interface	Defines which port the proxy listens on.
h323 t120	Enables the T.120 capabilities on your router and specifies bypass or proxy mode.

battery-reversal

To specify battery polarity reversal on a Foreign Exchange Office (FXO) or Foreign Exchange Station (FXS) port, use the **battery-reversal command in** voice-port configuration mode. To disable battery reversal, use the **no** form of this command.

battery-reversal [**answer**]

no battery-reversal [**answer**]

Syntax Description

answer	(Optional) Configures an FXO port to support answer supervision by detection of battery reversal.

Command Default Battery reversal is enabled

Command Modes Voice-port configuration

Command History

Release	Modification
12.0(7)XK	This command was introduced on the Cisco 2600 series and Cisco 3600 series and on the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.2(2)T	The **answer** keyword was added.

Usage Guidelines The **battery-reversal** command applies to FXO and FXS voice ports. On Cisco 2600 and 3600 series routers, only analog voice ports in VIC-2FXO-M1 and VIC-2FXO-M2 voice interface cards are able to detect battery reversal; analog voice ports in VIC-2FXO and VIC-2FXO-EU voice interface cards do not detect battery reversal. On digital voice ports, battery reversal is supported only on E1 Mercury Exchange Limited Channel Associated Signaling (MEL CAS); it is not supported in T1 channel associated signaling (CAS) or E1 CAS.

FXS ports normally reverse battery upon call connection. If an FXS port is connected to an FXO port that does not support battery reversal detection, you can use the **no battery-reversal** command on the FXS port to prevent unexpected behavior.

FXO ports in loopstart mode normally disconnect calls when they detect a second battery reversal (back to normal). You can use the **no battery-reversal** command on FXO ports to disable this action.

The **battery-reversal** command restores voice ports to their default battery-reversal operation.

If an FXO voice port is connected to the PSTN and supports battery reversal, use the **battery-reversal** command with the **answer** keyword to configure answer supervision. This configures the FXO voice port to detect when a call is answered in order to provide correct billing information.

If the voice port, PSTN, or PBX does not support battery reversal, do not use the **battery-reversal** command because it prevents outgoing calls from being connected. Use the **supervisory answer dualtone** command instead.

If an FXO port or its peer FXS port does not support battery reversal, avoid configuring **battery-reversal** or **battery-reversal answer** on the FXO port. On FXO ports that do not support battery reversal, the **battery-reversal** command can cause unpredictable behavior, and the **battery-reversal answer** command prevents calls from being answered. To ensure that battery reversal answer is disabled on FXO ports that do not support battery reversal, use the **no battery-reversal** command.

Examples

The following example disables battery reversal on voice port 1/0/0 on a router:

```
voice-port 1/0/0
 no battery-reversal
```

The following example enables battery reversal to provide answer supervision on voice port 1/0/0 on a router:

```
voice-port 1/0/0
 battery-reversal answer
```

Related Commands

Command	Description
show voice port	Displays voice port configuration information.
supervisory answer dualtone	Enables answer supervision on an FXO voice port on which battery reversal is not supported.

bearer-capability clear-channel

To specify the information transfer capability of the bearer capability information element (IE) in the outgoing ISDN SETUP message for Session Initiation Protocol (SIP) early-media calls that negotiate the clear-channel codec, use the **bearer-capability clear-channel** command in SIP configuration mode. To reset the information transfer capability of the bearer capability IE to **speech** (default), use the **no** form of this command.

bearer-capability clear-channel {**speech** | **udi** | **rdi** | **audio** | **tones** | **video**}

no bearer-capability clear-channel

Syntax Description

speech	Specifies speech as the information transfer capability (default).
udi	Specifies untrestricted digital information (UDI).
rdi	Specifies restricted digital information (RDI).
audio	Specifies 3.1 kHz audio.
tones	Specifies UDI with tones and announcements.
video	Specifies video as the information transfer capability.

Command Default

The default information transfer capability setting for the bearer-capability IE is **speech**.

Command Modes

SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

When a Cisco voice gateway receives a SIP early-media call and negotiates the clear-channel codec, the default for the information transfer capability octet (octet 3) of the bearer capability IE in the outgoing ISDN SETUP message is set to **speech**. Use the **bearer-capability clear-channel** command to change the information transfer capability of the bearer capability IE to a different value.

Note Changing the information transfer capability of the bearer capability IE affects only SIP early-media calls. The information transfer capability value is always **speech** for SIP delayed-media calls, even when the clear-channel codec is negotiated.

You can display the current information transfer capability setting for the bearer capability IE using the **show running-config** command. To show only voice service configuration information, limit the display output to the section on voice service (see the "Examples" section).

Note When the information transfer capability is set to the default value (**speech**), the output of the **show running-config** command does not include the bearer-capability information line.

Examples

The following examples show how to configure the information transfer capability of the bearer capability IE to UDI to allow for 64 kb/s data transfer over ISDN and how to display the current setting.

Use the following commands to change the information transfer capability setting in the bearer capability IE to **udi**:

```
voice service voip
 sip
  bearer-capability clear-channel udi
```

Use the following command to display the current information transfer capability setting:

```
Router# show running-config | section voice service

voice service voip
 h323
 sip
  bearer-capability clear-channel udi
```

billing b-channel

To enable the H.323 gateway to access B-channel information for all H.323 calls, use the **billing b-channel** command in H.323 voice service configuration mode. To return to the default setting, use the **no** form of this command.

billing b-channel

no billing b-channel

Syntax Description

This command has no arguments or keywords.

Command Default

B-channel information is disabled.

Command Modes

H.323 voice service configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

This command enables the H.323 application to receive B-channel information of incoming ISDN calls. The B-channel information appears in H.323 ARQ / LRQ messages and can be used during call transfer or to route a call.

Examples

The following example adds B-channel information to the H.323 gateway:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# billing b-channel
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.
voice service	Enters voice-service configuration mode and specifies the voice encapsulation type.

bind

To bind the source address for signaling and media packets to the IPv4 or IPv6 address of a specific interface, use the **bind** command in SIP configuration mode. To disable binding, use the **no** form of this command.

bind {**control** | **media** | **all**} **source-interface** *interface-id* [**ipv4-address** *ipv4-address* | **ipv6-address** *ipv6-address*]

no bind

Syntax Description

control	Binds Session Initiation Protocol (SIP) signaling packets.
media	Binds only media packets.
all	Binds SIP signaling and media packets. The source address (the address that shows where the SIP request came from) of the signaling and media packets is set to the IPv4 or IPv6 address of the specified interface.
source-interface	Specifies an interface as the source address of SIP packets.
interface-id	Specifies one of the following interfaces: • **Async**: ATM interface • **BVI**: Bridge-Group Virtual Interface • **CTunnel**: CTunnel interface • **Dialer**: Dialer interface • **Ethernet**: IEEE 802.3 • **FastEthernet**: Fast Ethernet • **Lex**: Lex interface • **Loopback**: Loopback interface • **Multilink**: Multilink-group interface • **Null**: Null interface • **Serial**: Serial interface (Frame Relay) • **Tunnel**: Tunnel interface • **Vif**: PGM Multicast Host interface • **Virtual-Template**: Virtual template interface • **Virtual-TokenRing**: Virtual token ring
ipv4-address *ipv4-address*	(Optional) Configures the IPv4 address. Several IPv4 addresses can be configured under one interface.
ipv6-address *ipv6-address*	(Optional) Configures the IPv6 address under an IPv4 interface. Several IPv6 addresses can be configured under one IPv4 interface.

Command Default

Binding is disabled.

Command Modes SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(2)XB2	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5850, and Cisco AS5400 in this release.
12.3(4)T	The **media** keyword was added.
12.4(22)T	Support for IPv6 was added.
Cisco IOS XE Release 2.5	This command was integrated into Cisco IOS XE Release 2.5

Usage Guidelines Async, Ethernet, FastEthernet, Loopback, and Serial (including Frame Relay) are interfaces within the SIP application.

If the **bind** command is not enabled, the IPv4 layer still provides the best local address.

Examples The following example sets up binding on a SIP network:

```
Router(config)# voice serv voip
Router(config-voi-serv)# sip
Router(config-serv-sip)# bind control source-interface FastEthernet 0
```

Related Commands

Command	Description
sip	Enters SIP configuration mode from voice service VoIP configuration mode.

bind interface

To bind an interface to a Cisco CallManager group, use the **bind interface** command in SCCP Cisco CallManager configuration mode. To unbind the selected interface, use the **no** form of this command.

bind interface {**dynamic** | *interface-type interface-number*}

no bind interface {**dynamic** | *interface-type interface-number*}

Syntax Description

dynamic	The transcoder interface is chosen based on the remote IP address.
interface-type	Type of selected interface.
interface-number	Number of the selected interface.

Command Default

Interfaces are not associated with any Cisco CallManager group.

Command Modes

SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
15.1(3)T1	This command was modified. The **dynamic** keyword was added.

Usage Guidelines

Normally a firewall only opens certain addresses or port combination to the outside world and those addresses can change dynamically. The VoIP technology requires the use of more than one address or port combination to pass information. The **bind interface** command allows administrators to dictate the use of one network to transport the signaling and another network to transport the media by assigning an interface to a Cisco CallManager group for a specific interface for the signaling or media application.

The selected interface is used for all calls that belong to the profiles that are associated to this Cisco CallManager group. If the **dynamic** keyword is configured, the transcoder interface is chosen based on the remote address. If the interface is not configured, the Skinny Call Control Protocol (SCCP) selects the best interface IP address in the gateway. Interfaces are selected according to user requirements. If there is only one group interface, configuration is not needed.

Note Only one interface can be selected. A given interface can be bound to more than one Cisco CallManager group.

Examples

The following example binds the interface to a specific Cisco CallManager group:

```
Router(config-sccp-ccm)# bind interface fastethernet 2:1
```

Related Commands

Command	Description
associate profile	Associates a DSP farm profile with a Cisco CallManager group.
sccp ccm group	Creates a Cisco CallManger group and enters SCCP Cisco CallManager configuration mode.

block

To configure global settings to drop (not pass) specific incoming Session Initiation Protocol (SIP) provisional response messages on a Cisco IOS voice gateway or Cisco Unified Border Element (Cisco UBE), use the **block** command in voice service SIP configuration mode. To disable a global configuration to drop incoming SIP provisional response messages, use the **no** form of this command.

block {**180** | **181** | **183**} [**sdp** {**absent** | **present**}]

no block {**180** | **181** | **183**}

Syntax Description

180	Specifies that incoming SIP 180 Ringing messages should be dropped (not passed to the other leg).
181	Specifies that incoming SIP 181 Call is Being Forwarded messages should be dropped (not passed to the other leg).
183	Specifies that incoming SIP 183 Session in Progress messages should be dropped (not passed to the other leg).
sdp	(Optional) Specifies that either the presence or absence of Session Description Protocol (SDP) information in the received response determines when the dropping of specified incoming SIP messages takes place.
absent	Configures the SDP option so that specified incoming SIP messages are dropped only if SDP is absent from the received provisional response.
present	Configures the SDP option so that specified incoming SIP messages are dropped only if SDP is present in the received provisional response.

Command Default

Incoming SIP 180, 181, and 183 provisional responses are forwarded.

Command Modes

Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(22)YB	This command was introduced. Only SIP 180 and SIP 183 messages are supported on Cisco UBEs.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.
15.0(1)XA	This command was modified. Support was added for SIP 181 messages on the Cisco IOS SIP gateway, SIP-SIP Cisco UBEs, and the SIP trunk of Cisco Unified Communications Manager Express (Cisco Unified CME).
15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines

Use the **block** command in voice service SIP configuration mode to globally configure Cisco IOS voice gateways and Cisco UBEs to drop specified SIP provisional response messages. Additionally, you can use the **sdp** keyword to further control when the specified SIP message is dropped based on either the absence or presence of SDP information.

To configure settings for an individual dial peer, use the **voice-class sip block** command in dial peer voice configuration mode. To disable global configurations for dropping specified incoming SIP messages on a Cisco IOS voice gateway or Cisco UBE, use the **no block** command in voice service SIP configuration mode.

Note This command is supported only on outbound dial peers—it is nonoperational if configured on inbound dial peers. You should configure this command on the outbound SIP leg that sends out the initial INVITE message. Additionally, this feature applies only to SIP-to-SIP calls and will have no effect on H.323-to-SIP calls.

Examples

The following example shows how to globally configure dropping of incoming SIP provisional response messages:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# block 181
```

The following example shows how to globally configure dropping of incoming SIP with SDP provisional response messages:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# block 183 sdp present
```

The following example shows how to globally configure dropping of incoming SIP without SDP provisional response messages:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# block 180 sdp absent
```

The following example shows how to globally configure passing all specified incoming SIP provisional response messages (except for those on individual dial peers that are configured to override the global configuration):

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# no block 181
```

Related Commands

Command	Description
map resp-code	Configures global settings on a Cisco UBE for mapping specific incoming SIP provisional response messages to a different SIP response message.
voice-class sip block	Configures an individual dial peer on a Cisco IOS voice gateway or Cisco UBE to drop specified SIP provisional response messages.
voice-class sip map resp-code	Configures a specific dial peer on a Cisco UBE to map specific incoming SIP provisional response messages to a different SIP response message.

block-caller

To configure call blocking on caller ID, use the **block-caller** command in dial peer voice configuration mode. To disable call blocking on caller ID, use the **no** form of this command.

block-caller *number*

no block-caller *number*

Syntax Description

number	Specifies the telephone number to block. You can use a period (.) as a digit wildcard. For example, the command **block-caller 5.51234** blocks all numbers beginning with the digit 5, followed by any digit, and then sequentially followed by the digits 5, 1, 2, 3, and 4.

Command Default

Call blocking is disabled; the router does not block any calls for any listed directory numbers (LDNs) based on caller ID numbers

Command Modes

Dial peer voice configuration

Command History

Release	Modification
12.1(2)XF	This command was introduced on the Cisco 800 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.

This command is available on Cisco 800 series routers that have plain old telephone service (POTS) ports. For each dial peer, you can enter up to ten caller ID numbers to block. The routers do not accept additional caller ID numbers if ten numbers are already present. In that case, a number must be removed before another caller ID number can be added for blocking.

If you do not specify the **block-caller** command for a local directory, all voice calls to that local directory are accepted. If you specify the **block-caller** command for a local directory, the router verifies that the incoming calling-party number does not match any caller ID numbers in that local directory before processing or accepting the voice call. Each specified caller ID number and incoming calling-party number is compared from right to left, up to the number of digits in the specified caller ID number or incoming calling-party number, whichever has fewer digits.

This command is effective only if you subscribe to caller ID service. If you enable call blocking on caller ID without subscribing to the caller ID service, the routers do not perform the verification process on calling-party numbers and do not block any calls.

Examples

The following example configures a router to block calls from a caller whose caller ID number is 408-555-0134.

```
dial-peer voice 1 pots
 block-caller 4085550134
```

Related Commands

Command	Description
caller-id	Identifies incoming calls with caller ID.
debug pots csm csm	Activates events from which an application can determine and display the status and progress of calls to and from POTS ports.
isdn i-number	Configures several terminal devices to use one subscriber line.
pots call-waiting	Enables local call waiting on a router.
registered-caller ring	Configures the Nariwake service registered caller ring cadence.

bootup e-lead off

To prevent an analog ear and mouth (E&M) voice port from keying the attached radio on router boot up, use the **bootup e-lead off** command in voice-port configuration mode. To allow the analog E&M voice port to key the attached radio on boot up, use the **no** form of this command.

bootup e-lead off

no bootup e-lead off

Syntax Description

This command has no arguments or keywords.

Command Default

The analog E&M voice port keys the attached radio on radio boot up.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

This command configures the E-lead behavior on boot up for both voice ports on the voice interface card (VIC).

Examples

The following example configures the analog E&M voice port to not key the attached radio on router boot up:

```
voice-port 1/0/0
 bootup e-lead off
```

busyout forced

To force a voice port into the busyout state, use the **busyout forced** command in voice-port configuration mode. To remove the voice port from the busyout state, use the **no** form of this command.

busyout forced

no busyout forced

Syntax Description

This command has no arguments or keywords.

Command Default

The voice-port is not in the busyout state.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.0(3)T	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on the Cisco 2600s series and Cisco 3600 series. On the Cisco MC3810, the **voice-port busyout** command was eliminated in favor of this command.
12.1(2)T	The command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

If a voice port is in the forced busyout state, only the **no busyout forced** command can restore the voice port to service.

To avoid conflicting command-line interface (CLI) commands, do not use the **busyout forced** command and the **ds0 busyout** command on the same controller.

Examples

The following example forces analog voice port 3/1/1 on a Cisco 3600 router into the busyout state:

```
voice-port 3/1/1
 busyout forced
```

The following example forces digital voice port 0/0:12 on a Cisco 3600 router into the busyout state:

```
voice-port 0/0:12
 busyout forced
```

Related Commands

Command	Description
busyout-monitor interface	Configures a voice port to monitor a serial interface for events that would trigger a voice-port busyout.
busyout seize	Changes the busyout seize procedure for a voice port.
show voice busyout	Displays information about the voice busyout state.

busyout monitor

To place a voice port into the busyout monitor state, enter the **busyout monitor** command in voice-port configuration mode. To remove the busyout monitor state from the voice port, use the **no** form of this command.

busyout monitor {**serial** *interface-number* | **ethernet** *interface-number* | **keepalive**} [**in-service**]

no busyout monitor {**serial** *interface-number* | **ethernet** *interface-number* | **keepalive**}

Syntax Description

serial	Specifies monitoring of a serial interface. More than one interface can be entered for a voice port.
ethernet	Specifies monitoring of an Ethernet interface. More than one interface can be entered for a voice port.
interface-number	The interface to be monitored for the voice port busyout function.
keepalive	In case of keepalive failures, the selected voice port or ports is busied out.
in-service	(Optional) Configures the voice port to be busied out when any monitored interface comes into service (its state changes to up). If the keyword is not entered, the voice port is busied out when all monitored interfaces go out of service (their state changes to down).

Command Default

The voice port does not monitor any interfaces.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.0(3)T	This command was introduced on the Cisco MC3810.
12.0(5)XE	This command was implemented on the Cisco 7200 series.
12.0(5)XK	This command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.0(7)T	This command was implemented on the Cisco 2600 series and Cisco 3600 series and integrated into Cisco IOS Release 12.0(7)T.
12.0(7)XK	The ability to monitor an Ethernet port was introduced and the **in-service** keyword was added. The **serial** keyword was first supported on the Cisco 2600 series and Cisco 3600 series.
12.1(1)T	The implementation of this command on the Cisco 7200 series was integrated into Cisco IOS Release 12.1(1)T.
12.1(2)T	The **serial** and **ethernet** keywords were added, the **in-service** keyword was integrated into Cisco IOS Release 12.1(2)T, and the *interface-number* argument was added to the **serial** and **ethernet** keywords.
12.1(3)T	The **interface** keyword was removed.
12.4(6)T	The **keepalive** keyword was added.

Usage Guidelines

When you place a voice port in the busyout monitor state, the voice port monitors the specified interface and enters the busyout state when the interface is down. This down state forces the rerouting of calls.

The **busyout monitor** command monitors only the up or down status of an interface—not end-to-end TCP/IP connectivity.

When an interface is operational, a busied-out voice port returns to its normal state.

This feature can monitor LAN, WAN, and virtual subinterfaces.

A voice port can monitor multiple interfaces at the same time. To configure a voice port to monitor multiple interfaces, reenter the **busyout monitor** command for each additional interface to be monitored.

If you specify more than one monitored interface for a voice port, all the monitored interfaces must be down to trigger busyout on the voice port.

You can combine in-service and out-of-service monitoring on a voice port. The following rule describes the action if monitored interfaces change state. A voice port is busied out if either of the following occurs:

- Any interface monitored for coming into service comes up.
- All interfaces monitored for going out of service go down.

Examples

The following example shows configuration of analog voice port 1/2 to busy out if serial port 0 or 1 comes into service:

```
voice-port 1/2
 busyout monitor serial 0 in-service
 busyout monitor serial 1 in-service
```

The following example shows configuration of digital voice port 1/2/2 on a Cisco 3600 series router to busy out if serial port 0 goes out of service:

```
voice-port 1/2/2
 busyout monitor serial 0
```

The following example shows configuration of the voice port to monitor two serial interfaces and an Ethernet interface. When all these interfaces are down, the voice port is busied out. When at least one interface is operating, the voice port is put back into a normal state.

```
voice-port 3/0:0
 busyout monitor ethernet 0/0
 busyout monitor serial 1/0
 busyout monitor serial 2/0
```

The following example shows configuration of the voice port to be busied out in case of a keepalive failure:

```
voice-port 10
 busyout monitor keepalive
```

Related Commands

Command	Description
busyout forced	Forces a voice port into the busyout state.
busyout monitor probe	Configures a voice port to enter busyout state if an SAA probe signal returned from a remote interface crosses a delay or loss threshold.

busyout seize	Changes the busyout seize procedure for a voice port.
show voice busyout	Displays information about the voice busyout state.
voice-port busyout	Places all voice ports associated with a serial or ATM interface into a busyout state.

busyout monitor action

To place a voice port into graceful or shutdown busyout state when triggered by the busyout monitor, use the **busyout monitor action** command in voice-port configuration mode. To remove the voice port from the busyout state, use the **no** form of this command.

busyout monitor action {**graceful** | **shutdown** | **alarm blue**}

no busyout monitor action {**graceful** | **shutdown** | **alarm blue**}

Syntax Description

graceful	Graceful busyout state.
shutdown	D-channel shutdown busyout state.
alarm blue	Shutdown state with a blue alarm, also known as an alarm-indication signal (AIS).

Command Default

Default voice busyout behavior without this command is a forced busyout.

Default voice busyout behavior for PRI depends on whether or not the ISDN switch type supports service messages:

- If the switch type supports service messages, default voice busyout behavior is to transmit B-channel out-of-service (OOS) messages and to keep the D channel active. D-Channel service-messages are supported on the following ISDN switch-types: NI, 4ESS (User Side only), 5ESS (User Side only), DMS100.
- If the switch type does not support service messages, default voice busyout behavior is to bring down the D channel.
- For switch-types not specified above, the D-channel is taken down when the **busyout monitor action graceful** is configured.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.2(13)T	The **busyout monitor action graceful** command was introduced on the following platforms: Cisco 2600 series, Cisco 2600XM, Cisco 2691, Cisco 3640, Cisco 3660, Cisco 3725, and Cisco VG200.
12.3(6)	The **busyout monitor action shutdown** command was introduced on the following platforms: Cisco 1700 series, Cisco IAD2420 series, Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3600 series, Cisco 3700 series, Cisco 4224, Cisco 7200 series, Cisco 7301, Cisco 7400 series, Cisco MC3810, Cisco WS-X4604-GWY, and Cisco VG200.
12.3(7)T	The **busyout monitor action shutdown** command was integrated into Cisco IOS Release 12.3(7)T and support was added for the Cisco IAD2430 series.

Release	Modification
12.4(6)T	The **busyout monitor action graceful** and **busyout monitor action shutdown** commands were introduced to replace the **busyout action graceful** and **busyout action shutdown** commands.
12.4(9)T	The **busyout monitor action** command was introduced to combine the **busyout monitor action graceful** and **busyout monitor action shutdown** commands. The **shutdown alarm blue** keywords were added.

Usage Guidelines

Use this command to control busyout behavior that is triggered by the **busyout monitor** command.

This command with the **graceful** keyword busies out the voice port immediately or, if there is an active call on this voice port, waits until the call is over.

This command with the **shutdown** keyword has the following attributes:

- Before Cisco IOS Release 12.2(8)T, when voice busyout is triggered on a PRI voice port, the D channel is deactivated until the busyout trigger is cleared. Some ISDN switch types, however, support in-service and OOS Q.931 messages that permit B channels to be taken out of service while still keeping the D channel active. Starting in Cisco IOS Release 12.3(8)T for these ISDN switch types, OOS messages are sent and the D channel is kept active when a voice busyout is triggered.
- This keyword is available only for PRI voice ports.
- For switch-types not specified above, the D-channel is be taken down when the **busyout monitor action graceful** command is configured.

Examples

The following example shows analog voice-port busyout state set to graceful:

```
voice-port 2/0:15
 busyout monitor action graceful
```

The following example shows E1 PRI voice-port busyout state set to shutdown:

```
voice-port 1/1:15 (E1 PRI)
 busyout monitor gatekeeper
 busyout monitor action shutdown
```

The following example shows T1 PRI voice-port busyout state set to shutdown:

```
voice-port 0/1:23 (T1 PRI)
 busyout monitor gatekeeper
 busyout monitor action shutdown
```

Related Commands

Command	Description
busyout forced	Forces a voice port into busyout state.
busyout monitor	Configures a voice port to monitor an interface for events that would trigger voice-port busyout.
busyout monitor backhaul	Configures a voice port to enter busyout-monitor state with backhaul-L3 connectivity monitoring during a WAN failure.
busyout monitor gatekeeper	Configures a voice port to enter busyout state if connectivity to the gatekeeper is lost.

Command	Description
busyout monitor probe	Configures a voice port to enter busyout state if an SAA probe signal returned from a remote, IP-addressable interface crosses a specified delay or loss threshold.
busyout seize	Changes the busyout seize procedure for a voice port.
show voice busyout	Displays information about voice-busyout state.
voice-port	Enters voice-port configuration mode and identifies the voice port to be configured.

busyout monitor backhaul

To configure a voice port to enter busyout-monitor state with backhaul-L3 connectivity monitoring during a wide-area-network (WAN) failure, use the **busyout monitor backhaul** command in voice-port configuration mode. To disable busyout-monitor state, use the **no** form of this command.

busyout monitor backhaul

no busyout monitor backhaul

Syntax Description This command has no arguments or keywords.

Command Default If this command is not used, the voice port is not configured to enter busyout state during a WAN failure.

Command Modes Voice-port configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines Use this command to implement backhaul-L3 connectivity monitoring.

Examples The following example configures a voice port to enter busyout-monitor state with backhaul-L3 connectivity monitoring during a WAN failure:

```
Router(config-voiceport)# busyout monitor backhaul
```

Related Commands

Command	Description
busyout monitor action	Places a voice port into busyout state.
busyout monitor	Configures a voice port to enter busyout-monitor state.

busyout monitor gatekeeper

To configure a voice port to enter the busyout state if connectivity to the gatekeeper is lost, use the **busyout monitor gatekeeper** command in voice-port configuration mode. To configure the monitor to trigger a busyout when any voice port assigned to a specific voice class loses connectivity to the gatekeeper, use the **busyout monitor gatekeeper** command in voice-class configuration mode. To disable the busyout monitoring state for the gatekeeper, use the **no** form of this command.

busyout monitor gatekeeper

no busyout monitor gatekeeper

Syntax Description

This command has no arguments or keywords.

Command Default

If this command is not used, the voice port or voice class is not configured to enter a busyout state if connectivity to the gatekeeper is lost.

Command Modes

Voice-port configuration
Voice-class configuration

Command History

Release	Modification
12.2(13)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 2600XM, Cisco 2691, Cisco 3640, Cisco 3660, Cisco 3725 and Cisco VG200.
12.4(6)T	This command was extended to include functionality in voice-class configuration mode.

Usage Guidelines

Use this command to monitor the connection between the gateway and gatekeeper.

Examples

The following example shows the busyout monitor state set to busyout the port according to the state of the gatekeeper:

```
voice-port 1/1/1
 busyout monitor gatekeeper
```

The following example enters voice-class (busyout) configuration mode and creates a voice class named 33. The monitor is set to busyout when any voice port in voice class 33 loses connectivity to the gatekeeper:

```
voice-class busyout 33
 busyout monitor gatekeeper
```

Related Commands

Command	Description
busyout monitor action graceful	Places a voice port into the graceful busyout state when triggered by the busyout monitor.
busyout monitor action graceful	Shuts down the voice port immediately, but if there is an active call it waits until the call is over.
busyout forced	Forces a voice port into the busyout state.
busyout monitor	Configures a voice port to monitor an interface for events that would trigger a voice-port busyout.
busyout monitor probe	Configures a voice port to enter the busyout state if an SAA probe signal returned from a remote, IP-addressable interface crosses a specified delay or loss threshold.
busyout seize	Changes the busyout seize procedure for a voice port.
show voice busyout	Displays information about the voice busyout state.
voice-port	Enters voice-port configuration mode and identifies the voice port to be configured.

busyout monitor probe

To configure a voice port to enter the busyout state if a Service Assurance Agent (SAA) probe signal is returned from a remote IP-addressable interface after the expiration of a specified delay or loss threshold, use the **busyout monitor probe** command in voice-port configuration mode or voice class busyout mode. To configure a voice port not to monitor SAA probe signals, use the **no** form of this command.

busyout monitor probe [**icmp-ping**] *ip-address* [**codec** *codec-type* | **size** *bytes*] [**icpif** *number* | **loss** *percent* **delay** *milliseconds*] [**grace-period** *seconds*] size

no busyout monitor probe *ip-address*

Syntax Description

icmp-ping	(Optional) Configures voice-port parameters to use ICMP pings to monitor IP destinations.
ip-address	The IP address of a target interface for the SAA probe signal.
codec	(Optional) Configures the profile of the SAA probe signal to mimic the packet size and interval of a specific codec type.
codec-type	(Optional) The codec type for the SAA probe signal. Available options are as follows: • **g711a**—G.711 a-law • **g711u**—G.711 mu-law (the default) • **g729**—G.729 • **g729a**—G.729 Annex A • **g729b**—G.729 Annex B
size *bytes*	(Optional) Size (in bytes) of the ping packet. Default is 32.
icpif	(Optional) Configures the busyout monitor probe to use an Impairment/Calculated Planning Impairment Factor (ICPIF) loss/delay busyout threshold, in accordance with ITU-T G.113. The ICPIF numbers represent predefined combinations of loss and delay.
number	(Optional) The ICPIF threshold for initiating a busyout condition. Range is from 0 to 30. Low numbers are equivalent to low loss and delay thresholds.
loss	(Optional) Configures the percentage-of-packets-lost threshold for initiating a busyout condition.
percent	(Optional) The loss value (expressed as a percentage) for initiating a busyout condition. Range is from 1 to 100.
delay	(Optional) Configures the average packet delay threshold for initiating a busyout condition.
milliseconds	(Optional) The delay threshold, in milliseconds, for initiating a busyout condition. Range is from 1 to 2,147,483,647.
grace-period	(Optional) Configures a time limit that the system waits before initiating a busyout condition after the loss of SAA probe connectivity.
seconds	(Optional) Number of seconds for the duration of the grace period. Range is from 30 to 300.

Command Default

If the **busyout monitor probe** command is not entered, the voice port does not monitor SAA probe signals.

If the **busyout monitor probe** command is entered with no optional keywords or arguments, the default codec type is G.711 a-law, the default loss and delay thresholds are the threshold values that are configured with the **call fallback threshold delay-loss** command, and the loss of SAA connectivity causes an immediate forced busyout condition.

Command Modes

Voice-port configuration and voice class busyout

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 and Cisco 3600 series and on the Cisco MC3810.
12.3(15)	This command was integrated into Cisco IOS Release 12.3(15) and the **grace-period** keyword and *seconds* argument were added.
12.4(1)	This command was integrated into Cisco IOS Release 12.4(1).
12.4(2)T	This command was integrated into Cisco IOS Release 12.4(2)T.

Usage Guidelines

A voice port can monitor multiple interfaces at the same time. To configure a voice port to monitor multiple interfaces, enter the **busyout monitor probe** command for each additional interface to be monitored.

Caution The **busyout monitor probe** command is effective only if the call fallback function is enabled on the source router, and the SAA responder is enabled on the target router. To enable the call fallback function, you must enter the **call fallback active** command for the **busyout monitor probe** command to work.

The SAA probe is transmitted periodically with a period determined by the call fallback function.

Low thresholds of ICPIF, loss, and delay result in early busyout when the link deteriorates, thereby raising the voice minimum quality level. High thresholds prevent busyout until loss and delay are long, allowing transmission of lower-quality voice.

Caution If thresholds are set too low, the link can alternate between in-service and out-of-service states, causing repeated interruptions of traffic.

Before the introduction of the **grace-period** keyword to the **busyout monitor probe** command, the loss of SAA probe connectivity was sufficient to immediately enforce busyout, causing service and connectivity problems in some networks because busyout conditions could occur frequently and abruptly. To improve busyout monitoring via SAA probes, the **grace-period** setting allows for an additional timer that must expire before a busyout condition is enforced. That is, the SAA probes and the period of grace must both expire before a busyout condition is invoked. If the SAA IP connectivity is restored within the period of grace, the busyout condition does not occur.

Note To disable the **grace-period** option, you must first enter the **no busyout monitor probe** command and then re-enter the **busyout monitor probe** command without the **grace-period** option.

The **grace-period** keyword is not available in Cisco IOS Release 12.3T.

Examples

The following example shows how to configure analog voice port 1/1/0 to use an SAA probe with a G.711a-law profile to probe the link to two remote interfaces that have IP addresses and to busy out the voice port if SAA probe connectivity is lost for at least 5 seconds. Both links have a loss exceeding 25 percent or a packet delay of more than 1.5 seconds.

```
voice-port 1/1/0
 busyout monitor probe 209.165.202.128 codec g711a loss 25 delay 1500 grace-period 45
 busyout monitor probe 209.165.202.129 codec g711a loss 25 delay 1500 grace-period 45
```

Related Commands

Command	Description
busyout monitor	Places a voice port into the busyout monitor state.
call fallback active	Enables the ICMP-ping or SAA (formerly RTR) probe mechanism for use with the dial-peer **monitor probe** or voice-port **busyout monitor probe** commands.
call fallback threshold delay-loss	Forces a voice port into the busyout state.
show voice busyout	Displays information about the voice busyout state.
voice class busyout	Creates a voice class for local voice busyout functions.

busyout seize

To change the busyout action for a Foreign Exchange Office (FXO) or Foreign Exchange Station (FXS) voice port, use the **busyout seize** command in voice-port configuration mode. To restore the default busyout action, use the **no** form of this command.

busyout seize {**ignore** | **repeat**}

no busyout seize

Syntax Description

ignore	Specifies the type of ignore procedure, depending on the type of voice port signaling. See Table 1 for more information.
repeat	Specifies the type of repeat procedure, depending on the type of voice port signaling. See Table 1 for more information.

Command Default

See Table 1 for the default actions for different voice ports and signaling types

Command Modes

Voice-port configuration

Command History

Release	Modification
12.0(3)T	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on the Cisco 2600 and Cisco 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

The **busyout seize** command is valid for both analog and digital voice ports. On digital voice ports, the busyout actions are valid whether the busyout results from a voice-port busyout event or from the **ds0-busyout** command.

The voice port returns to an idle state when the event that triggered the busyout disappears.

Table 1 describes the busyout actions for the **busyout seize** settings on each voice port type.

The busyout action for E and M voice ports is to seize the far end by setting lead busy.

Table 1 Busyout Seize Actions for Voice Ports

Voice Port Signaling Type	Procedure Setting (busyout-option command)	Busyout Actions
FXS loop start	Default	Removes the power from the loop. For analog voice ports, this is equivalent to removing the ground from the tip lead. For digital voice ports, the port generates the bit pattern equivalent to removing the ground from the tip lead, or it busies out if the bit pattern exists.
FXS loop start	Ignore	Ignores the ground on the ring lead.
FXS ground start	Default	Grounds the tip lead and stays at this state.
FXS ground start	Ignore	1. Leaves the tip lead open. 2. Ignores the ground on the ring lead.
FXS ground start	Repeat	1. Grounds the tip lead. 2. Waits for the far end to close the loop. 3. The far end closes the loop. 4. If the far end then opens the loop, FXS removes the ground from the tip lead. 5. FXS waits for several seconds before returning to Step 1.
FXO loop start	Default	Closes the loop and stays at this state.
FXO loop start	Ignore	1. Leaves the loop open. 2. Ignores the ringing current on the ring level.
FXO loop start	Repeat	1. Closes the loop. 2. After the detected far end starts the power denial procedure, FXO opens the loop. 3. After the detected far end has completed the power denial procedure, FXO waits for several seconds before returning to Step 1.
FXO ground start	Default	Grounds the tip lead.
FXO ground start	Ignore	1. Leaves the loop open. 2. Ignores the running current on the ring lead, or the ground current on the tip lead.
FXO ground start	Repeat	1. Grounds the ring lead. 2. Removes the ground from the ring lead and closes the loop after the detected far end grounds the tip lead. 3. When the detected far end removes the ground from tip lead, FXO opens the loop. 4. FXO waits for several seconds before returning to Step 1.

Examples

The following example shows configuration of analog voice port 1/1 to perform the ignore actions when busied out:

```
voice-port 1/1
 busyout seize ignore
```

The following example shows configuration of digital voice port 0:2 to perform the repeat actions when busied out:

```
voice-port 0:2
 busyout seize repeat
```

Related Commands

Command	Description
busyout forced	Forces a voice port into the busyout state.
busyout-monitor interface	Configures a voice port to monitor an interface for events that would trigger a voice port busyout.
ds0 busyout	Forces a DS0 time slot on a controller into the busyout state.
show voice busyout	Displays information about the voice busyout state.
voice-port busyout	Places all voice ports associated with a serial or ATM interface into a busyout state.

Cisco IOS Voice Commands: C

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Library.*

cac master

To configure the call admission control (CAC) operation as master, enter the **cac master** command in voice-service configuration mode. To restore CAC operation to slave, use the **no** form of this command.

cac master

no cac master

Syntax Description

This command has no arguments or keywords.

Defaults

CAC operation is slave

Command Modes

Voice-service configuration

Command History

Release	Modification
12.1(1)XA	This command was introduced on the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.2(2)T	This command was implemented on the Cisco 7200 series.

Usage Guidelines

You should configure the router at opposite ends of an ATM adaptation layer 2 (AAL2) trunk for the opposite CAC operation—master at one end and slave at the other end.

A router configured as a master always performs CAC during fax and modem upspeed. A router configured as a slave sends a request for CAC to the CAC master.

Examples

The following example shows configuration of the CAC operation of a router as master:

```
voice service voatm
 session protocol aal2
 cac master
```

The following example shows configuration of these entities being returned to slave status:

```
voice service voatm
 session protocol aal2
 no cac master
```

cac_off

To disable connection admission control (CAC), use the **cac_off** command in interface-ATM-VC configuration mode. To enable CAC, use the **no** form of this command.

cac_off

no cac_off

Syntax Description This command has no keywords or arguments.

Command Default Call admission control is enabled.

Command Modes Interface-ATM-VC configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines Connection admission control (CAC) is a set of actions taken by each ATM switch during connection setup to determine whether the requested quality of service (QoS) will violate the QoS guarantees for established connections. CAC reserves bandwidth for voice calls, however, the bandwidth required when the lossless compression codec (LLCC) is used is dynamic and usually less than what is generally reserved by CAC. Disabling CAC can help in better utilization of bandwidth when LLCC is used.

Examples The following example disables call admission control on a PVC:

```
interface ATM0/IMA1.1 point-to-point
 pvc test1 15/135
  cac_off
```

cache (neighbor BE)

To configure the local border element (BE) to cache the descriptors received from its neighbors, use the **cache** command in neighbor BE configuration mode. To disable caching, use the **no** form of this command.

cache

no cache

Syntax Description

This command has no arguments or keywords.

Defaults

Caching is not enabled

Command Modes

Neighbor BE configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300 universal access server, Cisco AS5350, Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

Use this command to configure the local BE to cache the descriptors received from its neighbor. If caching is enabled, the neighbors are queried at the specified interval for their descriptors.

Examples

The following example shows the border element enabled to cache the descriptors from its neighbors.

```
Router(config-annexg-neigh)# id neighbor-id
Router(config-annexg-neigh)# cache
```

Related Commands

Command	Description
id	Configures the local ID of the neighboring BE.
port	Configures the neighbor's port number that is used for exchanging Annex G messages.
query-interval	Configures the interval at which the local BE queries the neighboring BE.

cache reload time (global application configuration mode)

To configure the router to reload scripts from cache on a regular interval, use the **cache reload time** command in global application configuration mode. To set the value to the default, use the **no** form of this command.

cache reload time *bg-minutes*

no cache reload time

Syntax Description

bg-minutes	Number of minutes after which the background process is awakened. This background process checks the time elapsed since the script was last used and whether the script is current: • If the script has not been used in the last "unload time," it unloads the script and quits. The unload time is not configurable. • If the script has been used, the background process loads the script from the URL. It compares the scripts, and if they do not match, it begins using the new script for new calls.

Command Default 30 minutes

Command Modes Global application configuration

Command History

Release	Modification
12.3(14)T	The **call application cache reload time** command was moved to global application configuration mode and changed to **cache reload time**.

Examples The following example displays the **cache reload time** command configured to specify 15 minutes before a background process is awakened:

Enter application configuration mode to configure applications and services:

```
application
```

Enter global application configuration mode:

```
global
```

Configure the cache reload time:

```
cache reload time 15
```

Related Commands

Command	Description
call application cache reload time	Configures the router to reload the MGCP scripts from cache on a regular interval.
show call application voice	Displays all Tcl or MGCP scripts that are loaded.

cadence

To define the tone-on and tone-off durations for a call-progress tone, use the **cadence** command in call-progress dualtone configuration mode. To restore the default cadence, use the **no** form of this command.

cadence {*cycle-1-on-time cycle-1-off-time* [*cycle-2-on-time cycle-2-off-time*] [*cycle-3-on-time cycle-3-off-time*] [*cycle-4-on-time cycle-4-off-time*]} | **continuous**

no cadence

Syntax Description

cycle-1-on-time	Tone-on duration for the first cycle of the cadence pattern, in milliseconds (ms). Range is from 0 to 1000. The default is 0.
cycle-1-off-time	Tone-off duration for the first cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
cycle-2-on-time	(Optional) Tone-on duration for the second cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
cycle-2-off-time	(Optional) Tone-off duration for the second cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
cycle-3-on-time	(Optional) Tone-on duration for the third cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
cycle-3-off-time	(Optional) Tone-off duration for the third cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
cycle-4-on-time	(Optional) Tone-on duration for the fourth cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
cycle-4-off-time	(Optional) Tone-off duration for the fourth cycle of the cadence pattern, in milliseconds. Range is from 0 to 1000. The default is 0.
continuous	Continuous call-progress tone is detected.

Command Default Continuous

Command Modes Call-progress dualtone configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and the Cisco MC3810.
12.2(2)T	This command was implemented on the Cisco 1750 and integrated into Cisco IOS Release 12.2(2)T.

Usage Guidelines

This command specifies the cadence for a class of custom call-progress tones.

You must define each cadence that you want a voice port to detect. Reenter the command for each additional cadence to be detected.

You must associate the class of custom call-progress tones with a voice port for this command to affect tone detection.

Examples

The following example defines a cadence for a busy tone in the custom-cptone voice class with the name "country-x." This example defines 500 ms tone on and 500 ms tone off.

```
voice class custom-cptone country-x
 dualtone busy
 cadence 500 500
```

The following example configures detection of the default frequency and cadence values for the busy tone in the custom-cptone voice class with the name "country-x". The default frequency is a 300 Hz tone, and the default cadence is continuous.

```
voice class custom-cptone country-x
 dualtone busy
 no cadence
 no frequency
```

Related Commands

Command	Description
supervisory custom-cptone	Associates a class of custom call-progress tones with a voice port.
voice class custom-cptone	Creates a voice class for defining custom call-progress tones.
voice class dualtone-detect-params	Modifies the boundaries and limits for custom call-progress tones defined by the **voice class custom-cptone** command.

cadence-list

To specify a tone cadence pattern to be detected, use the **cadence-list** command in voice-class configuration mode. To delete a cadence pattern, use the **no** form of this command.

cadence-list *cadence-id cycle-1-on-time cycle-1-off-time* [*cycle-2-on-time cycle-2-off-time*] [*cycle-3-on-time cycle-3-off-time*] [*cycle-4-on-time cycle-4-off-time*]

no cadence-list *cadence-id*

Syntax Description

cadence-id	A tag to identify this cadence list. The range is from 1 to 10.
cycle-1-on-time	The tone duration for the first cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-1-off-time	The silence duration for the first cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-2-on-time	(Optional) The tone duration for the second cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-2-off-time	(Optional) The silence duration for the second cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-3-on-time	(Optional) The tone duration for the third cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-3-off-time	(Optional) The silence duration for the third cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-4-on-time	(Optional) The tone duration for the fourth cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.
cycle-4-off-time	(Optional) The silence duration for the fourth cycle of the cadence pattern. Range is from 0 to 1000 (0 milliseconds to 100 seconds). The default is 0.

Command Default

No cadence pattern is configured.

Command Modes

Voice-class configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, the Cisco MC3810.

Usage Guidelines

A cadence list enables the router to match a complex tone pattern from a PBX or public switched telephone network (PSTN). A tone is detected if it matches any configured cadence list. You can create up to ten cadence lists, enabling the router to detect up to ten different tone patterns. If the tone to be detected consists of only one on-off cycle, you can configure this in either of two ways:

- Create a cadence list using only the *cycle-1-on-time* and *cycle-1-off-time variables*.
- Use the **cadence-max-off-time** and **cadence-min-on-time** commands.

You must also configure the times of the **cadence-max-off-time** and **cadence-min-on-time commands** to be compatible with the on and off times specified by the **cadence-list** command. The time of the **cadence-max-off-time** must be equal to or greater than the longest **off-time** in the cadence list; the **cadence-min-on-time** must be equal to or less than the shortest **on-time** in the cadence list.

Examples

The following example shows configuration of cadence list 1 with three on/off cycles and cadence list 2 with two on/off cycles for voice class 100:

```
voice class dualtone 100
 cadence-list 1 100 100 300 300 100 200
 cadence-list 2 100 200 100 400
```

Related Commands

Command	Description
cadence-max-off-time	Specifies the maximum *off* duration for detection of a tone.
cadence-min-on-time	Specifies the minimum *on* duration for detection of a tone.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

cadence-max-off-time

To specify the maximum time that a tone can be off and still detected as part of a cadence, use the **cadence-max-off-time** command in voice-class configuration mode. To restore the default, use the **no** form of this command.

cadence-max-off-time *time*

no cadence-max-off-time

Syntax Description

time	The maximum *off* time of a tone that can be detected, in 10-millisecond increments. Range is from 0 to 5000 (0 milliseconds to 50 seconds). The default is 0.

Command Default

0 (no off time)

Command Modes

Voice-class configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series and the Cisco MC3810.

Usage Guidelines

Specify a time value greater than the *off* time of the tone to be detected, and use a time value greater than 0 to enable detection of a cadenced tone. With the default (0), the router detects only a continuous tone.

Examples

The following example shows configuration of a maximum *off* duration of 20 seconds for voice class 100:

```
voice class dualtone 100
 cadence-max-off-time 2000
```

Related Commands

Command	Description
cadence-min-on-time	Specifies the minimum *on* duration for detection of a tone.
cadence-variation	Specifies the cadence variation time allowed for detection of a tone.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

cadence-min-on-time

To specify the minimum time that a tone can be on and still detected as part of a cadence, use the **cadence-min-on-time** command in voice-class configuration mode. To restore the default, use the **no** form of this command.

cadence-min-on-time *time*

no cadence-min-on-time

Syntax Description

time	The minimum *on* time of a tone that can be detected, in 10-millisecond increments. Range is from 0 to 100 (0 milliseconds to 1 seconds). The default is 0.

Command Default

0 (no minimum on time)

Command Modes

Voice-class configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series and the Cisco MC3810.

Usage Guidelines

Specify a time value shorter than the *on* time of the tone to be detected. With the default (0), a tone of any length is detected.

Examples

The following example shows configuration of a minimum *on* duration of 30 milliseconds (three 10-ms time intervals) for voice class 100:

```
voice class dualtone 100
 cadence-min-on-time 3
```

Related Commands

Command	Description
cadence-max-off-time	Specifies the maximum *off* duration for detection of a tone.
cadence-variation	Specifies the cadence variation time allowed for detection of a tone.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

cadence-variation

To specify the cadence variation time allowed for detection of a tone, use the **cadence-variation** command in voice-class configuration mode. To restore the default cadence variation time, use the no form of this command.

cadence-variation *time*

no cadence-variation

Syntax Description

time	The maximum time by which the tone onset can vary from the specified onset time and still be detected, in 10-millisecond increments. Range is from 0 to 200 (0 milliseconds to 2 seconds). The default is 0.

Command Default 0 milliseconds

Command Modes Voice-class configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and the Cisco MC3810.
12.1(5)XM	This command was implemented on the Cisco 2600 series, Cisco 3600 series, and the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750 router.

Usage Guidelines Specify a time value greater than the cadence variation of the tone to be detected. With the default of 0, only those tones that match the configured cadence are detected.

This command creates a detection limit for one parameter within a voice class. You can apply the detection limit to any voice port.

Examples The following example specifies a cadence variation time of 30 milliseconds for voice class 100:

```
voice class dualtone 100
 cadence-variation 3
```

The following example specifies 80 ms (eight 10-ms time intervals) as the maximum allowable cadence variation in voice class 70:

```
voice class dualtone-detect-params 70
 cadence-variation 8
```

Related Commands

Command	Description
cadence-max-off-time	Specifies the maximum *off* duration for detection of a tone.
cadence-min-on-time	Specifies the minimum *on* duration for detection of a tone.
supervisory answer dualtone	Enables answer supervision on a voice port.
supervisory dualtone-detect-params	Assigns the boundary and detection tolerance parameters defined by the **voice class dualtone-detect-params** command to a voice port.

call accounting-template

To select an accounting template at a specific location, use the **call accounting-template** command in global configuration or application configuration mode. To deselect a specific accounting template, use the **no** form of this command.

call accounting-template *acctTempName url*

no call accounting-template *acctTempName url*

Syntax Description

acctTempName	Template name.
url	Location of the template.

Command Default

No default behavior or values

Command Modes

Global configuration
Application configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.
12.3(14)T	This command was added to the application configuration mode to replace the **call application voice accounting-template** command.

Usage Guidelines

For call detail records, the template name must have a .cdr extension. To select call records based on your accounting needs and to specify the location of an accounting template that defines the applicable vendor-specific attributes (VSAs) for generating those selected call records, use the **call accounting-template** command in global configuration mode.

The *acctTempName* argument refers to a specific accounting template file that you want to send to the RADIUS server. This template file defines only specific VSAs selected by you to control your call records based on your accounting needs.

Examples

The example below shows the accounting template cdr1 selected from a specific TFTP address.

```
call accounting-template temp-ivr tftp://kyer/sample/cdr/cdr1.cdr
```

Related Commands

Command	Description
call application voice accounting-template	Configures T.37 fax accounting with VoIP AAA nonblocking API.
show call accounting-template voice	Selects an accounting template at a specific location.

call accounting-template voice

To select an accounting template at a specific location, use the **call accounting-template voice** command in global configuration mode. To remove a specific accounting template, use the **no** form of this command.

call accounting-template voice *acctTempName url*

no call accounting-template voice *acctTempName url*

Syntax Description

acctTempName	Template name.
url	Location of the template.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.
12.3(14)T	The **call accounting-template voice** command is replaced by the **call accounting-template** command in application configuration mode. See the **call accounting-template** command for more information.

Usage Guidelines The template name must have a .cdr extension.

To select call records based on your accounting needs and to specify the location of an accounting template that defines the applicable vendor-specific attributes (VSAs) for generating those selected call records, use the **call accounting-template voice** command in global configuration mode.

The *acctTempName* argument refers to a specific accounting template file that you want to send to the RADIUS server. This template file defines only specific VSAs selected by you to control your call records based on your accounting needs.

Examples The example below shows the accounting template cdr1 selected from a specific TFTP address.

```
call accounting-template voice temp-ivr tftp://kyer/sample/cdr/cdr1.cdr
```

Related Commands

Command	Description
call accounting-template voice reload	Reloads the accounting template.
show call accounting-template voice	Selects an accounting template at a specific location.

call accounting-template voice reload

To reload the accounting template, use the **call accounting-template voice reload** command in privileged EXEC mode.

call accounting-template voice reload *acctTempName*

Syntax Description

reload	Reloads the accounting template from the address (for example, a tftp address) where the template is stored.
acctTempName	Name of the accounting template.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

Use the **call accounting-template voice reload** command to reload the template from the URL defined in the **call accounting-template voice** command. After bootup, if the template file fails to load from the TFTP server, the system tries to automatically reload the file at 5-minute intervals.

Examples

The example below shows how to reload accounting template cdr2:

```
call accounting-template voice reload cdr2
```

Related Commands

Command	Description
call accounting-template voice	Selects an accounting template at a specific location
gw-accounting aaa	Defines and loads the template file at the location defined by the URL.
show call accounting-template voice	Displays the VSAs that are contained in the accounting template.

call-agent

To define the call agent for a Media Gateway Control Protocol (MGCP) profile, use the **call-agent** command in MGCP profile configuration mode. To return to the default values, use the **no** form of this command.

call-agent {*dns-name* | *ip-address*} [*port*] [**service-type** *type*] [**version** *protocol-version*]

no call-agent

Syntax Description

dns-name	Fully qualified domain name (including host portion) for the call agent. For example, “ca123.example.net”.
ip-address	IP address of the call agent.
port	(Optional) User Datagram Protocol (UDP) port number over which the gateway sends messages to the call agent. Range is from 1025 to 65535. • The default call-agent UDP port is 2727 for MGCP 1.0, Network-based Call Signaling (NCS) 1.0, and Trunking Gateway Control Protocol (TGCP) 1.0. • The default call-agent UDP port is 2427 for MGCP 0.1 and Simple Gateway Control Protocol (SGCP).
service-type *type*	(Optional) Protocol service type valid values for the *type* argument are **mgcp**, **ncs**, **sgcp**, and **tgcp**. The default service type is **mgcp**.
version *protocol-version*	(Optional) Version number of the protocol. Valid values follow: • Service-type MGCP—**0.1**, **1.0** • Service-type NCS—**1.0** • Service-type SGCP—**1.1**, **1.5** • Service-type TGCP—**1.0** The default service type and version are **mgcp** and **0.1**.

Command Default

The default call-agent UDP port is 2727 for MGCP 1.0, Network-based Call Signaling (NCS) 1.0, and Trunking Gateway Control Protocol (TGCP) 1.0.
The default call-agent UDP port is 2427 for MGCP 0.1 and Simple Gateway Control Protocol (SGCP).
The default service type and version are MGCP 0.1.

Command Modes

MGCP profile configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

This command is used when values for a MGCP profile are configured.

Call-agent configuration for an MGCP profile (with this command) and global call-agent configuration (with the **mgcp call-agent** command) are mutually exclusive; the first to be configured on an endpoint blocks configuration of the other on the same endpoint.

Identifying call agents by Domain Name System (DNS) name rather than by IP address in the **call-agent** command provides call-agent redundancy, because a DNS name can have more than one IP address associated with it. If a call agent is identified by a DNS name and a message from the gateway fails to reach the call agent, the **max1 lookup** and **max2 lookup** commands enable a search from the DNS lookup table for a backup call agent at a different IP address.

The *port* argument configures the call agent port number (the UDP port over which the gateway sends messages to the call agent). The reverse, or the gateway port number (the UDP port over which the gateway receives messages from the call agent), is configured by specifying a port number in the **mgcp** command.

The service type **mgcp** supports the Restart In Progress (RSIP) error messages sent by the gateway if the **mgcp sgcp restart notify** command is enabled. The service type **sgcp** ignores the RSIP messages.

Examples

The following example defines a call agent for the MGCP profile named "tgcp_trunk":

```
Router(config)# mgcp profile tgcp_trunk
Router(config-mgcp-profile)# call-agent 10.13.93.3 2500 service-type tgcp version 1.0
```

Related Commands

Command	Description
max1 lookup	Enables DNS lookup of the MGCP call agent address when the suspicion threshold value is reached.
max2 lookup	Enables DNS lookup of the MGCP call agent address when the disconnect threshold value is reached.
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp call-agent	Configures the address of the call agent (media gateway controller).
mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints or to configure the default profile.

call application alternate

Note Effective with Cisco IOS Release 12.3(14)T, the **call application alternate** command is replaced by the **service** command in global application configuration mode. See the **service** command for more information.

To specify an alternate application to use if the application that is configured in the dial peer fails, use the **call application alternate** command in global configuration mode. To return to the default behavior, use the **no** form of this command.

call application alternate [*application-name*]

no call application alternate

Syntax Description

application-name	(Optional) Name of the specific voice application to use if the application in the dial peer fails. If a specific application name is not entered, the gateway uses the DEFAULT application.

Command Default The call is rejected if the application in the dial peer fails.

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.
12.3(14)T	This command was replaced by the **service** command in global application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines If this command is not configured, calls are rejected when the dial peer that matches the call does not specify a valid voice application.

In releases before Cisco IOS Release 12.2(11)T, the default application (DEFAULT) was automatically triggered if no application was configured in the dial peer or if the configured application failed. The default application is no longer automatically executed unless the **call application alternate** command is configured.

The application named DEFAULT is a simple application that outputs dial tone, collects digits, and places a call to the dialed number. This application is included in Cisco IOS software; you do not have to download it or configure it by using the **call application voice** command.

The **call application alternate** command specifies that if the application that is configured in the dial peer fails, the default voice application is executed. If the name of a specific application is entered, that application is triggered if the application configured in the dial peer fails. If the alternate application also fails, the call is rejected.

If an application name is entered, that application must first be configured on the gateway by using the **call application voice** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application alternate

        Warning: This command has been deprecated. Please use the following:
                 service
```

The following example configures the DEFAULT application as the alternate:

```
call application alternate
```

The following example configures the application *session* as the alternate:

```
call application alternate session
```

Related Commands

Command	Description
application	Enables a voice application on a dial peer.
call application voice	Defines the name of a voice application and specifies the location of the Tcl or VoiceXML document to load for this application.
service	Loads and configures a specific, standalone application on a dial peer.
show call application voice	Displays information about voice applications.

call application cache reload time

Note Effective with Cisco IOS Release 12.3(14)T, the **call application cache reload time** command is replaced by the **cache reload time** command in application configuration global mode. See the **cache reload time** command for more information.

To configure the router to reload the Media Gateway Control Protocol (MGCP) scripts from cache on a regular interval, use the **call application cache reload time** command in global configuration mode. To set the value to the default, use the **no** form of this command.

call application cache reload time *bg-minutes*

no call application cache reload time

Syntax Description

bg-minutes	Specifies the number of minutes after which the background process is awakened. This background process checks the time elapsed since the script was last used and whether the script is current: • If the script has not been used in the last "unload time," it unloads the script and quits. The unload time is not configurable. • If the script has been used, the background process loads the script from the URL. It compares the scripts, and if they do not match, it begins using the new script for new calls.

Command Default 30 minutes

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco AS5300.
12.3(14)T	This command was replaced by the **cache reload time** command in application configuration global mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application cache reload 20

        Warning: This command has been deprecated. Please use the following:
             cache reload time
```

The following example displays the **call application cache reload time** command configured to specify 30 minutes before a background process is awakened:

```
call application cache reload time 30
```

Related Commands

Command	Description
cache reload time	Configures the router to reload scripts from cache on a regular interval.
call application voice load	Allows reload of an application that was loaded via the MGCP scripting package.
show call application voice	Displays all Tcl or MGCP scripts that are loaded.

call application dump event-log

To flush the event log buffer for application instances to an external file, use the **call application dump event-log** command in privileged EXEC mode.

call application dump event-log

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

This command immediately writes the event log buffer to the external file whose location is defined with the **call application event-log dump ftp** command in global configuration mode.

Note The **call application dump event-log** command and the **call application event-log dump ftp** command are two different commands.

Examples

The following example flushes the application event log buffer:

```
Router# call application dump event-log
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
call application event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
show call application session-level	Displays event logs and statistics for voice application instances.

call application event-log

Note Effective with Cisco IOS Release 12.3(14)T, the **call application event-log** command is replaced by the **event-log** command in application configuration monitor mode. See the **event-log** command for more information.

To enable event logging for all voice application instances, use the **call application event-log** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application event-log

no call application event-log

Syntax Description

This command has no arguments or keywords.

Command Default

Event logging for voice applications is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **event-log** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command enables event logging globally for all voice application instances. To enable or disable event logging for a specific application, use the **call application voice event-log** command.

Note To prevent event logging from adversely impacting system resources for production traffic, the gateway uses a throttling mechanism. When free processor memory drops below 20%, the gateway automatically disables all event logging. It resumes event logging when free memory rises above 30%. While throttling is occurring, the gateway does not capture any new event logs even if event logging is enabled. You should monitor free memory and enable event logging only when necessary for isolating faults.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application event-log

        Warning: This command has been deprecated. Please use the following:
             event-log
```

The following example enables event logging for all application instances:

```
call application event-log
```

Related Commands

Command	Description
call application event-log error-only	Restricts event logging to error events only for application instances.
call application event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
call application interface event-log	Enables event logging for external interfaces used by voice applications.
call application stats	Enables statistics collection for voice applications.
call application voice event-log	Enables event logging for a specific voice application.
call leg event-log	Enables event logging for voice, fax, and modem call legs.
event-log	Enables event logging for applications.
monitor call application event-log	Displays the event log for an active application instance in real-time.
show call application session-level	Displays event logs and statistics for voice application instances.

call application event-log dump ftp

Note Effective with Cisco IOS Release 12.3(14)T, the **call application event-log dump ftp** command is replaced by the **event-log dump ftp** command in application configuration monitor mode. See the **event-log dump ftp** command for more information.

To enable the gateway to write the contents of the application event log buffer to an external file, use the **call application event-log dump ftp** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application event-log dump ftp *server*[**:***port*]*/file* **username** *username* **password** [*encryption-type*] *password*

no call application event-log dump ftp

Syntax Description

server	Name or IP address of FTP server where file is located.
:*port*	(Optional) Specific port number on server.
/file	Name and path of file.
username	Username required to access file.
encryption-type	(Optional) The Cisco proprietary algorithm used to encrypt the password. Values are 0 or 7. To disable encryption enter 0; to enable encryption enter 7. If you specify 7, you must enter an encrypted password (a password already encrypted by a Cisco router).
password	Password required to access file.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **event-log dump ftp** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command enables the gateway to automatically write the event log buffer to the named file either after an active application instance terminates or when the event log buffer becomes full. The default buffer size is 4 KB. To modify the size of the buffer, use the **call application event-log max-buffer-size** command. To manually flush the event log buffer, use the **call application dump event-log** command in privileged EXEC mode.

Note The **call application dump event-log** command and the **call application event-log dump ftp** command are two different commands.

Note Enabling the gateway to write event logs to FTP could adversely impact gateway memory resources in some scenarios, for example, when:

- The gateway is consuming high processor resources and FTP does not have enough processor resources to flush the logged buffers to the FTP server.
- The designated FTP server is not powerful enough to perform FTP transfers quickly
- Bandwidth on the link between the gateway and the FTP server is not large enough
- The gateway is receiving a high volume of short-duration calls or calls that are failing

You should enable FTP dumping only when necessary and not enable it in situations where it might adversely impact system performance.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application dump event-log

        Warning: This command has been deprecated. Please use the following:
             event-log dump ftp
```

The following example enables the gateway to write application event logs to an external file named app_elogs.log on a server named ftp-server:

```
call application event-log dump ftp ftp-server/:elogs/app-elogs.log username myname
password 0 mypass
```

The following example specifies that application event logs are written to an external file named app_elogs.log on a server with the IP address of 10.10.10.101:

```
call application event-log dump ftp 10.10.10.101/:elogs/app-elogs.log username myname
password 0 mypass
```

Related Commands

Command	Description
call application dump event-log	Flushes the event log buffer for application instances to an external file.
call application event-log	Enables event logging for voice application instances.
call application event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
show call application session-level	Displays event logs and statistics for voice application instances.

call application event-log error-only

Note Effective with Cisco IOS Release 12.3(14)T, the **call application event-log error-only** command is replaced by the **event-log error-only** command in application configuration monitor mode. See the **event-log error-only** command for more information.

To restrict event logging to error events only for application instances, use the **call application event-log error-only** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application event-log error-only

no call application event-log error-only

Syntax Description

This command has no arguments or keywords.

Command Default

All application events are logged.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **event-log error-only** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command limits new event logging to error events only; it does not enable logging. You must use this command with either the **call application event-log** command, which enables event logging for all voice applications, or with the **call application voice event-log** command, which enables event logging for a specific application. Any events logged before this command is issued are not affected.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application event-log error-only

        Warning: This command has been deprecated. Please use the following:
             event-log error-only
```

The following example enables event logging for error events only:

```
call application event-log
call application event-log error-only
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application history session event-log save-exception-only	Saves in history only the event logs for application instances that have at least one error.
call application voice event-log	Enables event logging for a specific voice application.
event-log error-only	Restricts event logging to error events only for application instances.
show call application app-level	Displays application-level statistics for voice applications.
show call application session-level	Displays event logs and statistics for voice application instances.

call application event-log max-buffer-size

Note Effective with Cisco IOS Release 12.3(14)T, the **call application event-log max-buffer-size** command is replaced by the **event-log max-buffer-size** command in application configuration monitor mode. See the **event-log max-buffer-size** command for more information.

To set the maximum size of the event log buffer for each application instance, use the **call application event-log max-buffer-size** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application event-log max-buffer-size *kilobytes*

no call application event-log max-buffer-size

Syntax Description

kilobytes	Maximum buffer size, in kilobytes. Range is 1 to 50. Default is 4.

Command Default 4 *kilobytes*

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **event-log max-buffer-size** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines If the event log buffer reaches the limit set by this command, the gateway allocates a second buffer of equal size. The contents of both buffers is displayed when you use the **show call application session-level** command. When the first event log buffer becomes full, the gateway automatically appends its contents to an external FTP location if the **call application event-log dump ftp** command is used.

A maximum of two buffers are allocated for an event log. If both buffers are filled, the first buffer is deleted and another buffer is allocated for new events (buffer wraps around). If the **call application event-log dump ftp** command is configured and the second buffer becomes full before the first buffer is dumped, event messages are dropped and are not recorded in the buffer.

Note Do not set the maximum buffer size to more than you need for a typical application session. After an active session terminates, the amount of memory used by the buffer is allocated to the history table and is maintained for the length of time set by the **call application history session retain-timer** command. Also consider that most fatal errors are captured at the end of an event log.

To conserve memory resources, write the event log buffer to FTP by using the **call application event-log dump ftp** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application event-log max-buffer-size

        Warning: This command has been deprecated. Please use the following:
             event-log max-buffer-size
```

The following example sets the application event log buffer to 8 kilobytes:

```
call application event-log
call application event-log max-buffer-size 8
```

Related Commands

Command	Description
call application dump event-log	Flushes the event log buffer for application instances to an external file.
call application event-log	Enables event logging for voice application instances.
call application event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
show call application session-level	Displays event logs and statistics for voice application instances.

call application global

Note Effective with Cisco IOS Release 12.3(14)T, the **call application global** command is replaced by the **global** command in application configuration mode. See the **global** command for more information.

To configure an application to use for incoming calls whose incoming dial peer does not have an explicit application configured, use the **call application global** command in global configuration mode. To remove the application, use the **no** form of this command.

call application global *application-name*

no call application global *application-name*

Syntax Description

application-name	Character string that defines the name of the application.

Command Default

The default application is **default** for all dial peers.

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)ZJ	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(14)T	This command was replaced by the **global** command in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

The application defined in the dial peer always takes precedence over the global application configured with the **call application global** command. The application configured with this command executes only when a dial peer has no application configured.

The application you configure with this command can be an application other than the default session application, but it must be included with the Cisco IOS software or be loaded onto the gateway with the **call application voice** command before using this command. If the application does not exist in Cisco IOS software or has not been loaded onto the gateway, this command will have no effect.

Note In Cisco IOS Release 12.3(4)T and later releases, the application-name default refers to the applicationCall Admission Control Based on CPU Utilization that supports Open Settlement Protocol (OSP), call transfer, and call forwarding. The default session application in Cisco IOS Release 12.2(13)T

and earlier releases has been renamed default.old.c and can still be configured for specific dial peers through the **application** command or globally configured for all inbound dial peers through the **call application global** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application global

        Warning: This command has been deprecated. Please use the following:
           global
```

In the following example, the clid_authen_collect application is configured as the global application for all inbound dial peers that do not have a specific application configured:

```
call application global clid_authen_collect
```

Related Commands

Command	Description
application	Enables a specific IVR application on a dial peer.
call application voice	Defines the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
global	Enters application configuration mode.

call application history session event-log save-exception-only

Note Effective with Cisco IOS Release 12.3(14)T, the **call application history session event-log save-exception-only** command is replaced by the **history session event-log save-exception-only** command in application configuration monitor mode. See the **history session event-log save-exception-only** command for more information.

To save in history only the event logs for application sessions that have at least one error, use the **call application history session event-log save-exception-only** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application history session event-log save-exception-only

no call application history session event-log save-exception-only

Syntax Description

This command has no arguments or keywords.

Command Default

All event logs for sessions are saved to history.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **history session event-log save-exception-only** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Application event logs move from active to history after an instance terminates. If you use this command, the voice gateway saves event logs only for instances that had one or more errors. Event logs for normal instances that do not contain any errors are not saved to history.

Note This command does not affect records saved to an FTP server by using the **call application dump event-log** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application history session event-log save-exception-only

        Warning: This command has been deprecated. Please use the following:
             history session event-log save-exception-only
```

The following example saves an event log in history only if the instance had an error:

```
call application history session event-log save-exception-only
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application event-log error-only	Restricts event logging to error events only for application instances.
call application event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
call application history session max-records	Sets the maximum number of application instance records saved in history.
call application history session retain-timer	Sets the maximum number of minutes for which application instance records are saved in history.
history session event-log save-exception-only	Saves in history only the event logs for application sessions that have at least one error.

call application history session max-records

Note Effective with Cisco IOS Release 12.3(14)T, the **call application history session max-records** command is replaced by the **history session max-records** command in application configuration monitor mode. See the **history session max-records** command for more information.

To set the maximum number of application instance records saved in history, use the **call application history session max-records** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application history session max-records *number*

no call application history session max-records

Syntax Description

number	Maximum number of records to save in history. Range is 0 to 2000. Default is 360.

Command Default 360

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **history session max-records** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines This command affects the number of records that display when you use the **show call application history session-level** command.

Examples Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application history session max-records

        Warning: This command has been deprecated. Please use the following:
             history session max-records
```

The following example sets the maximum record limit to 500:

```
call application history session max-records 500
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application history session event-log save-exception-only	Saves in history only the event logs for application instances that have at least one error.
call application history session retain-timer	Sets the maximum number of minutes that application instance records are saved in history.
history session max-records	Sets the maximum number of application instance records saved in history.
show call application session-level	Displays event logs and statistics for voice application instances.

call application history session retain-timer

Note Effective with Cisco IOS Release 12.3(14)T, the **call application history session retain-timer** command is replaced by the **history session retain-timer** command in application configuration monitor mode. See the **history session retain-timer** command for more information.

To set the maximum number of minutes for which application instance records are saved in history, use the **call application history session retain-timer** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application history session retain-timer *minutes*

no **call application history session retain-timer**

Syntax Description

minutes	Maximum time, in minutes, for which history records are saved. Range is 0 to 4294,967,295. Default is 15.

Command Default 15

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **history session retain-timer** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines This command affects the number of records that display when you use the **show call application history session-level** command.

Examples Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application history session retain-timer

        Warning: This command has been deprecated. Please use the following:
             history session retain-timer
```

The following example sets the maximum time to save history records to 1 hour:

```
call application history session retain-timer 60
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application history session event-log save-exception-only	Saves in history only the event logs for application instances that have at least one error.
call application history session max-records	Sets the maximum number of application instance records saved in history.
history session retain-timer	Sets the maximum number of minutes for which application instance records are saved in history.
show call application session-level	Displays event logs and statistics for voice application instances.

call application interface dump event-log

To flush the event log buffer for application interfaces to an external file, use the **call application interface dump event-log** command in privileged EXEC mode.

call application interface dump event-log

Syntax Description This command has no arguments or keywords.

Command Modes Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines This command immediately writes the event log buffer to the external file whose location is defined with the **call application interface event-log dump ftp** command in global configuration mode.

Note The **call application interface dump event-log** command and the **call application interface event-log dump ftp** command are two different commands.

Examples The following example writes the event log buffer to the external file named int_elogs:

```
Router(config)# call application interface event-log dump ftp ftp-server/int_elogs.log
username myname password 0 mypass
Router(config)# exit
Router# call application interface dump event-log
```

Related Commands

Command	Description
call application interface event-log	Enables event logging for external interfaces used by voice applications.
call application interface event-log dump ftp	Enables the voice gateway to write the contents of the interface event log buffer to an external file.
call application interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
show call application interface	Displays event logs and statistics for application interfaces.

call application interface event-log

Note Effective with Cisco IOS Release 12.3(14)T, the **call application interface event-log** command is replaced by the **interface event-log** command in application configuration monitor mode. See the **interface event-log** command for more information.

To enable event logging for interfaces that provide services to voice applications, use the **call application interface event-log** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application interface event-log [{**aaa** | **asr** | **flash** | **http** | **ram** | **rtsp** | **smtp** | **tftp** | **tts**} [**server** *server*] [**disable**]]

no call application interface event-log [{**aaa** | **asr** | **flash** | **http** | **ram** | **rtsp** | **smtp** | **tftp** | **tts**} [**server** *server*] [**disable**]]

Syntax Description

aaa	Authentication, authorization, and accounting (AAA) interface type.
asr	Automatic speech recognition (ASR) interface type.
flash	Flash memory of the Cisco gateway.
http	Hypertext Transfer Protocol (HTTP) interface type.
ram	Memory of the Cisco gateway.
rtsp	Real Time Streaming Protocol (RTSP) interface type.
smtp	Simple Mail Transfer Protocol (SMTP) interface type.
tftp	Trivial File Transfer Protocol (TFTP) interface type.
tts	Text-to-speech (TTS) interface type.
server *server*	(Optional) Server name or IP address.
disable	(Optional) Disables event logging for the specified interface type or server.

Command Default Event logging for application interfaces is disabled.

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **interface event-log** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command enables event logging globally for all interface types and servers unless you select a specific interface type or server. Specifying an interface type takes precedence over the global command for a specific interface type. Specifying an individual server takes precedence over the interface type.

Note To prevent event logging from adversely impacting system resources for production traffic, the gateway uses a throttling mechanism. When free processor memory drops below 20%, the gateway automatically disables all event logging. It resumes event logging when free memory rises above 30%. While throttling is occurring, the gateway does not capture any new event logs even if event logging is enabled. You should monitor free memory and enable event logging only when necessary for isolating faults.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application interface event-log

        Warning: This command has been deprecated. Please use the following:
             interface event-log
```

The following example enables event logging for all interfaces:

```
call application interface event-log
```

The following example enables event logging for HTTP interfaces only:

```
call application interface event-log http
```

The following example enables event logging for all interfaces except HTTP:

```
call application interface event-log
call application interface event-log http disable
```

The following example enables event logging for all HTTP servers except the server with the IP address of 10.10.1.1:

```
call application interface event-log http
call application interface event-log http server http://10.10.1.1 disable
```

Related Commands

Command	Description
call application interface event-log dump ftp	Enables the gateway to write the contents of the interface event log buffer to an external file.
call application interface event-log error-only	Restricts event logging to error events only for application interfaces.
call application interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
call application interface max-server-records	Sets the maximum number of application interface records that are saved.
call application interface stats	Enables statistics collection for application interfaces.
interface event-log	Enables event logging for interfaces providing services to voice applications.
show call application interface	Displays event logs and statistics for application interfaces.

call application interface event-log dump ftp

Note Effective with Cisco IOS Release 12.3(14)T, the **call application interface event-log dump ftp** command is replaced by the **interface event-log dump ftp** command in application configuration monitor mode. See the **interface event-log dump ftp** command for more information.

To enable the gateway to write the contents of the interface event log buffer to an external file, use the **call application interface event-log dump ftp** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application interface event-log dump ftp *server*[**:***port*]*/file* **username** *username* **password** [*encryption-type*] *password*

no call application interface event-log dump ftp

Syntax Description

server	Name or IP address of FTP server where the file is located.
:*port*	(Optional) Specific port number on server.
/file	Name and path of file.
username *username*	Username required to access file.
encryption-type	(Optional) Cisco proprietary algorithm used to encrypt the password. Values are 0 or 7. To disable encryption enter 0; to enable encryption enter 7. If you specify 7, you must enter an encrypted password (a password already encrypted by a Cisco router).
password *password*	Password required to access file.

Command Default Interface event log buffer is not written to an external file.

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **interface event-log dump ftp** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines This command enables the gateway to automatically write the interface event log buffer to the named file when the buffer becomes full. The default buffer size is 4 KB. To modify the size of the buffer, use the **call application interface event-log max-buffer-size** command. To manually flush the event log buffer, use the **call application interface dump event-log** command in privileged EXEC mode.

Note

- The **call application interface dump event-log** command and the **call application interface event-log dump ftp** command are two different commands.
- Enabling the gateway to write event logs to FTP can adversely impact gateway-memory resources in scenarios such as the following:
  - The gateway is consuming high processor resources and FTP does not have enough processor resources to flush the logged buffers to the FTP server.
  - The designated FTP server is not powerful enough to perform FTP transfers quickly
  - Bandwidth on the link between the gateway and the FTP server is not large enough
  - The gateway is receiving a high volume of short-duration calls or calls that are failing

  You should enable FTP dumping only when necessary and not enable it in situations where it might adversely impact system performance.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application interface event-log dump ftp

        Warning: This command has been deprecated. Please use the following:
           interface event-log dump ftp
```

The following example specifies that interface event log are written to an external file named int_elogs.log on a server named ftp-server:

```
call application interface event-log dump ftp ftp-server/elogs/int_elogs.log username
myname password 0 mypass
```

The following example specifies that application event logs are written to an external file named int_elogs.log on a server with the IP address of 10.10.10.101:

```
call application interface event-log dump ftp 10.10.10.101/elogs/int_elogs.log username
myname password 0 mypass
```

Related Commands

Command	Description
call application interface dump event-log	Flushes the event log buffer for application interfaces to an external file.
call application interface event-log	Enables event logging for external interfaces used by voice applications.
call application interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
call application interface max-server-records	Sets the maximum number of application interface records that are saved.
interface event-log dump ftp	Enables the gateway to write the contents of the interface event log buffer to an external file.
show call application interface	Displays event logs and statistics for application interfaces.

call application interface event-log error-only

Note Effective with Cisco IOS Release 12.3(14)T, the **call application interface event-log error-only** command is replaced by the **interface event-log error only** command in application configuration monitor mode. See the **interface event-log error only** command for more information.

To restrict event logging to error events only for application interfaces, use the **call application interface event-log error-only** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application interface event-log error-only

no call application interface event-log error-only

Syntax Description

This command has no arguments or keywords.

Command Default

All events are logged.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **interface event-log error only** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command limits the severity level of the events that are logged; it does not enable logging. You must use this command with the **call application interface event-log** command, which enables event logging for all application interfaces.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application interface event-log error-only

        Warning: This command has been deprecated. Please use the following:
             interface event-log error only
```

The following example enables event logging for error events only:

```
call application interface event-log error-only
```

Related Commands

Command	Description
call application interface event-log	Enables event logging for external interfaces used by voice applications.
call application interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
call application interface max-server-records	Sets the maximum number of application interface records that are saved.
interface event-log error-only	Restricts event logging to error events only for application interfaces.
show call application interface	Displays event logs and statistics for application interfaces.

call application interface event-log max-buffer-size

Note Effective with Cisco IOS Release 12.3(14)T, the **call application interface event-log max-buffer-size** command is replaced by the **interface event-log max-buffer-size** command in application configuration monitor mode. See the **interface event-log max-buffer-size** command for more information.

To set the maximum size of the event log buffer for each application interface, use the **call application interface event-log max-buffer-size** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application interface event-log max-buffer-size *kilobytes*

no call application interface event-log max-buffer-size

Syntax Description

kilobytes	Maximum buffer size, in kilobytes. Range is 1 to 10. Default is 4.

Command Default 4 kilobytes

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **interface event-log max-buffer-size** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines If the event log buffer reaches the limit set by this command, the gateway allocates a second buffer of equal size. The contents of both buffers is displayed when you use the **show call application interface** command. When the first event log buffer becomes full, the gateway automatically appends its contents to an external FTP location if the **call application interface event-log dump ftp** command is used.

A maximum of two buffers are allocated for an event log. If both buffers are filled, the first buffer is deleted and another buffer is allocated for new events (buffer wraps around). If the **call application interface event-log dump ftp** command is configured and the second buffer becomes full before the first buffer is dumped, event messages are dropped and are not recorded in the buffer.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application interface event-log max-buffer-size

        Warning: This command has been deprecated. Please use the following:
           interface event-log max-buffer-size
```

The following example sets the maximum buffer size to 8 kilobytes:

```
call application interface event-log max-buffer-size 8
```

Related Commands

Command	Description
call application interface dump event-log	Flushes the event log buffer for application interfaces to an external file.
call application interface event-log dump ftp	Enables the gateway to write the contents of the interface event log buffer to an external file.
call application interface max-server-records	Sets the maximum number of application interface records that are saved.
interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
show call application interface	Displays event logs and statistics for application interfaces.

call application interface max-server-records

Note Effective with Cisco IOS Release 12.3(14)T, the **call application interface max-server-records** command is replaced by the **interface max-server-records** command in application configuration monitor mode. See the **interface max-server-records** command for more information.

To set the maximum number of application interface records that are saved, use the **call application interface max-server-records** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application interface max-server-records *number*

no call application interface max-server-records

Syntax Description

number	Maximum number of records to save. Range is 1 to 100. Default is 10.

Command Default 10

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **interface max-server-records** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines Only the specified number of records from the most recently accessed servers are kept.

Examples Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application interface max-server-records

        Warning: This command has been deprecated. Please use the following:
             interface max-server-records
```

The following example sets the maximum saved records to 50:

```
call application interface max-server-records 50
```

Related Commands

Command	Description
call application interface event-log	Enables event logging for external interfaces used by voice applications.
call application interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
interface max-server-records	Sets the maximum number of application interface records that are saved.
show call application interface	Displays event logs and statistics for application interfaces.

call application interface stats

Note Effective with Cisco IOS Release 12.3(14)T, the **call application interface stats** command is replaced by the **interface stats** command in application configuration monitor mode. See the **interface stats** command for more information.

To enable statistics collection for application interfaces, use the **call application interface stats** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application interface stats

no call application interface stats

Syntax Description

This command has no arguments or keywords.

Command Default

Statistics collection is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **interface stats** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

To display the interface statistics enabled by this command, use the **show call application interface** command. To reset the interface counters to zero, use the **clear call application interface** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application interface stats

        Warning: This command has been deprecated. Please use the following:
             interface stats
```

The following example enables statistics collection for application interfaces:

```
call application interface stats
```

Related Commands

Command	Description
call application interface event-log	Enables event logging for external interfaces used by voice applications.
clear call application interface	Clears application interface statistics or event logs.
interface stats	Enables statistics collection for application interfaces.
show call application interface	Displays event logs and statistics for application interfaces.
stats	Enables statistics collection for voice applications.

call application session start (global)

Note Effective with Cisco IOS Release 12.3(14)T, the **call application session start** (global) command is replaced by the the **session start** command in application configuration mode. See the **session start** command for more information.

To start a new instance (session) of a Tcl IVR 2.0 application, use the **call application session start** command in global configuration mode. To stop the session and remove the configuration, use the **no** form of this command.

call application session start *instance-name application-name*

no call application session start *instance-name*

Syntax Description

instance-name	Alphanumeric label that uniquely identifies this application instance.
application-name	Name of the Tcl application. This is the name of the application that was assigned with the **call application voice** command.

Command Default

This command has no default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.3(14)T	The **call application session start** (global configuration) command was replaced by the **session start** command in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command starts a new session, or instance, of a Tcl IVR 2.0 application. It cannot start a session for a VoiceXML application because Cisco IOS software cannot start a VoiceXML application without an active call leg.

You can start an application instance only after the Tcl application is loaded onto the gateway with the **call application voice** command.

If this command is used, the session restarts if the gateway reboots.

The **no call application session start** command stops the Tcl session and removes the configuration from the gateway. You can stop an application session without removing the configuration by using the **call application session stop** command.

VoiceXML sessions cannot be stopped with the **no call application session start** command because VoiceXML sessions cannot be started with Cisco IOS commands.

If the application session stops running, it does not restart unless the gateway reboots. A Tcl script might intentionally stop running by executing a “call close” command for example, or it might fail because of a script error.

You can start multiple instances of the same application by using different instance names.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application session start

        Warning: This command has been deprecated. Please use the following:
             session start
```

The following example starts a session named my_instance for the application named demo:

```
call application session start my_instance demo
```

The following example starts another session for the application named demo:

```
call application session start my_instance2 demo
```

Related Commands

Command	Description
call application session start (privileged EXEC)	Starts a new instance (session) of a Tcl application from privileged EXEC mode.
call application session stop	Stops a voice application session that is running.
debug voip ivr	Displays debug messages for VoIP IVR interactions.
session start	Starts a new instance (session) of a Tcl IVR 2.0 application.
show call application services registry	Displays a one-line summary of all registered services.
show call application sessions	Displays summary or detailed information about voice application sessions.

call application session start (privileged EXEC)

To start a new instance (session) of a Tcl IVR 2.0 application, use the **call application session start** command in privileged EXEC mode.

call application session start *instance-name* [*application-name*]

Syntax Description

instance-name	Alphanumeric label that uniquely identifies this application instance.
application-name	(Optional) Name of the Tcl application. This is the name of the application that was assigned with the **call application voice** command. **Note** This argument is optional if the application instance was previously started and stopped.

Command Default None

Command Modes Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

This command starts a new session, or instance, of a Tcl IVR 2.0 application. It cannot start a session for a VoiceXML application because Cisco IOS software cannot start a VoiceXML application without an active call leg.

You can start an application instance only after the Tcl application is loaded onto the gateway with the **call application voice** command.

Using this command does not restart the session if the gateway reboots. To automatically restart the session if the gateway reboots, use the **call application session start** command in global configuration mode.

To stop an application session once it starts running, use the **call application session stop** command.

If the application session stops running, it does not restart unless the gateway reboots and the **call application session start** command is used in global configuration mode. A Tcl script might intentionally stop running by executing a “call close” command for example, or it might fail due to a script error.

You can start multiple instances of the same application by using different instance names.

Examples

The following example restarts an application session called my_instance:

```
call application session start my_instance
```

Related Commands

Command	Description
call application session start (global configuration)	Starts a new instance (session) of a Tcl application in global configuration mode.
call application session stop	Stops a voice application session that is running.
show call application services registry	Displays a one-line summary of all registered services.
show call application sessions	Displays summary or detailed information about voice application sessions.

call application session stop

To stop a voice application session that is running, use the **call application session stop** command in privileged EXEC mode.

call application session stop {**callid** *call-id* | **handle** *handle* | **id** *session-id* | **name** *instance-name*}

Syntax Description

callid *call-id*	Call-leg ID that can be displayed in the output from the **debug voip ivr script** command if the Tcl script uses puts commands.
handle *handle*	Handle of a session from the Tcl mod_handle infotag.
id *session-id*	Session ID that can be displayed with the **show call application sessions** command.
name *instance-name*	Instance name that was configured with the **call application session start** command.

Command Default None

Command Modes Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

This command stops a Tcl IVR 2.0 or VoiceXML application session that is identified by one of four different methods: call ID, handle, session ID, or instance name. To see a list of currently running applications, use the **show call application sessions** command.

A Tcl session that is stopped with this command receives a session terminate event. The session is expected to close all call legs and stop. If a session does not close itself after a 10-second timer, it is forcibly stopped and all call legs that it controls disconnect.

Using this command to stop a VoiceXML session immediately stops the document interpretation and disconnects the call leg. No VoiceXML events are thrown.

If you stop a Tcl session that is configured to start with the **call application session start** command in global configuration mode, you must remove the session by using the **no call application session start** command before you can restart it.

To see a list of stopped sessions, use the **show call application sessions** command. Only stopped sessions that are configured to start with the **call application session start** command in global configuration mode are displayed. If a session was started with the **call application session start** command in privileged EXEC mode, it is not tracked by the system and it is not shown as stopped in the output of the **show call application sessions** command.

Examples

The following example stops an application session called my_instance:

```
call application session stop name my_instance
```

Related Commands

Command	Description
call application session start (global configuration)	Starts a new instance (session) of a Tcl application from global configuration mode.
show call application services registry	Displays a one-line summary of all registered services.
show call application sessions	Displays summary or detailed information about voice application sessions.

call application stats

Note Effective with Cisco IOS Release 12.3(14)T, the **call application stats** command is replaced by the **stats** command in application configuration monitor mode. See the **stats** command for more information.

To enable statistics collection for voice applications, use the **call application stats** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application stats

no call application stats

Syntax Description

This command has no arguments or keywords.

Command Default

Statistics collection is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	This command was replaced by the **stats** command in application configuration monitor mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

To display the application statistics, use the **show call application session-level**, **show call application app-level**, or **show call application gateway-level** command. To reset the application counters in history to zero, use the **clear call application stats** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application stats

        Warning: This command has been deprecated. Please use the following:
             stats
```

The following example enables statistics collection for voice applications:

```
call application stats
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application interface stats	Enables statistics collection for application interfaces.
clear call application stats	Clears application-level statistics in history and subtracts the statistics from the gateway-level statistics.
show call application app-level	Displays application-level statistics for voice applications.
show call application gateway-level	Displays gateway-level statistics for voice application instances.
show call application session-level	Displays event logs and statistics for voice application instances.
stats	Enables statistics collection for voice applications.

call application voice

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice** command is replaced by the commands shown in Table 2. See these commands for more information.

To define the name of a voice application and specify the location of the Tool Command Language (Tcl) or VoiceXML document to load for this application, use the **call application voice** command in global configuration mode. To remove the defined application and all configured parameters associated with it, use the **no** form of this command.

call application voice *application-name* {*location* | *av-pair*}

no call application voice *application-name*

Syntax Description

application-name	Character string that defines the name of the voice application.
location	Location of the Tcl script or VoiceXML document in URL format. Valid storage locations are TFTP, FTP, HTTP, and flash memory.
av-pair	Text string that defines attribute-value (AV) pairs specified by the Tcl script and understood by the RADIUS server. Multiple AV pairs can be enclosed in quotes; up to 512 entries are supported.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XH	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T. The *location* argument was added.
12.1(3)T	The *av-pair* argument was added for AV pairs.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB	This command was modified to support VoiceXML applications and HTTP server locations on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.
12.2(4)XM	This command was implemented on the Cisco 1751. Support for other Cisco platforms is not included in this release.

Release	Modification
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 2600 series, Cisco 3600 series, Cisco 3725, Cisco 3745, and Cisco 7200 series.
12.2(11)T	This command was implemented for VoiceXML applications. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.2(15)T	MCID AV-pairs were added for the *av-pair* argument; they are mcid-dtmf, mcid-release-timer, and mcid-retry-limit.
12.3(8)T	Support was added to allow up to 512 multiple AV pairs (enclosed in quotes) to be used in a single command.
12.3(14)T	This command was replaced. The **call application voice** command was replaced by the commands shown in Table 2.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

The **call application voice** command was replaced by the commands shown in Table 2.

Table 2 call application voice Command Replacements

Command	Command Mode	Purpose
application	Global configuration	Enters application configuration mode to configure voice applications and services.
service	Application configuration	Enters service configuration mode to configure a standalone application, such as a debit card script.
package	Application configuration	Use to load and configure a package. A package is a linkable set of C or Tcl functions that provide functionality invoked by applications or other packages.
param	Application parameter configuration	Use to configure parameters for services or packages.

Use this command when configuring interactive voice response (IVR) or one of the IVR-related features (such as Debit Card) to define the name of an application and to identify the location of the Tcl script or VoiceXML document associated with the application.

A voice application must be configured by using this command before the application can be configured with the **application** command in a dial peer.

Tcl scripts and VoiceXML documents can be stored in any of the following locations: on TFTP, FTP, or HTTP servers, in the flash memory of the gateway, or on the removable disks of the Cisco 3600 series. The audio files that they use can be stored in any of these locations, and on Real-Time Streaming Protocol (RTSP) servers.

HTTP is the recommended protocol for loading applications and audio prompts because of its efficient design for loading information over the web. For example, it has methods for determining how long a file can be cached and whether a cached file is still valid.

Include the file type extension in the filename (.vxml or .tcl) when specifying the document used by the application. Tcl files require the extension .tcl, and VoiceXML documents require .vxml.

Note The **no call application voice** command causes all related call application commands—for instance, **call application voice language** and **call application voice set-location**—to be deleted. The **no call application voice** *application-name* command removes the entire application and all parameters, if configured.

Examples

Effective with Cisco IOS Release 12.3(14)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice

        Warning: This command has been deprecated. Please use the following:
             application
               service
                 package
                   param
```

The following example defines the fax-relay application and the TFTP server location of the associated Tcl script:

```
call application voice fax-relay tftp://keyer/faxrelay.tcl
```

The following example defines the application “prepaid” and the TFTP server location of the associated Tcl script:

```
call application voice prepaid tftp://keyer/debitcard.tcl
```

The following is an example of AV pair configuration:

```
set avsend(h323-ivr-out,)) "payphone:true"
set avsend(323-ivr-out,1) "creditTime:3400"
```

The AV pair (after the array is defined, as in the prior example) must be sent to the server using the authentication, authorization, and accounting (AAA) authenticate or AAA authorize verbs as follows:

```
aaa authenticate $account $password $avsend
```

The script would use this AV pair whenever it is needed to convey information to the RADIUS server that cannot be represented by the standard vendor-specific attributes (VSAs).

The following example shows how to define the VoiceXML application “vapptest1” and the flash memory location of the associated VoiceXML document “demo0.vxml”:

```
call application voice vapptest1 flash:demo0.vxml
```

The following example specifies the MCID application name, the TFTP server location of the associated Tcl script, and the AV-pairs associated with the MCID application:

```
call application voice mcid tftp://keyer/app_mcid.2.0.0.40.tcl
call application voice mcid mcid-dtmf #99
call application voice mcid-retry-limit 3
call application voice mcid mcid-release-timer 90
```

Related Commands

Command	Description
application (dial peer)	Defines the call application in the dial peer.
application (global configuation)	Enters application configuration mode to configure applications.
call application voice language	Defines the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script or VoiceXML document.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Defines the telephone number to which a call is redirected for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice security trusted	Sets the security level of a VoiceXML application to trusted so that ANI is not blocked.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
package	Enters application parameter configuration mode to load and configure a package.
param	Loads and configures parameters in a package or a service (application) on the gateway.
service	Loads and configures a specific, standalone application on a dial peer.
show call application voice	Displays information about voice applications.

call application voice access-method

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice access-method** command was replaced by the **param access-method** command in application parameter configuration mode. See the **param access-method** command for more information.

To specify the access method for two-stage dialing for the designated application, use the **call application voice access-method** command in global configuration mode. To restore default values for this command, use the **no** form of this command.

call application voice *application-name* **access-method** {**prompt-user** | **redialer**}

no call application voice *application-name* **access-method**

Syntax Description

application-name	Name of the application.
prompt-user	Specifies that no DID is set in the incoming POTS dial peer and that a Tcl script in the incoming POTS dial peer is used for two-stage dialing.
redialer	Specifies that no DID is set in the incoming POTS dial peer and that the redialer device are used for two-stage dialing.

Command Default Prompt-user (when DID is not set in the dial peer)

Command Modes Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into the Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was introduced on the Cisco 1750.
12.3(14)T	This command was replaced by the **param access-method** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines Use the **call application voice access-method** command to specify the access method for two-stage dialing when DID is disabled in the POTS dial peer.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice access-method

        Warning: This command has been deprecated. Please use the following:
             param access-method
```

The following example specifies prompt-user as the access method for two-stage dialing for the app_libretto_onramp9 IVR application:

```
call application voice app_libretto_onramp9 access-method prompt-user
```

Related Commands

Command	Description
call application voice	Loads a specified application onto the router from the TFTP server and gives it an application name by which it is known on the router.
call application voice language	Defines the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Defines the telephone number to which a call is redirected—for example, the operator telephone number of the service provider—for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
param access-method	Specifies the access method for two-stage dialing for the designated application.

call application voice account-id-method

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice account-id-method** command is replaced by the **param account-id-method** command in application parameter configuration mode. See the **param account-id-method** command for more information.

To configure the fax detection IVR application to use a particular method to assign the account identifier, use the **call application voice account-id-method** command in global configuration mode. To remove configuration of this account identifier, use the **no** form of this command.

call application voice *application-name* **account-id-method** {**none** | **ani** | **dnis** | **gateway**}

no call application voice *application-name* **account-id-method**

Syntax Description

application-name	Name of the defined fax detection IVR application.
none	Account identifier is blank. This is the default.
ani	Account identifier is the calling party telephone number (automatic number identification, or ANI).
dnis	Account identifier is the dialed party telephone number (dialed number identification service, or DNIS).
gateway	Account identifier is a router-specific name derived from the hostname and domain name, displayed in the following format: router-name.domain-name.

Command Default

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced for the Cisco AS5300.
12.2(2)XB	This command was implemented on the Cisco AS5400 and Cisco AS5350.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was implemented on the Cisco AS5300, the Cisco AS5350, and Cisco AS5400.
12.3(14)T	This command was replaced by the **param account-id-method** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

When an on-ramp application converts a fax into an e-mail, the e-mail contains a field called x-account-id, which can be used for accounting or authentication. The x-account-id field can contain information supplied as a result of this command, such as the calling party's telephone number (**ani**), the called party's telephone number (**dnis**), or the name of the gateway (**gateway**).

This command is not supported by Cisco IOS help; that is, if you type **the call application voice fax_detect account-id-method command and a question mark (?)**, the Cisco IOS help does not supply a list of entries that are valid in place of the question mark.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application fax_detect account-id-method gateway

        Warning: This command has been deprecated. Please use the following:
             param account-id-method
```

The following example sets the fax detection IVR application account identifier to the router-specific name derived from the hostname and domain name:

```
call application voice fax_detect account-id-method gateway
```

Related Commands

Command	Description
call application voice	Loads a specified IVR application onto the router from the TFTP server and gives it an application name by which it is known on the router.
call application voice fax-dtmf	Configures the fax detection IVR application to recognize a specified digit that indicates a fax call in default-voice and default-fax modes.
call application voice mode	Configures the fax detection IVR application to operate in one of its four modes.
call application voice prompt	Configures the fax detection IVR application to use the specified audio file as a user prompt in listen-first mode, default-voice mode, or default-fax mode.
call application voice voice-dtmf	Configures the fax detection IVR application to recognize a specified digit that indicate a voice call in default-voice and default-fax modes.
param account-id-method	Configures an application to use a particular method to assign the account identifier.

call application voice authentication enable

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice authentication enable** command is replaced by the **param authentication enable** command in application configuration mode. See the **param authentication enable** command for more information.

To enable authentication, authorization, and accounting (AAA) services for a Tool Command Language (TCL) application, use the **call application voice authentication enable** command in global configuration mode. To disable authentication for a TCL application, use the **no** form of this command.

call application voice *application-name* **authentication enable**

no call application voice *application-name* **authentication enable**

Syntax Description

application-name	Name of the application.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.3(14)T	This command was replaced by the **param authentication enable** command in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines This command enables AAA authentication services for a TCL application if a AAA authentication method list has been defined using both the **aaa authentication** command and the **call application voice authen-list** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice authentication enable

        Warning: This command has been deprecated. Please use the following:
           param authentication enable
```

The following example enables a AAA authentication method list (called “sample”) to be used with outbound store-and-forward fax.

```
call application voice app_eaample_onramp9 authen-list sample
call application voice app_example_onramp9 authentication enable
```

Related Commands

Command	Description
aaa authentication	Enables AAA accounting of requested services when you use RADIUS or TACACS+.
call application voice authen-list	Specifies the name of an authentication method list for a TCL application.
call application voice authen-method	Specifies the authentication method for a TCL application.

call application voice accounting-list

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice accounting-list** command is replaced by the **param accounting-list** in application configuration mode. See the **param accounting-list** command for more information.

To define the name of the accounting method list to be used for authentication, authorization, and accounting (AAA) with store-and-forward fax on a voice feature card (VFC), use the **call application voice accounting-list** command in global configuration mode. To undefine the accounting method list, use the **no** form of this command.

call application voice *application-name* **accounting-list** *method-list-name*

no call application voice *application-name* **accounting-list** *method-list-name*

Syntax Description

application-name	Name of the application.
method-list-name	Character string used to name a list of accounting methods to be used with store-and-forward fax.

Command Default No AAA accounting method list is defined

Command Modes Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.3(14)T	This command was replaced by the **param accounting-list** in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command defines the name of the AAA accounting method list to be used with store-and-forward fax. The method list itself, which defines the type of accounting services provided for store-and-forward fax, is defined using the **aaa accounting** command. Unlike standard AAA (in which each defined method list can be applied to specific interfaces and lines), the AAA accounting method lists that are used in store-and-forward fax are applied globally.

After the accounting method lists have been defined, they are enabled by using the **mmoip aaa receive-accounting enable** command.

This command applies to both on-ramp and off-ramp store-and-forward fax functions on VFCs. The command is not used on modem cards.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice accounting-list

        Warning: This command has been deprecated. Please use the following:
           param accounting-list
```

The following example defines a AAA accounting method list “example” to be used with store-and-forward fax:

```
aaa new-model
call application voice app_libretto_onramp9 accounting-list example
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services when you use RADIUS or TACACS+.
call application voice accounting enable	Enables AAA accounting for a TCL application.
mmoip aaa receive-accounting enable	Enables on-ramp AAA accounting services.

call application voice accounting-template

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice accounting-template** command is obsolete. Use the **call accounting-template** command in application configuration mode to configure a voice accounting template.

To configure T.37 fax accounting with VoIP authentication, authorization, and accounting (AAA) nonblocking Application Programming Interface (API), use the **call application voice accounting-template** command in global configuration mode. To remove the defined application and all configured parameters associated with it, use the **no** form of this command.

call application voice *application-name* **accounting-template** *template-name*

no call application voice *application-name* **accounting-template** *template-name*

Syntax Description

application-name	Defines the name of the T.37 voice application. • Use the **call application voice** command to define the name of a voice application and specify the location of the Tool Command Language (Tcl) or VoiceXML document to load for this application.
template-name	Defines the name of the template. • Use the **call accounting-template voice** command to define the template name.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.3(1)	This command was introduced.
12.3(14)T	This command is obsolete. Use the **call accounting-template** command in application configuration mode to configure a voice accounting template.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command enables T.37 fax to be consistent with VoIP AAA accounting services, which uses the Cisco IOS software nonblocking APIs. This command creates accounting templates for faxes by associating the template name with the T.37 onramp or offramp application.

You can define an accounting template to specify information that is included in an accounting packet.

Note This command applies only to T.37 fax.

Use the **show call active fax** and the **show call history fax** commands to check the configuration.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice accounting-template

        Warning: This command has been deprecated. Please use the following:
             call accounting-template
```

The following is an example configuration using the T.37 accounting template:

```
Router(config)# call application voice t37_onramp accounting-template sample-name
Router(config)# call application voice t37_offramp accounting-template sample-name
```

Related Commands

Command	Description
application	Defines the call application in the dial peer.
call accounting-template	Selects an accounting template at a specific location.
call accounting-template voice	Selects an accounting template at a specific location.
call application voice	Defines the name of a voice application and specifies the location of the Tcl or VoiceXML document to load for this application.
call application voice language	Defines the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script or VoiceXML document.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Defines the telephone number to which a call is redirected for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice security trusted	Sets the security level of a VoiceXML application to trusted so that ANI is not blocked.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
show call active fax	Displays call information for fax transmissions in progress.
show call application voice	Displays information about voice applications.
show call history fax	Displays the call history table for fax transmissions.

call application voice authen-list

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice authen-list** command was replaced by the **param authen-list** command in application configuration mode. See the **param authen-list** command for more information.

To specify the name of an authentication method list for a Tool Command Language (Tcl) application, use the **call application voice authen-list** command in global configuration mode. To disable the authentication method list for a Tcl application, use the **no** form of this command.

call application voice *application-name* **authen-list** *method-list-name*

no call application voice *application-name* **authen-list** *method-list-name*

Syntax Description

application-name	Name of the application.
method-list-name	Character string used to name a list of authentication methods to be used with T.38 fax relay and T.37 store-and-forward fax.

Command Default

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series and Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.3(14)T	This command was replaced by the **param authen-list** command in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command defines the name of the authentication, authorization, and accounting (AAA) method list to be used with fax applications on voice feature cards. The method list itself, which defines the type of authentication services provided for store-and-forward fax, is defined using the **aaa authentication** command. Unlike standard AAA (in which each defined method list can be applied to specific interfaces and lines), AAA method lists that are used with fax applications are applied globally.

After the authentication method lists have been defined, they are enabled by using the **call application voice authentication enable** command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice authen-list

        Warning: This command has been deprecated. Please use the following:
           param authen-list
```

The following example defines a AAA authentication method list (called “fax”) to be used with T.38 fax relay and T.37 store-and-forward fax:

```
call application voice app_libretto_onramp9 authen-list fax
```

Related Commands

Command	Description
aaa authentication	Enable AAA accounting of requested services for billing or security purposes.
call application voice authen-method	Specifies the authentication method for a Tcl application.
call application voice authentication enable	Enables AAA authentication services for a Tcl application.

call application voice authen-method

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice authen-method** command is replaced by the **param authen-method** command in application configuration mode. See the **param authen-method** command for more information.

To specify an authentication, authorization, and accounting (AAA) authentication method for a Tool Command Language (Tcl) application, use the **call application voice authen-method** command in global configuration mode. To disable the authentication method for a Tcl application, use the **no** form of this command.

call application voice *application-name* **authen-method** {**prompt-user** | **ani** | **dnis** | **gateway** | **redialer-id** | **redialer-dnis**}

no call application voice *application-name* **authen-method** {**prompt-user** | **ani** | **dnis** | **gateway** | **redialer-id** | **redialer-dnis**}

Syntax Description

application-name	Name of the application.
prompt-user	User is prompted for the Tcl application account identifier.
ani	Calling party telephone number (automatic number identification or ANI) is used as the Tcl application account identifier.
dnis	Called party telephone number (dialed number identification service or DNIS) is used as the Tcl application account identifier.
gateway	Router-specific name derived from the host name and domain name is used as the Tcl application account identifier, displayed in the following format: *router-name.domain-name*.
redialer-id	Account string returned by the external redialer device is used as the Tcl application account identifier. In this case, the redialer ID is either the redialer serial number or the redialer account number.
redialer-dnis	Called party telephone number (dialed number identification service or DNIS) is used as the Tcl application account identifier captured by the redialer if a redialer device is present.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.

Release	Modification
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.3(14)T	This command was replaced by the **param authen-method** command in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Normally, when AAA is used for simple user authentication, AAA uses the username information defined in the user profile for authentication. With T.37 store-and-forward fax and T.38 real-time fax, you can specify that the ANI, DNIS, gateway ID, redialer ID, or redialer DNIS be used to identify the user for authentication or that the user be prompted for the Tcl application.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice authen-method

        Warning: This command has been deprecated. Please use the following:
           param authen-method
```

The following example configures the router-specific name derived from the hostname and domain name as he Tcl application account identifier for the app_sample_onramp9 Tcl application:

```
call application voice app_sample_onramp9 authen-method gateway
```

Related Commands

Command	Description
call application voice authentication enable	Enables AAA authentication services for a Tcl application.
call application voice authen-list	Specifies the name of an authentication method list for a Tcl application.

call application voice accounting enable

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice accounting enable** command is replaced by the **param accounting enable** command in application configuration mode. See the **param accounting enable** command for more information.

To enable authentication, authorization, and accounting (AAA) accounting for a Tool Command Language (Tcl) application, use the **call application voice accounting enable** command in global configuration mode. To disable accounting for a Tcl application, use the **no** form of this command.

call application voice *application-name* **accounting enable**

no call application voice *application-name* **accounting enable**

Syntax Description

application-name	Name of the application.

Defaults

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series and Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.3(14)T	This command was replaced by the **param accounting enable** command in application configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command enables AAA accounting services if a AAA accounting method list has been defined using both the **aaa accounting** command and the **mmoip aaa method fax accounting** command.

This command applies to off-ramp store-and-forward fax functions.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice accounting enable

        Warning: This command has been deprecated. Please use the following:
           param accounting enable
```

The following example enables AAA accounting to be used with outbound store-and-forward fax:

```
call application voice app_libretto_onramp9 accounting enable
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services when you use RADIUS or TACACS+.
mmoip aaa method fax accounting	Defines the name of the method list to be used for AAA accounting with store-and-forward fax.

call application voice default disc-prog-ind-at-connect

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice default disc-prog-ind-at-connect** command is replaced. Use one of the following commands:

- **param convert-discpi-after-connect** (application parameter configuration mode)
- **paramspace session_xwork convert-discpi-after-connect** (service configuration mode)

To convert a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) to a regular DISCONNECT message when the call is in the active state, use the **call application voice default disc-prog-ind-at-connect** command in global configuration mode. To revert to a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) when the call is in the active state, use the **no** form of this command.

call application voice default disc-prog-ind-at-connect [**1** | **0**]

no call application voice default disc-prog-ind-at-connect [**1** | **0**]

Syntax Description

1	(Optional) Convert a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) to a regular DISCONNECT message when the call is in the active state.
0	(Optional) Revert to a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) when the call is in the active state.

Command Default

The DISCONNECT message has Progress Indicator set to PROG_INBAND (PI=8) when the call is in the active state.

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)ZJ	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(14)T	The **call application voice default disc-prog-ind-at-connect** command was replaced. Use one of the following commands: • **param convert-discpi-after-connect** (application parameter configuration mode) • **paramspace session_xwork convert-discpi-after-connect** (service configuration mode)
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command has no effect if the call is not in the active state.

This command is available for the default voice application. It may not be available when using some Tcl IVR applications.

The Cisco IOS command-line interface command completion and help features do not work with this command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice default disc-prog-ind-at-connect

        Warning: This command has been deprecated. Please use the following:
           param convert-discpi-after-connect
               paramspace session_xwork convert-discpi-after-connec
```

In the following example, a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) is converted to a regular DISCONNECT message when the call is in the active state:

```
call application voice default disc-prog-ind-at-connect 1
```

Related Commands

Command	Description
param convert-discpi-after-connect	Enables or disables conversion of a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) to a regular DISCONNECT message when the call is in the active state.
paramspace session_xwork convert-discpi-after-connect	Enables or disables conversion of a DISCONNECT message with Progress Indicator set to PROG_INBAND (PI=8) to a regular DISCONNECT message when the call is in the active state.

call application voice dsn-script

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice dsn-script** command is replaced by the **param dsn-script** command in application parameter configuration mode.

To specify the VoiceXML application to which the off-ramp mail application hands off calls for off-ramp delivery status notification (DSN) and message disposition notification (MDN) e-mail messages, use the **call application voice dsn-script** command in global configuration mode. To remove the application, use the **no** form of this command.

call application voice *mail-application-name* **dsn-script** *application-name*

no call application voice *mail-application-name* **dsn-script** *application-name*

Syntax Description

mail-application-name	Name of the off-ramp mail application that launches the app_voicemail_offramp.tcl script when the gateway receives an e-mail trigger.
application-name	Name of the VoiceXML application to which the off-ramp mail application hands off the call when the destination answers.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.3(14)T	This command was replaced by the **param dsn-script** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines When the off-ramp gateway receives a DSN or MDN e-mail message, it handles it in the same way as a voice e-mail trigger message. The dial peer is selected on the basis of dialed number identification service (DNIS), and the mail application hands off the call to the VoiceXML application that is configured with this command.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice dsn-script

        Warning: This command has been deprecated. Please use the following:
           param dsn-script
```

The following example shows how to define the DSN application and how to apply it to a dial peer:

```
call application voice offramp-mapp tftp://sample/tftp-users/tcl/app_voicemail_offramp.tcl
call application voice dsn-mapp-test tftp://sample/tftp-users/vxml/dsn-mapp-test.vxml
call application voice offramp-mapp dsn-script dsn-mapp-test
!
dial-peer voice 1000 mmoip
 application offramp-mapp
 incoming called-number 555....
 information-type voice
```

Related Commands

Command	Description
application	Defines a specific voice application in the dial peer.
call application voice	Defines the name of a voice application and specifies the location of the document (Tcl or VoiceXML) to load for the application.
param dsn-script	Specifies the VoiceXML application to which the off-ramp mail application hands off calls for off-ramp DSN and MDN e-mail messages.
show call application voice	Displays information about the configured voice applications.

call application voice event-log

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice event-log** is obsolete. To enable event logging for a specific voice application, use one of the following commands:

- **param event-log** (application parameter configuration mode)
- **paramspace appcommon event-log** (service configuration mod

To enable event logging for a specific voice application, use the **call application voice event-log** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application voice *application-name* **event-log** [**disable**]

no call application voice *application-name* **event-log**

Syntax Description

application-name	Name of the voice application.
disable	(Optional) Disables event logging for the named application.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(14)T	The **call application voice event-log** is obsolete. To enable event logging for a specific voice application, use one of the following commands: • **param event-log** (application parameter configuration mode) • **paramspace appcommon event-log** (service configuration mode)
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command is application-specific; it takes precedence over the global configuration command, **call application event-log**, which enables event logging for all voice applications.

Before you can use this command, you must configure the named application on the gateway by using the **call application voice** command.

Note To prevent event logging from adversely impacting system resources for production traffic, the gateway uses a throttling mechanism. When free processor memory drops below 20 percent, the gateway automatically disables all event logging. It resumes event logging when free memory rises above 30 percent. While throttling is occurring, the gateway does not capture any new event logs even if event logging is enabled. You should monitor free memory and enable event logging only when necessary for isolating faults.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call call application voice event-log
       Warning: This command has been deprecated. Please use the following:
           param event-log
               paramspace appcommon event-log
```

The following example enables event logging for all instances of the application named sample_app:

```
call application voice sample_app event-log
```

The following example enables event logging for all applications except the application sample_app:

```
call application event-log
call application voice sample_app event-log disable
```

Related Commands

Command	Description
call application event-log	Enables event logging for voice application instances.
call application event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
call application voice	Defines the name of a voice application and specifies the location of the script to load for the application.
monitor call application event-log	Displays the event log for an active application instance in real-time.
param event-log	Enables or disables logging for linkable Tcl functions (packages).
paramspace appcommon event-log	Enable or disables logging for a service (application).
show call application session-level	Displays event logs and statistics for voice application instances.

call application voice fax-dtmf

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice fax-dtmf** command is replaced by the **param fax-dtmf** command in application parameter configuration mode. See the **param fax-dtmf** command for more information.

To direct the fax detection interactive voice response (IVR) application to recognize a specified digit to indicate a fax call in default-voice and default-fax modes, use the **call application voice fax-dtmf** command in global configuration mode. To remove configuration of this digit, use the **no** form of this command.

call application voice *application-name* **fax-dtmf** {**0** | **1** | **2** | **3** | **4** | **5** | **6** | **7** | **8** | **9** | ***** | **#**}

no call application voice *application-name* **fax-dtmf** {**0** | **1** | **2** | **3** | **4** | **5** | **6** | **7** | **8** | **9** | ***** | **#**}

Syntax Description

application-name	The name of the fax detection IVR application that you defined when you loaded the application on the router.
0 | **1** | **2** | **3** | **4** | **5** | **6** | **7** | **8** | **9** | ***** | **#**	The telephone keypad digit processed by the calling party to indicate a fax call, in response to the audio prompt that plays during the default-voice or default-fax mode of the fax detection IVR application.

Command Default **2**

Command Modes Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced for the Cisco AS5300.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB	This command was implemented on the Cisco AS5400 and Cisco AS5350.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.3(14)T	This command was replaced by the **param fax-dtmf** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command is useful only when the fax detection IVR application is being configured in default-voice mode or default-fax mode as defined by the **call application voice mode** command.

Only one digit can be specified in this command, and that digit must be different from the digit specified in the **call application voice voice-dtmf** command. You are not notified immediately if you make the error of configuring them both to the same digit. To find this error, you must start the debugging with the **debug voip ivr script** command and then observe some failing calls.

This command is not supported by Cisco IOS help; that is, if you type **call application voice fax_detect fax-dtmf and a question mark (?)**, Cisco IOS help does not supply a list of entries that are valid in place of the question mark.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice fax-dtmf

        Warning: This command has been deprecated. Please use the following:
           param fax-dtmf
```

The following example selects DTMF digit 1 to indicate a fax call:

```
call application voice fax_detect script_url
call application voice fax_detect fax-dtmf 1
dial-peer voice 302 pots
 application fax_detect
```

Related Commands

Command	Description
call application voice	Loads an IVR application onto a router and gives it an application name.
call application voice account-id-method	Configures the fax detection IVR application to use a particular method to assign the account identifier.
call application voice mode	Configures the fax detection IVR application to operate in one of its four modes.
call application voice prompt	Configures the fax detection IVR application to use the specified audio file as a user prompt.
call application voice voice-dtmf	Configures the fax detection IVR application to recognize the specified digit to indicate a voice call.
debug voip ivr script	Displays debug information from the fax detection IVR script.
param fax-dtmf	Directs the fax detection IVR application to recognize a specified digit to indicate a fax call in default-voice and default-fax modes.

call application voice global-password

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice global-password** command is replaced by the **param global-password** command in application parameter configuration mode. See the **param global-password** command for more information.

To define a password to be used with CiscoSecure for Windows NT when using store-and-forward fax on a voice feature card, use the **call application voice global-password** command in global configuration mode. To restore the default value, use the **no** form of this command.

call application voice *application-name* **global-password** *password*

no call application voice *application-name* **global-password** *password*

Syntax Description

application-name	The name of the application.
password	Character string used to define the CiscoSecure for Windows NT password to be used with store-and-forward fax. The maximum length is 64 alphanumeric characters.

Command Default No password is defined

Command Modes Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.3(14)T	This command is replaced by the **param global-password** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines CiscoSecure for Windows NT might require a separate password to complete authentication, no matter what security protocol you use. This command defines the password to be used with CiscoSecure for Windows NT. All records on the Windows NT server use this defined password.

This command applies to on-ramp store-and-forward fax functions on Cisco AS5300 universal access server voice feature cards. It is not used on modem cards.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice global-password

        Warning: This command has been deprecated. Please use the following:
           param global-password
```

The following example shows a password (abercrombie) being used by AAA for the app_sample_onramp9 Tcl application:

```
call application voice app_sample_onramp9 global-password abercrombie
```

Related Commands

Command	Description
param global-password	Defines a password to be used with CiscoSecure for Windows NT when using store-and-forward fax on a voice feature card.

call application voice language

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice language** is replaced by the following commands:

- **param language** (application parameter configuration mode)
- **paramspace language** (service configuration mode)

See these commands for more information.

To specify the language for dynamic prompts used by an interactive voice response (IVR) application (Tool Command Language (Tcl) or VoiceXML), use the **call application voice language** command in global configuration mode. To remove this language specification from the application, use the **no** form of this command.

call application voice *application-name* **language** *digit language*

no call application voice *application-name* **language** *digit language*

Syntax Description

application-name	Name of the application to which the language parameters are being passed.
digit	Number that identifies the language used by the audio files. Any number can represent any language. Enter 1 to indicate the primary language and 2 to indicate the secondary language. Range is from 0 to 9.
language	Two-character code that identifies the language of the associated audio files. Valid entries are as follows: • **en**—English • **sp**—Spanish • **ch**—Mandarin • **aa**—all

Command Default If this command is not configured, the default language is English.

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB	This command was modified to support VoiceXML applications on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.

Release	Modification
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(4)XM	This command was implemented on the Cisco 1751.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800 and Cisco AS5850 is not included in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T for VoiceXML applications. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco 5800, and Cisco AS5850 in this release.
12.3(14)T	The **call application voice language** was replaced by the following commands: **param language** (application parameter configuration mode) **paramspace language** (service configuration mode)
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command identifies the number that users enter for a language; for example, “Enter 1 for English. Enter 2 for French.”

This number is used only with the Tcl IVR Debit Card feature. Although it is not used by VoiceXML, you still must enter a number from 0 to 9.

Instead of using this command, you can configure the language and location of the prerecorded audio files within a Tcl script or VoiceXML document. For more information, see the *Tcl IVR API Version 2.0 Programmer’s Guide* or *Cisco VoiceXML Programmer’s Guide*, respectively.

To identify the location of the language audio files that are used for the dynamic prompts, use the **call application voice set-location** command.

Tcl scripts and VoiceXML documents can be stored in any of the following locations: On the TFTP, FTP, or HTTP servers, in the flash memory of the gateway, or on the removable disks of the Cisco 3600 series. The audio files that they use can be stored in any of these locations, and on RTSP servers.

With the Pre-Paid Debitcard Multi-Language feature, you can create Tcl scripts and a two-character code for any language. See the *Cisco Pre-Paid Debitcard Multi-Language Programmer's Reference*.

With the multilanguage support for Cisco IOS IVR, you can create a Tcl language module for any language and any set of TTS notations for use with Tcl and VoiceXML applications. See the *Enhanced Multi-Language Support for Cisco IOS Interactive Voice Response* document.

Table 3 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 3 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None
clid_4digits_npw_3_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4. **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	This script authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	This script authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_npw_cli.tcl	This script authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice language

        Warning: This command has been deprecated. Please use the following:
           param language
               paramspace language
```

The following example shows how to define the application "prepaid" and then selects English and Spanish as the languages of the audio files that are associated with the application:

```
call application voice prepaid tftp://keyer/debitcard.tcl
call application voice prepaid language 1 en
call application voice prepaid language 2 sp
```

Related Commands

Command	Description
call application voice	Specifies the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
call application voice load	Reloads the designated Tcl script.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Specifies the telephone number to which a call is redirected for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
param language	Configures the language parameter in a service or package on the gateway.
paramspace language	Defines the category and location of audio files that are used for dynamic prompts by an IVR application (Tcl or VoiceXML).
show call application voice	Displays information about voice applications.

call application voice load

To reload the selected voice application script after it has been modified, use the **call application voice load** command in privileged EXEC mode. This command does not have a **no** form.

call application voice load *application-name*

Syntax Description

application-name	Name of the Tcl or VoiceXML application to reload.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(7)T	This command was introduced on the Cisco 2600 series and Cisco 3600 series (except for the Cisco 3660), and on the Cisco AS5300.
12.1(3)T	Support for dynamic script loading of Media Gateway Control Protocol (MGCP) was added.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB	This command was modified to support VoiceXML applications.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1751.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.
12.2(8)T	This command and implemented on the Cisco 7200 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T for VoiceXML applications. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and the Cisco AS5850 in this release.

Usage Guidelines

Use this command to reload an application Tcl script or VoiceXML document onto the gateway after it has been modified.

The location of the Tcl script or VoiceXML document for the specified application must have already been configured using the **call application voice** command.

Do not include the file type extension in the filename (.vxml or .tcl) when specifying the document used by the application.

Tcl scripts and VoiceXML documents can be stored in any of the following locations: on TFTP, FTP, or HTTP servers, in the flash memory of the gateway, or on the removable disks of the Cisco 3600 series. The audio files that they use can be stored on any of these locations, and on RTSP servers.

Before Cisco IOS Release 12.1(3)T, the software checked the signature in a Tcl script to ensure that it was supported by Cisco. A signature on Tcl scripts is no longer required. A signature has never been required for VoiceXML documents.

A Tcl script or VoiceXML document cannot be reloaded if it has active calls. Use the **show call application voice** command to verify that no active calls are using this application.

Tip If the **call application voice load** command fails to load the Tcl script or VoiceXML document that is associated with the application, enable the **debug voip ivr** command and retry. This debugging command can provide information on why loading fails.

Note MGCP scripting is not supported on the Cisco 1750 router or on Cisco 7200 series routers.

Examples

The following example shows the loading of a Tcl script called "clid_4digits_npw_3.tcl":

```
call application voice load clid_4digits_npw_3.tcl
```

The following example shows how to reload the VoiceXML application called "vapptest":

```
call application voice load vapptest
```

Related Commands

Command	Description
call application cache reload time	Configures the interval for reloading MGCP scripts.
call application voice	Creates and calls the application that interacts with the IVR feature.
debug http client	Displays information about the load an application that was loaded with HTTP.
show call application voice	Displays a list of the voice applications that are configured.

call application voice mail-script

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice mail-script** command is replaced by the **param mail-script** command in application parameter configuration mode. See the **param mail-script** command for more information.

To specify the VoiceXML application to which the off-ramp mail application hands off a call when the destination telephone answers, use the **call application voice mail-script** command in global configuration mode. To remove the application, use the **no** form of this command.

call application voice *mail-application-name* **mail-script** *application-name*

no call application voice *mail-application-name* **mail-script** *application-name*

Syntax Description

mail-application-name	Name of the off-ramp mail application that launches the app_voicemail_offramp.tcl script when the gateway receives an e-mail trigger.
application-name	Name of the VoiceXML application to which the off-ramp mail application hands off the call when the destination answers.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.3(14)T	This command was replaced by the **param mail-script** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines To load the mail application onto the gateway, use the **call application voice** command.

The off-ramp mail application must be configured in the Multimedia Mail over Internet Protocol (MMoIP) dial peer that matches the telephone number contained in the header of the incoming e-mail message.

The off-ramp mail application must use the Tool Command Language (Tcl) script named "app_voicemail_offramp.tcl" that is provided by Cisco. This Tcl script can be downloaded from the Cisco website by following this path: Cisco > Technical Support Help - TAC > Select & Download Software > Software Center > Access Software > TclWare.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice mail-script

        Warning: This command has been deprecated. Please use the following:
           param mail-script
```

The following example shows that the off-ramp mail application named "offramp-mapp" hands calls to the application named "mapp-test" if the telephone number in the e-mail header is seven digits beginning with 555:

```
call application voice offramp-mapp tftp://sample/tftp-users/tcl/app_voicemail_offramp.tcl
call application voice mapp-test tftp://sample/tftp-users/vxml/user-test.vxml
call application voice offramp-mapp mail-script mapp-test
!
dial-peer voice 1001 mmoip
 application offramp-mapp
 incoming called-number 555....
 information-type voice
```

Related Commands

Command	Description
application	Defines a specific voice application in the dial peer.
call application voice	Defines the name of a voice application and specifies the location of the document (Tcl or VoiceXML) to load for the application.
param mail-script	Specifies the VoiceXML application to which the off-ramp mail application hands off a call when the destination telephone answers.
show call application voice	Displays information about the configured voice applications.

call application voice mode

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice mode** command is replaced by the **param mode** command in application parameter configuration mode. See the **param mode** command for more information.

To direct the fax detection interactive voice response (IVR) application to operate in one of its four connection modes, use the **call application voice mode** command in global configuration mode. To return to the default connection mode, use the **no** form of this command.

call application voice *application-name* **mode** {**connect-first | listen-first | default-voice | default-fax**}

no call application voice *application-name* **mode** {**connect-first | listen-first | default-voice | default-fax**}

Syntax Description

application-name	Fax detection IVR application that was defined when the application was loaded on the router.
connect-first	Incoming calls are connected to the Real-Time Streaming Protocol (RTSP) server. This is the default.
listen-first	The gateway listens to the call first and then connects to the RTSP server. Any Dual tone multifrequency (DTMF) tones take the call to the voice server, but subsequent DTMF is forwarded as configured.
default-voice	Incoming calls are connected as voice calls to the RTSP server.
default-fax	Incoming calls are connected to the fax relay or store-and-forward fax application that is configured on the gateway.

Command Default **connect-first**

Command Modes Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced on the Cisco AS5300.
12.2(2)XB	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command is supported on the Cisco AS5300, Cisco AS5350, and Cisco AS5400 in this release.

Release	Modification
12.3(14)T	This command was replaced by the **param mode** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

The call application voice mode commands control the way that the gateway handles fax detection IVR applications calls.

When the **connect-first** keyword is selected and CNG (calling) tones from the originating fax machine are detected, the voice application is disconnected and the call is passed to the configured fax application. If the **listen-first** keyword is selected, the gateway listens for CNG and, if it is detected, passes the call to the fax relay or store-and-forward fax application, whichever is configured on the gateway. When the **default-voice** and **default-fax** keywords are selected, the gateway defaults to voice after listening for CNG or passes the call to the fax relay or store-and-forward fax application, whichever was configured on the gateway. If the gateway hears the Dual tone multifrequency (DTMF) tones that are specified in the **call application voice voice-dtmf** or **call application voice fax-dtmf** commands, the call is forwarded as appropriate.

Note that in all four connection modes, the router continues to listen for CNG throughout the call, even if the call has been connected to the voice server; if CNG is detected, the call is connected to fax relay or store-and-forward fax, whichever has been configured.

This command is not supported by Cisco IOS help. If you type the **call application voice fax_detect mode** command and a question mark (?), Cisco IOS help does not supply a list of valid entries in place of the question mark.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice mode

        Warning: This command has been deprecated. Please use the following:
           param mode
```

The following example shows a selection of default-voice mode for the fax detection application:

```
call application voice fax_detect script_url
call application voice fax_detect mode default-voice
dial-peer voice 302 pots
 application fax_detect
```

Related Commands

Command	Description
call application voice	Loads a specified IVR application onto the router from the TFTP server and gives it an application name by which it is known on the router.
call application voice account-id-method	Configures the fax detection IVR application to use a particular method to assign the account identifier.
call application voice fax-dtmf	Configures the fax detection IVR application to recognize a specified digit to indicate a fax call.

Command	Description
call application voice prompt	Configures the fax detection IVR application to use the specified audio file as a user prompt in listen-first mode, default-voice mode, or default-fax mode.
call application voice voice-dtmf	Configures the fax detection IVR application to recognize a specified digit to indicate a voice call.
param mode	Configures the call transfer mode for a package.

call application voice pin-len

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice pin-len** command is replaced with the **param pin-len** command in application parameter configuration mode. See the **param pin-len** command for more information.

To define the number of characters in the personal identification number (PIN) for the designated application, use the **call application voice pin-len** command in global configuration mode. To disable the PIN for the designated application, use the **no** form of this command.

call application voice *application-name* **pin-len** *number*

no call application voice *application-name* **pin-len** *number*

Syntax Description

application-name	Application name to which the PIN length parameter is being passed.
number	Number of allowable characters in PINs associated with the specified application. Range is from 0 to 10. The default is 4.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.
12.2(4)XM	This command was implemented on the Cisco 1751.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series.
12.2(11)T	This command is supported on the Cisco AS5350, Cisco AS5400 Cisco AS5800, and the Cisco AS5850 in this release.
12.3(14)T	The **call application voice pin-len** command was replaced with the **param pin-len** command in application parameter configuration mode.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Use this command when configuring interactive voice response (IVR)—depending on the Tool Command Language (Tcl) script being used—or one of the IVR-related features (such as Debit Card) to define the number of allowable characters in a PIN for the specified application and to pass that information to the specified application.

Table 4 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 4 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None
clid_4digits_npw_3_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4 **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	This script authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	This script authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_npw_cli.tcl	This script authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice pin-len

        Warning: This command has been deprecated. Please use the following:
           param pin-len
```

The following example shows how to define a PIN length of 4 characters for the application named "prepaid":

```
call application voice prepaid pin-len 4
```

Related Commands

Command	Description
call application voice	Specifies the name to be used for an application and indicates the location of the appropriate IVR script to be used with the application.
call application voice language	Specifies the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script.
call application voice redirect-number	Specifies the telephone number to which a call is redirected for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
param pin-len	Defines the number of characters in the PIN for an application.

call application voice prompt

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice prompt** command is replaced by the **param prompt** command. See the **param prompt** command for more information.

To direct the fax detection interactive voice response (IVR) application to use the specified audio file as a user prompt, use the **call application voice prompt** command in global configuration mode. To disable use of this audio file, use the **no** form of this command.

call application voice *application-name* **prompt** *prompt-url*

no call application voice *application-name* **prompt** *prompt-url*

Syntax Description

application-name	Name of the fax detection IVR application that you defined when you loaded the application on the router.
prompt-url	URL or Cisco IOS file system location on the TFTP server for the audio file containing the prompt for the application.

Command Default

The prompt space is empty and no prompt is played.

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced for the Cisco AS5300.
12.2(2)XB	This command was implemented on the Cisco AS5400 and Cisco AS5350.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.3(14)T	This command was replaced by the **param prompt** command.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command is useful only in the listen-first, default-voice, and default-fax modes of the fax detection application.

Audio files should be a minimum of 9 seconds long so that callers do not hear silence during the initial CNG detection period. Any .au file can be used; formats are described in the *Cisco IOS Voice, Video, and Fax Configuration Guide*, Release 12.2.

This command is not supported by Cisco IOS help. If you type the **call application voice fax_detect prompt** command with a question (?), the Cisco IOS help does not supply a list of entries that are valid in place of the question mark.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice prompt

        Warning: This command has been deprecated. Please use the following:
           param prompt
```

The following example associates the audio file" promptfile.au" with the application file "fax_detect", and the application with the inbound POTS dial peer:

```
call application voice fax_detect script_url
call application voice fax_detect mode default-voice
call application voice fax_detect prompt promptfile.au
dial-peer voice 302 pots
 application fax_detect
```

Related Commands

Command	Description
call application voice	Loads a specified IVR application onto the router from the TFTP server and gives it an application name by which it is known on the router.
call application voice account-id-method	Configures the fax detection IVR application to use a particular method to assign the account identifier.
call application voice fax-dtmf	Configures the fax detection IVR application to recognize a specified digit to indicate a fax call.
call application voice mode	Configures the fax detection IVR application to operate in one of its four modes.
call application voice voice-dtmf	Configures the fax detection IVR application to recognize a specified digit to indicate a voice call.
param prompt	Directs the fax detection IVR application to use the specified audio file as a user prompt.

call application voice redirect-number

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice redirect-number** command is replaced with the **param redirect-number** command in application parameter configuration mode. See the the **param redirect-number** command for more information.

To define the telephone number to which a call is redirected—for example, the operator telephone number of the service provider—for the designated application, use the **call application voice redirect-number** command in global configuration mode. To cancel the redirect telephone number, use the **no** form of this command.

call application voice *application-name* **redirect-number** *number*

no call application voice *application-name* **redirect-number** *number*

Syntax Description

application-name	Name of the application to which the redirect telephone number parameter is being passed.
number	Designated operator telephone number of the service provider (or any other number designated by the customer). This is the number where calls are terminated when, for example, allowed debit time has run out or the debit amount is exceeded.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced on the Cisco 2600 series, the Cisco 3600 series, and the Cisco AS5300.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1751.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.

Release	Modification
12.3(14)T	This command was replaced by the **param redirect-number**.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Use this command when configuring interactive voice response (IVR)—depending on the Tool Command Language (Tcl) script being used—or one of the IVR-related features (such as Debit Card) to define the telephone number to which a call is redirected.

Table 5 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 5 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None
clid_4digits_npw_3_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4. **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	This script authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	This script authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.

Table 5 Tcl Scripts and Commands (continued)

Tcl Script Name	Description	Commands to Configure
clid_col_npw_npw_cli.tcl	This script authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice redirect-number

        Warning: This command has been deprecated. Please use the following:
           param redirect-number
```

The following example shows how to define a redirect number for the application named “prepaid”:

```
call application voice prepaid redirect-number 5550111
```

Related Commands

Command	Description
call application voice	Specifies the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
call application voice language	Specifies the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
param redirect-number	Defines the telephone number to which a call is redirected—for example, the operator telephone number of the service provider—for an application.

call application voice retry-count

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice retry-count** command is replaced by the **param retry-count** command in application parameter configuration mode. See the the **param retry-count** command for more information.

To define the number of times that a caller is permitted to reenter the personal identification number (PIN) for the designated application, use the **call application voice retry-count** command in global configuration mode. To cancel the retry count, use the **no** form of this command.

call application voice *application-name* **retry-count** *number*

no call application voice *application-name* **retry-count** *number*

Syntax Description

application-name	Name of the application to which the number of possible retries is being passed.
number	Number of times the caller is permitted to reenter PIN digits. Range is 1 to 5. The default is 3.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1751.
12.2(4)T	This command was introduced on the Cisco 1750.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series. Support for the Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. This command is supported on the Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.3(14)T	This command was replaced by the **param retry-count** command.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Use this command when configuring interactive voice response (IVR)—depending on the Tool Command Language (Tcl) script being used—or one of the IVR-related features (such as Debit Card) to define how many times a user can reenter a PIN.

Table 6 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 6 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None
clid_4digits_npw_3_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4. **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	This script authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	This script authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_npw_cli.tcl	This script authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application retry-count

        Warning: This command has been deprecated. Please use the following:
           param retry-count
```

The following example shows how to define that for the application named "prepaid" that a user can reenter a PIN three times before being disconnected:

```
call application voice prepaid retry-count 3
```

Related Commands

Command	Description
call application voice	Specifies the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
call application voice language	Specifies the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Specifies the telephone number to which a call is redirected for the designated application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-len	Defines the number of characters in the UID for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
param retry-count	Defines the number of times that a caller is permitted to reenter the PIN for a package.

call application voice security trusted

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice security trusted** command is replaced by the the following commands:

- **param security trusted** (application parameter configuration mode)
- **paramspace appcommon security trusted** (service configuration mode)

See these commands for more information.

To set the security level of a VoiceXML application to "trusted" so that automatic number identification (ANI) is not blocked, use the **call application voice security trusted** command in global configuration mode. To restore the default condition, use the **no** form of this command.

call application voice *application-name* **security trusted**

no call application voice *application-name* **security trusted**

Syntax Description

application-name	Name of the application being configured as trusted.

Command Default The security level of the application is not set to trusted, and ANI is blocked.

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and implemented on the Cisco 3640 and Cisco 3660.
12.3(14)T	The **call application voice security trusted** command was replaced by the following commands: • **param security trusted** (application parameter configuration mode) • **paramspace appcommon security trusted** (service configuration mode)
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines This command is applicable only for VoiceXML applications.

Note Tool Command Language (Tcl) applications provide the security parameter to the application but do not use it.

If an application is configured as a trusted application, it is trusted not to provide the calling number to the destination party, so ANI is always provided if available.

Normally, the voice gateway does not provide the calling number (ANI) to a VoiceXML application if the caller ID is blocked. Caller ID is blocked if a call that comes into the voice gateway has the presentation indication field set to "presentation restricted". The session.telephone.ani variable is set to "blocked". When the **call application voice security trusted** command is configured, the gateway does not block caller ID; it provides the calling number to the VoiceXML application.

If the keyword of this command is set to anything other than **trusted**, the value is accepted and the application is treated as not trusted. For example, in the following configuration, the application "sample" is treated as not trusted, and caller ID is blocked:

```
call application voice sample security not_trusted
```

To enable Generic Transparency Descriptor (GTD) parameters in call signaling messages to map to VoiceXML and Tcl session variables, configure the **call application voice security trusted** command. If this command is not configured, the VoiceXML variables that correspond to GTD parameters are marked as not available. For a detailed description of the VoiceXML and Tcl session variables, see the *Cisco VoiceXML Programmer's Guide* and the *Tcl IVR API Version 2.0 Programmer's Guide*, respectively.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice security trusted

        Warning: This command has been deprecated. Please use the following:
           param security trusted (application parameter configuration mode)
               paramspace appcommon security trusted
```

The following example configures the application "sample" as a trusted application. Caller ID is available to this VoiceXML application if it is supported by the service provider.

```
call application voice sample flash:sample.vxml
call application voice sample security trusted
```

The following example configures the application "example" as not trusted. Caller ID can be blocked.

```
call application voice coldcall tftp://joeserver/sellcars.vxml
no call application voice example security trusted
```

Related Commands

Command	Description
call application voice	Defines the name of a voice application and specifies the location of the document (Tcl or VoiceXML) to load for the application.
call application voice language	Defines the language of the audio files used for dynamic prompts by the designated application.
call application voice load	Reloads a Tcl or VoiceXML document.
call application voice pin-len	Defines the number of characters in the PIN for the Tcl application.
call application voice redirect-number	Defines the telephone number to which a call is redirected for the designated application.

Command	Description
call application voice retry-count	Defines the number of times that a caller is permitted to reenter the PIN for a designated application.
call application voice uid-len	Defines the number of characters in the UID for the designated application.
call application voice warning-time	Defines the number of seconds for which a warning prompt is played before a user's account time runs out.
param security	Configures security for linkable Tcl functions (packages).
paramspace appcommon security	Configures security for a service (application).
show call application voice	Displays the following information associated with a voice application: the audio files, the prompts, the caller interaction, and the abort key operation.

call application voice set-location

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice set-location** command is replaced by the **paramspace language** command. See the **paramspace language** command for more information.

To define the category and location of audio files that are used for dynamic prompts by the specified IVR application (Tcl or VoiceXML), use the **call application voice set-location** command in global configuration mode. To remove these definitions, use the **no** form of this command.

call application voice *application-name* **set-location** *language category location*

no call application voice *application-name* **set-location** *language category location*

Syntax Description

application-name	Name of the application to which the **set-location** parameters are being passed.
language	Two-character code that identifies the language associated with the audio files. Valid entries are as follows: • **en**—English • **sp**—Spanish • **ch**—Mandarin • **aa**—All This is the same language code that was entered when configuring the **call application voice language** command .
category	Category group of the audio files (from 0 to 4). For example, audio files representing the days and months can be category 1, audio files representing units of currency can be category 2, and audio files representing units of time—seconds, minutes, and hours—can be category 3. Range is from 0 to 4; 0 means all categories.
location	URL of the audio files. Valid URLs refer to TFTP, FTP, HTTP, or RTSP servers, flash memory, or the removable disks on the Cisco 3600 series.

Command Default No location or category is set.

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and the Cisco AS5300.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.

Release	Modification
12.2(2)XB	This command was modified to support VoiceXML applications on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1751.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T for VoiceXML applications. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.3(14)T	This command was replaced by the **paramspace language** command.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Instead of using this command, you can configure the language and location of prerecorded audio files within a Tcl script or VoiceXML document. For more information, see the *Tcl IVR API Version 2.0 Programmer's Guide* or *Cisco VoiceXML Programmer's Guide*, respectively.

To identify the language of the audio files, use the **call application voice language** command.

Tcl scripts and VoiceXML documents can be stored in any of the following locations: On TFTP, FTP, or HTTP servers, in the flash memory on the gateway, or on the removable disks of the Cisco 3600 series. The audio files that they use can be stored in any of these locations, and on RTSP servers.

You can configure multiple set-location lines for a single application.

With the Pre-Paid Debitcard Multi-Language feature, you can create Tcl scripts and a two-character code for any language. See the *Cisco Pre-Paid Debitcard Multi-Language Programmer's Reference*.

With the multilanguage support for Cisco IOS IVR, you can create a Tcl language module for any language and any set of Text-to-Speech (TTS) notations for use with Tcl and VoiceXML applications. See the *Enhanced Multi-Language Support for Cisco IOS Interactive Voice Response* document.

Table 7 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 7 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None

Table 7 Tcl Scripts and Commands (continued)

Tcl Script Name	Description	Commands to Configure
clid_4digits_npw_3_cli.tcl	Authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4. **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	Authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	Authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	Authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_npw_cli.tcl	Authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice set-location

        Warning: This command has been deprecated. Please use the following:
           paramspace language
```

The following example shows how to configure the **call application voice set-location** command for the application named "prepaid." In this example, the language specified is English, the category into which the audio files are grouped is category 0 (meaning all), and the location is the keyer directory on the TFTP server.

```
call application voice prepaid set-location en 0 tftp://keyer/
```

The following example shows how to configure the **call application voice set-location** command for a fictitious VoiceXML application named "sample." In this example, as in the preceding example, the language defined is English, the category into which the audio files are grouped is category 0 (meaning "all") and the location is the example directory on an HTTP server.

```
call application voice sample set-location en 0 http://example/
```

The following example shows how to configure the **call application voice set-location** command for multiple set locations:

```
call application voice sample set-location en 0 http://example/en_msg/
call application voice sample set-location sp 0 http://example/sp_msg/
call application voice sample set-location ch 0 http://example/ch_msg/
```

Related Commands

Command	Description
call application voice	Specifies the application name and indicates the location of the IVR script to be used with this application.
call application voice language	Specifies the audio file language for the designated application.
call application voice load	Reloads the designated Tcl script.
call application voice pin-len	Specifies the number of characters in the PIN.
call application voice redirect-number	Specifies the telephone number to which a call is redirected.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN.
call application voice uid-len	Defines the number of characters in the UID for the designated application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
paramspace language	Defines the category and location of audio files that are used for dynamic prompts by an IVR application (Tcl or VoiceXML).
show call application voice	Displays information about voice applications.

call application voice transfer mode

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice transfer mode** command is replaced by the following commands:

- **param mode** (application parameter configuration mode)
- **paramspace callsetup mode** (service configuration mode)

See these commands for more information.

To specify the call-transfer method for Tool Command Language (Tcl) or VoiceXML applications, use the **call application voice transfer mode** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application voice *application-name* **transfer mode** {**redirect** | **redirect-at-alert** | **redirect-at-connect** | **redirect-rotary** | **rotary**}

no call application voice *application-name* **transfer mode**

Syntax Description

application-name	Name of the voice application for which the transfer method is set.
redirect	Gateway redirects the call leg to the redirected destination number.
redirect-at-alert	Gateway places a new call to the redirected destination number and initiates a call transfer when the outgoing call leg is in the alert state. If the call transfer is successful, the two call legs are disconnected on the gateway. If the transfer fails, the gateway bridges the two call legs. Provides support for Two B-Channel Transfer (TBCT).
redirect-at-connect	Gateway places a new call to the redirected destination number and initiates a call transfer when the outgoing call leg is in the connect state. If the call transfer is successful, the two call legs are disconnected on the gateway. If the transfer fails, the gateway bridges the two call legs. Provides support for TBCT.
redirect-rotary	Gateway redirects the call leg to the redirected destination number. If redirection fails, the gateway places a rotary call to the redirected destination number and hairpins the two call legs. For TBCT, this mode is the same as for the **redirect-at-connect** keyword.
rotary	Gateway places a rotary call for the outgoing call leg and hairpins the two call legs. Call redirection is not invoked. This is the default.

Command Default Rotary method; call redirection is not invoked.

Command Modes Global configuration

Command History

Release	Modification
12.3(1)	This command was introduced.
12.3(14)T	This command was replaced by the following commands: • **param mode** (application parameter configuration mode) • **paramspace callsetup mode** (service configuration mode)
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command determines whether a voice application can invoke TBCT or RTPvt. Before you can use this command, you must configure the named application on the gateway by using the **call application voice** command.

Redirect-rotary is the preferred transfer method because it ensures that a call-redirect method is always selected if the call leg is capable of it.

Tcl scripts can read the value of this command by using the info tag get cfg_avpair transfer-mode statement. For detailed information, see the *Tcl IVR API Version 2.0 Programmer's Guide*.

For VoiceXML applications, the value of this command becomes the default behavior if the com.cisco.transfer.mode property is not specified in the VoiceXML document. For detailed information, see the *Cisco VoiceXML Programmer's Guide*. The VoiceXML document property takes precedence over the gateway configuration.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice transfer mode

        Warning: This command has been deprecated. Please use the following:
           param mode
               paramspace callsetup mode
```

The following example sets the transfer method to redirect for the application callme:

```
call application voice callme transfer mode redirect
```

Related Commands

Command	Description
application	Enables a voice application on a dial peer.
call application voice	Defines the name of a voice application and specifies the location of the Tcl or VoiceXML document to load for this application.
call application voice transfer reroute-mode	Specifies the call-forwarding behavior of a Tcl application.
debug voip ivr callsetup redirect	Displays debugging information about H.450 calls that are redirected during setup.
debug voip ivr redirect	Displays debugging information about redirected H.450 calls.
isdn supp-service tbct	Enables ISDN TBCT on PRI trunks.
param mode	Configures the call transfer mode for a package.

Command	Description
paramspace callsetup mode	Configures the call transfer mode for an application.
show call active voice redirect	Displays information about active calls that are being redirected using RTPvt or TBCT.
show call application voice	Displays information about voice applications.
show call history voice redirect	Displays history information about calls that were redirected using RTPvt or TBCT.

call application voice transfer reroute-mode

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice transfer reroute-mode** command is replaced by the following commands:

- **param reroutemode** (application parameter configuration mode)
- **paramspace callsetup reroutemode** (service configuration mode)

See these commands for more information.

To specify the call-forwarding behavior of a Tool Command Language (Tcl) application, use the **call application voice transfer reroute-mode** command in global configuration mode. To reset to the default, use the **no** form of this command.

call application voice *application-name* **transfer reroute-mode** {**none** | **redirect** | **redirect-rotary** | **rotary**}

no call application voice *application-name* **transfer reroute-mode**

Syntax Description

application-name	Name of the voice application for which the transfer reroute method is set.
none	Call forwarding is not performed by the voice application.
redirect	Two call legs are directly connected. Provides support for RTPvt.
redirect-rotary	Two call legs are directly connected (redirect). If that fails, the two call legs are hairpinned on the gateway (rotary).
rotary	Gateway places a rotary call for the outgoing call leg and hairpins the two calls together. RTPvt is not invoked. This is the default.

Command Default

Rotary method; RTPvt is not invoked.

Command Modes

Global configuration

Command History

Release	Modification
12.3(1)	This command was introduced.
12.3(14)T	This command was replaced by the following commands: • **param reroutemode** (application parameter configuration mode) • **paramspace callsetup reroutemode** (service configuration mode)
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Before you can use this command, you must configure the named application on the gateway by using the **call application voice** command. This command is not supported for VoiceXML applications or for TBCT.

Redirect-rotary is the preferred transfer method because it ensures that a call-redirect method is always selected, provided that the call leg is capable of it.

Tcl scripts can read the value of this command by using the info tag get cfg_avpair reroute-mode statement. For detailed information, see the *Tcl IVR API Version 2.0 Programmer's Guide*.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice transfer reroute-mode

        Warning: This command has been deprecated. Please use the following:
           param reroutemode (application parameter configuration mode)
               paramspace callsetup reroutemode
```

The following example sets the call forwarding method to redirect for the application callme:

```
call application voice callme transfer reroute-mode redirect
```

Related Commands

Command	Description
application	Enables a voice application on a dial peer.
call application voice	Defines the name of a voice application and specifies the location of the Tcl or VoiceXML document to load for this application.
call application voice transfer mode	Specifies the call-transfer behavior of a Tcl or VoiceXML application.
isdn supp-service tbct	Enables ISDN TBCT on PRI trunks.
param reroutemode	Configures the call transfer reroutemode (call forwarding) for a package.
paramspace callsetup reroutemode	Configures the call reroute mode (call forwarding) for an application.
show call active voice redirect	Displays information about active calls that are being redirected using RTPvt or TBCT.
show call application voice	Displays information about voice applications.
show call history voice redirect	Displays history information about calls that were redirected using RTPvt or TBCT.

call application voice uid-length

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice uid-length** command is replaced by the **param uid-len** command. See the **param uid-len** command for more information.

To define the number of characters in the user identification (UID) number for the designated application and to pass that information to the specified application, use the **call application voice uid-length** command in global configuration mode. To restore the default setting for this command, use the **no** form of this command.

call application voice *application-name* **uid-length** *number*

no call application voice *application-name* **uid-length** *number*

Syntax Description

application-name	Name of the application to which the UID length parameter is passed.
number	Number of allowable characters in UIDs that are associated with the specified application. Range is from 1 to 20. The default is 10.

Command Default

number

Command Modes

Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and the Cisco AS5300.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1751. This release does not support any other Cisco platforms.
12.2(4)T	Support was added for the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 7200 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.3(14)T	This command was replaced by the **param uid-len** command.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Use this command when configuring interactive voice response (IVR)—depending on the Tool Command Language (Tcl) script being used—or one of the IVR-related features (such as Debit Card) to define the number of allowable characters in a UID for the specified application and to pass that information to the specified application.

Table 8 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 8 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None
clid_4digits_npw_3_cli.tcl	Authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4. **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	Authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	Authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	Authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_npw_cli.tcl	Authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice uid-length

        Warning: This command has been deprecated. Please use the following:
           param uid-len
```

The following example shows how to configure four allowable characters in the UID for the application named “sample”:

```
call application voice sample uid-length 4
```

Related Commands

Command	Description
call application voice	Specifies the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
call application voice language	Specifies the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Specifies the telephone number to which a call is redirected for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice warning-time	Defines, in seconds, how long in advance a user is warned before the allowed calling time expires for the designated application.
param uid-length	Defines the number of characters in the UID for a package.

call application voice voice-dtmf

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice voice-dtmf** command is replaced by the **param voice-dtmf** command. See the **param voice-dtmf** command for more information.

To direct the fax detection interactive voice response (IVR) application to recognize a specified digit to indicate a voice call, use the **call application voice voice-dtmf** command in global configuration mode. To remove configuration of this digit, use the **no** form of this command.

call application voice *application-name* **voice-dtmf** {*keypad-character*}

no call application voice *application-name* **voice-dtmf** {*keypad-character*}

Syntax Description

application-name	The name of the fax detection application that you defined when you loaded the application on the router.
keypad-character	Single character that can be dialed on a telephone keypad pressed by the calling party to indicate a voice call, in response to the audio prompt configured in default-voice and default-fax mode of the fax detection IVR application. Default is 1.

Command Default

1

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced for the Cisco AS5300.
12.2(2)XB	This command was implemented on the Cisco AS5400 and Cisco AS5350.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(11)T	This command was supported on the Cisco AS5300, Cisco AS5350, and Cisco AS5400 in this release.
12.3(14)T	This command was replaced by the **param voice-dtmf** command.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

This command is useful only when the fax detection IVR application is being configured in default-voice mode or default-fax mode, as defined by the **call application voice mode** command. Only one digit can be specified in this command, and that digit must be different from the digit specified in the **call**

application voice fax-dtmf command. You are not notified immediately if you make the error of configuring them both to the same digit. To find this error, you must start debugging with the **debug voip ivr script** command and then observe some failing calls.

This command is not supported by Cisco IOS help. If you type **the call application voice fax_detect voice-dtmf** command and a question mark (**?**), the Cisco IOS help does not supply a list of entries that are valid in place of the question mark.

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice voice-dtmf

        Warning: This command has been deprecated. Please use the following:
           param voice-dtmf
```

The following example selects digit 2 dual tone multifrequency (DTMF) to indicate a voice call:

```
call application voice fax_detect script_url
call application voice fax_detect voice-dtmf 2
dial-peer voice 302 pots
 application fax_detect
```

Related Commands

Command	Description
call application voice	Loads a specified IVR application onto the router from the TFTP server and gives it an application name by which it is known on the router.
call application voice account-id-method	Configures the fax detection IVR application to use a particular method to assign the account identifier.
call application voice fax-dtmf	Configures the fax detection IVR application to recognize a specified digit to indicate a fax call.
call application voice mode	Configures the fax detection IVR application to operate in one of its four modes.
call application voice prompt	Configures the fax detection IVR application to use the specified audio file as a user prompt.
param voice-dtmf	Directs the fax detection IVR application to recognize a specified digit to indicate a voice call.

call application voice warning-time

Note Effective with Cisco IOS Release 12.3(14)T, the **call application voice warning-time** command is replaced by the **param warning-time** command. See the **param warning-time** command for more information.

To define the number of seconds of warning that a user receives before the allowed calling time expires use the **call application voice warning-time** command in global configuration mode. To remove the configured warning period, use the **no** form of this command.

call application voice *application-name* **warning-time** *seconds*

no call application voice *application-name* **warning-time** *seconds*

Syntax Description

application-name	Name of the application to which the warning time parameter is being passed.
seconds	Length of the warning period, in seconds, before the allowed calling time expires. Range is from 10 to 600. This argument has no default value.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.1(5)T	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1751. Support for other Cisco platforms is not included in this release.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.
12.3(14)T	This command was replaced by the **param warning-time** command.
12.4(24)T	This command was modified. The automatic conversion to the new CLI is replaced with an explicit error message.

Usage Guidelines

Use this command when configuring interactive voice response (IVR)—depending on the Tool Command Language (Tcl) script being used—or one of the IVR-related features (such as Debit Card) to define the number of seconds in the warning period before the allowed calling time expires for the specified application and to pass that information to the specified application.

Table 9 lists Tcl script names and the corresponding commands that are required for each Tcl script.

Table 9 Tcl Scripts and Commands

Tcl Script Name	Description	Commands to Configure
app_libretto_onramp9.tcl	Authenticates the account and personal identification number (PIN) using the following: prompt-user, using automatic number identification (ANI), dialed number identification service (DNIS), gateway ID, redialer ID, and redialer DNIS.	None
app_libretto_offramp5.tcl	Authenticates the account and PIN using the following: envelope-from, envelope-to, gateway ID, and x-account ID.	None
clid_4digits_npw_3_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. The number of digits allowed for the account number and password, respectively, are configurable through the command-line interface (CLI). If the authentication fails, the script allows the caller to retry. The retry number is also configured through the CLI.	**call application voice uid-length** Range is 1 to 20. The default is 10. **call application voice pin-length** Range is 0 to 10. The default is 4. **call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_col_npw_cli.tcl	This script authenticates the account number and PIN, respectively, using ANI and NULL. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_authen_collect_cli.tcl	This script authenticates the account number and PIN using ANI and DNIS. If the authentication fails, the script allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected separately.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_3_cli.tcl	This script authenticates using ANI and NULL for account numbers and PINs, respectively. If the authentication fails, it allows the caller to retry. The retry number is configured through the CLI.	**call application voice retry-count** Range is 1 to 5. The default is 3.
clid_col_npw_npw_cli.tcl	This script authenticates using ANI and NULL for account and PIN, respectively. If authentication fails, it allows the caller to retry. The retry number is configured through the CLI. The account number and PIN are collected together.	**call application voice retry-count** Range is 1 to 5. The default is 3.
fax_rollover_on_busy.tcl	Used for on-ramp T.38 fax rollover to T.37 fax when the destination fax line is busy.	**voice hunt user-busy**

Examples

Effective with Cisco IOS Release 12.4(24)T, the following warning message is displayed to direct users to the replacement command options:

```
Router(config)# call application voice param warning-time

        Warning: This command has been deprecated. Please use the following:
           param warning-time
```

The following example shows how to configure a 30-second warning time for the application named "sample":

```
call application voice sample warning-time 30
```

Related Commands

Command	Description
call application voice language	Specifies the language of the audio file for the designated application and passes that information to the application.
call application voice load	Reloads the designated Tcl script.
call application voice location	Specifies the name to be used for an application and indicates the location of the appropriate IVR script to be used with this application.
call application voice pin-len	Defines the number of characters in the PIN for the application and passes that information to the application.
call application voice redirect-number	Specifies the telephone number to which a call is redirected for the designated application.
call application voice retry-count	Defines the number of times a caller is permitted to reenter the PIN for a designated application and passes that information to the application.
call application voice set-location	Defines the location, language, and category of the audio files for the designated application and passes that information to the application.
call application voice uid-length	Defines the number of characters in the UID for the designated application and passes that information to the application.
param warning-time	Defines the number of seconds of warning that a user receives before the allowed calling time expires.

call-block (dial peer)

To enable blocking of incoming calls, use the **call-block** command in dial peer configuration mode. To return to the default value, use the **no** form of this command.

call-block {**disconnect-cause incoming** {**call-reject** | **invalid-number** | **unassigned-number** | **user-busy**} | **translation-profile incoming** *name*}

no call-block {**disconnect-cause incoming** {**call-reject** | **invalid-number** | **unassigned-number** | **user-busy**} | **translation-profile incoming** *name*}

Syntax Description

disconnect-cause incoming	Associates a disconnect cause of incoming calls.
call-reject	Specifies call rejection as the cause for blocking a call during incoming call-number translation.
invalid-number	Specifies invalid number as the cause for blocking a call during incoming call-number translation.
unassigned-number	Specifies unassigned number as the cause for blocking a call during incoming call-number translation.
user-busy	Specifies busy as the cause for blocking a call during incoming call-number translation.
translation-profile incoming	Associates the translation profile for incoming calls.
name	Name of the translation profile.

Command Default

Disconnect cause: No Service (once the call-blocking translation profile is defined)
Translation profile: No default behavior or values

Command Modes

Dial peer configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

An incoming call can be blocked from the gateway if one of the call numbers (calling, called, or redirect) is matched with the reject translation rule of the incoming call-blocking translation profile.

The cause value is returned to the source of the call when a call is blocked during the incoming call-number translation.

This command is supported in POTS, VoIP, VoFR, and VoATM dial-peer configuration. For VoATM, only ATM Adaptation Layer 5 (AAL5) calls are supported.

The only option for call blocking is in the incoming direction. From the perspective of the voice gateway, the incoming direction can be either of the following:

- Incoming from a telephony device directly attached to a voice port on the gateway toward the gateway itself
- Incoming by way of an inbound Voice over X (VoX) call from a peer gateway

To configure incoming call blocking, define a translation rule with a **reject** keyword. For example:

```
voice translation-rule 1
 rule 1 reject /408252*/
```

Apply the rule to a translation profile for called, calling, or redirect-called numbers, such as:

```
voice translation profile call_block_profile
 translate calling 1
```

Include the translation profile within a dial peer definition. For example:

```
dial-peer voice 111 pots
 call-block translation-profile incoming call_block_profile
 call-block disconnect-cause incoming invalid_number
```

In this example, the gateway blocks any incoming time-division multiplexing (TDM) call that successfully matches inbound dial-peer 111 and has a calling number that starts with 408252. The gateway also returns the disconnect cause “invalid number” to the source of the call. (Other disconnect causes can be assigned: unassigned-number, user-busy, or call-rejected.)

Examples

The following example assigns the translation profile “example” to be used for incoming calls and returns the message “invalid number” as a cause for blocked calls:

```
Router(config)# dial-peer voice 5 pots
Router(config-dial-peer)# call-block translation-profile incoming example
Router(config-dial-peer)# call-block disconnect-cause incoming invalid-number
```

Following are two possible call-blocking scenarios:

Scenario 1: Block Inbound Calls from the PSTN/PBX/CO

We place the rejection profile on a POTS dial peer that is associated with the voice port on which we expect the inbound call. When the inbound call attempt is made, we see in the CCAPI debugs that POTS dial-peer 9 is matched for the telephony call leg. The call-block rule is checked and we send back user-busy to the switch.

```
voice translation-rule 1
 rule 1 reject /9193927582/   <<<<-------- filter out calls from this CallerID

voice translation-profile reject_ANI
 translate calling 1

dial-peer voice 9 pots
 destination-pattern 9T
 direct-inward-dial
 port 1/0:23
 call-block translation-profile incoming reject_ANI
 call-block disconnect-cause incoming user-busy
```

Scenario 2: Block Inbound VoX Calls from Using Local POTS Resources

We place the rejection profile on a VoIP/VoATM/VoFR dial peer that matches an inbound VoX call attempt. When the inbound call attempt is made, we see in the CCAPI debugs that VoIP dial-peer 7 is matched for the IP call leg. The call-block rule is checked and we send back user-busy to the switch.

```
voice translation-rule 1
 rule 1 reject /9193927582/   <<<<-------- filter out calls from this CallerID

voice translation-profile reject_ANI
 translate calling 1

dial-peer voice 7 voip
 destination-pattern 7T
 session target ipv4:A.B.C.D
 incoming called-number .   <<<<-------- force inbound IP call-leg match
 call-block translation-profile incoming reject_ANI
 call-block disconnect-cause incoming user-busy
```

Related Commands

Command	Description
dial-peer voice	Initiates the dial-peer voice configuration mode.
voice translation-profile	Defines a translation profile for voice calls.
voice translation-rule	Defines a translation rule for voice calls.

call-denial

The **call-denial** command is replaced by the **call threshold global** command. See the **call threshold global** command for more information.

call fallback

To enable a call request to fall back to a specific dial peer in case of network congestion, use the **call fallback** command in dial peer configuration mode. To disable PSTN fallback for a specific dial peer, use the **no** form of this command.

call fallback

no call fallback

Syntax Description

This command has no arguments or keywords.

Command Default

This command is enabled by default if the **call fallback active** command is enabled in global configuration mode

Command Modes

Dial peer configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The PSTN Fallback feature and enhancements were introduced on Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.

Usage Guidelines

Disabling the **call fallback** command for a dial peer causes the call fallback subsystem not to fall back to the specified dial peer. Disabling the command is useful when internetworking fallback capable H.323 gateways with the Cisco CallManager or third-party equipment that does not run fallback. Connected calls are not affected by this feature.

Examples

The following example disables a PSTN fallback for a specific dial peer:

```
no call fallback
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers.
call fallback cache-size	Specifies the call fallback cache size for network traffic probe entries.
call fallback cache-timeout	Specifies the time after which the cache entries of network conditions are purged.
call fallback instantaneous-value-weight	Configures the call fallback subsystem to take an average from the last two cache entries for call requests.

Command	Description
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe precedence	Specifies the priority of the jitter-probe transmission.
call fallback jitter-probe priority-queue	Assigns a priority queue for jitter-probe transmissions.
call fallback key-chain	Specifies use of MD5 authentication for sending and receiving SAA probes.
call fallback map address-list	Specifies that the call fallback router keep a cache table by IP addresses of distances for several destination peers that are sitting behind the router.
call fallback map subnet	Specifies that the call fallback router keep a cache table by subnet addresses of distances for several destination peers that are sitting behind the router.
call fallback probe-timeout	Sets the timeout for an SAA probe for call fallback purposes.
call fallback threshold delay loss	Specifies that the call fallback threshold use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
dial-peer voice number	Enters dial peer configuration mode.
show call fallback config	Displays the call fallback configuration.

call fallback active

To enable the Internet Control Message Protocol (ICMP)-ping or Service Assurance Agent (SAA) (formerly Response Time Reporter [RTR]) probe mechanism for use with the dial-peer **monitor probe** or voice-port **busyout monitor probe** commands, use the **call fallback active** command in global configuration mode. To disable these probe mechanisms, use the **no** form of this command.

call fallback active [**icmp-ping** | **rtr**]

no call fallback active [**icmp-ping** | **rtr**]

Syntax Description

icmp-ping	Uses ICMP pings to monitor the IP destinations.
rtr	Uses SAA (formerly RTR) probes to monitor the IP destinations. SAA (RTR) probes are the default.

Command Default

This command is disabled by default. If the command is entered without an optional keyword, the default is RTR.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented for Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

The **call fallback active** command creates and maintains a consolidated cache of probe results for use by the dial-peer **monitor probe** or voice-port **busyout monitor probe** commands.

Enabling the **call fallback active** command determines whether calls should be accepted or rejected on the basis of probing of network conditions. The **call fallback active** command checks each call request and rejects the call if the network congestion parameters are greater than the value of the configured threshold parameters of the destination. If this is the case, alternative dial peers are tried from the session application layer.

Use the **call fallback threshold delay loss** or **call fallback threshold icpif** command to set the threshold parameters.

Connected calls are not affected by this command.

Caution The **call fallback active icmp-ping** command must be entered before the **call fallback icmp-ping** command can be used. If you do not enter this command first, the **call fallback icmp ping** command will not work properly.

Note The Cisco SAA functionality in Cisco IOS software was formerly known as Response Time Reporter (RTR). The command-line interface still uses the keyword **rtr** for configuring RTR probes, which are now actually SAA probes.

Examples

The following example enables the **call fallback active** command and globally enables ICMP pinging to probe target destinations. The second command specifies values for the ping packets:

```
Router(config)# call fallback active icmp-ping
Router(config)# call fallback icmp-ping codec g729 interval 10 loss 10
```

Related Commands

Command	Description
call fallback cache-size	Specifies the call fallback cache size for network traffic probe entries.
call fallback cache-timeout	Specifies the time after which the cache entries of network conditions are purged.
call fallback instantaneous-value-weight	Specifies the call fallback subsystem to take an average from the last two cache entries for call requests.
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe precedence	Specifies the priority of the jitter-probe transmission.
call fallback jitter-probe priority-queue	Assigns a priority queue for jitter-probe transmissions.
call fallback key-chain	Specifies use of MD5 authentication for sending and receiving SAA probes.
call fallback map address-list	Specifies that the call fallback router keep a cache table by IP addresses of distances for several destination peers that are sitting behind the router.
call fallback map subnet	Specifies that the call fallback router keep a cache table by subnet addresses of distances for several destination peers that are sitting behind the router.
call fallback probe-timeout	Sets the timeout for an SAA probe for call fallback purposes.
call fallback threshold delay loss	Specifies that the call fallback threshold use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
dial-peer voice number	Enters dial peer configuration mode.

call fallback cache-size

To specify the call fallback cache size for network traffic probe entries, use the **call fallback cache-size** command in global configuration mode. To restore the default value, use the **no** form of this command.

call fallback cache-size *number*

no call fallback cache-size

Syntax Description

number	Cache size, in number of entries. Range is from 1 to 256. The default is 128.

Command Default

128 entries

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced..
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were introduced on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

The cache size can be changed only when the **call fallback active** command is not enabled.

The overflow process deletes up to one-fourth of the cache entries to allow for additional calls beyond the specified cache size. The cache entries chosen for deletion are the oldest entries in the cache.

If the cache size is left unchanged, it can be changed only when fallback is off. Use the **no** form of the **call fallback** command to turn fallback off.

Examples

The following example specifies 120 cache entries:

```
Router(config)# call fallback cache-size 120
```

Related Commands

Command	Description
call fallback	Enables a call request to fall back to a specific dial peer in case of network congestion
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.

Command	Description
call fallback cache-timeout	Specifies the time after which the cache entries of network conditions are purged.
show call fallback cache	Displays the current ICPIF estimates for all IP addresses in the cache.
show call fallback config	Displays the call fallback configuration.

call fallback cache-timeout

To specify the time after which the cache entries of network conditions are purged, use the **call fallback cache-timeout** command in global configuration mode. To disable the **call fallback cache-timeout** command, use the **no** form of this command.

call fallback cache-timeout *seconds*

no call fallback cache-timeout

Syntax Description

seconds	Cache timeout value, in seconds. Range is from 1 to 2147483. The default is 600.

Command Default

600 seconds

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

Enabling the **call fallback cache-timeout** command sends a Service Assurance Agent (SAA) probe out to the network to determine the amount of congestion in terms of configured thresholds. The network condition is based upon delay and loss, or Calculated Planning Impairment Factor (ICPIF) thresholds. Use the **call fallback threshold delay loss** or **call fallback threshold icpif** command to set the threshold parameters.

The cache keeps entries for every network congestion-checking probe sent and received between timeouts. The cache updates after each probe returns the current condition of network traffic. To set the probe frequency, use the **call fallback probe-timeout** command.

When a call comes into the router, the router matches a dial peer and obtains the destination information. The router calls the fallback subsystem to look up the specified destination in its network traffic cache. If the delay/loss or ICPIF threshold exists and is current, the router uses that value to decide whether to permit the call into the Voice over IP (VoIP) network. If the router determines that the network congestion is below the configured threshold (by looking at the value in the cache), the call is connected.

After each call request, the timer is reset. Purging of the cache occurs only when the cache has received no call requests during the timeout period (*seconds*). When the cache timeout expires, the entire cache is deleted, and a probe is sent to start a new cache entry. A call cannot be completed until this probe returns with network traffic information.

The network congestion probes continue in the background as long as the entry for the last call request remains in the cache.

Examples

The following example specifies an elapsed time of 1200 seconds before the cache times out:

```
Router(config)# call fallback cache-timeout 1200
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback cache-size	Specifies the call fallback cache size.
call fallback probe-timeout	Specifies the time after which the cache entries of network conditions are purged.
call fallback threshold delay loss	Configures the call fallback threshold to use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
show call fallback cache	Displays the current ICPIF estimates for all IP addresses in the cache.
show call fallback config	Displays the call fallback configuration.

call fallback expect-factor

To set a configurable value by which the call fallback expect factor feature will be activated, use the **call fallback expect-factor** command in global configuration mode. To disable the expect factor, use the **no** form of this command.

call fallback expect-factor *value*

no call fallback expect-factor

Syntax Description

value	Configures the expect-factor A. Range: 0 to 20. Default: 10.

Command Default No value for the expect-factor is configured.

Command Modes Global configuration

Command History

Release	Modification
12.3(3)	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines The expect-factor is the level of expected voice quality that the user may have during a call. For example, you expect higher voice quality from a call on your home than on your cell phone. The expect-factor is a subjective value determined by the local administrators.

Call fallback is used by the software to generate a series of probes across an IP network to help make a Impairment/Calculated Impairment Planning Factor (ICPIF) calculation. The value calculated by the probes, ICPIF, is modified by the configured expect factor using the following formula:

ICPIF = Idd + Ie–A

Idd represents the impairment due to end-end delay, Ie, represents the impairment due to packet loss and the impact of the codec being used on the call, and A represents the expect-factor value. The expect-factor is the value to be subtracted from the calculated ICPIF value. This expect factor is known as the Advantage Factor (A) as specified in G.107 and takes into account the user's expected level of voice quality based upon the type of call being made.

Examples The following example shows the **call fallback expect-factor** command and the **call fallback threshold icpicf** command being configured. A calculated ICPIF value of 20 based on Idd and Ie from the probes set on a IP network would not activate the call fallback feature in this configuration. Even though the calculated ICPIF value of 20 exceeds the configured threshold of 10, subtraction of the expect-value of 15 would leave a value of 5, which is below the threshold value.

```
Router(config)# call fallback expect-factor 15
Router(config)# call fallback threshold icpif 10
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers.
call fallback cache-size	Specifies the call fallback cache size for network traffic probe entries.
call fallback cache-timeout	Specifies the time after which the cache entries of network conditions are purged.
call fallback instantaneous-value-weight	Configures the call fallback subsystem to take an average from the last two cache entries for call requests.
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe precedence	Specifies the priority of the jitter-probe transmission.
call fallback jitter-probe priority-queue	Assigns a priority queue for jitter-probe transmissions.
call fallback key-chain	Specifies use of MD5 authentication for sending and receiving SAA probes.
call fallback map address-list	Specifies that the call fallback router keep a cache table by IP addresses of distances for several destination peers that are sitting behind the router.
call fallback map subnet	Specifies that the call fallback router keep a cache table by subnet addresses of distances for several destination peers that are sitting behind the router.
call fallback probe-timeout	Sets the timeout for an SAA probe for call fallback purposes.
call fallback threshold delay loss	Specifies that the call fallback threshold use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
dial-peer voice number	Enters dial peer configuration mode.
show call fallback config	Displays the call fallback configuration.

call fallback icmp-ping

To specify Internet Control Message Protocol (ICMP) ping as the method for network traffic probe entries to IP destinations and configure parameters for the ping packets, use the **call fallback icmp-ping** command in global configuration mode. To restore the default value, use the **no** form of this command.

call fallback icmp-ping [**count** *packets*] [**codec** *codec-type* | **size** *bytes*] **interval** *seconds* [**loss** *percent]* **timeout** *milliseconds*]

no call fallback icmp-ping [**count** *packets*] [**codec** *codec-type* | **size** *bytes*] **interval** *seconds* [**loss** *percent]* **timeout** *milliseconds*]

Syntax Description

count *packets*	(Optional) Number of ping packets that are sent to the destination address.
codec	(Optional) Configures the profile of the SAA probe signal to mimic the packet size and interval of a specific codec type.
codec-type	(Optional) The codec type for the SAA probe signal. Available options are as follows: • **g711a**—G.711 a-law • **g711u**—G.711 mu-law • **g729**—G.729 (the default) • **g729b**—G.729 Annex B
size *bytes*	(Optional) Size (in bytes) of the ping packet. Default is 32.
interval *seconds*	Time (in seconds) between ping packet sets. Default is 5. This number should be higher than the **timeout** *milliseconds* value.
loss *percent*	(Optional) Configures the percentage-of-packets-lost threshold for initiating a busyout condition.
timeout *milliseconds*	(Optional) Timeout (in milliseconds) for echo packets. Default is 500.

Command Default

If this command is not configured, Response Time Reporter (RTR) is the probe method used.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(2)T	This command was introduced in a release earlier than Cisco IOS Release 12.4(2)T.

Usage Guidelines

The values configured by the global configuration version of the **call fallback icmp-ping** command are appllied globally for measurements on probes and pings. If the **call fallback icmp-ping** is configured in dial-peer configuration mode, these values override the global configuration for the specific dial peer.

One of these two commands must be in effect before the **monitor probe icmp-ping** command can be used. If neither of the **call fallback** commands is in effect, the **monitor probe icmp-ping** command will not work properly.

Examples

The following example shows how to configure an ICMP ping probe with a G.729 profile to probe the link with an interval value of 10 seconds and a packet-loss threshold of 10 percent:

```
call fallback active icmp-ping
call fallback icmp-ping codec g729 interval 10 loss 10
```

Related Commands

Command	Description
call fallback active	Forces a voice port into the busyout state.
call fallback icmp-ping (dial peer)	Specifies Internet Control Message Protocol (ICMP) ping as the method for network traffic probe entries to IP destinations.
monitor probe icmp-ping	Enables dial-peer status changes based on the results of probes.

call fallback icmp-ping (dial peer)

To specify Internet Control Message Protocol (ICMP) ping as the method for network traffic probe entries to IP destinations, use the **call fallback icmp-ping** command in dial-peer configuration mode. To restore the default value, use the **no** form of this command.

call fallback [**icmp-ping** | **rtr**]

no call fallback [**icmp-ping** | **rtr**]

Syntax Description

icmp-ping	(Optional) Specifies ICMP ping as the method for monitoring the session target and updating the status of the dial peer.
rtr	(Optional) Specifies that the Response Time Reporter (RTR) probe is the method for monitoring the session target and updating the status of the dial peer.

Command Default

If this command is not entered, the globally configured method is used for measurements.

Command Modes

Dial-peer configuration (config-dial-peer)

Command History

Release	Modification
12.2(11)T	This command was introduced in a release earlier than Cisco IOS Release 12.2(11)T.

Usage Guidelines

The principal use of this command is to specify ICMP ping as the probe method, even though the option for selecting RTR is also available.

If the **call fallback icmp-ping** command is not entered, the **call fallback active** command in global configuration is used for measurements. If the **call fallback icmp-ping** command is entered, these values override the global configuration.

One of these two commands must be in effect before the **monitor probe icmp-ping** command can be used. If neither of the **call fallback** commands is in effect, the **monitor probe icmp-ping** command will not work properly.

Note The Cisco Service Assurance Agent (SAA) functionality in Cisco IOS software was formerly known as Response Time Reporter (RTR). The command-line interface still uses the keyword **rtr** for configuring RTR probes, which are now actually the SAA probes.

Examples

The following example specifies that ICMP ping is used for monitoring the session target IP address and for updating the status of the dial peer:

```
Router(config)# dial-peer voice 10 voip
Router(config-dial-peer)# call fallback icmp-ping
```

Related Commands

Command	Description
call fallback	Enables a call request to fall back to a specific dial peer in case of network congestion
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
monitor probe icmp-ping	Specifies that ICMP ping is the method used for probes.
show call fallback config	Displays the call fallback configuration.

call fallback instantaneous-value-weight

To configure the call fallback subsystem to take an average from the last two probes registered in the cache for call requests, use the **call fallback instantaneous-value-weight** command in global configuration mode. To return to the default before the average was calculated, use the **no** form of this command.

call fallback instantaneous-value-weight *percent*

no call fallback instantaneous-value-weight

Syntax Description

percent	Instantaneous value weight, in expressed as a percentage. Range is from 0 to 100. The default is 66.

Command Default 66 percent

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines Probes that return the network congestion information are logged into the cache to determine whether the next call request is granted. When the network is regularly busy, the cache entries reflect the heavy traffic conditions. However, one probe may return with low traffic conditions, which is in contrast to normal conditions. All call requests received between the time of this probe and the next use this entry to determine call acceptance. These calls are allowed through the network, but before the next probe is sent and received, the normal, heavy traffic conditions must have returned. The calls sent through congest the network and cause worsen traffic conditions.

Use the **call fallback instantaneous-value-weight** command to gradually recover from heavy traffic network conditions. While the system waits for a call, probes update the cache. When a new probe is received, the *percentage* is set and indicates how much the system is to rely upon the new probe and the previous cache entry. If the *percentage* is set to 50 percent, the system enters a cache entry based upon an average from the new probe and the most recent entry in the cache. Call requests use this blended entry to determine acceptance. This allows the call fallback subsystem to keep conservative measures of network congestion.

The configured *percentate* applies to the new probe first. If the **call fallback instantaneous-value-weight** command is configured with the default *percentage* of 66 percent, the new probe is given a higher value to calculate the average for the new cache entry.

Examples

The following example specifies a fallback value weight of 50 percent:

```
Router(config)# call fallback instantaneous-value-weight 50
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
show call fallback config	Displays the call fallback configuration.

call fallback jitter-probe dscp

To specify the differentiated services code point (DSCP) of the jitter-probe transmission, use the **call fallback jitter-probe dscp** command in global configuration mode. To disable this feature and restore the default value of jitter-probe precedence, use the **no** form of this command.

call fallback jitter-probe dscp *dscp-number*

no call fallback jitter-probe dscp

Syntax Description

dscp-number	DSCP value. Range is from 0 to 63.

Command Default None

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.3(9)	This command was implemented in Cisco IOS Release 12.3(9).

Usage Guidelines

Network devices that support differentiated services (DiffServ) use a DSCP in the IP header to select a per-hop behavior (PHB) for a packet. Cisco implements queuing techniques that can base their PHB on the IP precedence or DSCP value in the IP header of a packet. On the basic of DSCP or IP precedence, traffic can be put into a particular service class. Packets within a service class are treated alike.

The **call fallback jitter-probe dscp** command allows you to set a DSCP for jitter-probe packets. The specified DSCP is stored, displayed, and passed in probing packets to the Service Assurance Agent (SAA). This command enables the router to reserve some bandwidth so that during network congestion some of the jitter-probe packets do not get dropped. This command avoids the conflict that occurs with traditional precedence bits.

The **call fallback jitter-probe dscp** command is mutually exclusive with the **call fallback jitter-probe precedence** command. Only one of these command can be enabled on the router. When the **call fallback jitter-probe dscp** command is configured, the precedence value is replaced with the DSCP value. The **no call fallback jitter-probe dscp** command restores the default value for precedence.

Examples

The following example specifies the jitter-probe DSCP as 10. DSCP configuration replaces the set jitter-probe precedence value with the DSCP value.

```
call fallback jitter-probe dscp 10
```

The following configuration disables the DSCP value and restores the default value for precedence, which is set to 2:

```
no call fallback jitter-probe dscp
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe precedence	Specifies the priority of the jitter-probe transmission.
call fallback jitter-probe priority-queue	Assigns a priority queue for jitter-probe transmissions.
show call fallback config	Displays the call fallback configuration.

call fallback jitter-probe num-packets

To specify the number of packets in a jitter probe used to determine network conditions, use the **call fallback jitter-probe num-packets** command in global configuration mode. To restore the default number of packets, use the **no** form of this command.

call fallback jitter-probe num-packets *number-of-packets*

no call fallback jitter-probe num-packets

Syntax Description

number-of-packets	Number of packets. Range is from 2 to 50. The default is 15.

Command Default 15 packets

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines A jitter probe, consisting of 2 to 50 packets, details the conditions of the network. More than one packet is used by the probe to calculate an average of delay/loss or Calculated Planning Impairment Factor (ICPIF). After the packets return to the probe, the probe delivers the traffic information to the cache where it is logged for call acceptance/denial. Use the **call fallback threshold delay loss** or **call fallback threshold icpif** command to set the threshold parameters. The newly specified number of packets take effect only for new probes.

To get a more realistic estimate on the network congestion, increase the number of packets. If more probing packets are sent, better estimates of network conditions are obtained, but the bandwidth for other network operations is negatively affected. Use fewer packets when you need to maximize bandwidth.

Examples The following example specifies 20 packets in a jitter probe:

```
Router(config)# call fallback jitter-probe num-packets 20
```

Related Commands

Command	Description
call fallback threshold icpif	Specifies the ICPIF threshold.
call fallback threshold delay loss	Specifies the call fallback threshold delay and loss values.

call fallback jitter-probe precedence

To specify the priority of the jitter-probe transmission, use the **call fallback jitter-probe precedence** command in global configuration mode. To restore the default priority, use the **no** form of this command.

call fallback jitter-probe precedence *precedence-value*

no call fallback jitter-probe precedence

Syntax Description

precedence-value	Jitter-probe precedence. Range is from 0 to 6. The default is 2.

Defaults

Enabled
Value set to 2

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

Every IP packet has a precedence header. Precedence is used by various queueing mechanisms in routers to determine the priority of traffic passing through the system.

Use the **call fallback jitter-probe precedence** command if there are different queueing mechanisms in your network. Enabling the **call fallback jitter-probe precedence** command sets the precedence for jitter probes to pass through your network.

If you require your probes to be sent and returned quickly, set the *precedence* to a low number (0 or 1): the lower the precedence, the higher the priority given.

The **call fallback jitter-probe precedence** command is mutually exclusive with the **call fallback jitter-probe dscp** command. Only one of these commands can be enabled on the router. Usually the **call fallback jitter-probe precedence** command is enabled. When the **call fallback jitter-probe dscp** command is configured, the precedence value is replaced by the DSCP value. To disable DSCP and restore the default jitter probe precedence value, use the **no call fallback jitter-probe dscp** command.

Examples

The following example specifies a jitter-probe precedence of 5, or low priority.

```
call fallback jitter-probe precedence 5
```

The following configuration restores the default value for precedence:

```
no call fallback jitter-probe precedence
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback jitter-probe dscp	Specifies the dscp of the jitter-probe transmission.
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe priority-queue	Assigns a priority queue for jitter-probe transmissions.
show call fallback config	Displays the call fallback configuration.

call fallback jitter-probe priority-queue

To assign a priority queue for jitter-probe transmissions, use the **call fallback jitter-probe priority-queue** command in global configuration mode. To return to the default state, use the **no** form of this command.

call fallback jitter-probe priority-queue

no call fallback jitter-probe priority-queue

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines This command is applicable only if the queueing method used is IP Real-Time Transport Protocol (RTP) priority. This command is unnecessary when low latency queueing (LLQ) is used because these packets follow the priority queue path (or not) based on the LLQ classification criteria.

This command works by choosing between sending the probe on an odd or even Service Assurance Agent (SAA) port number. The SAA probe packets go out on randomly selected ports chosen from within the top end of the audio User Datagram Protocol (UDP) defined port range (16384 to 32767). The port pair (RTP Control Protocol [RTCP] port) is selected, and by default, SAA probes for call fallback use the RTCP port (odd) to avoid going into the priority queue, if enabled. If call fallback is configured to use the priority queue, the RTP port (even) is selected.

Examples The following example specifies that a probe be sent to an SAA port:

```
Router(config)# call fallback jitter-probe priority-queue
```

Note In order for this command to have any effect on the probes, the IP priority queueing must be set for UDP voice ports numbered from 16384 to 32767.

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe precedence	Specifies the jitter-probe precedence.
ip rtp priority	Provides a strict priority queueing scheme for delay-sensitive data.
show call fallback config	Displays the call fallback configuration.

call fallback key-chain

To specify the use of message digest algorithm 5 (MD5) authentication for sending and receiving Service Assurance Agents (SAA) probes, use the **call fallback key-chain** command in global configuration mode. To disable MD5, use the **no** form of this command.

call fallback key-chain *name-of-chain*

no call fallback key-chain *name-of-chain*

Syntax Description

name-of-chain	Name of the chain. This name is alphanumeric and case-sensitive text. There is no default value.

Command Default

MD5 authentication is not used.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

This command is used to enable the SAA probe authentication using MD5. If MD5 authentication is used, the keys on the sender and receiver routers must match.

Examples

The following example specifies “sample” as the fallback key chain:

```
Router(config)# call fallback key-chain sample
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
key chain	Enables authentication for routing protocols by identifying a group of authentication keys.
key-string	Specifies the authentication string for a key.
show call fallback config	Displays the call fallback configuration.

call fallback map address-list

To specify that the call fallback router keep a cache table by IP addresses of distances for several destination peers, use the **call fallback map address-list** command in global configuration mode. To restore the default values, use the **no** form of this command.

call fallback map *map* **target** *ip-address* **address-list** *ip-address1 ... ip-address7*

no call fallback map *map* **target** *ip-address* **address-list** *ip-address1 ... ip-address7*

Syntax Description

map	Fallback map. Range is from 1 to 16. There is no default.
target *ip-address*	Target IP address.
ip-address1 ... ip-address7	Lists the IP addresses that are kept in the cache table. The maximum number of IP addresses is seven.

Command Default

No call fallback maps are defined.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

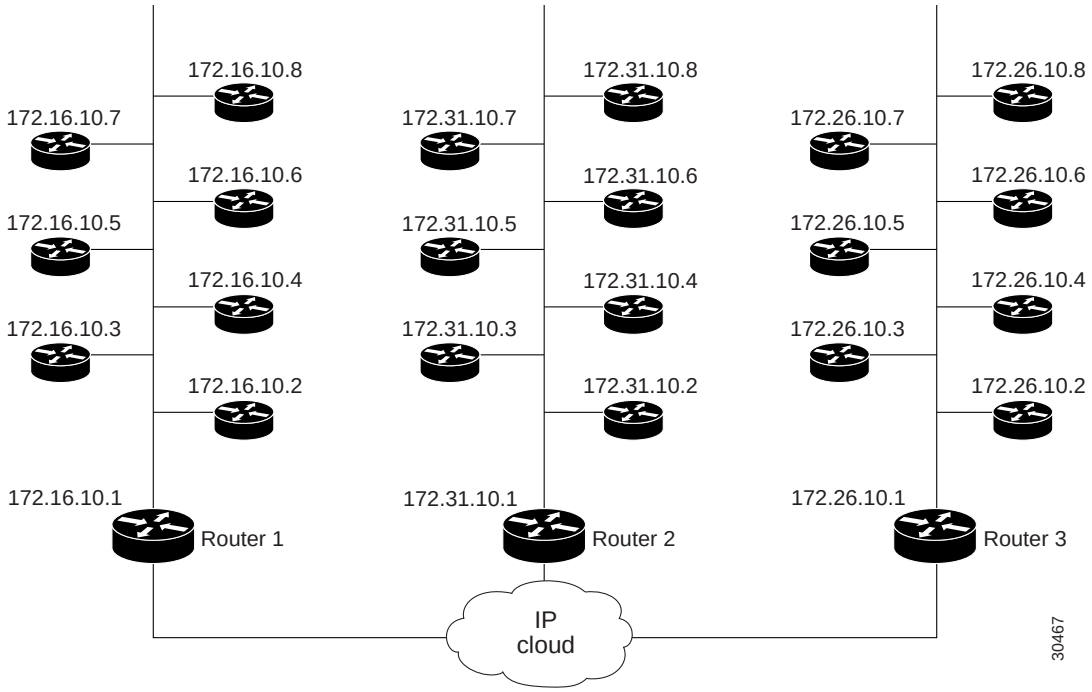
Usage Guidelines

Use this command when several destination peers are in one common node.

Call fallback map setup allows the decongestion of traffic caused by a high volume of call probes sent across a network to query a large number of dial peers. One router/common node can keep the distances in a cache table of the numerous IP addresses/destination peers in a network. When the fallback is queried for network congestion to a particular IP address (that is, the common node), the map addresses are searched to find the target IP address. If a match is determined, the probes are sent to the target address rather than to the particular IP address.

In Figure 1, the three routers (1, 2, and 3) keep the cache tables of distances for the destination peers behind them. When a call probe comes from somewhere in the IP cloud, the cache routers check their distance tables for the IP address/destination peer where the call probe is destined. This distance checking limits congestion on the networks behind these routers by directing the probe to the particular IP address and not to the entire network.

Figure 1 Call Fallback Map with IP Addresses



Examples

The following example specifies call fallback map address-list configurations for 172.32.10.1 and 172.46.10.1:

```
Router(config)# call fallback map 1 target 172.32.10.1 address-list 172.32.10.2
172.32.10.3 172.32.10.4 172.32.10.5 172.32.10.6 172.32.10.7 172.32.10.8

Router(config)# call fallback map 2 target 172.46.10.1 address-list 172.46.10.2
172.46.10.3 172.46.10.4 172.46.10.5 172.46.10.6 172.46.10.7 172.46.10.8
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback map subnet	Specifies that the call fallback router keep a cache table by subnet addresses of distances for several destination peers that are sitting behind the router.
show call fallback config	Displays the call fallback configuration.

call fallback map subnet

To specify that the call fallback router keep a cache table by subnet addresses of distances for several destination peers, use the **call fallback map subnet** command in global configuration mode. To restore the default values, use the **no** form of this command.

call fallback map *map* **target** *ip-address* **subnet** *ip-network netmask*

no call fallback map *map* **target** *ip-address* **subnet** *ip-network netmask*

Syntax Description

map	Fallback map. Range is from 1 to 16. There is no default.
target *ip-address*	Target IP address.
subnet *ip-network*	Subnet IP address.
netmask	Network mask number.

Command Default

No call fallback maps are defined.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command is supported on the Cisco AS5850 in this release.

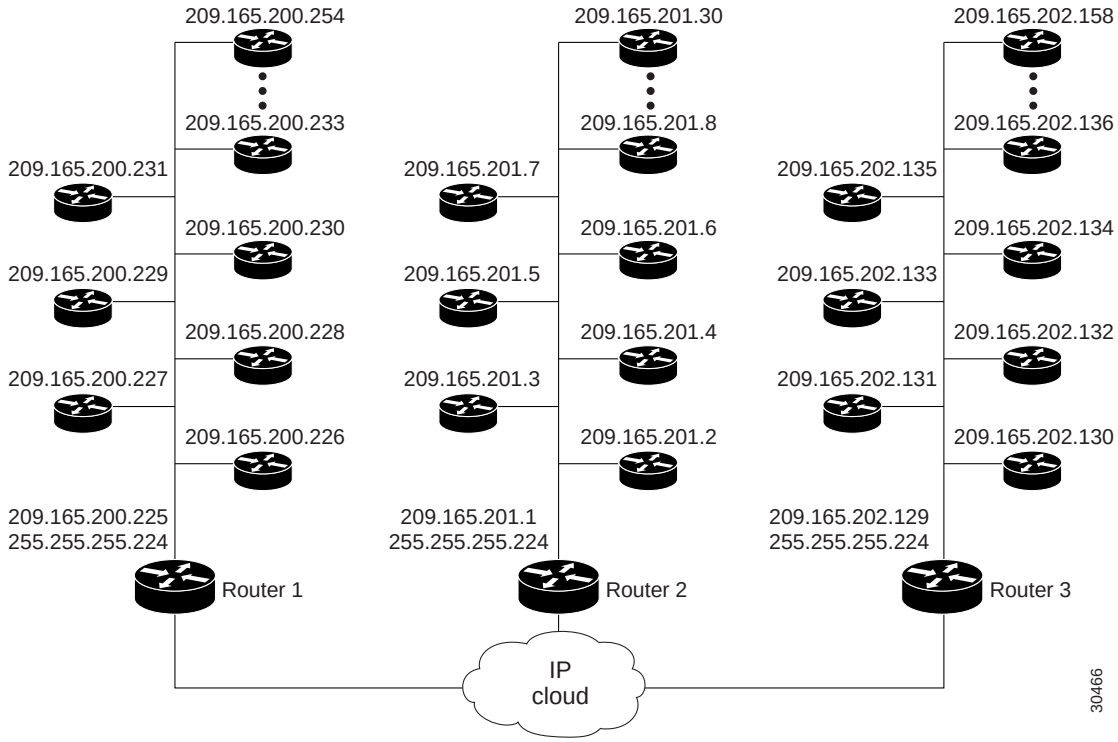
Usage Guidelines

Use this command when several destination peers are in one common node.

Call fallback map setup allows the decongestion of traffic caused by a high volume of call probes sent across a network to query a large number of dial peers. One router/common node can keep the distances in a cache table of the numerous IP addresses within a subnet (destination peers) in a network. When the fallback is queried for network congestion to a particular IP address (that is, the common node), the map addresses are searched to find the target IP address. If a match is determined, the probes are sent to the target address rather than to the particular IP address.

In Figure 2, the three routers (1, 2, and 3) keep the cache tables of distances for the destination peers behind them. When a call probe comes from somewhere in the IP cloud, the cache routers check their distance tables for the subnet address/destination peer where the call probe is destined. This distance checking limits congestion on the networks behind these routers by directing the probe to the particular subnet address and not to the entire network.

Figure 2 Call Fallback Map with Subnet Addresses



Examples

The following examples specify the **call fallback map subnet** configuration for two different IP addresses:

```
Router(config)# call fallback map 1 target 209.165.201.225 subnet
209.165.201.224 255.255.255.224

Router(config)# call fallback map 2 target 209.165.202.225 subnet
209.165.202.224 255.255.255.224
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback map address-list	Specifies that the call fallback router keep a cache table by IP addresses of distances for several destination peers that are sitting behind the router.
show call fallback config	Displays the call fallback configuration.

call fallback monitor

To enable the monitoring of destinations without call fallback to alternate dial peers, use the **call fallback monitor** command in global configuration mode. To disable monitoring without fallback, use the **no** form of this command.

call fallback monitor

no call fallback monitor

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were introduced on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

The **call fallback monitor** command is used as a statistics collector of network conditions based upon probes (detailing network traffic) and connected calls. There is no H.323 call checking/rejecting as with the **call fallback active** command. All call requests are granted regardless of network traffic conditions.

Configure the **call fallback threshold delay loss** or **call fallback threshold icpif** command to set threshold parameters. The thresholds are ignored, but for statistics collecting, configuring one of the thresholds allows you to monitor cache entries for either delay/loss or Calculated Planning Impairment Factor (ICPIF) values.

Examples

The following example enables the **call fallback monitor** command:

```
Router(config)# call fallback monitor
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback threshold delay loss	Specifies that the call fallback threshold use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
show call fallback config	Displays the call fallback configuration.

call fallback probe-timeout

To set the timeout for a Service Assurance Agent (SAA) probe for call fallback purposes, use the **call fallback probe-timeout** command in global configuration mode. To restore the default value, use the **no** form of this command.

call fallback probe-timeout *seconds*

no call fallback probe-timeout

Syntax Description

seconds	Interval, in seconds. Range is from 1 to 2147483. The default is 30.

Command Default

30 seconds

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

SAA probes collect network traffic information based upon configured delay and loss or Calculated Planning Impairment Factor (ICPIF) values and report this information to the cache for call request determination. Use the **call fallback threshold delay loss** or **call fallback threshold icpif** command to set the threshold parameters.

When the probe timeout expires, a new probe is sent to collect network statistics. To reduce the bandwidth taken up by the probes, increase the probe-timeout interval (*seconds*). Probes do not have a great effect upon bandwidth unless several thousand destinations are involved. If this is the case in your network, use a longer timeout. If you need more network traffic information, and bandwidth is not an issue, use a lower timeout. The default interval, 30 seconds, is a low timeout.

When the **call fallback cache-timeout** command is configured or expires, new probes are initiated for data collection.

Examples

The following example configures a 120-second interval:

```
Router(config)# call fallback probe-timeout 120
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback cache-timeout	Specifies the time after which the cache entries of network conditions are purged.
call fallback threshold delay loss	Specifies that the call fallback threshold use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
show call fallback config	Displays the call fallback configuration.

call fallback reject-cause-code

To enable a specific call fallback reject cause code in case of network congestion, use the **call fallback reject-cause-code** command in global configuration mode. To reset the code to the default of 49, use the **no** form of this command.

call fallback reject-cause-code *number*

no call fallback reject-cause-code

Syntax Description

number	Specifies the cause code as defined in the International Telecommunication Union (ITU) standard Q.850 except the code for normal call clearing, which is code 16. The default is 49. See Table 10 for ITU cause-code numbers.

Command Default

49 (quality of service is unavailable)

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.

Usage Guidelines

Enabling the **call fallback reject-cause-code** command determines the code to display when calls are rejected because of probing of network conditions.

Note Connected calls are not affected by this command.

Table 10 ITU cause codes and their associated display message and meanings.

Cause Code	Displayed Message	Meaning
1	Unallocated (unassigned) number	Indicates that the called party cannot be reached because, although the called party number is in a valid format, it is not currently allocated (assigned).
2	No route to specified transit network (national use)	Indicates that the equipment that is sending this code has received a request to route the call through a particular transit network that it does not recognize. The equipment that is sending this code does not recognize the transit network either because the transit network does not exist or because that particular transit network, although it does exist, does not serve the equipment that is sending this cause. This code is supported on a network-dependent basis.

Table 10 ITU cause codes and their associated display message and meanings. (continued)

Cause Code	Displayed Message	Meaning
3	No route to destination	Indicates that the called party cannot be reached because the network through which the call has been routed does not serve the destination desired. This code is supported on a network-dependent basis.
4	Send special information tone	Indicates that the called party cannot be reached for reasons that are of a long-term nature and that the special information tone should be returned to the calling party.
5	Misdialed trunk prefix (national use)	Indicates the erroneous inclusion of a trunk prefix in the called party number.
6	Channel unacceptable	Indicates that the channel most recently identified is not acceptable to the sending entity for use in this call.
7	Call awarded and being delivered in an established channel	Indicates that the user has been awarded the incoming call and that the incoming call is being connected to a channel that is already established to that user for similar calls (for example, packet-mode X.25 virtual calls).
8	Preemption	Indicates that the call is being preempted.
9	Preemption - circuit reserved for reuse	Indicates that the call is being preempted and that the circuit is reserved for reuse by the preempting exchange.
16	Normal call clearing	Indicates that the call is being cleared because one of the users involved in the call has requested that the call be cleared. Under normal situations, the source of this code is not the network.
17	User busy	Indicates that the called party is unable to accept another call. The user busy code may be generated by the called user or by the network. If the called user generates the user busy code, it is noted that the user equipment is compatible with the call.
18	No user responding	Indicates when a called party does not respond to a call establishment message with either an alerting or a connect indication within the prescribed period of time allocated.
19	No answer from user (user alerted)	Indicates when the called party has been alerted but does not respond with a connect indication within a prescribed period of time. **Note** This code is not necessarily generated by ITU standard Q.931 procedures but may be generated by internal network timers.
20	Subscriber absent	Indicates when a mobile station has logged off, when radio contact is not obtained with a mobile station, or when a personal telecommunication user is temporarily not addressable at any user-network interface.
21	Call rejected	Indicates that the equipment that is sending this code does not want to accept this call although it could have accepted the call because the equipment that is sending this code is neither busy nor incompatible. The network may also generate this code, indicating that the call was cleared because of a supplementary service constraint. The diagnostic field may contain additional information about the supplementary service and reason for rejection.
22	Number changed	Indicates when the called-party number indicated by the calling party is no longer assigned. The new called-party number may be included in the diagnostic field. If a network does not support this code, codeNo. 1, an unallocated (unassigned) number, shall be used.
26	Non-selected user clearing	Indicates that the user has not been sent the incoming call.

Table 10 ITU cause codes and their associated display message and meanings. (continued)

Cause Code	Displayed Message	Meaning
27	Destination out of order	Indicates that the destination indicated by the user cannot be reached because the interface to the destination is not functioning correctly. The term "not functioning correctly" indicates that a signaling message was unable to be delivered to the remote party; for example, a physical layer or data link layer failure at the remote party, or the equipment of the user is offline.
28	Invalid number format (address incomplete)	Indicates that the called party cannot be reached because the called party number is not in a valid format or is not complete.
29	Facility rejected	Indicates when a supplementary service requested by the user cannot be provided by the network.
30	Response to STATUS ENQUIRY	Indicates when the reason for generating the STATUS message was the prior receipt of a STATUS ENQUIRY message.
31	Normal, unspecified	Reports a normal event only when no other code in the normal class applies.
34	No circuit/channel available	Indicates that no appropriate circuit or channel is available to handle the call.
38	Network out of order	Indicates that the network is not functioning correctly and that the condition is likely to last a relatively long period of time; for example, immediately reattempting the call is not likely to be successful.
39	Permanent frame mode connection out-of-service	Indicates in a STATUS message that a permanently established frame mode connection is out-of-service (for example, due to equipment or section failure) (see the ITU standard, Annex A/Q.933).
40	Permanent frame mode connection operational	Indicates in a STATUS message to indicate that a permanently established frame mode connection is operational and capable of carrying user information (see the ITU standard, Annex A/Q.933).
41	Temporary failure	Indicates that the network is not functioning correctly and that the condition is not likely to last a long period of time; for example, the user may want to try another call attempt almost immediately.
42	Switching equipment congestion	Indicates that the switching equipment that is generating this code is experiencing a period of high traffic.
43	Access information discarded	Indicates that the network could not deliver access information to the remote user as requested, that is, user-to-user information, low layer compatibility, high layer compatibility, or subaddress, as indicated in the diagnostic. It is noted that the particular type of access information discarded is optionally included in the diagnostic.
44	Requested circuit/channel not available	Indicates when the circuit or channel indicated by the requesting entity cannot be provided by the other side of the interface.
46	Precedence call blocked	Indicates that there are no preemptable circuits or that the called user is busy with a call of an equal or higher preemptable level.
47	Resource unavailable, unspecified	Reports a resource-unavailable event only when no other cause in the resource-unavailable class applies.
49	Quality of service not available	Reports that the requested quality of service, as defined in ITU recommendation X.213, cannot be provided (for example, throughput or transit delay cannot be supported).

Table 10 ITU cause codes and their associated display message and meanings. (continued)

Cause Code	Displayed Message	Meaning
50	Requested facility not subscribed	Indicates that the user has requested a supplementary service that is implemented by the equipment that generated this cause but that the user is not authorized to use this service.
53	Outgoing calls barred within CUG	Indicates that, although the calling party is a member of the closed user group (CUG) for the outgoing CUG call, outgoing calls are not allowed for this member of the CUG.
55	Incoming calls barred within CUG	Indicates that, although the called party is a member of the CUG for the incoming CUG call, incoming calls are not allowed for this member of the CUG.
57	Bearer capability not authorized	Indicates that the user has requested a bearer capability that is implemented by the equipment that generated this cause but that the user is not authorized to use this capability.
58	Bearer capability not presently available	Indicates that the user has requested a bearer capability that is implemented by the equipment that generated this cause but that is not available at this time.
62	Inconsistency in designated outgoing access information and subscriber class	Indicates that there is an inconsistency in the designated outgoing access information and subscriber class.
63	Service or option not available, unspecified	Reports a service or option not available event only when no other cause in the service or option not available class applies.
65	Bearer capability not implemented	Indicates that the equipment that is sending this code does not support the bearer capability requested.
66	Channel type not implemented	Indicates that the equipment that is sending this code does not support the channel type requested.
69	Requested facility not implemented	Indicates that the equipment that is sending this code does not support the requested supplementary service.
70	Only restricted digital information bearer capability is available (national use)	Indicates that the calling party has requested an unrestricted bearer service but that the equipment that is sending this cause supports only the restricted version of the requested bearer capability.
79	Service or option not implemented, unspecified	Reports a service or option not implemented event only when no other code in the service or option not implemented class applies.
81	Invalid call reference value	Indicates that the equipment that is sending this code has received a message with a call reference that is not currently in use on the user-network interface.
82	Identified channel does not exist	Indicates that the equipment that is sending this code has received a request to use a channel not activated on the interface for a call. For example, if a user has subscribed to those channels on a PRI numbered from 1 to 12 and the user equipment or the network attempts to use channels 13 through 23, this cause is generated.
83	A suspended call exists, but this call identity does not	Indicates that a call resume has been attempted with a call identity that differs from that in use for any suspended calls.
84	Call identity in use	Indicates that the network has received a call suspended request that contains a call identity (including the null call identity) that is already in use for a suspended call within the domain of interfaces over which the call might be resumed.

Table 10 ITU cause codes and their associated display message and meanings. (continued)

Cause Code	Displayed Message	Meaning
85	No call suspended	Indicates that the network has received a call resume request that contains a call identity information element that does not indicate any suspended call within the domain of interfaces over which calls may be resumed.
86	Call having the requested call identity has been cleared	Indicates that the network has received a call resume request that contains a call identity information element that indicates a suspended call that has in the meantime been cleared while suspended (either by network timeout or by the remote user).
87	User not member of CUG	Indicates that the called user for the incoming CUG call is not a member of the specified CUG or that the calling user is an ordinary subscriber that is calling a CUG subscriber.
88	Incompatible destination	Indicates that the equipment that is sending this code has received a request to establish a call that has low layer compatibility, high layer compatibility, or other compatibility attributes (for example, data rate) that cannot be accommodated.
90	Non-existent CUG	Indicates that the specified CUG does not exist.
91	Invalid transit network selection (national use)	Indicates that a transit network identification was received that is of an incorrect format as defined in ITU standard Annex C/Q.931.
95	Invalid message, unspecified	Reports an invalid message event only when no other code in the invalid message class applies.
96	Mandatory information element is missing	Indicates that the equipment that is sending this code has received a message that is missing an information element that must be present in the message before that message can be processed.
97	Message type non-existent or not implemented	Indicates that the equipment that is sending this code has received a message with a message type that it does not recognize because this is a message not defined or defined but not implemented by the equipment that is sending this cause.
98	Message not compatible with call state or message type non-existent or not implemented	Indicates that the equipment that is sending this code has received a message that the procedures do not indicate as a permissible message to receive while in the call state, or that a STATUS message that indicates an incompatible call state was received.
99	Information element/parameter non-existent or not implemented	Indicates that the equipment that is sending this code has received a message that includes information elements or parameters not recognized because the information element identifiers or parameter names are not defined or are defined but not implemented by the equipment sending the code. This code indicates that the information elements or parameters were discarded. However, the information element is not required to be present in the message for the equipment that is sending the code to process the message.
100	Invalid information element contents	Indicates that the equipment that is sending this code has received an information element that it has implemented; however, one or more fields in the information element are coded in a way that has not been implemented by the equipment that is sending this code.
101	Message not compatible with call state	Indicates that a message has been received that is incompatible with the call state.
102	Recovery on timer expired	Indicates that a procedure has been initiated by the expiration of a timer in association with error-handling procedures.

Table 10 ITU cause codes and their associated display message and meanings. (continued)

Cause Code	Displayed Message	Meaning
103	Parameter non-existent or not implemented - passed on	Indicates that the equipment that is sending this code has received a message that includes parameters not recognized because the parameters are not defined or are defined but not implemented by the equipment that is sending the code. The code indicates that the parameters were ignored. In addition, if the equipment that is sending this code is an intermediate point, this code indicates that the parameters were passed on unchanged.
110	Message with unrecognized parameter discarded	Indicates that the equipment that is sending this code has discarded a received message that includes a parameter that is not recognized.
111	Protocol error, unspecified	Reports a protocol error event only when no other code in the protocol error class applies.
127	Interworking, unspecified	Indicates that there has been interworking with a network that does not provide codes for actions it takes. Thus, the precise code for a message that is being sent cannot be ascertained.

Examples

The following example enables the **call fallback reject-cause-code** command and specifies cause code 34:

```
call fallback reject-cause-code 34
```

Related Commands

Command	Description
call fallback cache-size	Specifies the call fallback cache size for network traffic probe entries.
call fallback cache-timeout	Specifies the time after which the cache entries of network conditions are purged.
call fallback instantaneous-value-weight	Specifies that the call fallback subsystem take an average from the last two cache entries for call requests.
call fallback jitter-probe num-packets	Specifies the number of packets in a jitter probe that are used to determine network conditions.
call fallback jitter-probe precedence	Specifies the priority of the jitter-probe transmission.
call fallback jitter-probe priority-queue	Assigns a priority queue for jitter-probe transmissions.
call fallback key-chain	Specifies MD5 authentication for sending and receiving SAA probes.
call fallback map address-list	Specifies that the call fallback router keep a cache table by IP addresses of distances for several destination peers that are sitting behind the router.
call fallback map subnet	Specifies that the call fallback router keep a cache table by subnet addresses of distances for several destination peers that are sitting behind the router.
call fallback probe-timeout	Sets the timeout for an SAA probe for call fallback purposes.

Command	Description
call fallback threshold delay loss	Specifies that the call fallback threshold use only packet delay and loss values.
call fallback threshold icpif	Specifies that call fallback use the ICPIF threshold.
show call fallback config	Displays the call fallback configuration.

call fallback threshold delay loss

To specify that the call fallback threshold use only packet delay and loss values, use the **call fallback threshold delay loss command in** global configuration mode. To restore the default value, use the **no** form of this command.

call fallback threshold delay *milliseconds* **loss** *percent*

no call fallback threshold delay *milliseconds* **loss** *percent*

Syntax Description

milliseconds	The delay value, in milliseconds (ms). Range is from 1 to 2147483647. There is no default value.
percent	The loss value, expressed as a percentage. The valid range is from 0 to 100. There is no default value.

Command Default None

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.

Usage Guidelines During times of heavy voice traffic, two parties in a conversation may notice a significant delay in transmission or hear only part of a conversation because of voice-packet loss.

Use the **call fallback threshold delay loss** command to configure parameters for voice quality. Lower values of delay and loss allow higher quality of voice. Call requests match the network information in the cache with the configured thresholds of delay and loss.

The amount of delay set by the **call fallback threshold delay loss** command should not be more than half the amount of the time-to-wait value set by the **call fallback wait-timeout** command; otherwise the threshold delay will not work correctly. Because the default value of the **call fallback wait-timeout** command is set to 300 ms, the user can configure a delay of up to 150 ms for the **call fallback threshold delay loss** command. If the user wants to configure a higher threshold, the time-to-wait delay has to be increased from its default (300 ms) using the **call fallback wait-timeout** command.

Note The delay configured by the **call fallback threshold delay loss** command corresponds to a one-way delay, whereas the time-to-wait period configured by the **call fallback wait-timeout** command corresponds to a round-trip delay.

If you enable the **call fallback active** command, the call fallback subsystem uses the last cache entry compared with the configured delay/loss threshold to determine whether the call is connected or denied. If you enable the **call fallback monitor** command, all calls are connected, regardless of the configured threshold or voice quality. In this case, configuring the **call fallback threshold delay loss** command allows you to collect network statistics for further tracking.

Note The **call fallback threshold delay loss** command differs from the **call fallback threshold icpif** command because the **call fallback threshold delay loss** command uses only packet delay and loss parameters, and the **call fallback threshold icpif** command uses packet delay and loss parameters plus other International Telecommunication Union (ITU) G.113 factors to gather impairment information.

Setting this command does not affect bandwidth. Available bandwidth for call requests is determined by the call fallback subsystem using probes. The number of probes on the network affects bandwidth.

Examples

The following example configures a threshold delay of 20 ms and a threshold loss of 50 percent:

```
Router(config)# call fallback threshold delay 20 loss 50
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback monitor	Enable the monitoring of destinations without call fallback to alternate dial peers.
call fallback threshold icpif	Specifies the ICPIF threshold.
call fallback wait-timeout	Specifies the time to wait for a response to a probe.
show call fallback config	Displays the call fallback configuration.

call fallback threshold icpif

To specify that call fallback use the Calculated Planning Impairment Factor (ICPIF) threshold, use the **call fallback threshold icpif** command in global configuration mode. To restore the default value, use the **no** form of this command.

call fallback threshold icpif *threshold-value*

no **call fallback threshold icpif**

Syntax Description

threshold-value	Threshold value. Range is from 0 to 34. The default is 5.

Command Default 5

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were introduced on the Cisco 7200 series routers and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(8)T	Support for the Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines During times of heavy voice traffic, the parties in a conversation may notice a significant delay in transmission or hear only part of a conversation because of voice-packet loss.

Use the **call fallback threshold icpif** command to configure parameters for voice quality. A low ICPIF value allows for higher quality of voice. Call requests match the network information in the cache with the configured ICPIF threshold. If you enable the **call fallback active** command, the call fallback subsystem uses the last cache entry compared with the configured ICPIF threshold to determine whether the call is connected or denied. If you enable **the call fallback monitor** command, all calls are connected regardless of the configured threshold or voice quality. In this case, configuring the **call fallback threshold icpif** command allows you to collect network statistics for further tracking.

A lower ICPIF value tolerates less delay and loss of voice packets (according to ICPIF calculations). Use lower values for higher quality of voice. Configuring a value of 34 equates to 100 percent packet loss.

The ICPIF is calculated and used according to the International Telecommunication Union (ITU) G.113 specification.

Note The **call fallback threshold delay loss** command differs from the **call fallback threshold icpif** command because the **call fallback threshold delay loss** command uses only packet delay and loss parameters, while the **call fallback threshold icpif** command uses packet delay and loss parameters plus other ITU G.113 factors to gather impairment information.

Setting this command does not affect bandwidth. Available bandwidth for call requests is determined by the call fallback subsystem using probes. The number of probes on the network affects bandwidth.

Examples

The following example sets the **ICPIF threshold** to 20:

```
Router(config)# call fallback threshold icpif 20
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
call fallback monitor	Enables the monitoring of destinations without call fallback to alternate dial peers.
call fallback threshold delay loss	Specifies the call fallback threshold delay and loss values.
show call fallback config	Displays the call fallback configuration.

call fallback wait-timeout

To modify the time to wait for a response to a probe, use the **call fallback wait-timeout** command in global configuration mode. To return to the default value, use the **no** form of this command.

call fallback wait-timeout *milliseconds*

no call fallback wait-timeout *milliseconds*

Syntax Description

milliseconds	The time-to-wait value in milliseconds (ms). The range is 100 to 3000 milliseconds.

Command Default

300 milliseconds

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)T9	This command was introduced.

Usage Guidelines

This command is enabled by default. The time to wait for a response to a probe is set to 300 ms. This command allows the user to modify the amount of time to wait for a response to a probe. The *milliseconds* argument allows the user to configure a time-to-wait value from 100 ms and 3000 ms. A user that has a higher-latency network may want to increase the value of the default timer.

The time-to-wait period set by the **call fallback wait-timeout** command should always be greater than or equal to twice the amount of the threshold delay time set by the **call fallback threshold delay loss** command; otherwise the probe will fail.

Note The delay configured by the **call fallback threshold delay loss** command corresponds to a one-way delay, whereas the time-to-wait period configured by **call fallback wait-timeout** command corresponds to a round-trip delay. The threshold delay time should be set at half the value of the time-to-wait value.

Examples

The following example sets the amount of time to wait for a response to a probe to 200 ms:

```
call fallback wait-timeout 200
```

Related Commands

Command	Description
call fallback threshold delay loss	Specifies the call fallback threshold delay and loss values.

call filter match-list voice

To enter the call filter match list configuration mode and create a call filter match list for debugging voice calls, use the **call filter match-list voice** command in global configuration mode. To remove the filter, use the **no** form of this command.

call filter match-list *number* **voice**

no call filter match-list *number* **voice**

Syntax Description

number	Numeric label that uniquely identifies the match list. Range is 1 to 16.

Command Default None

Command Modes Global configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines Configure the **call filter match-list voice** command to set the conditions for filtering voice call debugging. After the conditions are set with this command, use the **debug condition match-list** command in privileged EXEC mode to get the filtered debug output.

Examples The following example shows that the call filter match list designated as list 1 filters the debug output for an incoming calling number matching 8288807, an incoming called number matching 6560729, and on incoming port 7/0:D:

```
call filter match-list 1 voice
 incoming calling-number 8288807
 incoming called-number 6560729
 incoming port 7/0:D
```

Related Commands

Command	Description
debug condition match-list	Runs a filtered debug on a voice call.
show call filter match-list	Displays call filter match lists.

call forward all

To define a a feature code for a Feature Access Code (FAC) to access Call Forward All (CFA) on an analog phone, use the **call forward all** command in STC application feature access-code configuration mode. To return the code to its default, use the **no** form of this command.

call forward all *keypad-character*

no call forward all

Syntax Description

keypad-character	Character string that can be dialed on a telephone keypad (0-9, *, #). Default: 1. Before Cisco IOS Release 12.4(20)YA, this is a single character. In Cisco IOS Release 12.5(20)YA and later releases, the string can be any of the following: • A single character (0-9, *, #) • Two digits (00-99) • Two to four characters (0-9, *, #) and the leading or ending character must be an asterisk (*) or number sign (#) In Cisco IOS Release 15.0(1)M and later releases, the string can also be any of the following: • Three digits (000-999) • Four digits (0000-9999)

Command Default

The default value of the feature code for CFA is 1.

Command Modes

STC application feature access-code configuration (config-stcapp-fac).

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.4(20)YA	This command was modified. The length of the *keypad-character* argument was changed to 1 to 4 characters.
12.4(22)T	This command was integrated into Cisco IOS Release 12.4(22)T.
15.0(1)M	This command was modified.

Usage Guidelines

This command changes the value of the feature code for Call Forward All from the default (1) to the specified value.

In Cisco IOS Release 12.4(20)YA and later releases, if the length of the *keypad-character* argument is at least two characters and the leading or ending character of the string is an asterisk (*) or a number sign (#), phone users are not required to dial a prefix to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 78#, the phone user dials only 78#, without the FAC prefix, to access the corresponding feature.

In Cisco IOS Release 15.0(1)M and later releases, if the length of the keypad-character argument is three or four digits, phone users are not required to dial a prefix or any special characters to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 788, the phone user dials only 788, without the FAC prefix, to access the corresponding feature.

In Cisco IOS Release 12.4(20)YA and later releases, if you attempt to configure this command with a value that is already configured for another FAC, for a speed-dial code, or for the Redial FSD, you receive a message. If you configure a duplicate code, the system implements the first matching feature in the order of precedence shown in the output of the **show stcapp feature codes** command.

In Cisco IOS Release 12.4(20)YA and later releases, if you attempt to configure this command with a value that precludes or is precluded by another FAC, by a speed-dial code, or by the Redial FSD, you receive a message. If you configure a feature code to a value that precludes or is precluded by another code, the system always executes the call feature with the shortest code and ignores the longer code. For example, #1 will always preclude #12 and #123. You must configure a new value for the precluded code in order to enable phone user access to that feature.

To display a list of all FACs, use the **show stcapp feature codes** command.

Examples

The following example shows how to change the value of the feature code for Call Forward All from the default (1). This configuration also changes the value of the prefix for all FACs from the default (**) to ##. With this configuration, a phone user must press ##3 on the keypad and then dial a target number, to forward all incoming calls to the target number.

```
Router(config)# stcapp feature access-code
Router(config-stcapp-fac)# prefix ##
Router(config-stcapp-fac)# call forward all 3
Router(config-stcapp-fac)# exit
```

The following example shows how to configure all-numeric three or four digit flexible feature access codes so that users are not required to dial a prefix or special characters:

```
VG224(config-stcapp-fac)# call forward all 111
do not use prefix. call forward all is 111
```

Related Commands

Command	Description
call-forward all	Configures call forwarding so that all incoming calls to a particular directory number are forwarded to another directory number.
call forward cancel	Defines a feature code for a feature access code (FAC) to cancel the call-forward-all condition.
call forward to voicemail	Configures call forwarding to voicemail so that all incoming calls are forwarded to voicemail.
prefix (stcapp-fac)	Defines the prefix for feature access codes (FACs).

Command	Description
show stcapp feature codes	Displays all feature access codes (FACs).
stcapp feature access-code	Enables feature access codes (FACs) and enters STC application feature access-code configuration mode for changing values of the prefix and features codes from the default.

call forward cancel

To define a a feature code for a Feature Access Code (FAC) to access Call Forward All Cancel, use the **call forward cancel** command in STC application feature access-code configuration mode. To return the feature code to its default, use the **no** form of this command.

call forward cancel *keypad-character*

no call forward cancel

Syntax Description

keypad-character	Character string that can be dialed on a telephone keypad (0-9, *, #). Default: 2. Before Cisco IOS Release 12.4(20)YA, this is a single character. In Cisco IOS Release 12.4(20)YA and later releases, the string can be any of the following: • A single character (0-9, *, #) • Two digits (00-99) • Two to four characters (0-9, *, #) and the leading or ending character must be an asterisk (*) or number sign (#) In Cisco IOS Release 15.0(1)M and later releases, the string can also be any of the following: • Three digits (000-999) • Four digits (0000-9999)

Command Default The default value of the feature code is 2.

Command Modes STC application feature access-code configuration (config-stcapp-fac)

Command History

Release	Modification
12.4(2)T	This command was introduced.
12.4(20)YA	The length of the *keypad-character* argument was changed to 1 to 4 characters.
12.4(22)T	This command was integrated into Cisco IOS Release 12.4(22)T.
15.0(1)M	This command was modified.

Usage Guidelines

This command changes the value of the feature code for Call Forward All Cancel from the default (2) to the specified value.

In Cisco IOS Release 12.4(20)YA and later releases, if the length of the *keypad-character* argument is at least two characters and the leading or ending character of the string is an asterisk (*) or a number sign (#), phone users are not required to dial a prefix to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 78#, the phone user dials only 78#, without the FAC prefix, to access the corresponding feature.

In Cisco IOS Release 15.0(1)M and later releases, if the length of the keypad-character argument is three or four digits, phone users are not required to dial a prefix or any special characters to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 788, the phone user dials only 788, without the FAC prefix, to access the corresponding feature.

In Cisco IOS Release 12.4(20)YA and later releases, if you attempt to configure this command with a value that is already configured for another FAC, for a speed-dial code, or for the Redial FSD, you receive a message. If you configure a duplicate code, the system implements the first matching feature in the order of precedence shown in the output of the **show stcapp feature codes** command.

In Cisco IOS Release 12.4(20)YA and later releases, if you attempt to configure this command with a value that precludes or is precluded by another FAC, by a speed-dial code, or by the Redial FSD, you receive a message. If you configure a feature code to a value that precludes or is precluded by another code, the system always executes the call feature with the shortest code and ignores the longer code. For example, #1 will always preclude #12 and #123. You must configure a new value for the precluded code in order to enable phone user access to that feature.

To display a list of all FACs, use the **show stcapp feature codes** command.

Note To disable call-forward-all on a particular directory number associated with SCCP endpoints connected to Cisco Unified CME through an analog voice gateway, use the **no call-forward all** command in ephone-dn or ephone-dn-template configuration mode.

Examples

The following example shows how to change the value of the feature code for Call Forward Cancel from the default (2). This configuration also changes the value of the prefix for all FACs from the default (**) to ##. With this configuration, a phone user must press ##3 on the phone keypad to cancel all-call forwarding.

```
Router(config)# stcapp feature access-code
Router(config-stcapp-fac)# prefix ##
Router(config-stcapp-fac)# call forward cancel 3
Router(config-stcapp-fac)# exit
```

Related Commands

Command	Description
call forward all	Defines the feature code in the feature access code (FAC) for forwarding all calls.
call-forward all	Configures call forwarding so that all incoming calls to a particular directory number are forwarded to another directory number.
prefix (stcapp-fac)	Defines the prefix for feature access codes (FACs).

Command	Description
show stcapp feature codes	Displays all feature access codes (FACs).
stcapp feature access-code	Enables feature access codes (FACs) and enters STC application feature access-code configuration mode for changing values of the prefix and features codes from the default.

call-forward-to-voicemail

To configure forwarding of calls to voicemail so that all incoming calls to a directory number are forwarded to voicemail, use the **forward-to-voicemail** command. The **stcapp feature access-code** command must be enabled on the Cisco voice gateway. To disable call forwarding, use the **no** form of this command.

forward-to-voicemail *forward-to-voicemail-code*

no forward-to-voicemail

Syntax Description

forward-to-voicemail-code	Default prefix and code is **7.
keypad-character	In Cisco IOS Release 15.0(1)M and later releases, the string can be either of the following: • Three digits (000-999) • Four digits (0000-9999)

Command Default

Call forwarding to voicemail is not set.

Command Modes

STC application feature access-code configuration (config-stcapp-fac).

Command History

Cisco IOS Release	Cisco Product	Modification
12.4(11)T	Cisco Unified CME 4.0(3)	This command was introduced.
15.0(1)M	—	This command was modified. The default user behavior of the feature access code was modified.

Usage Guidelines

In Cisco IOS Release 15.0(1)M and later releases, if the length of the keypad-character argument is three or four digits, phone users are not required to dial a prefix or any special characters to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 788, the phone user dials only 788, without the FAC prefix, to access the corresponding feature.

The FAC for forward-to-voicemail follows the same rules as for other FAC, such as **call forward all,** in terms of allowable string as its FAC code.

Examples

The following example show how to configure forward-to-voicemail using a four digit code:

```
VG224(config-stcapp-fac)# forward-to-voicemail 1234
do not use prefix. forward-to-voicemail is 1234
```

Related Commands

Command	Description
call-forward all	Configures call forwarding so that all incoming calls to a particular directory number are forwarded to another directory number.
call forward cancel	Defines a feature code for a FAC to cancel the call-forward-all condition.
show stcapp feature codes	Displays all FACs.
stcapp feature access-code	Enables FACs and enters STC application feature access-code configuration mode for changing values of the prefix and features codes from the default.

call history max

To retain call history information and to specify the number of call records to be retained, use the **call history max** command in global configuration mode.

call history max *number*

Syntax Description

number	The maximum number of call history records to be retained in the history table. Values are from 0 to 1200. The default is 15.

Command Default

If this command is not configured, no call history is maintained for disconnected calls. If the command is configured, the default value for number of records is 15.

Command Modes

Global configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

The number of disconnected calls displayed is the number specified in the number argument. This maximum number helps to reduce CPU usage in the storage and reporting of this information.

Examples

The following example configures the history table on the gatekeeper to retain 25 records:

```
Router# call history max 25
```

Related Commands

Command	Description
show call history voice	Displays historical information on disconnected calls.

call-history-mib

To define the history MIB parameters, use the **call-history-mib** command in global configuration mode. To disable the configured parameters, use the **no** form of this command.

call-history-mib {**max-size** *num-of-entries* | **retain-timer** *seconds*}

no call-history-mib {**max-size** *num-of-entries* | **retain-timer** *seconds*}

Syntax Description

max-size	Specifies the maximum size of the call history MIB table.
number-of-entries	Number of entries in the call history MIB table. The valid range is from 0 to 500. The default value is 100.
retain-timer	Specifies the timer for entries in the call history MIB table.
seconds	Time in minutes, for removing an entry. The valid range is from 0 to 500. The default time is 15 minutes.

Command Default

The default values are set if the command is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines

CISCO-CALL-HISTORY-MIB describes the objects defined and used for storing the call information for all calls. The MIB contains a table that stores the past call information. The call information will include the destination number, the call connect time, the call disconnect time and the disconnection cause. These calls could be circuit switched or they could be virtual circuits. The history of each call will be stored. An entry will be created when a call gets disconnected. At the time of creation, the entry will contain the connect time and the disconnect time and other call information.

The history table is characterized by two values, the maximum number (*number-of-entries*) of entries that could be stored in a period of time (*seconds*).

The **max-size** value specifies the maximum size of the call history MIB table.

The **retain-timer** value specifies the length of time, in minutes, that entries will remain in the call history MIB table. Setting the value to 0 prevents any call history from being retained.

Examples

The following examples shows how to set call history MIB parameters:

```
Router# configure terminal
Router(config)# call-history-mib max-size 250
Router# configure terminal
Router(config)# call-history-mib retain-timer 250
```

Related Commands

Command	Description
show startup-config	Displays the contents of the startup configuration file.

call language voice

To configure an external Tool Command Language (Tcl) module for use with an interactive voice response (IVR) application, use the **call language voice command in** global configuration mode.

call language voice *language url*

Syntax Description

language	Two-character abbreviation for the language; for example, "**en**" for English or "**ru**" for Russian.
url	URL that points to the Tcl module.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(2)T	This command was introduced.
12.3(14)T	This is obsolete in Cisco IOS Release 12.3(14)T. Use the **param language** command in application parameter configuration mode.

Usage Guidelines The built-in languages are English (*en)*, Chinese (*ch)*, and Spanish (*sp)*. If you specify "**en**", "**ch**", or **sp**", the new Tcl module replaces the built-in language functionality. When you add a new Tcl module, you create your own prefix to identify the language. When you configure and load the new languages, any upper-layer application (Tcl IVR) can use the language.

You can use the language abbreviation in the *language* argument of any **call application voice** command. The language and the text-to-speech (TTS) notations are available for the IVR application to use after they are defined by the Tcl module.

Examples The following example adds Russian (**ru**) as a Tcl module:

```
call language voice ru tftp://box/unix/scripts/multi-lang/ru_translate.tcl
```

Related Commands

Command	Description
call application voice	Configures an application.
debug voip ivr	Specifies the type of VoIP IVR debug output that you want to view.
param language	Configures the language parameter in a service or package on the gateway.
show language voice	Displays information about configured languages and applications.

call language voice load

To load or reload a Tool Command Language (Tcl) module from the configured URL location, use the **call language voice load** command in EXEC mode.

call language voice load *language*

Syntax Description

language	The two-character prefix configured with the **call language voice** command in global configuration mode; for example, "en" for English or "ru" for Russian.

Command Default No default behavior or values

Command Modes EXEC

Command History

Release	Modification
12.2(2)T	This command was introduced.

Usage Guidelines You cannot use this command if the interactive voice response (IVR) application using the language that you want to configure has an active call. A language that is configured under an IVR application is not necessarily in use. To determine if a call is active, use the **show call application voice** command.

Examples The following example loads French (fr) into memory:

```
call language voice load fr
```

Related Commands

Command	Description
call application voice load	Loads an application.
debug voip ivr	Specifies the type of VoIP IVR debug output that you want to view.
show language voice	Displays information about configured languages and applications.

call leg dump event-log

To flush the event log buffer for call legs to an external file, use the **call leg dump event-log** command in privileged EXEC mode.

call leg dump event-log

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

This command immediately writes the event log buffer to the external file whose location is defined with the **call leg event-log dump ftp** command in global configuration mode.

Note The **call leg dump event-log** command and the **call leg event-log dump ftp** command are two different commands.

Examples

The following example writes the event log buffer to an external file named leg_elogs:

```
Router(config)# call leg event-log dump ftp ftp-server/elogs/leg_elogs.log username myname
password 0 mypass
Router(config)# exit
Router# call leg dump event-log
```

Related Commands

Command	Description
call leg event-log	Enables event logging for voice, fax, and modem call legs.
call leg event-log dump ftp	Enables the voice gateway to write the contents of the call-leg event log buffer to an external file.
call leg event-log max-buffer-size	Sets the maximum size of the event log buffer for each call leg.
monitor call leg event-log	Displays the event log for an active call leg in real-time.
show call leg	Displays event logs and statistics for voice call legs.

call leg event-log

To enable event logging for voice, fax, and modem call legs, use the **call leg event-log** command in global configuration mode. To reset to the default, use the **no** form of this command.

call leg event-log

no call leg event-log

Syntax Description This command has no arguments or keywords.

Command Default Event logging for call legs is disabled.

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines This command enables event logging for telephony call legs. IP call legs are not supported.

Note To prevent event logging from adversely impacting system performance for production traffic, the system includes a throttling mechanism. When free processor memory drops below 20%, the gateway automatically disables all event logging. It resumes event logging when free memory rises above 30%. While throttling is occurring, the gateway does not capture any new event logs even if event logging is enabled. You should monitor free memory on the gateway and enable event logging only when necessary to isolate faults.

Examples The following example enables event logging for all telephony call legs:

```
call leg event-log
```

Related Commands

Command	Description
call leg dump event-log	Flushes the event log buffer for call legs to an external file.
call leg event-log dump ftp	Enables the voice gateway to write the contents of the call-leg event log buffer to an external file.
call leg event-log error-only	Restricts event logging to error events only for voice call legs.
call leg event-log max-buffer-size	Sets the maximum size of the event log buffer for each call leg.

Command	Description
call leg history event-log save-exception-only	Saves to history only event logs for call legs that had at least one error.
monitor call leg event-log	Displays the event log for an active call leg in real-time.
show call leg	Displays event logs and statistics for voice call legs.

call leg event-log dump ftp

To enable the gateway to write the contents of the call-leg event log buffer to an external file, use the **call leg event-log dump ftp** command in global configuration mode. To reset to the default, use the **no** form of this command.

call leg event-log dump ftp *server*[**:***port*]**/***file* **username** *username* **password** [*encryption-type*] *password*

no call leg event-log dump ftp

Syntax Description

server	Name or IP address of FTP server where the file is located.
port	(Optional) Specific port number on server.
file	Name and path of file.
username	Username required for accessing file.
encryption-type	(Optional) The Cisco proprietary algorithm used to encrypt the password. Values are 0 or 7. 0 disables encryption; 7 enables encryption. If you specify 7, you must enter an encrypted password (a password already encrypted by a Cisco router).
password	Password required for accessing the file.

Command Default Event logs are not written to an external file.

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines This command enables the gateway to automatically write the event log buffer to the named file either after an active call leg terminates or when the event log buffer becomes full. The default buffer size is 4 KB. To modify the size of the buffer, use the **call leg event-log max-buffer-size** command. To manually flush the event log buffer, use the **call leg dump event-log** command in privileged EXEC mode.

Note The **call leg dump event-log** command and the **call leg event-log dump ftp** command are two different commands.

Note Enabling the gateway to write event logs to FTP could adversely impact gateway memory resources in some scenarios, for example, when:

- The gateway is consuming high processor resources and FTP does not have enough processor resources to flush the logged buffers to the FTP server.
- The designated FTP server is not powerful enough to perform FTP transfers quickly
- Bandwidth on the link between the gateway and the FTP server is not large enough
- The gateway is receiving a high volume of short-duration calls or calls that are failing

You should enable FTP dumping only when necessary and not enable it in situations where it might adversely impact system performance.

Examples

The following example enables the gateway to write call leg event logs to an external file named leg_elogs.log on a server named ftp-server:

```
call leg event-log dump ftp ftp-server/elogs/leg_elogs.log username myname password 0
mypass
```

The following example specifies that call leg event logs are written to an external file named leg_elogs.log on a server with the IP address 10.10.10.101:

```
call leg event-log dump ftp 10.10.10.101/elogs/leg_elogs.log username myname password 0
mypass
```

Related Commands

Command	Description
call leg dump event-log	Flushes the event log buffer for call legs to an external file.
call leg event-log	Enables event logging for voice, fax, and modem call legs.
call leg event-log error-only	Restricts event logging to error events only for voice call legs.
call leg event-log max-buffer-size	Sets the maximum size of the event log buffer for each call leg.
call leg history event-log save-exception-only	Saves to history only event logs for call legs that had at least one error.
monitor call leg event-log	Displays the event log for an active call leg in real-time.
show call leg	Displays event logs and statistics for voice call legs.

call leg event-log errors-only

To restrict event logging to error events only for voice call legs, use the **call leg event-log errors-only** command in global configuration mode. To reset to the default, use the **no** form of this command.

call leg event-log errors-only

no call leg event-log errors-only

Syntax Description This command has no arguments or keywords.

Command Default All call leg events are logged.

Command Modes Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines This command limits the severity level of the events that are logged; it does not enable logging. You must use this command with the **call leg event-log** command, which enables event logging for call legs.

Examples The following example shows how to capture event logs only for call legs with errors:

```
Router(config)# call leg event-log
Router(config)# call leg event-log errors-only
```

Related Commands

Command	Description
call leg event-log	Enables event logging for voice, fax, and modem call legs.
call leg event-log dump ftp	Enables the gateway to write the contents of the call-leg event log buffer to an external file.
call leg event-log max-buffer-size	Sets the maximum size of the event log buffer for each call leg.
call leg history event-log save-exception-only	Saves to history only event logs for call legs that had at least one error.
monitor call leg event-log	Displays the event log for an active call leg in real-time.
show call leg	Displays event logs and statistics for voice call legs.

call leg event-log max-buffer-size

To set the maximum size of the event log buffer for each call leg, use the **call leg event-log max-buffer-size** command in global configuration mode. To reset to the default, use the **no** form of this command.

call leg event-log max-buffer-size *kbytes*

no call leg event-log max-buffer-size

Syntax Description

kbytes	Maximum buffer size, in kilobytes (KB). Range is 1 to 20. Default is 4.

Command Default

4 KB

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

If the event log buffer reaches the limit set by this command, the gateway allocates a second buffer of equal size. The contents of both buffers is displayed when you use the **show call leg** command. When the first event log buffer becomes full, the gateway automatically appends its contents to an external FTP location if the **call leg event-log dump ftp** command is used.

A maximum of two buffers are allocated for an event log. If both buffers are filled, the first buffer is deleted and another buffer is allocated for new events (buffer wraps around). If the **call leg event-log dump ftp** command is configured and the second buffer becomes full before the first buffer is dumped, event messages are dropped and are not recorded in the buffer.

Examples

The following example sets the maximum buffer size to 8 KB:

```
call leg event-log max-buffer-size 8
```

Related Commands

Command	Description
call leg dump event-log	Flushes the event log buffer for call legs to an external file.
call leg event-log dump ftp	Enables the voice gateway to write the contents of the call-leg event log buffer to an external file.
monitor call leg event-log	Displays the event log for an active call leg in real-time.
show call leg	Displays event logs and statistics for voice call legs.

call leg history event-log save-exception-only

To save to history only event logs for call legs that had at least one error, use the **call leg history event-log save-exception-only** command in global configuration mode. To reset to the default, use the **no** form of this command.

call leg history event-log save-exception-only

no call leg history event-log save-exception-only

Syntax Description

This command has no arguments or keywords.

Command Default

By default all the events will be logged.

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Call leg event logs move from the active to the history table after the call leg terminates. If you use this command, event logs are saved only for those legs that had errors. Event logs for normal legs that do not contain any errors are not saved.

Note This command does not affect records saved to an FTP server by using the **call leg dump event-log** command.

Examples

The following example saves to history only call leg records that have errors:

```
call leg history event-log save-exception-only
```

Related Commands

Command	Description
call leg dump event-log	Flushes the event log buffer for call legs to an external file.
call leg event-log	Enables event logging for voice, fax, and modem call legs.
call leg event-log error-only	Restricts event logging to error events only for voice call legs.
call leg event-log max-buffer-size	Sets the maximum size of the event log buffer for each call leg.
show call leg	Displays event logs and statistics for voice call legs.

callmonitor

To enable call monitoring messaging functionality on a SIP endpoint in a VoIP network, use the **callmonitor** command in voice-service configuration mode. To return to the default, use the **no** form of this command.

callmonitor

no callmonitor

Syntax Description

This command has no arguments or keywords.

Command Default

Monitoring service is disabled.

Command Modes

Voice-service configuration (config-voi-serv)

Command History

Cisco IOS Release	Modification
12.4(11)XW2	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use this command in voice service configuration mode to allow a SIP endpoint, such as an external feature server, to watch call activity on a VoIP network.

To view call activity, use the **show callmon** command.

Examples

The following example enables call monitoring messaging functionality on a SIP endpoint:

```
Router(config-voi-serv)# callmonitor
```

Related Commands

Command	Description
show callmon	Displays call-monitor information.

call preserve

To enable the preservation of H.323 VoIP calls, use the **call preserve** command in h323, voice-class h323, and voice service voip configuration modes. To reset to the default, use the **no** form of this command.

call preserve [**limit-media-detection**]

no call preserve [**limit-media-detection**]

Syntax Description

limit-media-detection	Limits RTP and RTCP inactivity detection and bidirectional silence detection (if configured) to H.323 VoIP preserved calls only.

Command Default

H.323 VoIP call preservation is disabled.

Command Modes

h323, voice-class h323, or voice service voip

Command History

Release	Modification
12.4(4)XC	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines

The **call preserve** command activates H.323 VoIP call preservation for following types of failures and connections:

Failure Types

- WAN failures that include WAN links flapping or degraded WAN links
- Cisco Unified CallManager software failure, such as when the ccm.exe service crashes on a Cisco Unified CallManager server.
- LAN connectivity failure, except when a failure occurs at the local branch

Connection Types

- Calls between two Cisco Unified CallManager controlled endpoints
  - During Cisco Unified CallManager reloads
  - When a Transmission Control Protocol (TCP) connection between one or both endpoints and Cisco Unified CallManager used for signaling H.225.0 or H.245 messages is lost or flapping
  - Between endpoints that are registered to different Cisco Unified CallManagers in a cluster and the TCP connection between the two Cisco Unified CallManagers is lost
  - Between IP phones and the PSTN at the same site
- Calls between Cisco IOS gateway and an endpoint controlled by a softswitch where the signaling (H.225.0, H.245 or both) flows between the gateway and the softswitch and media flows between the gateway and the endpoint.

  - When the softswitch reloads.
  - When the H.225.0 or H.245 TCP connection between the gateway and the softswitch is lost, and the softswitch does not clear the call on the endpoint
  - When the H.225.0 or H.245 TCP connection between softswitch and the endpoint is lost, and the soft-switch does not clear the call on the gateway
- Call flows that involve a Cisco IP in IP (IPIP) gateway running in media flow-around mode that reload or lose connection with the rest of the network

When bidirectional silence and RTP and RTCP inactivity detection are configured, they are enabled for all calls by default. To enable them for H.323 VoIP preserved calls only, you must use the **call preserve** command's **limit-media-detection** keyword.

H.323 VoIP call preservation can be applied globally to all calls and to a dial peer.

Examples

The following example enables H.323 VoIP call preservation for all calls.

```
voice service voip
 h323
  call preserve
```

The following configuration example enables H.323 VoIP call preservation for dial peer 1.

```
voice-class h323 4
 call preserve
dial-peer voice 1 voip
 voice-class h323 4
```

The following example enables H.323 VoIP call preservation and enables RTP and RTCP inactivity detection and bidirectional silence detection for preserved calls only:

```
voice service voip
 h323
  call preserve limit-media-detection
```

The following example enables RTP and RTCP inactivity detection. Note that for H.323 VoIP call preservation VAD must be set to off (**no vad** command).

```
dial-peer voice 10 voip
 no vad
gateway
 timer receive-rtcp
ip rtcp report-interval
```

The following configuration example enables bidirectional silence detection:

```
gateway
 timer media-inactive
ip rtcp report interval
```

Related Commands

Command	Description
h323	Enables the H.323 voice service configuration commands.
show h323 calls preserved	Displays data about active H.323 VoIP preserved calls.
voice-class h323	Assigns an H.323 voice class to a VoIP dial peer.
voice service voip	Enters voice-service configuration mode

call-route

To enable header-based routing, at the global configuration level, use the **call-route** command in voice service VoIP SIP configuration mode. To disable header-based routing, use the **no** form of this command.

call-route {**p-called-party-id** | **history-info**}

no call-route {**p-called-party-id** | **history-info**}

Syntax Description

p-called-party-id	Enables call routing based on the p-called-party-id header.
history-info	Enables call routing based on the history-info header.

Command Default

Support for call routing based on the header in a received INVITE message is disabled.

Command Modes

Voice service VoIP SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(22)YB	This command was introduced.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.
15.1(2)T	This keyword was modified. The **history-info** keyword was added.

Usage Guidelines

Use the **call-route** command to enable the Cisco Unified Border Element to route calls based on the P-Called-Party-ID or history-header in a received INVITE message.

Examples

The following example shows how to enable call routing based on the header value:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# call-route p-called-party-id
Router(conf-serv-sip)# call-route history-info
```

Related Commands

Command	Description
voice-class sip call-route	Enables call routing based on the p-called-party-id and history-info header values at the dial-peer configuration level.

call-router h323-annexg

To enable the Annex G border element (BE) configuration commands by invoking H.323 Annex G configuration mode, use the **call-router** command in global configuration mode. To remove the definition of a BE, use the **no** form of this command.

call-router h323-annexg *border-element-id*

no call-router h323-annexg

Syntax Description

border-element-id	Identifier of the BE that you are provisioning. Possible values are any International Alphabet 5 (IA5) string, without spaces and up to 20 characters in length. This value must match the value that you specified for the BE ID in the **border-element** command.

Command Default

No default behaviors or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

Use this command to enter Annex G configuration mode and to identify BEs.

Examples

The following example shows that Annex G configuration mode is being entered for a BE named “be20”:

```
Router(config)# call-router h323-annexg be20
```

Related Commands

Command	Description
show call history	Displays the fax call history table for a fax transmission.
show call-router status	Displays the Annex G BE status.

call-routing hunt-scheme

To enable capacity based load-balancing, use the **call-routing hunt-scheme** command in gatekeeper configuration mode. To disable this function, use the **no** form of this command.

call-routing hunt-scheme percentage-capacity-util

no call-routing hunt-scheme

Syntax Description

percentage-capacity-util	Selects the one with least percentage capacity utilized among the gateways.

Command Default

This command is disabled.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

Use the **call-routing hunt-scheme** command to turn on load balancing based on capacity of gateway and verify that the gateway capacity reporting is enabled.

Examples

The following example shows the gateway with the with least percentage capacity being selected:

```
Router(gk-config)# call-routing hunt-scheme percentage-capacity-util
```

Related Commands

Command	Description
timer cluster-element	Sets the time between resource update messages to gatekeepers in local cluster.

call rscmon update-timer

To change the value of the resource monitor throttle timer, use the **call rscmon update-timer** command in privileged EXEC mode. To revert to the default value, use the **no** form of this command.

call rscmon update-timer *milliseconds*

no call rscmon update-timer

Syntax Description

milliseconds	Duration of the resource monitor throttle timer, in milliseconds (ms). Range is from 20 to 3500. The default is 2000.

Command Default

2000 ms

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

This command specifies the duration of the resource monitor throttle timer. When events are delivered to the resource monitor process, the throttle timer is started and the event is processed after the timer expires (unless the event is a high-priority event). The timer ultimately affects the time it takes the gateway to send Resource Availability Indicator (RAI) messages to the gatekeeper. This command allows you to vary the timer according to your needs.

Examples

The following example shows how the timer is to be configured:

```
Router(config)# call rscmon update-timer 1000
```

Related Commands

Command	Description
resource threshold	Configures a gateway to report H.323 resource availability to its gatekeeper.

call rsvp-sync

To enable synchronization between Resource Reservation Protocol (RSVP) signaling and the voice signaling protocol, use the **call rsvp-sync** command in global configuration mode. To disable synchronization, use the **no** form of this command.

call rsvp-sync

no call rsvp-sync

Syntax Description

This command has no keywords or arguments.

Command Default

Synchronization is enabled between RSVP and the voice signaling protocol (for example, H.323).

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco 2600 series, 3600 series, 7200 series, Cisco AS5300, Cisco AS5800, and Cisco MC3810.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

The **call rsvp-sync** command is enabled by default.

Examples

The following example enables synchronization between RSVP and the voice signaling protocol:

```
call rsvp-sync
```

Related Commands

Command	Description
call rsvp-sync resv-timer	Sets the timer for reservation requests.
call start	Forces the H.323 Version 2 gateway to use fast connect or slow connect procedures for a dial peer.
debug call rsvp-sync events	Displays the events that occur during RSVP synchronization.
h323 call start	Forces an H.323 Version 2 gateway to use fast connect or slow connect procedures for all VoIP services.
ip rsvp bandwidth	Enables the use of RSVP on an interface.
show call rsvp-sync conf	Displays the RSVP synchronization configuration.
show call rsvp-sync stats	Displays statistics for calls that have attempted RSVP reservation.

call rsvp-sync resv-timer

To set the timer on the terminating VoIP gateway for completing RSVP reservation setups, use the **call rsvp-sync resv-timer** command in global configuration mode. To restore the default value, use the **no** form of this command.

call rsvp-sync resv-timer *seconds*

no call rsvp-sync resv-timer

Syntax Description

seconds	Number of seconds in which the reservation setup must be completed, in both directions. Range is from 1 to 60. The default is 10.

Command Default 10 seconds

Command Modes Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco AS5300, Cisco AS5800, and Cisco MC3810.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines The reservation timer is started on the terminating gateway when the session protocol receives an indication of the incoming call. This timer is not set on the originating gateway because the resource reservation is confirmed at the terminating gateway. If the reservation timer expires before the RSVP setup is complete, the outcome of the call depends on the acceptable quality of service (QoS) level configured in the dial peer; either the call proceeds without any bandwidth reservation or it is released. The timer must be set long enough to allow calls to complete but short enough to free up resources. The optimum number of seconds depends on the number of hops between the participating gateways and the delay characteristics of the network.

Examples The following example sets the reservation timer to 30 seconds:

```
call rsvp-sync resv-timer 30
```

Related Commands

Command	Description
call rsvp-sync	Enables synchronization of RSVP and the H.323 voice signaling protocol.
debug call rsvp-sync events	Displays the events that occur during RSVP synchronization.
show call rsvp-sync conf	Displays the RSVP synchronization configuration.
show call rsvp-sync stats	Displays statistics for calls that have attempted RSVP reservation.

call service stop

To shut down VoIP call service on a gateway, use the **call service stop** command in voice service SIP or voice service H.323 configuration mode. To enable VoIP call service, use the **no** form of this command. To set the command to its defaults, use the **default call service stop** command

call service stop [**forced**] [**maintain-registration**]

no call service stop

default call service stop

Syntax Description

forced	(Optional) Forces the gateway to immediately terminate all in-progress calls.
maintain-registration	(Optional) Forces the gateway to remain registered with the gatekeeper.

Command Default

VoIP call service is enabled.

Command Modes

Voice service SIP configuration (conf-serv-sip)
Voice service H.323 configuration (conf-serv-h323)

Command History

Release	Modification
12.3(1)	This command was introduced.
12.4(22)T	Support for IPv6 was added.
12.4(23.08)T01	The default behavior was clarified for SIP and H.323 protocols.

Usage Guidelines

Use the **call service stop** command to shut down the SIP or H.323 services regardless of whether the **shutdown** or **no shutdown** command was configured in voice service configuration mode.

Use the **no call service stop** command to enable SIP or H.323 services regardless of whether the **shutdown** or **no shutdown** command was configured in voice service configuration mode.

Use the **default call service stop** command to set the command to its defaults. The defaults are as follows:

- Shut down SIP or H.323 service, if the **shutdown** command was configured in voice service configuration mode.
- Enable SIP or H.323 service, if the **no shutdown** command was configured in voice service configuration mode.

Examples

The following example shows SIP call service being shut down on a Cisco gateway:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# call service stop
```

The following example shows H.323 call service being enabled on a Cisco gateway:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# no call service stop
```

The following example shows SIP call service being enabled on a Cisco gateway because the **no shutdown** command was configured in voice service configuration mode:

```
Router> enable
Router# configure terminal
Router(config)#voice service voip
Router(conf-voi-serv)# no shutdown
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# default call service stop
```

The following example shows H.323 call service being shut down on a Cisco gateway because the **shutdown** command was configured in voice configuration mode:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# shutdown
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# default call service stop
```

Related Commands

Command	Description
bandwidth audio as-modifier	Allows SIP SDP bandwidth-related options.
billing b-channel	Enables the H.323 gateway to access B-channel information for all H.323 calls.
outbound-proxy	Configures an outbound proxy server.
telephony-service ccm-compatible	Enables the detection of a Cisco CallManager system in the network and allows the exchange of calls.

call spike

To configure the limit on the number of incoming calls received in a short period of time (a call spike), use the **call spike** command in global or dial peer voice configuration mode. To disable this command, use the **no** form of this command.

call spike *call-number* [**steps** *number-of-steps* **size** *milliseconds*]

no call spike

Dial Peer Voice Configuration Mode

call spike *threshold* [**steps** *number-of-steps* **size** *milliseconds*]

Syntax Description

call-number	Incoming call count for the spiking threshold. Range is 1 to 2147483647.
steps *number-of-steps*	(Optional) Specifies the number of steps for the spiking sliding window. Range is from 3 to 10. The default is 5.steps for the spiking sliding window.
size *milliseconds*	(Optional) Specifies step size in milliseconds. Range is from 100 to 250. The default is 200.
threshold	Threshold for the incoming call count for spiking. Range is 1 to 2147483647.

Command Default

The limit on the number of incoming calls received during a specified period is not configured.

Command Modes

Global configuration (config)
Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. This release does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on Cisco 1750 and Cisco 1751 routers. Support for other Cisco platforms was not included in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on Cisco 7200 series routers. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 was not included in this release.
12.2(11)T	Support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.
15.1(3)T	This command was modified. Support for this command was added in the dial peer level.

Usage Guidelines

A call spike occurs when a large number of incoming calls arrive from the Public Switched Telephone Network (PSTN) in a short period of time (for example, 100 incoming calls in 10 milliseconds). Setting this command allows you to control the number of call requests that can be received in a configured time period. The sliding window buffers the number of calls that get through. The counter resets according to the specified step size.

The period of the sliding window is calculated by multiplying the number of steps by the size. If an incoming call exceeds the configured call number during the period of the sliding window the call is rejected.

If the **call spike** is configured at both the global and dial-peer levels, the dial-peer level takes precedence and the call spike is calculated. If the call spike threshold is exceeded the call gets rejected, and the call spike calculation is done at the global level.

Examples

The following example shows how to configure the **call spike** command with a call-number and the of 1, a sliding window of 10 steps, and a step size of 200 milliseconds. The period of the sliding window is 2 seconds. If the gateway receives more than 1 call within 2 seconds the call is rejected.

```
Router(config)# call spike 1 steps 10 size 200
```

The following example shows how to configure the **call spike** command with a call number of 30, a sliding window of 10 steps, and a step size of 2000 milliseconds:

```
Router(config)# call spike 30 steps 10 size 2000
```

The following example shows how to configure the **call spike** command in dial peer voice mode with threshold of 20, a sliding window of 7, and a step size of 2000 milliseconds:

```
Router(config)# dial-peer voice 400 voip
Router(config-dial-peer)# call spike 20 steps 7 size 2000
```

Related Commands

Command	Description
dtmf-relay (Voice over IP)	Specifies how an H.323 gateway relays DTMF tones between telephony interfaces and an IP network.
show call spike status	Displays the configuration of the threshold for incoming calls.

call start

To force an H.323 Version 2 gateway to use either fast connect or slow connect procedures for a dial peer, use the **call start** command in H.323 voice-service configuration mode. To restore the default setting, use the **no** form of this command.

call start {**fast** | **slow** | **system** | **interwork**} [**sync-rsvp slow-start**]

no call start

Syntax Description

fast	Gateway uses H.323 Version 2 (fast connect) procedures.
slow	Gateway uses H.323 Version 1 (slow connect) procedures.
system	Gateway defaults to voice-service configuration mode.
interwork	(Optional) Gateway interoperates between fast-connect and slow-connect procedures. **Note** The **interwork** keyword is applicable to IP-to-IP gateways only and supports basic audio calls Dual-tone multi-frequency (DTMF), fax, and audio transcoding calls are not supported).
sync-rsvp slow-start	(Optional) Gateway uses Resource Reservation Protocol (RSVP) synchronization for slow-start calls.

Command Default

system

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco AS5300, Cisco AS5800, and Cisco MC3810.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(2)XA	This command was changed to use the H.323 voice-service configuration mode from the voice-class configuration mode.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.
12.3(4)T	The **synch-rsvp slow-start** keywords were added.
12.3(8)T	The **interwork** keyword was added.

Usage Guidelines

In Cisco IOS Release 12.1(3)XI and later releases, H.323 VoIP gateways by default use H.323 Version 2 (fast connect) for all calls, including those initiating RSVP. Previously, gateways used only slow-connect procedures for RSVP calls. To enable Cisco IOS Release 12.1(3)XI gateways to be backward-compatible with earlier releases of Cisco IOS Release 12.1T, the **call start** command allows the originating gateway to initiate calls using slow connect.

The **call start** command is configured as part of the voice class assigned to an individual VoIP dial peer. It takes precedence over the **h323 call start** command that is enabled globally to all VoIP calls, unless the **system** keyword is used, in which case the gateway defaults to Version 2.

The **sync-rsvp slow-start keyword**, when used in H.323 voice-class configuration mode, controls RSVP synchronization for all slow-start calls handled by the gateway. When t**he sync-rsvp slow-start keyword is** used in an H.323 voice-class definition, the behavior can be specified for individual dial peers by invoking the voice class in dial-peer voice configuration mode. This command is enabled by default in some Cisco IOS images, and in this situation the **show running-config** command displays this information only when the **no** form of the command is used.

Note The **call start** command supports only H.323 to H.323 calls.

The **interwork** keyword is only used with IP-to-IP gateways connecting fast connect from one side to slow connect on the other for basic audio calls. Configure the **interwork** keyword in voice-class H.323 configuration mode or on both the incoming and outgoing dial peers. Codecs must be specified on both dial peers for interworking to function. When the **interwork** keyword is configured, codecs need to be specified on both dial-peers and the **codec transparent** command should not be configured.

Examples

The following example shows slow connect for the voice class 1000 being selected:

```
voice service class h323 1000
 call start slow
!
dial-peer voice 210 voip
 voice-class h323 1000
```

The following example shows the gateway configured to use the H.323 Version 1 (slow connect) procedures:

```
h323
 call start slow
```

Related Commands

Command	Description
acc-qos	Selects the acceptable quality of service for a dial peer.
call rsvp-sync	Enables synchronization between RSVP and the H.323 voice signaling protocol.
call rsvp-sync resv-timer	Sets the timer for RSVP reservation setup.
codec transparent	Enables codec capabilities to be passed transparently between endpoints in a Cisco IPIPGW.
debug call rsvp-sync events	Displays the events that occur during RSVP synchronization.
h323	Enables H.323 voice service configuration commands.
req-qos	Selects the desired quality of service to use in reaching a dial peer.

show call rsvp-sync conf	Displays the RSVP synchronization configuration.
show call rsvp-sync stats	Displays statistics for calls that attempted RSVP reservation.
show running-config	Displays the contents of the currently running configuration file.
voice class h323	Enters voice-class configuration mode and creates a voice class for H.323 attributes.

call threshold global

To enable the global resources of a gateway, use the **call threshold global** command in global configuration mode. To disable the global resources of the gateway, use the **no** form of this command.

call threshold global *trigger-name* **low** *percent* **high** *percent* [**busyout**] [**treatment**]

no call threshold global *trigger-name*

Syntax Description

trigger-name	Specifies the global resources on the gateway. The *trigger-name* argument can be one of the following: • **cpu-5sec**—CPU utilization in the last 5 seconds. • **cpu-avg**—Average CPU utilization. • **io-mem**—I/O memory utilization. • **proc-mem**—Processor memory utilization. • **total-calls**—Total number of calls. • **total-mem**—Total memory utilization.
low *percent*	Value of low threshold: Range is from 1 to 100% for the utilization triggers; 1 to 10000 calls for the **total-calls.**
high *percent*	Value of high threshold: Range is from 1 to 100% for the utilization triggers; 1 to 10000 calls for the **total-calls**.
busyout	(Optional) Busy out the T1/E1 channels if the resource is not available.
treatment	(Optional) Applies call treatment from the session application if the resource is not available.

Command Default

The default is **busyout** and **treatment** for global resource triggers.

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751 routers. Support for other Cisco platforms is not included in this release

Release	Modification
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on Cisco 7200 series routers. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800 in this release.

Usage Guidelines

Use this command to enable a trigger and define associated parameters to allow or disallow new calls on the router. Action is enabled when the trigger value goes above the value specified by the **high** keyword and is disabled when the trigger drops below the value specified by the **low** keyword.

You can configure these triggers to calculate Resource Availability Indicator (RAI) information. An RAI is forwarded to a gatekeeper so that it can make call admission decisions. You can configure a trigger that is global to a router or is specific to an interface.

Examples

The following example shows how to busy out the total calls when a low of 5 or a high of 5000 is reached:

```
call threshold global total-calls low 5 high 5000 busyout
```

The following example shows how to busy out the average CPU utilization if a low of 5 percent or a high of 65 percent is reached:

```
call threshold global cpu-avg low 5 high 65 busyout
```

Related Commands

Command	Description
call threshold (interface)	Enables interface resources of a gateway.
call threshold poll-interval	Enables a polling interval threshold for CPU or memory.
clear call threshold	Clears enabled triggers and their associated parameters.
show call threshold	Displays enabled triggers, current values for configured triggers, and number of API calls that were made to global and interface resources.

call threshold interface

To enable the interface resources of a gateway, use the **call threshold interface** command in global configuration mode. To disable the interface resources of the gateway, use the **no** form of this command.

call threshold interface *name number* **int-calls low** *value* **high** *value*

no call threshold interface *name number* **int-calls**

Syntax Description

name	Specifies the interface name.
number	Number of calls through the interface.
int-calls	Number of calls transmitted through the interface.
low *value*	Low threshold number of calls allowed: Range is 1 to 10000 calls.
high *value*	High threshold numer of calls allowed: Range is 1 to 10000 calls.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751 routers. This command does not support any other Cisco platforms in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series routers. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.

Usage Guidelines

Use this command to specify thresholds that allow or disallow new calls on the router.

Examples

The following example enables thresholds as low as 5 and as high as 2500 for interface calls on interface Ethernet interface 0/1:

```
call threshold interface Ethernet 0/1 int-calls low 5 high 2500
```

Related Commands

Command	Description
call threshold (global)	Enables global resources of a gateway.
call threshold poll-interval	Enables a polling interval threshold for CPU or memory.
clear call threshold	Clears enabled triggers and their associated parameters.
show call threshold	Displays enabled triggers, current values for configured triggers, and number of API calls that were made to global and interface resources.

call threshold poll-interval

To enable a polling interval threshold for assessing CPU or memory thresholds, use the **call threshold poll-interval** command in global configuration mode. To disable this command, use the **no** form of this command.

call threshold poll-interval {**cpu-average** | **memory**} *seconds*

no call threshold poll-interval {**cpu-average** | **memory**}

Syntax Description

cpu-average	The CPU average interval, in seconds. The default is 60.
memory	The average polling interval for the memory, in seconds. The default is 5.
seconds	Window of polling interval, in seconds. Range is from 10 to 300 for the CPU average interval, and from 1 to 60 for the memory average polling interval.

Command Default

cpu-average: 60 seconds
memory: 5 seconds

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on Cisco 1750 and Cisco 1751 routers. This release does not support any other Cisco platforms in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series routers. This release does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Examples

The following example shows how to specify that memory thresholds be polled every 10 seconds:

```
call threshold poll-interval memory 10
```

Related Commands

Command	Description
call threshold	Enables the global resources of the gateway.
clear call threshold	Clears enabled triggers and their associated parameters.
show call threshold	Displays enabled triggers, current values for configured triggers, and number of API calls that were made to global and interface resources.

call treatment action

To configure the action that the router takes when local resources are unavailable, use the **call treatment action** command in global configuration mode. To disable call treatment action, use the **no** form of this command.

call treatment action{**hairpin** | **playmsg** *url* | **reject**}

no call treatment action

Syntax Description

hairpin	Hairpins the calls through the POTS dial peer. **Note** The **hairpin** keyword is not available on Cisco 1750 and Cisco 1751 routers.
playmsg	Plays a specified message to the caller.
url	Specifies the URL of the audio file to play.
reject	Disconnects the call and pass-down cause code.

Command Default

No treatment is applied.

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751 routers. This command does not support any other Cisco platforms in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series routers. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. Support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Usage Guidelines

Use this command to define parameters to disconnect (with cause code), or hairpin, or whether a message or busy tone is played to the user.

Examples

The following example shows how to enable the call treatment feature with a “hairpin” action:

```
call treatment on
call treatment action hairpin
```

The following example shows how to enable the call treatment feature with a “playmsg” action. The file “congestion.au” plays to the caller when local resources are not available to handle the call.

```
call treatment on
call treatment action playmsg tftp://keyer/prompts/conjestion.au
```

Related Commands

Command	Description
call threshold	Clears enabled triggers and their associated parameters.
call treatment on	Enables call treatment to process calls when local resources are unavailable.
clear call treatment stats	Clears the call treatment statistics.
show call treatment	Displays the call treatment configuration and statistics for handling calls on the basis of resource availability.

call treatment cause-code

To specify the reason for the disconnection to the caller when local resources are unavailable, use the **call treatment cause-code** command in global configuration mode. To disable the call treatment cause-code specification, use the **no** form of this command.

call treatment cause-code {**busy** | **no-QoS** | **no-resource**}

no call treatment cause-code

Syntax Description

busy	Indicates that the gateway is busy.
no-QoS	Indicates that the gateway cannot provide quality of service (QoS).
no-resource	Indicates that the gateway has no resources available.

Command Default Disconnect reason is not specified to the caller.

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751 routers. This command does not support any other Cisco platforms in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series routers. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. Support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Usage Guidelines Use this command to associate a cause-code with a disconnect event.

Examples The following example shows how to configure a call treatment cause code to reply with “no-Qos” when local resources are unavailable to process a call:

```
call treatment on
call treatment cause-code no-Qos
```

Related Commands

Command	Description
call threshold	Clears enabled triggers and their associated parameters.
call treatment on	Enables call treatment to process calls when local resources are unavailable.
clear call treatment stats	Clears the call treatment statistics.
show call treatment	Displays the call treatment configuration and statistics for handling calls on the basis of resource availability.

call treatment isdn-reject

To specify the rejection cause code for ISDN calls when all ISDN trunks are busied out and the switch ignores the busyout trunks and still sends ISDN calls into the gateway, use the **call treatment isdn-reject** command in global configuration mode. To disable call treatment, use the **no** form of this command.

call treatment isdn-reject *cause-code*

no call treatment isdn-reject

Syntax Description

cause-code	Selects the ISDN reject cause code. Valid entries are as follows:	
	Code	**Description**
	34	No circuit/channel available—The connection cannot be established because no appropriate channel is available to take the call.
	38	Network out of order—The destination cannot be reached because the network is not functioning correctly, and the condition might last for an extended period of time. An immediate reconnect attempt will probably be unsuccessful.
	41	Temporary failure—An error occurred because the network is not functioning correctly. The problem will be resolved shortly.
	42	Switching equipment congestion—The destination cannot be reached because the network switching equipment is temporarily overloaded.
	43	Access information discarded—Discarded information element identifier. The network cannot provide the requested access information.
	44	Requested circuit/channel not available—The remote equipment cannot provide the requested channel for an unknown reason. This might be a temporary problem.
	47	Resources unavailable, unspecified—The requested channel or service is unavailable for an unknown reason. This might be a temporary problem.

Command Default No value is specified.

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Release	Modification
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751 routers. This command does not support any other Cisco platforms in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series routers. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Usage Guidelines

Use this command only when all ISDN trunks are busied out and the switch ignores the busyout trunks and still sends ISDN calls into the gateway. The gateway should reject the call in the ISDN stack using the configured cause code.

Under any other conditions, the command has no effect.

Examples

The following example shows how to configure the call treatment to reply to an ISDN call with an ISDN rejection code for “temporary failure” when local resources are unavailable to process a call:

```
call treatment on
call treatment isdn-reject 41
```

Related Commands

Command	Description
call threshold	Clears enabled triggers and their associated parameters.
call treatment on	Enables call treatment to process calls when local resources are unavailable.
clear call treatment stats	Clears the call treatment statistics.
show call treatment	Displays the call treatment configuration and statistics for handling calls on the basis of resource availability.

call treatment on

To enable call treatment to process calls when local resources are unavailable, use the **call treatment on** command in global configuration mode. To disable call treatment, use the **no** form of this command.

call treatment on

no call treatment on

Syntax Description This command has no arguments or keywords.

Command Default Treatment is inactive.

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on the Cisco 1750 and Cisco 1751 routers. This command does not support any other Cisco platforms in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series routers. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. Support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Usage Guidelines Use this command to enable a trigger and define associated parameters to disconnect (with cause code), or hairpin, or whether a message or busy tone is played to the user.

Examples The following example shows how to enable the call treatment feature with a “hairpin” action:

```
call treatment on
call treatment action hairpin
```

The following example shows how to enable the call treatment feature with a “playmsg” action. The file “congestion.au” plays to the caller when local resources are not available to handle the call.

```
call treatment on
call treatment action playmsg tftp://keyer/prompts/conjestion.au
```

The following example shows how to configure a call treatment cause code to reply with “no-QoS” when local resources are unavailable to process a call:

```
call treatment on
call treatment cause-code no-QoS
```

Related Commands

Command	Description
call threshold	Clears enabled triggers and their associated parameters.
call treatment action	Configures the action that the router takes when local resources are unavailable.
call treatment cause-code	Specifies the reason for the disconnection to the caller when local resources are unavailable.
call treatment isdn-reject	Specifies the rejection cause-code for ISDN calls when local resources are unavailable.
clear call treatment stats	Clears the call treatment statistics.
show call treatment	Displays the call treatment configuration and statistics for handling calls on the basis of resource availability.

call-waiting

To enable call waiting, use the **call-waiting** command in interface configuration mode. To disable call waiting, use the **no** form of this command.

call-waiting

no call-waiting

Syntax Description This command has no arguments or keywords.

Command Default Call waiting is enabled.

Command Modes Interface configuration

Command History

Release	Modification
12.0(3)T	This command was introduced on the Cisco 800 series.

Usage Guidelines This command is applicable to Cisco 800 series routers.

You must specify this command when creating a dial peer. This command does not work if it is not specified within the context of a dial peer. For information on creating a dial peer, refer to the *Cisco 800 Series Routers Software Configuration Guide*.

Examples The following example disables call waiting:

```
no call-waiting
```

Related Commands

Command	Description
destination-pattern	Specifies either the prefix, the full E.164 telephone number, or an ISDN directory number (depending on the dial plan) to be used for a dial peer.
dial peer voice	Enters dial peer configuration mode, defines the type of dial peer, and defines the tag number associated with a dial peer.
port (dial peer)	Enables an interface on a PA-4R-DTR port adapter to operate as a concentrator port.
ring	Sets up a distinctive ring for telephones, fax machines, or modems connected to a Cisco 800 series router.
show dial peer voice	Displays configuration information and call statistics for dial peers.

called-number (dial peer)

To enable an incoming Voice over Frame Relay (VoFR) call leg to get bridged to the correct plain old telephone service (POTS) call leg when a static FRF.11 trunk connection is used, use the **called-number** command in dial peer configuration mode. To disable a static trunk connection, use the **no** form of this command.

called-number *string*

no called-number

Syntax Description

string	A string of digits, including wildcards, that specifies the telephone number of the voice port dial peer.

Command Default This command is disabled.

Command Modes Dial peer configuration

Command History

Release	Modification
12.0(4)T	This command was introduced on the Cisco 2600 series and Cisco 3600 series.

Usage Guidelines The **called-number** command is used only when the dial peer type is VoFR and you are using the frf11-trunk (FRF.11) session protocol. It is ignored at all times on all other platforms using the Cisco-switched session protocol.

Because FRF.11 does not provide any end-to-end messaging to manage a trunk, the **called-number** command is necessary to allow the router to establish an incoming trunk connection. The E.164 number is used to find a matching dial peer during call setup.

Examples The following example shows how to configure a static FRF.11 trunk connection to a specific telephone number (555-0150), beginning in global configuration mode:

```
voice-port 1/0/0
 connection trunk 55Router0
 exit

dial-peer voice 100 pots
 destination pattern 5550150
 exit

dial-peer voice 200 vofr
 session protocol frf11-trunk
 called-number 5550150
 destination pattern 55Router0
```

Related Commands

Command	Description
codec (dial peer)	Specifies the voice coder rate of speech for a VoFR dial peer.
connection	Specifies a connection mode for a voice port.
destination-pattern	Specifies either the prefix, the full E.164 telephone number, or an ISDN directory number (depending on the dial plan) to be used for a dial peer.
dtmf-relay (VoFR)	Enables the generation of FRF.11 Annex A frames for a dial peer.
fax-rate	Establishes the rate at which a fax is sent to the specified dial peer.
preference	Indicates the preferred order of a dial peer within a rotary hunt group.
session protocol	Establishes a session protocol for calls between the local and remote routers via the packet network.
session target	Specifies a network-specific address for a specified dial peer or destination gatekeeper.
signal-type	Sets the signaling type to be used when connecting to a dial peer.
vad (dial peer)	Enables VAD for the calls using a particular dial peer.

caller-id (dial peer)

To enable caller ID, use the **caller-id** command in dial peer configuration mode. To disable caller ID, use the **no** form of the command.

caller-id

no caller-id

Syntax Description This command contains no arguments or keywords.

Command Default Caller ID is disabled

Command Modes Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.1.(2)XF	This command was introduced on the Cisco 800 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.

Usage Guidelines This command is available on Cisco 800 series routers that have plain old telephone service (POTS) ports. The command is effective only if you subscribe to caller ID service. If you enable caller ID on a router without subscribing to the caller ID service, caller ID information does not appear on the telephone display.

The configuration of caller ID must match the device connected to the POTS port. That is, if a telephone supports the caller ID feature, use the **caller-id** command to enable the feature. If the telephone does not support the caller ID feature, use the command default or disable the caller ID feature. Odd ringing behavior might occur if the caller ID feature is disabled when it is a supported telephone feature or enabled when it is not a supported telephone feature.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on Cisco.com.

Examples The following example enables a router to use the caller ID feature:

```
dial-peer voice 1 pots
 caller-id
```

Related Commands

Command	Description
block-caller	Configures call blocking on caller ID.
debug pots csm csm	Activates events from which an application can determine and display the status and progress of calls to and from POTS ports.
isdn i-number	Configures several terminal devices to use one subscriber line.
pots call-waiting	Enables local call waiting on a router.
registered-caller ring	Configures the Nariwake service-registered caller ring cadence.

caller-id alerting dsp-pre-alloc

To statically allocate a digital signal processor (DSP) resource for receiving caller ID information for on-hook (Type 1) caller ID at a receiving Foreign Exchange Office (FXO) voice port, use the **caller-id alerting dsp-pre-alloc** command in voice-port configuration mode. To disable the command's effect, use the **no** form of this command.

caller-id alerting dsp-pre-alloc

no caller-id alerting dsp-pre-alloc

Syntax Description

This command contains no arguments or keywords.

Command Default

No preallocation of DSP resources

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced on the Cisco MC3810, Cisco 2600 series, and Cisco 3600 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

The **caller-id alerting dsp-pre-alloc** command may be required on an FXO port if the central office uses line polarity reversal to signal the start of caller-ID information transmission. Preallocating a DSP allows the DSP to listen for caller-ID information continuously without requiring an alerting signal from the central office (CO).

This command is the FXO counterpart to the **caller-id alerting line-reversal** command, which is applied to the Foreign Exchange Station (sending) end of the caller-ID call.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on Cisco.com.

Examples

The following example configures a voice port where caller-ID information is received:

```
voice-port 1/0/1
  cptone US
  caller-id enable
  caller-id alerting line-reversal
  caller-id alerting dsp-pre-alloc
```

Related Commands

Command	Description
caller-id alerting line-reversal	Sets the line-reversal method of caller-ID call alerting.

caller-id alerting line-reversal

To set the line-reversal alerting method for caller-ID information for on-hook (Type 1) caller ID at a sending Foreign Exchange Station (FXS) voice port, use the **caller-id alerting line-reversal** command in voice-port configuration mode. To disable the command's effect, use the **no** form of this command.

caller-id alerting line-reversal

no caller-id alerting line-reversal

Syntax Description This command has no arguments or keywords.

Command Default No line-reversal alert

Command Modes Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines This command is required only when the telephone device attached to an FXS port requires the line-reversal method to signal the start of a caller-ID transmission. Use it on FXS voice ports that send caller-ID information.

This command is the FXS counterpart to the **caller-id alerting dsp-pre-alloc** command, which is applied to the FXO (receiving) end of the caller-ID call with the line-reversal alerting method.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on Cisco.com.

Examples The following example configures a voice port from which caller-ID information is sent:

```
voice-port 1/0/1
   cptone US
   station name  A. sample
   station number 4085550111
   caller-id alerting line-reversal
   caller-id alerting dsp-pre-alloc
```

Related Commands

Command	Description
caller-id alerting dsp-pre-alloc	At the receiving end of a line-reversal alerting caller-ID call, preallocates DSPs for caller ID calls.

caller-id alerting pre-ring

To set a 250-millisecond prering alerting method for caller ID information for on-hook (Type 1) caller ID at a sending Foreign Exchange Station (FXS) voice port, use the **caller-id alerting pre-ring** command in voice-port configuration mode. To disable the command, use the **no** form of this command.

caller-id alerting pre-ring

no caller-id alerting pre-ring

Syntax Description

This command has no arguments or keywords.

Defaults

No prering alert

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced on the Cisco MC3810, Cisco 2600 series, and Cisco 3600 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

This command is required only when the telephone device attached to an FXS port requires the prering (immediate ring) method to signal the start of caller ID transmission. Use it on FXS voice ports that send caller ID information. This command allows the FXS port to send a short prering preceding the normal ring cadence. On an FXO port, an incoming prering (immediate ring) is simply counted as a normal ring using the **caller-id alerting ring** command.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on Cisco.com.

Examples

The following example configures a voice port from which caller ID information is sent:

```
voice-port 1/0/1
   cptone US
   station name  A. sample
   station number 4085550111
   caller-id alerting pre-ring
```

Related Commands

Command	Description
caller-id alerting line-reversal	Enables caller ID operation and sets the line-reversal alerting type at an FXS port.
caller-id alerting ring	Enables caller ID operation and sets an alerting ring type at an FXO or FXS port.

caller-id alerting ring

To set the ring-cycle method for receiving caller ID information for on-hook (Type 1) caller ID at a receiving Foreign Exchange Office (FXO) or a sending Foreign Exchange Station (FXS) voice port, use the **caller-id alerting ring** command in voice-port configuration mode. To set the command to the default, use the **no** form of this command.

caller-id alerting ring {**1** | **2**}

no caller-id alerting ring

Syntax Description

1	Use this setting if your telephone service provider specifies it to provide caller ID alerting (display) after the first ring at the receiving station. This is the most common setting.
2	Use this setting if your telephone service provider specifies it to provide caller ID alerting (display) after the second ring. This setting is used in Australia, where the caller ID information is sent following two short rings (double-pulse ring).

Command Default

1

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

This setting is determined by the Bellcore/Telcordia or ETSI standard that your telephone service provider uses for caller ID. Use it on FXO loop-start and ground-start voice ports where caller ID information arrives and on FXS voice ports from which caller ID information is sent.

This setting must match on the sending and receiving ends of the telephone line connection.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on line.

Examples

The following example configures a voice port where caller ID information is received:

```
voice-port 1/0/1
   cptone US
   caller-id alerting ring 1
```

The following example configures a voice port from which caller ID information is sent:

```
voice-port 1/0/1
   cptone northamerica
   station name A. sample
   station number 4085550111
   caller-id alerting ring 1
```

Related Commands

Command	Description
caller-id alerting line-reversal	Enables caller ID operation and sets the line-reversal alerting type at an FXS port.
caller-id alerting pre-ring	Enables caller ID operation and sets the pre-ring alerting method at an FXS port.

caller-id attenuation

To set the attenuation for caller ID at a receiving Foreign Exchange Office (FXO) voice port, use the **caller-id attenuation** command in voice-port configuration mode. To set the command to the default, use the **no** form of this command.

caller-id attenuation [*attenuation*]

no caller-id attenuation

Syntax Description

attenuation	(Optional) specifies the attenuation, in decibels (dB). Range is from 0 to 64. The default is 14.

Command Default

The default value is 14 dB, signal level of –14 dBm.

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

Use this setting to specify the attenuation for a caller ID FXO port. If the setting is not used, the attenuation is set to 14 dB, signal level of –14 dBm.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on line.

Examples

The following example configures a voice port where caller ID information is received:

```
voice-port 1/0/1
   cptone US
   caller-id attenuation 0
```

caller-id block

To request the blocking of the display of caller ID information at the far end of a call from calls originated at a Foreign Exchange Station (FXS) port, use the **caller-id block** command in voice-port configuration mode at the originating FXS voice port. To allow the display of caller ID information, use the **no** form of this command.

caller-id block

no caller-id block

Syntax Description

This command has no arguments or keywords.

Command Default

No blocking of caller ID information

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

This command is used on FXS voice ports that are used to originate on-net telephone calls. This command affects all calls sent to a far-end FXS station from the configured originating FXS station. Calling number and called number are provided in the H.225 setup message for VoIP, through the H.225 Octet 3A field. Calling name information is included in a display information element.

Note Cisco-switched calls using Voice over Frame Relay (VoFR) and Voice over ATM (VoATM) carry calling party information in the Cisco proprietary setup message. For standards-based, point-to-point VoFR (FRF.11) trunks where transparent signaling is applied for FXS-to-FXO calls, only pass-through of in-band automatic number identification (ANI) is supported. ANI information is always unblocked for these communications. Interface technology using transparent channel-associated signaling (CAS) can support only ANI through Feature Group D (in-band MF signaling). The Caller ID feature cannot be used with fixed point-to-point trunk connects created using the **connection trunk** command.

Note Specific hardware is required to provide full support for the caller ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on Cisco.com.

Examples

The following example configures a voice port from which caller ID information is sent:

```
voice-port 1/0/1
   cptone US
   station name A. sample
   station number 4085550111
   caller-id block
```

Related Commands

Command	Description
caller-id enable	Enables caller ID operation.

caller-id block (voice register template)

Note Effective with Cisco IOS Release 12.4(11)XJ, the **caller-id block (voice register template)** command is not available in Cisco IOS software.

To enable caller-ID blocking for outbound calls from a specific SIP phone, use the **caller-id block** command in voice register template configuration mode. To disable caller-ID blocking, use the **no** form of this command.

caller-id block

no caller-id block

Syntax Description

This command has no arguments or keywords.

Command Default

Caller ID blocking is disabled.

Command Modes

Voice register template configuration (config-register-temp)

Command History

Cisco IOS Release	Cisco Product	Modification
12.4(4)T	Cisco CME 3.4	This command was introduced.
12.4(11)XJ	Cisco Unified CME 4.1	This command was removed.
12.4(15)T	Cisco Unified CME 4.1	This command was removed in Cisco IOS Release 12.4(15)T.

Usage Guidelines

This command sets caller-ID blocking for outbound calls originating from any SIP phone that uses the specified template. This command requests the far-end gateway device to block the display of the calling party information for calls received from the specified SIP phone. This command does not affect the calling party information displayed for inbound calls received by the SIP phone. To apply a template to a SIP phone, use the **template** command in voice register pool configuration mode.

Examples

The following example shows how to enable caller-ID blocking in template 1:

```
Router(config)# voice register template 1
Router(config-register-temp)# caller-id block
```

Related Commands

Command	Description
anonymous block (voice register template)	Enables anonymous call blocking in a SIP phone template.
template (voice register pool)	Applies a template to a SIP phone.
voice register template	Enters voice register template configuration mode and defines a template of common parameters for SIP phones.

caller-id enable

To allow the sending or receiving of caller-ID information, use the **caller-id enable** command in voice-port configuration mode at the sending foreign exchange station (FXS) voice port or the receiving foreign exchange office (FXO) voice port. To disable the sending and receiving of caller-ID information, use the **no** form of this command.

caller-id enable [**type** {**1** | **2**}]

no caller-id enable [**type** {**1** | **2**}]

Syntax Description

type	(Optional) Indicates that the following keyword is a caller-ID type. • **1**—Type I only. Type I transmits the signal when the receiving phone is on hook. • **2**—Type II only. Type II transmits the signal when the receiving phone is off hook, for instance to display the caller ID of an incoming call when the receiving phone is busy (call-waiting caller ID).

Command Default

The sending and receiving of caller-ID information is disabled.

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.
12.3(7)T	The **type 1** and **type 2** keywords were added.

Usage Guidelines

This command applies to FXS voice ports that send caller-ID information and to FXO ports that receive caller-ID information. Calling number and called number are provided in the H.225.0 setup message for VoIP through the H.225.0 Octet 3A field. Calling name information is included in a display information element.

Some users that do not have caller ID type II support on their phones hear noise when type II caller ID is enabled. The **caller-id enable type 1** command allows only type I on the voice port and disables type II, so that the user does not hear this noise.

If this command is used without the optional **type** keyword, both type I and type II caller ID are enabled.

Note The **no** form of this command also clears all other caller-ID configuration settings for the voice port.

Note Cisco-switched calls using Voice over Frame Relay (VoFR) and Voice over ATM (VoATM) carry calling-party information in the Cisco-proprietary setup message. For standards-based, point-to-point VoFR (FRF.11) trunks where transparent signaling is applied for FXS-to-FXO calls, only pass-through of in-band automatic number identification (ANI) is supported. ANI information is always unblocked for these communications. Interface technology using transparent channel-associated signaling (CAS) can support only ANI through Feature Group D (in-band multifrequency signaling). Caller ID cannot be used with fixed point-to-point trunk connections created using the **connection trunk** command.

If the **station name, station number**, or a **caller-id alerting** command is configured on the voice port, caller ID is automatically enabled, and the **caller-id enable** command is not necessary.

Note Specific hardware is required to provide full support for the caller-ID features. To determine support for these features in your configuration, review the appropriate hardware documentation and data sheets. This information is available on line.

Examples

The following example configures a Cisco 2600 series or Cisco 3600 series router voice port at which caller-ID information is received:

```
voice-port 1/0/1
 cptone US
 caller-id enable
```

The following example configures a Cisco 2600 series or Cisco 3600 series router voice port from which caller-ID information is sent:

```
voice-port 1/0/1
 cptone northamerica
 station name A. sample
 station number 4085550111
 caller-id enable
```

The following example enables only type I caller ID on port 2/0:

```
voice-port 2/0
 caller-id enable type 1
```

Related Commands

Command	Description
caller-id alerting line-reversal	Enables caller ID operation and sets the line-reversal alerting type at an FXS port.
caller-id alerting pre-ring	Enables caller ID operation and sets the pre-ring alerting method at an FXS port.
caller-id alerting ring	Enables caller ID operation and sets an alerting ring type at an FXO or FXS port.
caller-id block	Disables the sending of caller ID information from an FXS port.
station name	Enables caller ID operation and sets the name sent from an FXS port.
station number	Enables caller ID operation and sets the number sent from an FXS port.

caller-number (dial peer)

To associate a type of ring cadence with a specific caller ID, use the **caller-number** command in dial peer voice configuration mode. To disable the type of ring cadence for a specific caller ID, use the **no** form of this command.

caller-number *number* **ring** *cadence*

no caller-number *number* **ring** *cadence*

Syntax Description

number	Caller ID for which the user wants to set the cadence. Twenty numbers along with their respective cadences may be set for each of the plain old telephone service (POTS) ports.
ring *cadence*	Ring cadence level. The three cadence levels (0, 1, and 2), which differ in duration and cadence, are as follows: • **0**—The ring cadence is 1 second on and 2 seconds off (NTT-defined regular ring). • **1**—The ring cadence is 0.25 seconds on, 0.2 seconds off, 0.25 seconds on, and 2.3 seconds off (NTT-defined nonregular ring). • **2**—The ring cadence is 0.5 seconds on, 0.25 seconds off, 0.25 seconds on, and 2 seconds off (Cisco-defined nonregular ring).

Command Default

The router does not associate any caller ID with a cadence level. Therefore, there is no distinctive ring.

Command Modes

Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.2(8)T	This command was introduced on the Cisco 803, Cisco 804, and Cisco 813 routers.

Usage Guidelines

You can enter the **caller-number** command for each POTS port. A maximum of 20 caller IDs can be associated with distinct ring cadences. After 20 numbers per port have been set, you cannot set more numbers (and their ring cadences) for that port until you have removed any of the numbers that have already been set. To remove already-set numbers and their ring cadences, use the **no** form of the **caller-number** command.

The command must be set within each dial peer. Six dial peers are available, you can specify 20 caller IDs per port, for a maximum of 120 caller ID numbers.

Note If you have already subscribed to Nariwake service, the priority goes to the Nariwake caller ID cadence.

To disable distinctive ringing based on a caller ID number, configure the **no caller-number** command. Disabling the ringing removes the specific cadence that has been set for that particular number. If you have set 20 numbers and their ring cadences, you need to set the **no caller-number** command for each of the 20 numbers.

Use the **show running-config** command to check distinctive ringing status.

Examples

The following output examples show that three caller ID numbers and their ring cadences have been set for POTS port 1 and that five caller ID numbers and their ring cadences have been set for POTS port 2:

```
dial-peer voice 1 pots
 destination-pattern 5550102
 port 1
 no call-waiting
 ring 0
 volume 4
 caller-number 1111111 ring 2
 caller-number 2222222 ring 1
 caller-number 3333333 ring 1

dial-peer voice 2 pots
 destination-pattern 5550110
 port 2
 no call-waiting
 ring 0
 volume 2
 caller-number 4444444 ring 1
 caller-number 6666666 ring 2
 caller-number 7777777 ring 0
 caller-number 8888888 ring 1
 caller-number 9999999 ring 2
```

Related Commands

Command	Description
call-waiting	Enables call waiting.
volume	Configures the receiver volume level in the router.

calling-info pstn-to-sip

To specify calling information treatment for public switched telephone network (PSTN) to Session Initiation Protocol (SIP) calls, use the **calling-info pstn-to-sip** command in SIP user agent configuration mode. To disable calling information treatment for PSTN-to-SIP calls, use the **no** form of this command.

calling-info pstn-to-sip {**unscreened discard** | {**from** | **remote-party-id** | **asserted-id** {**name set** *name* | **number set** *number*}}}

no calling-info pstn-to-sip

Syntax Description

unscreened discard	(Optional) Specifies that the calling name and number be discarded.
from name set *name*	(Optional) Specifies that the display-name of the From header is unconditionally set to the configured ASCII string in the forwarded INVITE message.
from number set *number*	(Optional) Specifies that the user part of the From header is unconditionally set to the configured ASCII string in the forwarded INVITE message.
remote-party-id name set *name*	(Optional) Specifies that the display-name of the Remote-Party-ID header is unconditionally set to the configured ASCII string in the forwarded INVITE message.
remote-party-id number set *number*	(Optional) Specifies that the user part of the Remote-Party-ID header is unconditionally set to the configured ASCII string in the forwarded INVITE message.
asserted-id name set *name*	(Optional) Specifies that the display-name in the Asserted-ID header is unconditionally set to the configured ASCII string in the forwarded INVITE message.
asserted-id number set *number*	(Optional) Specifies that the user part in the Asserted-ID header is unconditionally set to the configured ASCII string in the forwarded INVITE message.

Command Default

This command is disabled.

Command Modes

SIP UA configuration (config-sip-ua)

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.4(15)T	The **asserted-id** keyword was added.

Usage Guidelines

When a call exits the gateway, the **calling-info pstn-to-sip** treatments are applied.

Examples

The following example enables calling information treatment for PSTN-to-SIP calls and sets the company name and number:

```
Router(config-sip-ua)# calling-info pstn-to-sip from name set CompanyA
Router(config-sip-ua)# calling-info pstn-to-sip from number set 5550101
Router(config-sip-ua)# exit
Router(config)# exit

Router# show running-config
Building configuration...

.
.
.
!
sip-ua
 calling-info pstn-to-sip from name set CompanyA
 calling-info pstn-to-sip from number set 5550101
 no remote-party-id
!
.
.
.
```

Related Commands

Command	Description
asserted-id	Sets the privacy level and enables either P-Asserted-Identity (PAI) or P-Preferred-Identity (PPI) privacy headers in outgoing SIP requests or response messages.
calling-info sip-to-pstn	Specifies calling information treatment for SIP-to-PSTN calls.
debug ccsip events	Enables tracing of SIP SPI events.
debug ccsip messages	Enables tracing SIP messages exchanged between the SIP UA client and the access server.
debug isdn q931	Displays call setup and teardown of ISDN connections.
debug voice ccapi error	Enables tracing error logs in the call control API.
debug voip ccapi in out	Enables tracing the execution path through the call control API.

calling-info sip-to-pstn

To specify calling information treatment for Session Initiation Protocol (SIP) to public switched telephone network (PSTN) calls, use the **calling-info sip-to-pstn** command in SIP user agent configuration mode. To disable calling information treatment for SIP-to-PSTN calls, use the **no** form of this command.

calling-info sip-to-pstn {**unscreened discard** | **name set** *name* | **number set** *number*}

no calling-info sip-to-pstn

Syntax Description

unscreened *discard*	(Optional) Specifies that the calling name and number be discarded.
name set *name*	(Optional) Specifies that the calling name be unconditionally set to the configured ASCII string in the forwarded Setup mesage.
number set *number*	(Optional) Specifies that the calling number be unconditionally set to the configured ASCII string in the forwarded Setup message.

Command Default

This command is disabled.

Command Modes

SIP user agent configuration (config-sip-ua)

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

When a call enters the gateway, the **calling-info sip-to-pstn** treatments are applied.

Examples

The following example enables calling information treatment for SIP-to-PSTN calls and sets the company name to CompanyA and the number to 5550100:

```
Router(config-sip-ua)# calling-info sip-to-pstn name set CompanyA
Router(config-sip-ua)# calling-info sip-to-pstn number set 5550100
Router(config-sip-ua)# exit
Router(config)# exit
```

```
Router# show running-config
Building configuration...

.
.
.
!
sip-ua
 calling-info sip-to-pstn name set CompanyA
     calling-info sip-to-pstn number set 5550100
!
.
.
.
```

Related Commands

Command	Description
debug ccsip events	Enables tracing of SIP SPI events.
debug ccsip messages	Enables SIP SPI message tracing.
debug isdn q931	Displays call setup and teardown of ISDN connections.
debug voip ccapi in out	Enables tracing the execution path through the call control API.
calling-info pstn-to-sip	Specifies calling information treatment for PSTN-to-SIP calls.

calling-number outbound

To specify automatic number identification (ANI) to be sent out when T1-channel-associated signaling (T1-CAS) Feature Group D-Exchange Access North American (FGD-EANA) is configured as the signaling type, use the **calling-number outbound** command in dial peer or voice-port configuration mode. To disable this command, use **no** form of this command.

calling-number outbound {**range** *string1 string2* | **sequence** *string1*... *string5* | **null**}

no calling-number outbound {**range** *string1 string2* | **sequence** *string1*... *string5* | **null**}

Syntax Description

range	Generates the sequence of ANI by rotating through the specified range (*string1* to *string2*).
sequence	Configures a sequence of discrete strings (*string1*... *string5*) to be passed out as ANI for successive calls using the peer **Note** The ellipses (**...**) is entered as shown above.
null	Suppresses ANI. If used, no ANI is passed when this dial peer is selected.
string#...	Valid E.164 telephone number strings. Strings must be of equal length and cannot be more than 32 digits long.

Command Default

No outbound calling number is specified.

Command Modes

Dial peer configuration (config-dial-peer)
Voice-port configuration (config-voiceport)

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco AS5300.

Usage Guidelines

This command is effective only for FGD-EANA signaling.

Examples

Use the **calling-number outbound** command to enable or disable the passing of ANI on a T1-CAS FGD-EANA configured T1 interface for outgoing calls. Syntax for this command is the same for both voice-port mode and dial peer mode. Examples are given for both modes.

calling-number outbound Range

```
calling-number outbound range string1 string2
```

The values *string1* and *string2* are valid E.164 telephone number strings. Both strings must be of the same length and cannot be more than 32 digits long. Only the last four digits are used for specifying the range (*string1* to *string2*) and for generating the sequence of ANI by rotating through the range until *string2* is reached and then starting from *string1* again. If strings are fewer than four digits in length, then entire strings are used.

ANI is generated by using the 408555 prefix and by rotating through 0100 to 0101 for each call using this peer.

Dial peer configuration mode:

```
dial-peer voice 1 pots
 calling-number outbound range 4085550100 4085550101
 calling Number Outbound is effective only for fgd_eana signaling
```

Voice-port configuration mode:

```
voice-port 1:D
 calling-number outbound range 4085550100 4085550105
 Calling Number Outbound is effective only for fgd_eana signaling
```

calling-number outbound Sequence

```
calling-number outbound sequence string1 string2 string3
string4 string5
```

This option configures a sequence of discrete strings (*string1... string5*) to be passed out as ANI for successive calls using the peer. The limit is five strings. All strings must be valid E.164 numbers, up to 32 digits in length.

Dial peer configuration mode:

```
dial-peer voice 1 pots
 calling-number outbound sequence 6000 6006 4000 5000 5025
 Calling Number Outbound is effective only for fgd_eana signaling
```

Voice-port configuration mode:

```
voice-port 1:D
 calling-number outbound sequence 6000 6006 4000 5000 5025
 Calling Number Outbound is effective only for fgd_eana signaling
```

calling-number outbound Null

```
calling-number outbound null
```

This option suppresses ANI. If used, no ANI is passed when this dial peer is selected.

Dial peer configuration mode:

```
dial-peer voice 1 pots
 calling-number outbound null
 Calling Number Outbound is effective only for fgd_eana signaling
```

Voice-port configuration mode:

```
voice-port 1:D
 calling-number outbound null
 Calling Number Outbound is effective only for fgd_eana signaling
```

Related Commands

Command	Description
info-digits string1	Configures two information digits to be prepended to the ANI string.

cancel-call-waiting

To define a feature code for a Feature Access Code (FAC) to enable the Cancel Call Waiting feature, use the **cancel-call-waiting** command in STC application feature access-code configuration mode. To reset the feature code to its default, use the **no** form of this command.

cancel-call-waiting *keypad-character*

no cancel-call-waiting

Syntax Description

keypad-character	Character string that can be dialed on a telephone keypad (0-9, *, #). Default: 8. The string can be any of the following: • A single character (0-9, *, #) • Two digits (00-99) • Two to four characters (0-9, *, #) and the leading or ending character must be an asterisk (*) or number sign (#)

Command Default Feature code for Cancel Call Waiting is 8.

Command Modes STC application feature access-code configuration (config-stcapp-fac)

Command History

Release	Modification
15.0(1)XA	This command was introduced.
15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines This command changes the default value of the feature code for Cancel Call Waiting (8).

If you attempt to configure this command with a value that is already configured for another FAC, speed-dial code, or the Redial FSD, you receive a message. If you configure a duplicate code, the system implements the first matching feature in the order of precedence shown in the output of the **show stcapp feature codes** command.

If you attempt to configure this command with a value that precludes or is precluded by another FAC, speed-dial code, or the Redial FSD, you receive a message. If you configure a feature code to a value that precludes or is precluded by another code, the system always executes the call feature with the shortest code and ignores the longer code. For example, #1 will always preclude #12 and #123. You must configure a new value for the precluded code in order to enable phone user access to that feature.

To display a list of all FACs, use the **show stcapp feature codes** command.

Examples

The following example shows how to change the value of the feature code for cancel call waiting. With this configuration, a phone user must press **9 on the phone keypad to cancel call waiting.

```
Router(config)# stcapp feature access-code
Router(config-stcapp-fac)# cancel-call-waiting **9
```

Related Commands

Command	Description
prefix (stcapp-fac)	Defines the prefix for FACs.
show stcapp feature codes	Displays all FACs.

capacity update interval (dial peer)

To change the capacity update for prefixes associated with this dial peer, use the **capacity update interval** command in dial peer configuration mode. To return to the default, use the **no** form of this command.

capacity update interval *seconds*

no capacity update interval *seconds*

Syntax Description

seconds	Interval, in seconds, between the sending of periodic capacity updates. This can be a number in the range 10 to 1000. The default value is 25 seconds.

Command Default

25 seconds

Command Modes

Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines

The update interval should be set depending how many updates that are sent. Updates are sent more often when more calls are coming in, which can lead to data getting out of synchrony. If the interval is too short for the number of updates, the location server can be overwhelmed.

If a dial peer gets too much traffic, set the *seconds* argument to a higher value.

Examples

The following example shows that POTS dial peer 10 is having the capacity update occur every 35 seconds:

```
Router(config)# dial-peer voice 10 pots
Router(config-dial-peer)# capacity update interval 35
```

Related Commands

Command	Description
dial-peer voice	Enters dial-peer configuration mode and specifies the method of voice-related encapsulation.

capacity update interval (trunk group)

To change the capacity update for carriers or trunk groups, use the **capacity update interval** command in trunk group configuration mode. To return to the default, use the **no** form of this command.

capacity {**carrier** | **trunk-group**} **update interval** *seconds*

no capacity {**carrier** | **trunk-group**}

Syntax Description

carrier	Carrier capacity.
trunk-group	Trunk group capacity.
seconds	Interval, in seconds, between the sending of periodic capacity updates. This can be a number in the range 10 to 1000. The default value is 25 seconds.

Command Default 25 seconds

Command Modes Trunk group configuration (config-trunkgroup)

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines The update interval should be set depending how many updates that are sent. Updates are sent more often when more calls are coming in, which can lead to data getting out of synchrony. If the interval is too short for the number of updates, the location server can be overwhelmed.

If a dial peer gets too much traffic, set the *seconds* argument to a higher value.

Examples The following example sets the capacity update for trunk group 101 to occur every 45 seconds:

```
Router(config)# trunk group 101
Router(config-trunkgroup)# capacity trunk-group update interval 45
```

Related Commands

Command	Description
trunk group	Defines the trunk group and enters trunk group configuration mode.

cap-list vfc

To add a voice codec overlay file to the capability file list, use the **cap-list vfc** command in global configuration mode. To disable a particular codec overlay file that has been added to the capability list, use the **no** form of this command.

cap-list *filename* **vfc** *slot-number*

no cap-list *filename* **vfc** *slot-number*

Syntax Description

filename	Identifies the codec file stored in voice feature card (VFC) flash memory.
slot-number	Identifies the slot where the VFC is installed. Range is 0 to 2. There is no default value.

Command Default

No default behavior or values

Command Modes

Global configuration (config)

Command History

Release	Modification
11.3NA	This command was introduced on the Cisco AS5300.

Usage Guidelines

When VCWare is unbundled, it automatically adds DSPWare to flash memory, creates both the capability and default file lists, and populates these lists with the default files for the particular version of VCWare. The capability list defines the available voice codecs for H.323 capability negotiation. Use the **cap-list vfc** command to add the indicated voice codec overlay file (defined by *filename*) to the capability file list in flash memory.

Examples

The following example adds the following codec to the list included in flash memory:

```
config terminal
 cap-list cdc-g711-1.0.14.0.bin vfc 0
```

Related Commands

Command	Description
default-file vfc	Specifies an additional (or different) file from the ones in the default file list and stored in VFC Flash memory.

card type (T1-E1)

To configure a T1 or E1 card type, use the **card type** command in global configuration mode. To deselect the card type on non-SPA platforms, use the **no** form of this command. The **no** form of this command is not available on the SPA platforms.

card type {**t1** | **e1**} *slot* [*bay*]

no card type {**t1** | **e1**} *slot* [*bay*]

Channelized T/E1 Shared Port Adapters

card type {**t1** | **e1**} *slot subslot*

Syntax Description

t1	Specifies T1 connectivity of 1.544 Mbps through the telephone switching network, using AMI or B8ZS coding.
e1	Specifies a wide-area digital transmission scheme used predominantly in Europe that carries data at a rate of 2.048 Mbps.
slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
bay	(Optional) Card interface bay number in a slot (route switch processor [RSP] platform only). This option is not available on other platforms.
subslot	(Channelized T/E1 Shared Port Adapters Only) Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.

Defaults

No default behavior or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(5)XE	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.
12.3(1)	This command was integrated into Cisco IOS Release 12.3(1) and support was added for Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 platforms.
12.2S	This command was integrated into Cisco IOS Release 12.2S.

Release	Modification
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Changes made using this command on non-SPA platforms, do not take effect unless the **reload** command is used or the router is rebooted.

Channelized T1/E1 Shared Port Adapters

There is no card type when the SPA is inserted for first time. The user must configure this command before they can configure individual ports.

The **no** form of this command is not available on the SPA platforms. To change an existing card type on SPA platforms, perform the following steps:

1. Remove the SPA from its subslot.
2. Save the configuration.
3. Reboot the router.
4. Insert the new SPA into the subslot.
5. Configure the new card using this command.

Examples

The following example configures T1 data transmission on slot 1 of the router:

```
Router(config)# card type t1 1
```

The following example configures all ports of an 8-Port Channelized T1/E1 SPA, seated in slot 5, subslot 2, in T1 mode:

```
Router(config)# card type t1 5 2
```

Related Commands

Command	Description
controller	Configures a T1 or E1 controller and enters controller configuration mode.
reload	Reloads the operating system.
show controller	Displays the controller state that is specific to controller hardware
show interface serial	Displays the serial interface type and other information.

card type (T3-E3)

To configure a T3 or E3 card type, use the **card type** command in global configuration mode. To deselect the card type, use the **no** form of this comand. The **no** form of this command is not supported on the 2-Port and 4-Port Clear Channel T3/E3 SPA on Cisco 12000 series routers.

T3 or E3 Controllers

card type {**t3** | **e3**} *slot*

no card type {**t3** | **e3**} *slot*

Clear Channel T3/E3 Shared Port Adapters

card type {**t3** | **e3**} *slot subslot*

no card type {**t3** | **e3**} *slot subslot*

Clear Channel T3/E3 Shared Port Adapters on Cisco 12000 Series Routers

card type {**t3** | **e3**} *slot subslot*

Syntax Description

t3	Specifies T3 connectivity of 44210 kbps through the network, using B8ZS coding.
e3	Specifies a wide-area digital transmission scheme used predominantly in Europe that carries data at a rate of 34010 kbps.
slot	Slot number of the interface.
subslot	(Clear Channel T3/E3 Shared Port Adapters Only) Secondary slot number on a SIP where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.

Defaults

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Release	Modification
12.3(1)	This command was integrated into Cisco IOS Release 12.3(1) and support was added for Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 platforms.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Usage guidelines vary slightly from platform to platform as follows:

T3 or E3 Controllers

Once a card type is issued, you enter the **no card type** command and then another **card type** command to configure a new card type. You must save the configuration to the NVRAM and reboot the router in order for the new configuration to take effect.

When the router comes up, the software comes up with the new card type. Note that the software will reject the configuration associated with the old controller and old interface. You must configure the new controller and serial interface and save it.

Clear Channel T3/E3 Shared Port Adapters

To change all the SPA ports from T3 to E3, or vice versa, you enter the **no card type** command and then another **card type** command to configure a new card type.

When the router comes up, the software comes up with the new card type. Note that the software will reject the configuration associated with the old controller and old interface. You must configure the new controller and serial interface and save it.

Clear Channel T3/E3 Shared Port Adapters on Cisco 12000 Series Routers

The **no** form of this command is not available on the 2-Port and 4-Port Clear Channel T3/E3 SPA on Cisco 12000 series routers. To change an existing card type on Cisco 12000 series routers, perform the following steps:

1. Remove the SPA from its subslot.
2. Save the configuration.
3. Reboot the router.
4. Insert the new SPA into the subslot.
5. Configure the new card using this command.

Examples

The following example shows T3 data transmission configured in slot 1:

```
Router(config)# card type t3 1
```

The following example configures all ports of 2-Port and 4-Port Clear Channel T3/E3 SPA, seated in slot 5, subslot 2, in T3 mode:

```
Router(config)# card type t3 5 2
```

Related Commands

Command	Description
controller	Configures a T3 or E3 controller and enters controller configuration mode.
reload	Reloads the operating system.
show interface serial	Displays the serial interface type and other information.

carrier-id (dial peer)

To specify the carrier associated with a VoIP call in a dial peer, use the **carrier-id** command in dial peer configuration mode. To delete the source carrier ID, use the **no** form of this command.

carrier-id {**source** | **target**} *name*

no carrier-id {**source** | **target**} *name*

Syntax Description

source	Indicates the carrier that the dial peer uses as a matching key for inbound dial-peer matching.
target	Indicates the carrier that the dial peer uses as a matching key for outbound dial-peer matching.
name	Specifies the ID of the carrier to use for the call. Valid carrier IDs contain a maximum of 127 alphanumeric characters.

Command Default

No default behavior or values

Command Modes

Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

A Gatekeeper Transaction Message Protocol (GKTMP) route server-based application at the terminating gateway uses the source carrier ID to select a target carrier that routes the call over a plain old telephone service (POTS) line.

The terminating gateway uses the target carrier ID to select a dial peer for routing the call over a POTS line.

For IP-to-IP calls, the **carrier-id** command alone is not an oubound dialpeer match criterion.

Examples

The following example indicates that dial peer 112 should use carrier ID “east17” for outbound dial-peer matching in the terminating gateway:

```
Router(config)# dial-peer voice 112 pots
Router(config-dial-peer)# carrier-id target east17
```

The following example indicates that dial peer 111 should use carrier ID “beta23” for inbound dial-peer matching in the terminating gateway:

```
Router(config)# dial-peer voice 111 voip
Router(config-dial-peer)# carrier-id source beta23
```

Related Commands

Command	Description
translation-profile (dial peer)	Associates a translation profile with a dial peer.
trunkgroup (dial peer)	Assigns a trunk group to a source IP group or dial peer for trunk group label routing.

carrier-id (global)

To set the carrier ID for trunk groups when a local carrier ID is not configured, use the **carrier-id** command in global configuration mode. To disable the carrier ID, use the **no** form of this command.

carrier-id *name* [**cic**]

no carrier-id *name* [**cic**]

Syntax Description

name	Identifier for the carrier ID. Must be four-digit numeric carrier identification code to be advertised as a TRIP carrier family but can be alphanumeric if used otherwise.
cic	(Optional) Specifies that the carrier ID is a circuit identification code (CIC).

Command Default

No default behavior or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines

To advertise the carrier as a TRIP carrier family, the **cic** keyword must be used. When the **cic** keyword is used, only numeric values can be accepted for the *name* value. If the **cic** keyword is not used, the *name* value can be alphanumeric but is not advertised to TRIP location servers.

Examples

The following example shows a carrier ID using the circuit identification code:

```
Router(config)# carrier-id 1234 cic
```

Related Commands

Command	Description
carrier-id (trunk group)	Configures the carrier ID locally on the trunk group.

carrier-id (trunk group)

To specify the carrier associated with a trunk group, use the **carrier-id** command in trunk group configuration mode. To delete the source carrier ID, use the **no** form of this command.

carrier-id *name* [**cic**]

no carrier-id *name* [**cic**]

Syntax Description

name	The ID of the carrier to use for the call. Valid carrier IDs contain a maximum of 127 alphanumeric characters. To be advertised as a TRIP carrier family, this must be set to a four-digit numeric carrier identification code.
cic	(Optional) Specifies that the carrier ID is a circuit identification code.

Command Default No default behavior or values

Command Modes Trunk group configuration (config-trunkgroup)

Command History

Release	Modification
12.2(11)T	This command was introduced.
12.3(1)	The **cic** keyword was added.

Usage Guidelines In a network, calls are routed over incoming trunk groups and outgoing trunk groups. The *name* arguments identifies the carrier that handles the calls for a specific trunk group. In some cases, the same trunk group may be used to carry both incoming calls and outgoing calls.

The carrier ID configured locally on the trunk group supersedes the globally configured carrier ID.

To advertise the carrier as a TRIP carrier family, the **cic** keyword must be used. When **cic** is used, only numeric values can be accepted for the *name* value. If **cic** is not used, the *name* value can be alphanumeric but is not advertised to TRIP location servers.

Examples The following example indicates that carrier “alpha1” carries calls for trunk group 5:

```
Router(config)# trunk group 5
Router(config-trunk-group)# carrier-id alpha1
```

The following example shows that the carrier with circuit identification code 1234 carries calls for trunk group 101. This trunk group can carry TRIP advertisements.

```
Router(config)# trunk group 101
Router(config-trunk-group)# carrier-id 1234 cic
```

Related Commands

Command	Description
carrier-id (global)	Configures the carrier ID globally for all trunk groups.
translation-profile (trunk group)	Associates a translation profile with a trunk group.
trunk group	Initiates the definition of a trunk group.

carrier-id (voice source group)

To specify the carrier associated with a VoIP call, use the **carrier-id** command in voice source group configuration mode. To delete the source carrier ID, use the **no** form of this command.

carrier-id {**source** | **target**} *name*

no carrier-id {**source** | **target**} *name*

Syntax Description

source	Indicates the carrier ID associated with an incoming VoIP call at the terminating gateway.
target	Indicates the carrier ID used by the terminating gateway to match an outbound dial peer.
name	The ID of the carrier to use for the call. Valid carrier IDs contain a maximum of 127 alphanumeric characters.

Command Default No default behavior or values

Command Modes Voice source group configuration (cfg-source-grp)

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines A Gatekeeper Transaction Message Protocol (GKTMP) server application at the terminating gateway uses the source carrier ID to select a target carrier that routes the call over a plain old telephone service (POTS) line. The terminating gateway uses the target carrier ID to select a dial peer for routing the call over a POTS line.

Note If an incoming H.323 VoIP call matches a source IP group that has a target carrier ID, the source IP group's target carrier ID overrides the VoIP call's H.323 setup message.

Examples The following example indicates that voice source IP group "group1" should use carrier ID named "source3" for incoming VoIP calls and carrier ID named "target17" for outbound dial-peer matching in the terminating gateway:

```
Router(config)# voice source-group group1
Router(cfg-source-grp)# carrier-id source source3
Router(cfg-source-grp)# carrier-id target target17
```

Related Commands

Command	Description
voice source-group	Initiates the definition of a source IP group.

cause-code

To represent internal failures with former and nonstandard H.323 or Session Initiation Protocol (SIP) cause codes, use the **cause-code** command in voice service VoIP configuration mode. To use standard cause-code categories, use the **no** form of this command.

cause-code legacy

no cause-code legacy

Syntax Description

legacy	Sets the internal cause code to the former and nonstandard set of H.323 and SIP values.

Command Default

The default for SIP and H.323 is to use standard cause-code categories, so the command is disabled.

Command Modes

Voice service VoIP configuration (config-voi-srv)

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

This command is used for backward compatibility purposes.

Examples

The following example sets the internal cause codes to the former and nonstandard set of SIP and H.323 values for backward compatibility:

```
Router(config)# voice service voip
Router(config-voi-srv)# cause-code legacy
```

Related Commands

Command	Description
show call history voice	Displays the call history table for voice calls.

cbarge

To enable idle phones to join an active call on a shared line on a Foreign Exchange Station (FXS) port by going offhook, use the **cbarge** command in supplementary-service voice-port configuration mode. To return to the command default, use the **no** form of this command.

cbarge

no cbarge

Syntax Description

This command has no arguments or keywords.

Command Default

cBarge is disabled and idle phones are unable to join an active call on a shared line.

Command Modes

Supplementary-service voice-port configuration mode (config-stcapp-suppl-serv-port)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use the **cbarge** command to allow one idle IP or analog phone that is connected to the same FXS port to automatically join an active call on the shared line by going offhook.

The **hold-resume** command must be configured on each port before the **cbarge** command is configured.

Only one analog phone is allowed to join an active call.

Examples

The following example shows how to enable idle phones to join active calls on ports 2/2, 2/3, and 2/4 on a Cisco VG224:

```
Router(config)# stcapp supplementary-services
Router(config-stcapp-suppl-serv)# port 2/2
Router(config-stcapp-suppl-serv-port)# hold-resume
Router(config-stcapp-suppl-serv-port)# cbarge
Router(config-stcapp-suppl-serv)# port 2/3
Router(config-stcapp-suppl-serv-port)# hold-resume
Router(config-stcapp-suppl-serv-port)# cbarge
Router(config-stcapp-suppl-serv)# port 2/4
Router(config-stcapp-suppl-serv-port)# hold-resume
Router(config-stcapp-suppl-serv-port)# cbarge
Router(config-stcapp-suppl-serv-port)# end
```

Related Commands

Command	Description
hold-resume	Turns the STCAPP supplementary-service features on and off using hookflash.
stcapp supplementary-services	Enters supplementary-service configuration mode for configuring STCAPP supplementary-service features on an FXS port.

ccm-manager application redundant-link port

To configure the port number for the redundant link application, use the **ccm-manager application redundant-link port** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ccm-manager application redundant-link port *number*

no ccm-manager application redundant-link port

Syntax Description

port *number*	Port number for the transport protocol. The protocol may be User Data Protocol (UDP), Reliable User Datagram Protocol (RDUP), or TCP. Range is from 0 to 65535, and the specified value must not be a well-known reserved port number such as 1023. The default is 2428.

Command Default

Port number: 2428

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was introduced with Cisco CallManager Version 3.0 and the Cisco Voice Gateway 200 (VG200).
12.2(2)XA	The command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T.

Usage Guidelines

Use this command only when defining an application-specific port other than the default.

Examples

In the following example, the port number of the redundant link application is 2429:

```
ccm-manager application redundant-link port 2429
```

Related Commands

Command	Description
ccm-manager redundant-host	Configures the IP address or the DNS name of up to two backup Cisco CallManagers.
ccm-manager switchback	Configures the switchback mode that determines when the primary Cisco CallManager is used if it becomes available again while a backup Cisco CallManager is being used.

ccm-manager config

To specify the TFTP server from which the Media Gateway Control Protocol (MGCP) gateway downloads Cisco Unified Communications Manager (Cisco UCM) Extensible Markup Language (XML) configuration files and to enable the download of the configuration, use the **ccm-manager config** command in global configuration mode. To disable the dial-peer and server configurations, use the **no** form of this command.

ccm-manager config [**dialpeer-prefix** *prefix* | **server** {*ip-address* | *name*}]

no ccm-manager config [**dialpeer-prefix** *prefix* | **server**]

Syntax Description

dialpeer-prefix *prefix*	(Optional) Specifies the prefix to use for autogenerated dial peers. Range is 1 to 2147483647. The default is 999. **Note** When manually adding a dial peers prefix, select a prefix number other than the default.
server {*ip-address* | *name*}	(Optional) Specifies the IP address or logical name of the TFTP server from which the XML configuration files are downloaded. The arguments are as follows: • *ip-address*—IP address of the TFTP server from which to download the XML configuration files to the local MGCP voice gateway. • *name*—Logical (symbolic) name of the TFTP server from which to download XML configuration files to the local MGCP voice gateway.

Command Default

The configuration download feature is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(2)XN	This command was introduced and implemented on the Cisco 2600 series, Cisco 3600 series, and the Cisco VG200.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and implemented on the Cisco IAD2420 series.

Usage Guidelines

The **ccm-manager config** command is required to enable the download of Cisco UCM XML configuration files. If you separate the MGCP and H.323 dial peers under different dial-peer tags, ensure that the MGCP dial peers are configured before the H.323 dial peers. Direct-inward-dial (DID) is required for E1 PRI dial peers.

Note To keep manually added dial peers from being deleted from the running configuration when Cisco UCM downloads the configuration to the gateway, use a dial peer-prefix value other than the default (999).

Do not delete the POTS dial peer created by the automatic download process. However, if a dial peer has been deleted, you can restore the deleted dial peer by entering the following commands to repeat the download of the configuration file:

```
no mgcp
no ccm-manager config
ccm-manager config
mgcp
```

After you enter these commands, use the **show ccm-manager config-download** command to display the the configuration file downloaded from the TFTP server via the interface specified. The following is an example of the output:

```
Loading sample.cnf.xml from 9.13.22.100 (via GigabitEthernet0/0): !
[OK - 12759 bytes]
```

Examples

The following example shows how to enable the automatic download of configuration files:

```
ccm-manager config
```

In the following example, the IP address of the TFTP server from which a configuration file is downloaded is identified:

```
ccm-manager config server 10.10.0.21
```

Related Commands

Command	Description
debug ccm-manager config-download	Displays dialog during configuration download from the Cisco UCM to the gateway.
show ccm-manager config-download	Displays whether the Cisco UCM configuration is enabled.

Usage Guidelines

The **ccm-manager config** command is required to enable the download of Cisco UCM XML configuration files. If you separate the MGCP and H.323 dial peers under different dial-peer tags, ensure that the MGCP dial peers are configured before the H.323 dial peers. Direct-inward-dial (DID) is required for E1 PRI dial peers.

Note To keep manually added dial peers from being deleted from the running configuration when Cisco UCM downloads the configuration to the gateway, use a dial peer-prefix value other than the default (999).

Do not delete the POTS dial peer created by the automatic download process. However, if a dial peer *has* been deleted, you can restore the deleted dial peer by entering the following commands to repeat the download of the configuration file:

```
no mgcp
no ccm-manager config
ccm-manager config
mgcp
```

After you enter these commands, use the **show ccm-manager config-download** command to display the the configuration file downloaded from the TFTP server via the interface specified. The following is an example of the output:

```
Loading sample.cnf.xml from 9.13.22.100 (via GigabitEthernet0/0): !
[OK - 12759 bytes]
```

Examples

The following example shows how to enable the automatic download of configuration files:

```
ccm-manager config
```

In the following example, the IP address of the TFTP server from which a configuration file is downloaded is identified:

```
ccm-manager config server 10.10.0.21
```

Related Commands

Command	Description
debug ccm-manager config-download	Displays dialog during configuration download from the Cisco UCM to the gateway.
show ccm-manager config-download	Displays whether the Cisco UCM configuration is enabled.

ccm-manager download-tones

To configure a Cisco IOS gateway to download a XML configuration file that contains custom tone information from a TFTP server at the time of gateway registration, use the **ccm-manager download-tones** command in global configuration mode. To disable this functionality, use the **no** form of this command.

ccm-manager download-tones

no ccm-manager download-tones

Syntax Description

This command has no arguments or keywords.

Command Default

Cisco CallManager download tones are disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(15)ZJ	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Examples

The following example shows a Cisco IOS gateway being configured to download an XML configuration file that contains custom tone information from a TFTP server:

```
Router(config)# ccm-manager download-tones
```

Related Commands

Command	Description
cptone	Specifies a regional voice-interface-related tone, ring, and cadence setting.
debug ccm-manager	Displays debugging of Cisco CallManager.
show ccm-manager	Displays a list of Cisco CallManager servers and their current status and availability.

ccm-manager fallback-mgcp

To enable the gateway fallback feature and allow a Media Gateway Control Protocol (MGCP) voice gateway to provide call processing services when Cisco CallManager is unavailable, use the **ccm-manager fallback-mgcp** command in global configuration mode. To disable fallback on the MGCP voice gateway, use the **no** form of this command.

ccm-manager fallback-mgcp

no ccm-manager fallback-mgcp

Syntax Description

This command has no arguments or keywords.

Command Default

The gateway fallback feature is enabled

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(2)XN	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and the Cisco VG200.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2 and implemented on Cisco IAD2420 series.
12.2(15)ZJ	This command was integrated into Cisco IOS Release 12.2(15)ZJ.
12.3(2)T	This command was implemented on the Cisco 26xxXM, Cisco 2691, Cisco 3640, Cisco 3640A, Cisco 3660, and Cisco 37xx.

Usage Guidelines

This command causes the gateway to fall back and provide call processing services if connectivity is lost between the gateway and all Cisco CallManager servers. The mode and timing are set by default.

Examples

The following example enables fallback:

```
Router(config)# ccm-manager fallback-mgcp
```

Related Commands

Related Command	Purpose
ccm-manager config	Supplies the local MGCP voice gateway with the IP address or logical name of the TFTP server from which to download XML configuration files and enable the download of the configuration.
debug ccm-manager	Displays debugging information about the Cisco CallManager.
show ccm-manager fallback-mgcp	Displays the status of the MGCP gateway fallback feature.

ccm-manager fax protocol

To enable fax-relay protocol for endpoints on a gateway, use the **ccm-manager fax protocol** command in global configuration mode. To disable fax-relay protocol, use the **no** form of this command.

ccm-manager fax protocol cisco

no ccm-manager fax protocol cisco

Syntax Description		
	cisco	Cisco-proprietary fax-relay protocol. This is the only choice.

Command Default Cisco-proprietary fax-relay protocol is enabled by default.

Command Default Fax relay is enabled.

Command Modes Global configuration

Command History	Release	Modification
	12.2(9)T	This command was introduced.

Usage Guidelines Use the **no** form of this command to disable fax relay.

Because fax relay is enabled by default, the **show running-config** command does not explicitly show it to be enabled.

Fax over IP enables interoperability of traditional analog fax machines with IP telephony networks. In its original form, fax data is digital. For transmission across a traditional public switched telephone network (PSTN), it is converted to analog form. For transmission across the IP (packet) network, it is reconverted to digital form, and then, at the destination fax machine, converted again to analog form.

Most Cisco voice gateways support two methods of transmitting fax traffic across the IP network:

- Cisco fax relay—The gateway terminates the T.30 fax signaling. This is the preferred method.
- Fax pass-through—The gateway does not distinguish a fax call from a voice call. All Cisco voice gateways support fax pass-through.

Examples The following example configures a Media Gateway Control Protocol (MGCP) gateway for Cisco fax relay:

```
Router(config)# ccm-manager fax protocol cisco
Router(config)# mgcp fax t38 inhibit
```

The following example configures an MGCP gateway for fax pass-through:

```
Router(config)# ccm-manager fax protocol cisco
Router(config)# mgcp modem passthrough voip mode nse
Router(config)# mgcp modem passthrough voip codec g711ulaw
```

Related Commands

Command	Description
debug ccm-manager	Displays debugging of Cisco CallManager.
show ccm-manager	Displays a list of Cisco CallManager servers and their current status and availability.
show running-config	Displays the contents of the currently running configuration file.

ccm-manager mgcp

To enable the gateway to communicate with Cisco CallManager through the Media Gateway Control Protocol (MGCP) and to supply redundant control agent services, use the **ccm-manager mgcp** command in global configuration mode. To disable communication with Cisco CallManager and redundant control agent services, use the **no** form of this command.

ccm-manager mgcp [**codec-all**]

no ccm-manager mgcp [**codec-all**]

Syntax Description

codec-all	(Optional) Enables all codec on the gateway for the Cisco CallManager.

Command Default

Cisco CallManager does not communicate with the gateway through MGCP.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was introduced with Cisco CallManager Version 3.0 on the Cisco VG200.
12.2(2)XA	The command was integrated into Cisco IOS Release 12.2(2)XA and implemented on the Cisco 2600 series and Cisco 3600 series.
12.2(2)XN	Support for enhanced MGCP voice gateway interoperability was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, 3600 series, and Cisco VG200.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was integrated into the Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2 and was implemented on the Cisco IAD2420 series routers.
12.2(11)YU	This command was integrated into Cisco IOS Release 12.2(11)YU and implemented on the Cisco 1760 gateway.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **codec-all** keyword was added.

Usage Guidelines

This command enables the gateway to communicate with Cisco CallManager through MGCP. This command also enables control agent redundancy when a backup Cisco CallManager server is available.

Examples

In the following example, support for Cisco CallManager and redundancy is enabled within MGCP:

```
Router# configure terminal
Router(config)# ccm-manager mgcp
```

Related Commands

Command	Description
ccm-manager redundant-host	Configures the IP address or the DNS name of up to two backup Cisco CallManagers.
ccm-manager switchback	Configures the switchback mode that determines when the primary Cisco CallManager is used if it becomes available again while a backup Cisco CallManager is being used.
mgcp	Enables Media Gateway Control Protocol mode.

ccm-manager music-on-hold

To enable the multicast music-on-hold (MOH) feature on a voice gateway, use the **ccm-manager music-on-hold** command in global configuration mode. To disable the MOH feature, use the **no** form of this command.

ccm-manager music-on-hold

no ccm-manager music-on-hold

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration (config)

Command History

Release	Modification
12.2(2)XN	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2 and implemented on the Cisco IAD 2420 series routers.

Examples The following example shows multicast MOH configured for a MGCP voice gateway:

```
mgcp call-agent 10.0.0.21 2427 service-type mgcp version 0.1
mgcp dtmf-relay voip codec all mode out-of-band
mgcp rtp unreachable timeout 1000
mgcp modem passthrough voip mode cisco
mgcp package-capability rtp-package
mgcp package-capability sst-package
no mgcp timer receive-rtcp
call rsvp-sync
!
ccm-manager redundant-host 10.0.0.21
ccm-manager mgcp
ccm-manager music-on-hold
ccm-manager config server 10.0.0.21
!
```

Related Commands

Command	Description
ccm-manager music-on-hold bind	Enables the multicast MOH feature on a voice gateways.
debug ccm-manager music-on-hold	Displays debugging information for MOH.
show ccm-manager music-on-hold	Displays MOH information.

ccm-manager music-on-hold bind

To bind the multicast music-on-hold (MOH) feature to an interface type, use the **ccm-manager music-on-hold bind** command in global configuration mode. To unbind the MOH feature on the interface type, use the **no** form of this command.

ccm-manager music-on-hold bind *type slot/port*

no ccm-manager music-on-hold bind *type slot/port*

Syntax Description

type	Interface type to which the MOH feature is bound. The options follow: • **async**—Asynchronous interface • **bvi**—Bridge-Group Virtual Interface • **ctunnel**—CTunnel interface • **dialer**—Dialer interface • **ethernet**—IEEE 802.3 • **lex**—Lex interface • **loopback**—Loopback interface • **mfr**—Multilink Frame Relay bundle interface • **multilink**—Multilink interface • **null**—Null interface • **serial**—Serial interface • **tunnel**—Tunnel interface • **vif**—PGM Multicast Host interface • **virtual-FrameRelay**—Virtual Frame Relay interface • **virtual-Template**—Virtual template interface • **virtual-TokenRing**—Virtual Token Ring
slot/port	Number of the slot being configured. See the appropriate hardware manual for slot and port information.

Command Default

This command is disabled by default, so the MOH feature is not bound to an interface type.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

Use the **ccm-manager music-on-hold bind** command to bind the multicast music-on-hold (MOH) feature to an interface type. Dynamic configuration of multicast MOH bind is not supported.

Examples

The following example shows multicast MOH bound to serial interface 0/0:

```
ccm-manager music-on-hold bind serial 0/0
```

Related Commands

Command	Description
ccm-manager music-on-hold	Enables the MOH feature.
debug ccm-manager music-on-hold	Displays debugging information for MOH.
show ccm-manager music-on-hold	Displays MOH information.

ccm-manager redundant-host

To configure the IP address or the Domain Name System (DNS) name of one or two backup Cisco CallManager servers, use the **ccm-manager redundant-host** command in global configuration mode. To disable the use of backup Cisco CallManager servers as call agents, use the **no** form of this command.

ccm-manager redundant-host {*ip-address* | *dns-name*} [*ip-address* | *dns-name*]

no ccm-manager redundant-host {*ip-address* | *dns-name*} [*ip-address* | *dns-name*]

Syntax Description

ip-address	IP address of the backup Cisco CallManager server.
dns-name	DNS name of the backup Cisco CallManager server.

Command Default

If you do not configure a backup Cisco CallManager, the redundancy is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was introduced with Cisco CallManager Version 3.0 on the Cisco Voice Gateway 200 (VG200).
12.2(2)XA	The command was implemented on the Cisco 2600 series and Cisco 3600 series. The *dns-name* argument was added.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T.
12.2(2)XN	Support for enhanced MGCP voice gateway interoperability was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, 3600 series, and the Cisco VG200.
12.2(11)T	This command was integrated into the Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2 and implemented on the Cisco IAD2420 series routers.

Usage Guidelines

The list of IP addresses or DNS names is an ordered and prioritized list. The Cisco CallManager server that was defined with the **mgcp call-agent** command has the highest priority—it is the primary Cisco CallManager server. The gateway selects a Cisco CallManager server on the basis of the order of its appearance in this list.

Examples

In the following example, the IP address 10.0.0.50 is configured as the backup Cisco CallManager :

```
ccm-manager redundant-host 10.0.0.50
```

Related Commands

Command	Description
ccm-manager application	Configures the port number for the redundant link application.
ccm-manager switchback	Configures the switchback mode that determines when the primary Cisco CallManager is used if it becomes available again while a backup Cisco CallManager is being used.
ccm-manager switchover-to-backup	Redirects (manually and immediately) a Cisco 2600 series router or Cisco 3600 series router to the backup Cisco CallManager server.
mgcp call-agent	Defines the Cisco CallManager server as the highest priority.

ccm-manager sccp

To enable Cisco CallManager autoconfiguration of the Cisco IOS gateway, use the **ccm manager sccp** command in global configuration mode. To disable autoconfiguration, use the **no** form of this command.

ccm-manager sccp

no ccm-manager sccp

Syntax Description This command has no arguments or keywords.

Command Default Autoconfiguration is disabled.

Command Modes Global configuration (config)

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines Use this command to trigger TFTP download of the eXtensible Markup Language (XML) configuration file. Issuing this command immediately triggers the download, and also enables the Skinny Client Control Protocol (SCCP) and SCCP Telephony Control Application (STCAPP), applications that enable Cisco CallManager control of gateway-connected telephony endpoints.

Examples The following example enables autoconfiguration of gateway-connected endpoints:

```
Router(config)# ccm-manager sccp
```

Related Commands

Command	Description
ccm-manager config	Specifies the TFTP server from which the Cisco IOS gateway downloads Cisco CallManager XML configuration files.
ccm-manager sccp local	Selects the local interface for SCCP application use for Cisco CallManager registration.
show ccm-manager config-download	Displays information about the status of the Cisco IOS gateway configuration download.

ccm-manager sccp local

To select the local interface that the Skinny Client Control Protocol (SCCP) application uses to register with Cisco CallManager, use the **ccm-manager sccp local** command in global configuration mode. To deselect the interface, use the **no** form of this command.

ccm-manager sccp local *interface-type interface-number*

no ccm-manager sccp local *interface-type interface-number*

Syntax Description

interface-type	Interface type that the SCCP application uses for Cisco CallManager registration.
interface-number	Interface number that the SCCP application uses for Cisco CallManager registration.

Command Default No local interface is selected.

Command Modes Global configuration (config)

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines You must specify this interface before enabling the Cisco CallManager autoconfiguration process. The MAC address of this interface is used to identify gateway endpoints.

Examples The following example configures a FastEthernet interface for SCCP application use for Cisco CallManager registration:

```
Router(config)# ccm-manager sccp local fastethernet 0/0
```

Related Commands

Command	Description
show ccm-manager	Displays a list of Cisco CallManager servers and their current status and availability.

ccm-manager shut-backhaul-interfaces

To disable ISDN Layer 2 connectivity on a Cisco Call Manager Media Gateway Control Protocol (MGCP) PRI or BRI backhauled trunk when communication is lost between the Cisco Call Manager and the MGCP gateway, use the **ccm-manager shut-backhaul-interfaces** command in global configuration mode. To restore the default behavior, where ISDN Layer 2 is maintained between the MGCP gateway and the ISDN switch even when no connectivity exists between the MGCP gateway and any Cisco Call Manager, use the **no** form of this command.

ccm-manager shut-backhaul-interfaces

no ccm-manager shut-backhaul-interfaces

Syntax Description

This command has no arguments or keywords.

Command Default

The default behavior is for the ISDN Layer 2 connection to be maintained (to make the Cisco Call Manager MGCP PRI or BRI backhaul continue to function) between the MGCP gateway and the ISDN switch even if no connectivity exists between the MGCP gateway and any Cisco Call Manager.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(8)	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.
12.4(3f)	This command was integrated into Cisco IOS Release 12.4(3f).
12.4(5c)	This command was integrated into Cisco IOS Release 12.4(5c).
12.4(7c)	This command was integrated into Cisco IOS Release 12.4(7c).
12.4(4)T5	This command was integrated into Cisco IOS Release 12.4(4)T5.
12.4(6)T4	This command was integrated into Cisco IOS Release 12.4(6)T4.

Usage Guidelines

Use this command on Cisco IOS voice routers configured for Cisco Call Manager MGCP PRI or BRI backhaul.

Prior to the introduction of the **ccm-manager shut-backhaul-interfaces** command, a Cisco Call Manager MGCP PRI or BRI backhaul trunk would maintain ISDN Layer 2 connectivity between the MGCP gateway and the ISDN switch in a MULTIPLE_FRAMES_ESTABLISHED state even if Layer 3 Q.931 backhaul connectivity between the Cisco Call Manager and the MGCP gateway was unavailable. This causes problems because the ISDN switch interprets the PRI or BRI trunk as being active and continues to place calls to the MGCP gateway, even though all of the calls fail. After you enter the **ccm-manager shut-backhaul-interfaces** command, Layer 2 is disabled when connectivity between the Cisco Call Manager and the MGCP gateway is unavailable.

Examples

The following example disables ISDN Layer 2 connectivity on a Cisco Call Manager MGCP PRI or BRI backhauled trunk when communication is lost between Cisco Call Manager and the MGCP gateway:

```
ccm-manager shut-backhaul-interfaces
```

The following example restores the default behavior (functionality of the **ccm-manager shut-backhaul-interfaces** command is disabled) so that the ISDN Layer 2 connection is maintained between the MGCP gateway and the ISDN switch, even when no connectivity exists between the MGCP gateway and any Cisco Call Manager:

```
no ccm-manager mgcp
no ccm-manager shut-backhaul-interfaces
ccm-manager mgcp
```

Related Commands

Command	Description
ccm-manager mgcp	Enables the gateway to communicate with the Cisco Call Manager through the MGCP and to supply redundant control agent services.

ccm-manager shut-interfaces-tftp-fails

To configure the number of TFTP download failures allowed before the gateway shuts down ports, use the **ccm-manager shut-interfaces-tftp-fails** command in global configuration mode. To return to the default configuration, use the **no** form of this command.

ccm-manager shut-interfaces-tftp-fails *retries*

no ccm-manager shut-interfaces-tftp-fails

Syntax Description

retries	Number or TFTP retries. Range is from 2 to 10. The default is 2.

Command Default

Ports shut down after the second TFTP retry. However TFTP download attempts continue.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T2	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use the **ccm-manager shut-interfaces-tftp-fails** command to configure the number of TFTP download failures allowed before the gateway put the port in a shutdown state.

Examples

The following example shows a gateway being configured to put the port in a shutdown state after four TFTP download failures:

```
Router(config)# ccm-manager shut-interfaces-tftp-fails 4
```

Related Commands

Command	Description
show ccm-manager	Displays a list of Cisco Unified Communications Manager servers and their current status and availability.

ccm-manager switchback

To specify the time when control is to be returned to the primary Cisco CallManager server once it becomes available, use the **ccm-manager switchback** command in global configuration mode. To reset to the default, use the **no** form of this command.

ccm-manager switchback {**graceful** | **immediate** | **never** | **schedule-time** *hh*:*mm* | **uptime-delay** *minutes*}

no ccm-manager switchback

Syntax Description

graceful	Specifies that control is returned to the primary Cisco CallManager server after the last active call ends (when there is no voice call in active setup mode on the gateway). Default value.
immediate	Specifies an immediate switchback to the primary Cisco CallManager server when the TCP link to the primary Cisco CallManager server is established, regardless of current call conditions.
never	Specifies not to return control to the primary Cisco CallManager server, as long as the secondary is up and running. The gateway registers to primary if the secondary is down and when the primary is up and running.
schedule-time *hh*:*mm*	Specifies an hour and minute, based on a 24-hour clock, when control is returned to the primary Cisco CallManager server. If the specified time is earlier than the current time, the switchback occurs at the specified time on the following day.
uptime-delay *minutes*	Specifies the number of minutes the primary Cisco CallManager server must run after the TCP link to is reestablished and control is returned to that primary call agent. Valid values are from 1 to 1440 (1 minute to 24 hours).

Command Default

Graceful switchback

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was modified. This command was introduced with Cisco CallManager Version 3.0 on the Cisco VG200.
12.2(2)XA	The command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.2(2)XN	Support for enhanced Media Gateway Control Protocol (MGCP) voice gateway interoperability was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, 3600 series, and the Cisco VG200.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco IAD2420 series routers.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **never** keyword was added.

Usage Guidelines

This command allows you to configure switchback to the higher priority Cisco CallManager when it becomes available. Switchback allows call control to revert to the original (primary) Cisco CallManager once service has been restored.

Examples

In the following example, the primary Cisco CallManager is configured to be used as soon as it becomes available:

```
Router# configure terminal
Router(config)# ccm-manager switchback immediate
```

Related Commands

Command	Description
ccm-manager application	Configures the port number for the redundant link application.
ccm-manager redundant-host	Configures the IP address or the DNS name of up to two backup Cisco CallManagers.
ccm-manager switchover-to-backup	Redirects a Cisco 2600 series or Cisco 3600 series router to the backup Cisco CallManager.

ccm-manager switchover-to-backup

To manually redirect a gateway to the backup Cisco CallManager server, use the **ccm-manager switchover-to-backup** command in privileged EXEC mode.

ccm-manager switchover-to-backup

Syntax Description This command has no arguments or keywords.

Defaults No default behavior or values

Command Modes Privileged EXEC (#)

Command History

Release	Modification
12.2(2)XN	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2 and implemented on the Cisco IAD2420 series.

Usage Guidelines Switchover to the backup Cisco CallManager server occurs immediately. This command does not switch the gateway to the backup Cisco CallManager server if you have the **ccm-manager switchback** command option set to “immediate” and the primary Cisco CallManager server is still running.

Examples In the following example, the backup Cisco CallManager server is configured to be used as soon as it becomes available:

```
ccm-manager switchover-to-backup
```

Related Commands

Command	Description
ccm-manager application redundant-link	Configures the port number for the redundant link application (that is, for the secondary Cisco CallManager server).
ccm-manager redundant-host	Configures the IP address or the DNS name of up to two backup Cisco CallManager servers.
ccm-manager switchback	Specifies the time at which control is returned to the primary Cisco CallManager server once the server is available.

ccs connect (controller)

To configure a common channel signaling (CCS) connection on an interface configured to support CCS frame forwarding, use the **ccs connect** command in controller configuration mode. To disable the CCS connection on the interface, use the **no** form of this command.

ccs connect {**serial** | **atm**} *number* [*dlci* | **pvc** *vpi/vci* | **pvc** *name*] [*cidnumber*]

no ccs connect {**serial** | **atm**} *number* [*dlci* | **pvc** *vpi/vci* | **pvc** *name*] [*cidnumber*]

Syntax Description

serial	Makes a serial CCS connection for Frame Relay.
atm	Makes an Asynchronous Transfer Mode (ATM) CCS connection.
dlci	(Optional) Specifies the data link connection identifier (DLCI) number.
pvc *vpi/vci*	(Optional) Specifies the permanent virtual circuit (PVC) virtual path identifier or virtual channel identifier. Range is from 0 to 255; the slash is required.
pvc *name*	(Optional) Specifies the PVC string that names the PVC for recognition.
cidnumber	(Optional) If you have executed the **ccs encap frf11** command, the *cidnumber* argument allows you to specify any channel identification (CID) number from 5 to 255.

Command Default

No CCS connection is made.

Command Modes

Controller configuration

Command History

Release	Modification
12.0(2)T	This command was introduced on the Cisco MC3810.
12.0(7)XK	The *cidnumber* argument was added; the **dlci** keyword and **vcd** options were removed.
12.1(2)T	The CID syntax addition and removal of the **dlci** keyword and **vcd** options were integrated into Cisco IOS Release 12.1(2)T.
12.1(2)XH	This command was implemented on the Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco 7500 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

Use this command to configure a CCS connection. If the CCS connection is over Frame Relay, specify a serial interface and the DLCI. If the CCS connection is over ATM, specify **atm**, the slot number, and the PVC.

If you have executed the **ccs encap frf11** command, the *cidnumber* option allows you to specify any CID from 5 to 255. If you do not issue the **ccs encap frf11** command, Cisco encapsulation is used, and any CID value other than 254 is ignored.

Note CDP and keepalives are disabled by default on a D-channel interface.

Examples

To configure a Frame Relay CCS frame-forwarding connection on DLCI 100 by using the default CID of 254, enter the following command:

```
ccs connect serial 1 100
```

or:

```
ccs connect serial 1 100 10
```

To configure a CCS frame-forwarding connection over an ATM PVC, enter the following command:

```
ccs connect atm0 pvc 100/10
```

or:

```
ccs connect atm0 pvc 10/100 21
```

or:

```
ccs connect atm0 pvc mypvc_10 21
```

To configure a Frame Relay CCS frame-forwarding connection on DLCI 100 using a CID of 110, enter the following command:

```
ccs connect serial 1 100 110
```

Related Commands

Command	Description
ccs encap frf11	Allows the specification of the standard Annex-C FRF.11 format.

ccs connect (interface)

To configure a common channel signaling (CCS) connection on an interface configured to support CCS frame forwarding, use the **ccs connect** command in interface configuration mode. To disable the CCS connection on the interface, use the **no** form of this command.

ccs connect {**serial** | **atm**} *number* [*dlci* | **pvc** *vpi/vci* | **pvc** *name*] [*cid-number*]

no ccs connect {**serial** | **atm**} *number* [*dlci* | **pvc** *vpi/vci* | **pvc** *name*] [*cid-number*]

Syntax Description

serial	Makes a serial CCS connection for Frame Relay.
atm	Makes an Asynchronous Transfer Mode (ATM) CCS connection.
dlci	(Optional) Data-link connection identifier (DLCI) number.
pvc *vpi/vci*	(Optional) Permanent virtual circuit (PVC) virtual path identifier or virtual channel identifier. Range is from 0 to 255; the slash is required.
pvc *name*	(Optional) PVC string that names the PVC for recognition.
cid-number	(Optional) If you have executed the **ccs encap frf11** command, the ***cid-number*** argument allows you to specify any channel identification (CID) number from 5 to 255.

Command Default No CCS connection is made.

Command Modes Interface configuration

Command History

Release	Modification
12.0(2)T	This command was introduced on the Cisco MC3810.
12.0(7)XK	The *cid-number* argument was added; the **dlci** keyword and **vcd** options were removed.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.2(2)T	This command was implemented on the Cisco 7200 series router and integrated into Cisco IOS Release 12.2(2)T.

Usage Guidelines Use this command to configure a CCS connection. If the CCS connection is over Frame Relay, specify a serial interface and the DLCI. If the CCS connection is over ATM, specify **atm**, the interface number (0), and the PVC. If you have executed the **ccs encap frf11** command, the *cid-number* option allows you to specify any CID from 5 to 255. If you do not issue the **ccs encap frf11** command, Cisco encapsulation is used, and any CID value other than 254 is ignored.

Note Cisco Discovery Protocol (CDP) and keepalives are disabled by default on a D-channel interface.

Examples

To configure a Frame Relay CCS frame-forwarding connection on DLCI 100 by using the default CID of 254, enter the following command:

```
ccs connect serial 1 100
```

or

```
ccs connect serial 1 100 10
```

To configure a CCS frame-forwarding connection over an ATM PVC, enter the following command:

```
ccs connect atm0 pvc 100/10
```

or

```
ccs connect atm0 pvc 10/100 21
```

or

```
ccs connect atm0 pvc mypvc_10 21
```

To configure a Frame Relay CCS frame-forwarding connection on DLCI 100 using a CID of 110, enter the following command:

```
ccs connect serial 1 100 110
```

Related Commands

Command	Description
ccs encap frf11	Allows the specification of the standard Annex-C FRF.11 format.

ccs encap frf11

To configure the common channel signaling (CCS) packet encapsulation format for FRF.11, use the **ccs encap frf11** command in interface configuration mode. To disable CCS encapsulation for FRF11, use the **no** form of this command.

ccs encap frf11

no ccs encap frf11

Syntax Description

This command has no keywords or arguments.

Command Default

By default, the format is a Cisco packet format, using a channel ID (CID) of 254

Command Modes

Interface configuration

Command History

Release	Modification
12.0(7)XK	This command was introduced for the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.1(2)XH	This command was implemented on the Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco 7500 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

This command allows the specification of the standard Annex-C format. Use this command to define the packet format for the CCS packet; it places the FRF.11 Annex-C (Data Transfer Syntax) standard header on the CCS packets only.

Once the **ccs encap frf11** command is executed, you can use the **ccs connect** command to specify a CID other than 254.

Examples

The following example shows how to configure a serial interface for Frame Relay:

```
interface Serial1:15
 ccs encap frf11
 ccs connect Serial0 990 100
```

Related Commands

Command	Description
mode ccs frame-forwarding	Set to forward frames on the controller.

cdr-format

To select the format of the call detail records (CDRs) generated for file accounting, use the **cdr-format** command in gateway accounting configuration mode. To reset to the default, use the **no** form of this command.

cdr-format {**compact** | **detailed**}

no cdr-format

Syntax Description

compact	Compact set of voice attributes is generated in CDRs.
detailed	Full set of voice attributes is generated in CDRs. Default value.

Command Default

Detailed (full version of CDRs is generated).

Command Modes

Gateway accounting file configuration (config-gw-accounting-file)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

This command determines whether the CDRs generated by the file accounting process contain the complete set of voice attributes or a compact set of 17 voice attributes.

For a list of the complete set of voice attributes generated with the **detailed** keyword, see the "VSAs Supported by Cisco Voice Products" section in the *RADIUS VSA Voice Implementation Guide*.

The name and order of the attributes generated with the **compact** keyword are: CallLegType, ConnectionId, SetupTime, PeerAddress, PeerSubAddress, DisconnectCause, DisconnectText, ConnectTime, DisconnectTime, CallOrigin, ChargedUnits, InfoType, TransmitPackets, TransmitBytes, ReceivePackets, ReceiveBytes, feature_vsa.

Examples

The following example shows the CDR format set to compact:

```
gw-accounting file
 primary ftp server1/cdrtest1 username bob password temp
 maximum buffer-size 60
 maximum fileclose-timer 720
 cdr-format compact
```

Related Commands

Command	Description
acct-template	Selects a group of voice vendor-specific attributes to collect in accounting records.
maximum buffer-size	Sets the maximum size of the file accounting buffer.
maximum fileclose-timer	Sets the maximum time for saving records to an accounting file before closing the file and creating a new one.
primary	Sets the primary location for storing the CDRs generated for file accounting.

ces-clock

To configure the clock for the CES interface, use the **ces-clock** command in controller configuration mode. To disable the ces clock, use the **no** form of this command.

ces-clock {**adaptive | srts | synchronous**}

no ces-clock {**adaptive | srts | synchronous**}

Syntax Description

adaptive	Adjusts output clock on a received ATM Adaptation Layer 1 (AAL1) on first-in, first-out basis. Use in unstructured mode.
srts	Sets the clocking mode to synchronous residual time stamp.
synchronous	Configures the timing recovery to synchronous for structured mode.

Command Default

The default setting is synchronous

Command Modes

Controller configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines

This command is used on Cisco 3600 series routers that have OC-3/STM-1 ATM CES network modules.

Examples

The following example configures the CES clock mode for synchronous residual time stamp:

```
ces-clock srts
```

Related Commands

Command	Description
controller	Configures the T1 or E1 controller.

cgma-agent

To enable the Cisco Gateway Management Agent (CGMA) on the Cisco IOS gateway, use the **cgma-agent** command in global configuration mode. To disable the CGMA, use the **no** form of this command.

cgma-agent [tcp-port *number***] | [time-period** *seconds***]**

no cgma-agent

Syntax Description

tcp-port *number*	(Optional) Specifies the TCP port number for the CGMA to use in communication with a third-party management system. Range is from 5000 to 65535. The default is 5000.
time-period *seconds*	(Optional) Specifies the maximum time period, in seconds for maintaining the link between the CGMA and the third-party management system during a period of inactivity. If twice the timeout value is met or exceeded with no message received from the client, the TCP connection is closed. Additionally, a 60-second timer is maintained in the CGMA, which closes the connection if no handshake query message is received from the third-party management system for 60 seconds. Range is from 45 to 300. The default is 45.

Command Default

Default *number* value is 5000.
Default *seconds* value is 45.

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco 2600 series, Cisco 3600 series, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5800 for this Cisco IOS release only.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800 is not included in this release.

Usage Guidelines

Use this command to enable the CGMA on the Cisco IOS gateway. The CGMA communicates with the third-party management system to provide real-time information for gateway management, including the following:

- Handshake query, status query, and response messages between the CGMA and the third-party management system
- Call information such as start and end of call from call detail records (CDRs) sent using extensible markup language (XML) over TCP/IP
- Shows if T1 or E1 controllers and analog ports are up or down, and are also generated at the removal or addition of a “pri-group” or “ds0-group” under the T1 or E1 controller.

Examples

The following example shows that the CGMA is enabled on TCP port 5300 and that the CGMA times out after 300 seconds and closes its connection to the third-party management system because of inactivity in the link:

```
Router(config)# cgma-agent tcp-port 5300 time-period 300

Router# show running-config

channel-group

To configure serial WAN on a T1 or E1 interface, use the **channel-group** command in controller configuration mode. To clear a channel group, use the **no** form of this command.

Cisco 2600 Series

channel-group *channel-group-number* **timeslots** *range* [**speed** *kbps*] [**aim** *aim-slot-number*]

no channel-group *channel-group-number*

Cisco 2611 (Cisco Signaling Link Terminal [SLT])

channel-group *channel-number*

no channel-group *channel-number*

Cisco 2600XM Series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745

channel-group *channel-group-number* {**timeslots** *range* [**speed** {**56** | **64**}] | **unframed**} [**aim** *aim-slot-number*]

no channel-group [*channel-group-number* **timeslots** *range*]

Cisco AS5350 and Cisco AS5400 Series

channel-group *channel-group-number*

no channel-group *channel-group-number*

Cisco MC3810

channel-group *channel-number* **timeslots** *range* [**speed** *kbps*}]

no channel-group [*channel-number* **timeslots** *range*]

Syntax Description

channel-group-number	Channel-group number on the Cisco 2600 series, Cisco 2600XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 routers. When a T1 data line is configured, channel-group numbers can be values from 0 to 23. When an E1 data line is configured, channel-group numbers can be values from 0 to 30. Valid values can be 0 or 1 on the Cisco AS5350 and Cisco AS5400.
timeslots *range*	Specifies one or more time slots separated by commas, or ranges of time slots belonging to the channel group separated by a dash. The first time slot is numbered 1. For a T1 controller, the time slots range from 1 to 24. For an E1 controller, the time slots range from 1 to 31. You can specify a time slot range (for example, 1-29), individual time slots separated by commas (for example 1, 3, 5), or a combination of the two (for example 1-14, 15, 17-31). See the "Examples" section for samples of different timeslot ranges.

speed {**56** | **64**}	(Optional) Specifies the speed of the underlying DS0s in kilobits per second. Valid values are 56 and 64. The default line speed when configuring a T1 controller is 56 kbps on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and the Cisco MC3810. The default line speed when configuring an E1 controller is 64 kbps on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and the Cisco MC3810. The line speed controls real-time (VBR-RT) traffic shaping, and the maximum burst size (MBS) is 255 cells.
aim *aim-slot-number*	(Optional) Directs HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 digital signaling processor (DSP) card on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745.
channel-number	Number of the channel. Valid values can be 0 or 1 on the Cisco SLT (Cisco 2611).
unframed	Specifies the use of all 32 time slots for data. None of the 32 time slots are used for framing signals on the Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745. This is applicable to E1 only.

Command Default

The T1/E1 line is connected to the Motorola MPC-860x processor serial communication controller (SCC) or network module with two voice or WAN interface card (VIC or WIC) slots and 0/1/2 FastEthernet ports DSCC4 by default on Cisco 2600 series, Cisco 2600XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 routers.

There is no default behavior or values on the Cisco SLT (Cisco 2611).

The serial interface object encapsulation is set to HDLC on a network access server (NAS) (Cisco AS5350 and Cisco AS5400 series routers).

The default line speed is 56 kbps when a T1 controller is configured on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and the Cisco MC3810.

The default line speed is 64 kbps when an E1 controller is configured on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and the Cisco MC3810.

Command Modes

Controller configuration

Command History

Release	Modification
11.3 MA	This command was introduced on the Cisco MC3810.
12.0	This command was integrated into Cisco IOS Release 12.0 on the Cisco MC3810.
12.0(7)XE	This command was implemented on the Catalyst 6000 family switches.
12.1(1)E	This command was integrated into Cisco IOS Release 12.1(1)E.

Release	Modification
12.1(1)T	This command was modified to accommodate two channel groups on a port on 1- and 2-port T1/E1 Multiflex voice or WAN interface cards on the Cisco 2600 and Cisco 3600 series routers.
12.1(3a)E3	The number of valid values for *kbps* was changed on the Cisco MC3810; see the "Usage Guidelines" section for valid values.
12.2(11)T	This command was modified for use on the Cisco AS5350 and Cisco AS5400.
12.2(11)T	The **aim** keyword was added for use on the Cisco 2600 series (including the Cisco 2691), Cisco 2600XM, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(1)	The **unframed** keyword was added for use on the Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745.

Usage Guidelines

Use this command to direct High-Level Data Link Control (HDLC) traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 DSP card. A channel group is created using Advanced Integration Module (AIM) HDLC resources when a **channel-group** command with the **aim** keyword is parsed during system initialization or when the command is entered during configuration. You must specify the **aim** keyword under a T1/E1 controller port to direct HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 DSP card on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745.

Note Neither the Cisco AS5400 series NAS nor the Cisco MC3810 is supported with the integrated voice and data WAN on T1/E1 interfaces using the AIM-ATM-VOICE-30 module.

If previous **channel-group** commands are configured with the **aim** keyword, subsequent **channel-group** commands without the **aim** keyword are rejected. Similarly, if a regular **channel-group** command is followed by another **channel-group** command with the **aim** keyword implemented, the second command is rejected on the Cisco 2600 and Cisco 2600XM.

A channel group using AIM HDLC resources is deleted only when a **no channel-group** command is entered.

By default, the **channel-group** command on a NAS sets the serial interface object encapsulation to HDLC. You must override the default by entering the **encapsulation ss7** command for that serial interface object. Once you override the default, encapsulation cannot be changed again for that object. The SS7 encapsulation option is new to the **Integrated Signaling Link Terminal** feature and is available only for interface serial objects created by the **channel-group** command. The Integrated Signaling Link Terminal feature added SLT functionality on Cisco AS5350 and Cisco AS5400 platforms.

A digital SS7 link can be deleted by entering the **no channel-group** *channel-group-number* command on the associated T1/E1 controller. The link must first be stopped using the **no shutdown** command. It is not necessary to remove the channel ID association first.

Use the **channel-group** command in configurations where the router or access server must communicate with a T1 or E1 fractional data line. The channel group number may be arbitrarily assigned and must be unique for the controller. The time slot range must match the time slots assigned to the channel group. The service provider defines the time slots that comprise a channel group.

Note Channel groups, channel-associated signaling (CAS) voice groups, DS0 groups, and time-division multiplexing (TDM) groups all use group numbers. All group numbers configured for channel groups, CAS voice groups, and TDM groups must be unique on the local Cisco MC3810 concentrator. For example, you cannot use the same group number for a channel group and for a TDM group. Furthermore, on the Cisco MC3810, only one channel group can be configured on a controller.

The channel group number can be 0 or 1 on the Cisco SLT (Cisco 2611).

The **channel-group** command also applies to Voice over Frame Relay, Voice over ATM, and Voice over HDLC on the Cisco MC3810.

Examples

The following example shows basic configuration directing HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 DSP card, starting in global configuration mode:

```
Router(config)# controller e1 1/0
Router(config-controller)# clock source internal
Router(config-controller)# channel-group 0 timeslots 1-31 aim 0
```

The following example explicitly sets the encapsulation type to PPP to override the HDLC default:

```
Router# configure terminal
Router(config)# controller t1 6/0
Router(config-controller)# channel-group 2 timeslots 3 aim 0
Router(config-controller)# exit
Router(config)# interface serial 6/0:2
Router(config-if)# encapsulation ppp
Router(config-if)# ip address 12.0.0.1 255.0.0.0
Router(config-if)# no shutdown
Router(config-if)# end
```

The following example shows how to explicitly set the encapsulation type to SS7 to override the HDLC default using the Integrated Signaling Link Terminal feature. This example uses an 8PRI DFC card inserted into slot 7, and DS0-timeslot 3 on trunk 5 of that card is used as an SS7 link:

```
Router# configure terminal
Router(config)# controller t1 7/5
Router(config-controller)# channel-group 2 timeslots 3
Router(config-controller)# exit
Router(config)# interface serial 7/5:2
Router(config-if)# encapsulation ss7
Router(config-if)# channel-id 0
Router(config-if)# no shutdown
Router(config-if)# end
```

The following example defines three channel groups. Channel-group 0 consists of a single time slot, channel-group 8 consists of seven time slots and runs at a speed of 64 kbps per time slot, and channel-group 12 consists of two time slots.

```
Router(config-controller)# channel-group 0 timeslots 1
Router(config-controller)# channel-group 8 timeslots 5,7,12-15,20 speed 64
Router(config-controller)# channel-group 12 timeslots 2
```

The following example configures a channel group on controller T1 0 on a Cisco MC3810:

```
Router(config)# controller T1 0
Router(config-controller)# channel-group 10 timeslots 10-64
```

The following example configures a channel group on controller E1 1 and specifies that all time slots are used for data:

```
controller e1 1
channel-group 1 unframed
```

Note SS7 digital F-link support for the 8PRI line card requires use of a third onboard TDM stream to route trunk DS0 messages to the onboard Media Gateway Controllers (MGCs).

Related Commands

Command	Description
framing	Specifies the frame type for the T1 or E1 data line.
invert data	Enables channel inversion.
linecode	Specifies the line code type for the T1 or E1 line.
voice-card	Configures a card with voice processing resources and enters voice card configuration mode.

channel-id

To assign a session channel ID to an SS7 serial link or assign an SS7 link to an SS7 session set on a Cisco AS5350 or Cisco AS5400, use the **channel-id** command in interface configuration mode. To disable a session channel ID link, use the **no** form of this command.

channel-id *channel-id* [**session-set** *session-set-id*]

no channel-id

Syntax Description

channel-id	Selects a unique session channel ID. This session channel ID is needed when the link with a Reliable User Datagram Protocol (RUDP) session to the media gateway controller (MGC) is associated.
session-set *session-set-id*	(Optional) Creates an SS7-link-to-SS7-session-set association on the Cisco AS5350- and Cisco AS5400-based Cisco Signaling Link Terminals (SLTs). The *session-set-id* argument represents the SS7 session ID. Valid values are 0 or 1. Default is 0.

Command Default No default behavior or values

Command Modes Interface configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco AS5350 and Cisco AS5400.
12.2(15)T	The **session-set** *session-set-id* keyword and argument were added.

Usage Guidelines The **channel-id** command is visible only if the object's encapsulation type is changed to SS7.

Before an SS7 serial link can be enabled using the **no shutdown** command, you must enter the **channel-id** command in interface configuration mode to assign a session channel ID to the SS7 serial link. This ID is unique to the Cisco AS5350 and Cisco AS5400, and the command is visible only for provisioned objects whose encapsulation type is the new SS7 value.

The channel identifier is reserved when you explicitly assign an ID using the **channel-id** command for the associated serial interface object. This fails if the selected channel identifier is currently assigned to another link or if all channel identifiers are already assigned.

A channel identifier is released when the **no channel-id** command is entered. The link must first be shut down to do this. If the **no channel-id** command is used with the Mulitple OPC Support for the Cisco Signaling Link Terminal feature, the associated SS7 link has no channel ID. In this state the link is not fully configured and is incapable of supporting signaling traffic.

If the **session-set** keyword is omitted, the command is applied to SS7 session set 0, which is the default. Reissuing the **session-set** keyword with a different SS7 session ID is sufficient to remove the associated SS7 link from its existing SS7 session set and add it to the new one.

Examples

The following example shows a unique session channel ID zero being assigned to the Cisco AS5350 or Cisco AS5400:

```
Router(config-if)# channel-id 0
```

The following example assigns an SS7 link to an SS7 session set on a Cisco AS5350 or Cisco AS5400:

```
Router(config-if)# channel-id 0 session-set 1
```

Related Commands

Command	Description
channel-group	Assigns a channel group and selects the DS0 timeslot(s) desired for SS7 links.
encapsulation ss7	Sets the encapsulation type to SS7.
no shutdown	Changes the administrative state of a port from out-of-service to in-service.
session-set	Creates a Signaling System 7 (SS7)-link-to-SS7-session-set association or to associate an SS7 link with an SS7 session set on the Cisco 2600-based Signaling Link Terminal (SLT).
ss7 mtp2 variant bellcore	Configures the device for Telcordia (formerly Bellcore) standards. This command is hidden in the running configuration with this feature.

clear backhaul-session-manager group stats

To reset the statistics or traffic counters for a specified session group, use the **clear backhaul-session-manager group stats** command in privileged EXEC mode.

clear backhaul-session-manager group stats {**all** | **name** *group-name*}

Syntax Description

all	All available session groups.
name *group-name*	A specified session group.

Command Default The statistical information accumulates

Command Modes Privileged EXEC

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200.
12.2(4)T	This command was implemented on the Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on Cisco IAD2420 series.
12.2(11)T	This command was implemented on the Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Usage Guidelines A session is the connection between a client and a server, and a session group is a collection of sessions in a group to implement switchover in case of a session failure. This command clears all statistics that pertain to the backhaul session manager group.

Examples The following example clears all statistics for all available session groups:

```
Router(config)# clear backhaul-session-manager group stats all
```

Related Commands

Command	Description
show backhaul-session-manager group	Displays status, statistics, or configuration of a specified group or all session groups.

clear call application interface

To clear application interface statistics and event logs, use the **clear call application interface** command in privileged EXEC mode.

clear call application interface [[{**aaa** | **asr** | **flash** | **http** | **ram** | **rtsp** | **smtp** | **tftp** | **tts**} [**server** *server*]] [**event-log** | **stats**]]

Syntax Description

event-log	(Optional) Clears event logs.
stats	(Optional) Clears statistic counters.
aaa	Authentication, authorization, and accounting (AAA) interface type.
asr	Automatic speech recognition (ASR) interface type.
flash	Flash memory of the Cisco gateway.
http	Hypertext Transfer Protocol (HTTP) interface type.
ram	Memory of the Cisco gateway.
rtsp	Real-time Streaming Protocol (RTSP) interface type.
smtp	Simple Mail Transfer Protocol (SMTP) interface type.
tftp	Trivial File Transfer Protocol (TFTP) interface type.
tts	Text-to-speech (TTS) interface type.
server *server*	(Optional) Clears statistics or event logs for the specified server.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

This command resets statistic counters to zero and clears event logs for application interfaces. If you do not use any keywords or arguments, this command clears statistics and event logs for all application interfaces.

Examples

The following example clears statistics and event logs for application interfaces:

```
Router# clear call application interface
```

Related Commands

Command	Description
call application interface event-log	Enables event logging for external interfaces used by voice applications.
call application interface stats	Enables statistics collection for application interfaces.

Command	Description
clear call application stats	Clears application-level statistics in history and subtracts the statistics from the gateway-level statistics.
show call application interface	Displays event logs and statistics for application interfaces.

clear call application stats

To clear application-level statistics in history and subtract the statistics from the gateway-level statistics, use the **clear call application stats** command in privileged EXEC mode.

clear call application [**app-tag** *application-name*] **stats**

Syntax Description

app-tag *application-name*	(Optional) Clears statistics for the specified voice application.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

This command resets application-level counters in history to zero and subtracts the counters from the gateway-level history. If you do not specify an application name, this command clears statistics for all applications at the application level and gateway level.

Note Statistic counters are automatically cleared for an application if the application is deleted with the **no call application voice** command or the script is reloaded with the **call application voice load** command.

Examples

The following example clears statistics for the application named sample_app:

```
Router# clear call application stats sample_app
```

Related Commands

Command	Description
call application stats	Enables statistics collection for voice applications.
clear call application interface	Clears application interface statistics and event logs.
show call application app-level	Displays application-level statistics for voice applications.
show call application gateway-level	Displays gateway-level statistics for voice application instances.

clear call fallback cache

To clear the cache of the current Calculated Planning Impairment Factor (ICPIF) estimates for all IP addresses or a specific IP address, use the **clear call fallback cache** command in EXEC mode.

clear call fallback cache [*ip-address*]

Syntax Description

ip-address	(Optional) Specifies the target IP address. If no IP address is specified, all IP addresses are cleared.

Command Default If no IP address is specified, all IP addresses are cleared.

Command Modes EXEC

Command History

Release	Modification
12.1(3)T	This command was introduced on Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on Cisco 7200 series routers and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines If no IP address is specified, this command clears the cache of all ICPIF estimates for all IP addresses.

Examples The following example clears the cache of the ICPIF estimate for IP address 10.0.0.0:

```
Router# clear call fallback cache 10.0.0.0
```

Related Commands

Command	Description
show call fallback cache	Displays the current ICPIF estimates for all IP addresses in the call fallback cache.

clear call fallback stats

To clear the call fallback statistics, use the **clear call fallback stats** command in EXEC mode.

clear call fallback stats

Syntax Description This command has no arguments or keywords.

Command Modes EXEC

Command History

Release	Modification
12.1(3)T	This command was introduced on Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850 platform.
12.2(4)T	The PSTN Fallback feature and enhancements were implemented on Cisco 7200 series and integrated into Cisco IOS Release 12.2(4)T.
12.2(4)T2	This command was implemented on the Cisco 7500 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples The following example clears the call fallback statistics:

```
Router# clear call fallback stats
```

Related Commands

Command	Description
show call fallback stats	Displays the call fallback statistics.

clear callmon

To clear call monitor logs, use the **clear callmon** command in privileged EXEC mode.

clear callmon {**dead-memory** | **trace**}

Syntax Description

dead-memory	Clears unreleased Communication Media Module (CMM) line card memory.
trace	Clears CMM trace buffers.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows how to clear unreleased CMM memory:

```
Router# clear callmon dead-memory
```

The following example shows how to clear CMM trace buffers:

```
Router# clear callmon trace
```

Related Commands

Command	Description
clear tgrep neighbor	Clears TGREP counters and sessions.

clear call threshold

To clear enabled call threshold statistics, use the **clear call threshold command in privileged** EXEC mode.

clear call threshold {**stats | total-calls** [*value*] | **interface** *int-name* **int-calls** [*value*]}

Syntax Description

stats	Resets all call threshold statistics.
total-calls	Resets the counter when the call volume reaches the specified number.
value	Represents call volume. Range is from 0 to 10000 calls. The default is 0.
interface *int-name*	Specifies the interface through which calls arrive. Types of interfaces and their numbers depends upon the configured interfaces.
int-calls	Number of calls transmitted through the interface.
value	Clears calls when they reach a specified volume through the interface. Range is from 0 to 10000 calls. The default is 0.

Command Default

The default setting of 0 for **total-calls** and **int-calls** resets all threshold statistics immediately. **stats** is the default keyword.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400, is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on Cisco 1750 and Cisco 1751 routers. Support for other Cisco platforms is not included in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on Cisco 7200 series routers. Support for Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.

Examples

The following example resets all call threshold statistics:

```
clear call threshold stats
```

The following example also resets the counter for all call volume in the gateway:

```
clear call threshold total-calls
```

The following example resets the counter when the call volume on Ethernet interface 0/1 reaches 5000 calls:

```
clear call threshold interface ethernet 0/1 int-calls 5000
```

Related Commands

Command	Description
call threshold	Enables the global resources of a gateway.
call threshold poll-interval	Enables a polling interval threshold for CPU or memory.
show call treatment	Displays the call treatment configuration and statistics for handling the calls on the basis of resource availability.

clear call treatment stats

To clear call treatment statistics, use the **clear call treatment stats** command in privileged EXEC mode.

clear call treatment stats

Syntax Description This command has no arguments or keywords.

Command Modes Privileged EXEC

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	The command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on Cisco 1750 and Cisco 1751 routers. Support for other Cisco platforms is not included in this release.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on Cisco 7200 series routers. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This feature was integrated into Cisco IOS Release 12.2(11)T and support was added for Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Examples The following example clears the call treatment statistics:

```
clear call treatment stats
```

Related Commands

Command	Description
call treatment on	Enables call treatment to process calls when local resources are unavailable.
call treatment action	Configures the action that the router takes when local resources are unavailable.
call treatment cause-code	Specifies the reason for the disconnection to the caller when local resources are unavailable.
call treatment isdn-reject	Specifies the rejection cause-code for ISDN calls when local resources are unavailable.
show call treatment	Displays the call treatment configuration and statistics for handling calls on the basis of resource availability.

clear call voice

To clear one or more voice calls detected as inactive because there is no RTP or RTCP activity, use the **clear call voice** command in EXEC or privileged EXEC mode.

clear call voice causecode *identifier*{**id** *identifier* | **media-inactive** | **calling-number** *number* | **called-number** *number*}

Syntax Description

causecode	Specifies a Q.850 disconnect cause code.
identifier	Numeric cause code identifier; a number 1 through 127.
id	Clears one specific call with the ID specified.
identifier	Call identifier as shown in brief format.
media-inactive	Clears calls wherever a status of media inactive is detected and notified.
calling-number	Clears a call with a specific calling number pattern.
called-number	Clears a call with a specific called number pattern.
number	Specific call number pattern of a called number or calling number.

Command Default

This command is disabled, and no calls are cleared.

Command Modes

User EXEC

Privileged EXEC

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2	This command was integrated into Cisco IOS Release 12.2.
12.3(4)T	The **voice** keyword was added.
12.4(4)T	The **calling-number** and **called-number** keywords were added.

Usage Guidelines

This command can be used to clear all voice calls detected as media inactive or it can be used to clear individual voice calls. There is no **no** form of this command.

Examples

The following example clears inactive voice calls with the cause code ID of 112B:

```
Router# clear call voice causecode 1 id 112B
```

Related Commands

Command	Description
show call active voice	Displays active voice calls, based on specified parameters.

clear call-router routes

To remove the dynamic routes cached in the border element (BE), enter the **clear call-router routes** command in privileged EXEC mode.

clear call-router routes

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.

Examples

The following example shows how to remove dynamic routes cached in the BE:

```
Router# clear call-router routes
```

Related Commands

Command	Description
call-router	Enables the Annex G BE configuration commands.
show call history	Displays the fax history table for a fax transmission.

clear controller call-counters

To clear the system DS0 high water marks (HWM) and all individual controller statistics, use the **clear controller call-counters** command in privileged EXEC mode.

clear controller call-counters {**system-hwm** | **all**}

Syntax Description

system-hwm	Clears the system HWMs only.
all	Clears *all* controller call counters including the individual controller time slots in use and the number of calls on those time slots since the last reset was done. The HWMs are set to 0.

Command Default No default behavior or values

Command Modes Privileged EXEC

Command History

Release	Modification
12.0(1)T	This command was introduced.
12.1(1)T	This command was implemented on the voice/WAN interface cards (VWICs) for Cisco 2600 series and Cisco 3600 series.
12.1(2)T	This command was implemented on the Cisco AS5300, Cisco AS5400, and Cisco AS5800.

Usage Guidelines The **clear controller call-counters all** command clears the system DS0 HWMs and all individual controller statistics, including Total Calls and Total Duration. The **clear controller call-counters system-hwm** command clears the system DS0 HWMs and leaves all other call-counter statistics untouched.

Refer to the comments below for the meaning of call counters displayed before and after executing **clear controller call-counters** and **clear controller t1 call-counters** related commands.

- The numbers displayed under TotalCalls for each time slot represent *total* calls that were connected successfully. If a call comes into time slot 10, then the **show controllers t1 call-counters** command displays 1 under the TotalCalls column for time slot 10. A value of 20 displayed under TotalCalls for time slot 10 indicates a total of 20 calls connected on time slot 10 since the last time call counters were cleared.
- The DS0s Active field indicates the number of active calls on the specified controller. This number indicates the current number of calls on the controller at any given time.
- The DS0s Active High Water Mark field indicates the peak number of calls on the controller since the last time HWMs or calls were cleared. If the number of active calls “DS0s Active” is less than DS0s HWM, then HWM remains untouched. If new calls come in and the active DS0s are more than the HWM, then the HWM is incremented to reflect the new peak number of calls on that controller.

This value is reset to the current and active DS0s when call counters are cleared. For example, initially the HWM is 0. When a new call comes in, the HWM is 1. When the next call comes in, the HWM is 2.

If 20 calls come in, the HWM is 20 and the active DS0s are 20. If 5 calls get disconnected, the DS0 active is 15, but the HWM is 20. When a **clear controller** command is input for the specified controller, the HWM is reset to 15, which is the current and active DS0s also. If 10 calls get disconnected, the Active DS0s is set to 5 and the HWM remains at 15 until another **clear controller command** is input. If Active DS0s exceed 15, then the HWM is updated.

- The System DS0s High Water Mark field reflects the HWM at a system level including all DS0s controllers.

Examples

The following sample output shows what happens after the HWMs are cleared:

```
Router# clear controller call-counters system-hwm
!
Router# show controllers t1 call-counters

T1 1/3/0:3:

     22       pri            0       00:01:39
     23       pri            0       00:00:00

System's DS0's Active High Water Mark: 3
```

In the example above, the system HWM is reset to the total number of active calls in the system, which is 3. The number was 4. When a call goes down, HWM values are untouched. Only the DS0 Active value changes. Above, there is only one call on 1/3/0:3. Observe the HWM for individual controllers. Total number of active calls is 1.

The following is sample output when the **clear controller call-counters system-hwm** command is used:

```
Router# clear controller call-counters system-hwm
!
Router# show controllers t1 call-counters
T1 1/3/0:3:
  DS0's Active: 1
  DS0's Active High Water Mark: 2

     23       pri           0       00:00:00

System's DS0's Active High Water Mark: 1
```

In the previous example, only the system HWM is reset to active. For controllers 1/3/0:3 and 1/3/0:8, the HWMs are untouched.

The following is sample output when the **all** keyword is used, clearing at the system level:

```
Router# clear controller call-counters all
!
Router# show controllers t1 call-counters

T1 1/3/0:3:
  DS0's Active: 0
  DS0's Active High Water Mark: 0
  TimeSlot   Type   TotalCalls   TotalDuration
      1       pri           0       00:00:00
      2       pri           0       00:00:00
      3       pri           0       00:00:00
      4       pri           0       00:00:00
      5       pri           0       00:00:00
      6       pri           0       00:00:00
      7       pri           0       00:00:00
      8       pri           0       00:00:00
      9       pri           0       00:00:00
     10       pri           0       00:00:00

     23       pri             0       00:00:00
System's DS0's Active High Water Mark: 0
```

In the previous example, clearing at the system level using the **clear controller call-counters** command clears all DS0 controllers in the system and also clears the system HWMs.

The following is sample output showing four active calls:

Related Commands

Command	Description
clear controller t1 call-counters	Clears call statistics on a specific T1 controller.
controller	Enters controller configuration mode.
show controllers t1 call-counters	Displays the total number of calls and call durations on a T1 controller.

clear controller t1

To clear the system DS0 high water marks (HWM) and all individual controller statistics, use the **clear controller t1** command in privileged EXEC mode.

clear controller t1 [*slot*] **call-counters** *timeslots* | **firmware-status**

slot	(Optional) Clears an individual T1 controller.
call-counters *timeslots*	Clears the call counters in the specified T1 time slots.
firmware-status	Clears the Neat crash history.

Command Default No default behavior or values

Command Modes Privileged EXEC

Command History

Release	Modification
12.0(1)T	This command was introduced.
12.1(1)T	This command was implemented on the voice and WAN interface cards (VWICs) for Cisco 2600 series and Cisco 3600 series.
12.1(2)T	This command was implemented on the Cisco AS5300, Cisco AS5400, and Cisco AS5800.

Usage Guidelines Refer to the comments below for the meaning of call counters displayed before and after executing **clear controller t1 call-counters** related commands.

- The numbers displayed under TotalCalls for each time slot represent *total* calls that were connected successfully. If a call comes into time slot 10, then the **show controllers t1 call-counters** command displays 1 under the TotalCalls column for time slot 10. A value of 20 displayed under TotalCalls for time slot 10 indicates a total of 20 calls connected on time slot 10 since *the last time call counters were cleared*.

  If a timeslot or timeslot range is specified, only the counters for those channels are cleared. The TotalCalls field shows the time slots that have calls connected since the last clear was done and does not show the number of active calls in the controller. The TotalDuration field shows the same information as the TotalCalls field.

- The DS0s Active field indicates the number of active calls on the specified controller. This number indicates the current number of calls on the controller at any given time.

- The DS0s Active High Water Mark field indicates the peak number of calls on the controller since the last **clear controller t1 1/0/0 call-counters** command was entered. If the number of active calls "DS0s Active" is less than DS0s HWM, then HWM remains untouched. If new calls come in and the active DS0s are more than the HWM, then the HWM is incremented to reflect the new peak number of calls on that controller.

  This value is reset to the *current* and active DS0s when the **clear controller t1 1/3/0 call-counters** command is entered. For example, initially the HWM is 0. When a new call comes in, the HWM is 1. When the next call comes in, the HWM is 2.

If 20 calls come in, the HWM is 20 and the active DS0s are 20. If 5 calls get disconnected, the DS0 active is 15, but the HWM is 20. When a **clear controller** command is input for the specified controller, the HWM is reset to 15, which is the current and active DS0s also. If 10 calls get disconnected, the Active DS0s is set to 5 and the HWM remains at 15 until another **clear controller command** is input. If Active DS0s exceed 15, then the HWM is updated.

- The System DS0s High Water Mark field reflects the HWM at a system level including all DS0s controllers.

Examples

The following is sample output that shows two controllers numbered 1/3/0:3 and 1/3/0:8. Note the differences in the output shown by the **show controllers t1 call-counters** command and how the **clear controller t1 call-counters** command affects the output:

```
Router#  show controllers t1 call-counters
T1 1/3/0:3:
  DS0's Active: 0
  DS0's Active High Water Mark: 0
  TimeSlot   Type   TotalCalls   TotalDuration
      1       pri           0       00:00:00
      2       pri           0       00:00:00
      3       pri           0       00:00:00
      4       pri           0       00:00:00
      5       pri           0       00:00:00
      6       pri           0       00:00:00
      7       pri           0       00:00:00
      8       pri           0       00:00:00

      9       pri           0       00:00:00
     10       pri           0       00:00:00
     11       pri           0       00:00:00
     12       pri           0       00:00:00
     13       pri           0       00:00:00
     14       pri           0       00:00:00
     15       pri           0       00:00:00
     16       pri           0       00:00:00
```

```
     17       pri            0       00:00:00
     18       pri            0       00:00:00
     19       pri            0       00:00:00
     20       pri            0       00:00:00
     21       pri            0       00:00:00
     22       pri            0       00:00:00
     23       pri            0       00:00:00

System's DS0's Active High Water Mark: 0
```

Note In the previous example, all the fields are zero indicating that no calls have come in since system startup or since the last clear was made by the **clear controller** command.

The following is sample output that shows that four calls have been initiated on the 1/5/12, 1/5/13, 1/5/14, and 1/5/15 controllers:

```
Router# show users

    Line       User       Host(s)              Idle       Location
*  0 con 0                 idle                 00:00:00
  tty 1/5/12   Router Async interface      00:01:05   PPP: 55.61.1.1
  tty 1/5/13   Router Async interface      00:00:48   PPP: 55.62.1.1
  tty 1/5/14   Router Async interface      00:00:33   PPP: 55.54.1.1
  tty 1/5/15   Router Async interface      00:00:19   PPP: 55.52.1.1

  Interface  User      Mode                     Idle Peer Address

Router# show controllers t1 call-counters

T1 1/3/0:3:
  DS0's Active: 2
  DS0's Active High Water Mark: 2

     4       pri            0       00:00:00
     5       pri            0       00:00:00
     6       pri            0       00:00:00
     7       pri            0       00:00:00
     8       pri            0       00:00:00
     9       pri            0       00:00:00
    10       pri            0       00:00:00
    11       pri            0       00:00:00
    12       pri            0       00:00:00
    13       pri            0       00:00:00
    14       pri            0       00:00:00
    15       pri            0       00:00:00
    16       pri            0       00:00:00
    17       pri            0       00:00:00
    18       pri            0       00:00:00
    19       pri            0       00:00:00
    20       pri            0       00:00:00
    21       pri            0       00:00:00
    22       pri            1       00:02:14
    23       pri            1       00:02:46

System's DS0's Active High Water Mark: 4
```

In the example above, if a **clear controller** command is entered for a controller that has active calls, which have been connected during the last 30 minutes, the TotalCalls and TotalDuration fields are reset to zero.

The following is sample output that shows controller 1/3/0:3, with time slots 22 and 23 connected and active. When the **clear controller t1 1/3/0:3 call-counters** command is entered, the corresponding fields are set to zero.

```
Router# clear controller t1 1/3/0:3 call-counters
!
Router# show controllers t1 call-counters

T1 1/3/0:3:
  DS0's Active: 2
  DS0's Active High Water Mark: 2

     22       pri            0       00:00:35
     23       pri            0       00:00:00

System's DS0's Active High Water Mark: 4
```

In the previous example, after clearing call counters for controller 1/3/0:8, TotalCalls and TotalDuration reset. In addition the DS0 HWM is also *cleared* to the number of active DS0s. Whenever the DS0 HWM is cleared, it does not reset to zero, but rather it is set to Active DS0s. For 1/3/0:8, the HWM is 1 after clearing because DS0 Active is 1 (1 active call). TotalDuration is 35 seconds for time slot 22, and TotalCall is 0 because they got reset when the **clear controller call-counters** command was entered. Total calls on this time slot is incremented when a new call comes in on this time slot.

The following is sample output when controller 1/5/15 is cleared:

```
Router# clear line 1/5/15
[confirm]
 [OK]
Router# show controllers t1 call-counters

T1 1/3/0:3:
```

```
  DS0's Active: 0
  DS0's Active High Water Mark: 2
  TimeSlot   Type   TotalCalls   TotalDuration
      1       pri           0       00:00:00

Related Commands

Command	Description
clear controller call-counters	Clears all call statistics or system HWMs on a router.
controller	Enters controller configuration mode.
show controllers t1 call-counters	Displays the total number of calls and call durations on a T1 controller.

clear csm-statistics modem

To clear the call switching module (CSM) statistics for a modem or group of modems, use the **clear csm-statistics modem** command in privileged EXEC mode.

clear csm-statistics modem [*slot/port* | *modem-group-number*]

Syntax Description

slot/port	(Optional) Identifies the location (and thereby the identity) of a specific modem.
modem-group-number	(Optional) Designates a defined modem group.

Command Default

No default behaviors or values

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3 NA	This command was introduced.

Usage Guidelines

Use the **clear csm-statistics modem** command to clear CSM statistics for a particular modem or group of modems. If the *slot/port* argument is specified, the CSM call statistics for calls using the identified modem is cleared. If a modem group number is specified, then the CSM call statistics for calls using the modems associated with that group are cleared. If no argument is specified, all CSM call statistics for all modems are cleared.

Examples

The following example clears CSM call statistics for calls coming in on modems associated with modem group 2:

```
Router# clear csm-statistics modem 2
```

Related Commands

Command	Description
clear csm-statistics voice	Clears the CSM statistics for a particular or for all DSP channels.

clear csm-statistics voice

To clear the call switching module (CSM) statistics for a particular or for all digital signal processor (DSP) channels, use the **clear csm-statistics voice** command in privileged EXEC mode.

clear csm-statistics voice [*slot/dspm/dsp/dsp-channel*]

Syntax Description

slot/dspm/dsp/dsp-channel	(Optional) Identifies the location of a particular DSP channel.

Command Default

No default behaviors or values

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3 NA	This command was introduced.

Usage Guidelines

Use the **clear csm-statistics voice** command to clear CSM statistics for a particular DSP channel. If the *slot/dspm/dsp/dsp-channel* argument is specified, the CSM call statistics for calls using the identified DSP channel are cleared. If no argument is specified, all CSM call statistics for all DSP channels are cleared.

Examples

The following example clears CSM call statistics for calls coming in on all DSP channels:

```
Router# clear csm-statistics voice
```

Related Commands

Command	Description
clear csm-statistics modem	Clears the CSM statistics for a modem or group of modems.

clear h323 gatekeeper call

To force the disconnection of a specific call or of all calls active on a particular gatekeeper, use the **clear h323 gatekeeper call** command in privileged EXEC mode.

clear h323 gatekeeper call {**all** | **local-callID** *local-callID*}

Syntax Description

all	Forces all active calls currently associated with this gatekeeper to be disconnected.
local-callID	Forces a single active call associated with this gatekeeper to be disconnected.
local-callID	Specifies the local call identification number (CallID) that identifies the call to be disconnected.

Command Default No default behaviors or values

Command Modes Privileged EXEC

Command History

Release	Modification
12.0(5)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and on the Cisco MC3810.
12.1(5)XM2	The command was introduced for the Cisco AS5350 and Cisco AS5400.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco AS5300. Support for the Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Usage Guidelines If you want to force a particular call to be disconnected (as opposed to all active calls on the gatekeeper), use the CallID number to identify that specific call. You can find the local CallID number for a specific call by using the **show gatekeeper calls** command; the ID number is displayed in the LocalCallID column.

Examples The following example shows that an active call on the gatekeeper is being forced to disconnect. The local ID number of the active call is 12-3339.

```
Router# clear h323 gatekeeper call local-callID 12-3339
```

The following example shows that all active calls on the gatekeeper are being forced to disconnect:

```
Router# clear h323 gatekeeper call all
```

The following sample output from the **show gatekeeper calls** command displays information about a specific active call having a call ID of 12-3339:

```
Router# show gatekeeper calls
```

```
Total number of active calls =1
                    Gatekeeper Call Info
                    ====================
LocalCallID                     Age (secs)      BW
12-3339                         94              768 (Kbps)
 Endpt(s): Alias    E.164Addr     CallSignalAddr   Port   RASSignalAddr    Port

```

Related Commands

Command	Description
show gatekeeper calls	Displays the status of each ongoing call of which a gatekeeper is aware.

clear h323 gatekeeper endpoint

To unregister endpoints, use the **clear h323 gatekeeper endpoint** command in privileged EXEC mode.

clear h323 gatekeeper endpoint {alias e164 ***digits*** **| alias h323id** ***name*** **| all | id** ***number*** **| ipaddr** ***address*** **[***port***]}**

Syntax Description

alias e164 *digits*	E.164 alphanumeric address that is specified in the local alias table.
alias h323id *name*	H.323 ID name that is specified in the local alias table and is an alternate way to reach an endpoint.
all	All endpoints.
id *number*	ID of the endpoint.
ipaddr *address* [*port*]	Call signaling address and port (optional) of the endpoint. If a value for the *port* argument is not specified, the default is 1720.

Command Default

Default for the *port* argument is 1720.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and implemented on the Cisco 3660 and Cisco MC3810.

Usage Guidelines

Using this command forces the gatekeeper to send an unregistration request (URQ) message to the specified endpoint or all endpoints and removes the endpoint from the gatekeeper registration database.

For gatekeeper cluster configurations, this command must be entered on the gatekeeper where the endpoint is registered. Use the **show gatekeeper endpoints** command to locate the endpoint in a gatekeeper cluster.

Note The endpoint that was unregistered using this command can come back if it sends the registration request (RRQ) back to the gatekeeper after the unregistration.

Examples

The following example shows how to unregister all endpoints:

```
GK# clear h323 gatekeeper endpoint all
GK# show gatekeeper endpoints

                    GATEKEEPER ENDPOINT REGISTRATION
                    ================================
CallSignalAddr  Port  RASSignalAddr   Port  Zone Name         Type    Flags
--------------- ----- --------------- ----- ---------         ----    -----
Total number of active registrations = 0
```

Related Commands

Command	Description
show gatekeeper endpoints	Locates the endpoint in a gatekeeper cluster.

clear h323 gatekeeper stats

To clear statistics about gatekeeper performance, use the **clear h323 gatekeeper stats** command in privileged EXEC mode.

clear h323 gatekeeper stats

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Usage Guidelines

The **clear h323 gatekeeper stats** command resets the gatekeeper performance counters to zero and records the time at which the last clear was performed.

Examples

The following is sample output from the **show gatekeeper performance stats** command that shows the counters have been reset to zero after entering the **clear h323 gatekeeper stats** command.

```
clear h323 gatekeeper stats
show gatekeeper performance stats

RAS inbound message counters:
Originating ARQ: 0 Terminating ARQ: 0 LRQ: 0
RAS outbound message counters:
ACF: 2  ARJ: 0 LCF: 2  LRJ: 0
ARJ due to overload: 0
LRJ due to overload: 0
Load balancing events: 0
Real endpoints: 2
```

Related Commands

Command	Description
show gatekeeper performance statistics	Displays information about the number of calls accepted and rejected by the gatekeeper.

clear h323 gateway

To clear the H.323 gateway counters, use the **clear h323 gateway command in privileged EXEC mode.**

clear h323 gateway [**cause-code stats | h225 | ras**]

Syntax Description

cause-code stats	(Optional) Clears only the disconnect cause-code statistics counters.
h225	(Optional) Clears only the H.225 counters.
ras	(Optional) Clears only the Registration, Admission, and Status (RAS) counters.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(4)T	This command was introduced on all Cisco H.323 platforms except for the Cisco AS5300, Cisco AS5350, and Cisco AS5400.

Usage Guidelines

To clear all H.323 counters, use the **clear h323 gateway** command without any of the optional keywords. After you have used the **clear h323 gateway** command, the respective counters are set to zero.

Examples

In the following example from a Cisco 3640 router, the **clear h323 gateway** command is used without keywords to clear all H.323 counters:

```
Router# clear h323 gateway

All H.323 stats cleared at 01:54:38
```

In the following example from a Cisco 3640 router, the **clear h323 gateway** command is used with the **cause-code stats** keyword to clear the disconnect cause-code stats counters:

```
Router# clear h323 gateway cause-code stats

Cause code stats cleared at 01:54:08
```

In the following example from a Cisco 3640 router, the **clear h323 gateway** command is used with the **h225** keyword to clear the H.225 counters:

```
Router# show h323 gateway h225

H.225 stats cleared at 01:53:18
```

In the following example from a Cisco 3640 router, the **clear h323 gateway** command is used with the **ras** keyword to clear the RAS counters:

```
Router# clear h323 gateway ras

RAS stats cleared at 01:53:25
```

Related Commands

Command	Description
debug cch323	Provides debug output for various components within the H.323 subsystem.
show h323 gateway	Displays the statistics for H.323 gateway messages that have been sent and received and displays the reasons for which H.323 calls have been disconnected.

clear http client statistics

To reset to zero all the counters that collect the information about the communication between the HTTP server and the client displayed in the output from the **show http client statistics** command, use the **clear http client statistics** command in user EXEC or privileged EXEC mode.

clear http client statistics

Syntax Description

This command has no arguments or keywords.

Command Modes

User EXEC (>)
Privileged EXEC (#)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Use the **show http client statistics** command to display the data collected by the counters the **clear http client statistics** command resets to zero.

Examples

The following example resets the counters to zero:

```
Router# clear http client statistics
```

Related Commands

Command	Description
show http client statistics	Displays information about the communication between the HTTP server and the client.

clear interface cable-modem

To reset the controller for a specified cable modem daughter card, use the **clear interface cable-modem** command in privileged EXEC mode. This command does not have a **no** version.

clear interface cable-modem

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(11)T	This command was introduced.

Examples

The following example shows how the **clear interface cable-modem** command clears the interface on the selected slot and port:

```
Router# clear interface cable-modem

*May 17 16:36:57.344: %CABLE_MODEM_HWIC-6-RESET: Interface Cable-Modem0/2/0 has been
reset: clear command
*May 17 16:37:05.348: %LINK-3-UPDOWN: Interface Cable-Modem0/2/0, changed state to down
*May 17 16:37:06.348: %LINEPROTO-5-UPDOWN: Line protocol on Interface Cable-Modem0/2/0,
changed state to down
*May 17 16:37:19.740: %LINK-3-UPDOWN: Interface Cable-Modem0/2/0, changed state to up
*May 17 16:37:27.996: %LINEPROTO-5-UPDOWN: Line protocol on Interface Cable-Modem0/2/0,
changed state to up
```

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured.
show interfaces cable-modem	Displays statistics for all interfaces configured on the port.

clear mgcp src-stats

To clear the statistics gathered for Media Gateway Control Protocol (MGCP) System Resource Check (SRC) Call Admission Control (CAC) on an MGCP gateway, use the **clear mgcp src-stats** command in privileged EXEC mode.

clear mgcp src-stats

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(11)T	This command was implemented on the Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Usage Guidelines

Use the **clear mgcp src-stats** command to clear the MGCP gateway buffer that holds SRC CAC statistics gathered during the most recent inspection interval.

Examples

The following example clears MGCP VoIP SRC CAC statistics:

```
Router# clear mgcp src-stats
```

Related Commands

Command	Description
show mgcp statistics	Displays MGCP statistics regarding received and transmitted network messages.

clear mgcp statistics

To reset the Media Gateway Control Protocol (MGCP) statistical counters, use the **clear mgcp statistics** command in privileged EXEC mode.

clear mgcp statistics

Syntax Description This command has no arguments or keywords.

Command Modes Privileged EXEC

Command History

Release	Modification
12.1(1)T	This command was introduced for the Cisco AS5300.
12.1(3)T	This command was implemented on the Cisco 3660, Cisco UBR924, and Cisco 2600 series.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines None

Examples The following is an example of how to enter the command:

```
Router# clear mgcp statistics
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
show mgcp statistics	Displays statistics for received and transmitted packets.

clear mrcp client statistics

To clear all Media Resource Control Protocol (MRCP) statistics, use the **clear mrcp client statistics** command in privileged EXEC mode.

clear mrcp client statistics {**all** | **hostname** {*hostname* | *ip-address*}}

Syntax Description

all	Clears the accumulated MRCP session statistics for all hosts.
hostname	Clears the accumulated MRCP session statistics for the specified host.
hostname	Host name of the MRCP server. Format uses host name only or *hostname*:*port*.
ip-address	IP address of the MRCP server.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.

Usage Guidelines

This command resets all MRCP session statistics to 0. Use the **show mrcp client statistics hostname** command to display the current statistics.

Examples

The following example resets the statistics for the host called “asr_server”:

```
Router# clear mrcp client statistics hostname asr_server
```

Related Commands

Command	Description
show mrcp client statistics hostname	Displays cumulative information about MRCP sessions.

clear rlm group

To reset all Redundant Link Manager (RLM) time stamps to zero, use the **clear rlm group** command in privileged EXEC mode.

clear rlm group [*group-number*] [**link** | **statistics**]

Syntax Description

group-number	(Optional) RLM group number. Range is from 0 to 255. There is no default value.
link	(Optional) Specifies the RLM group link.
statistics	(Optional) Specifies the RLM group statistics.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
11.3(7)	This command was introduced.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **statistics** keyword was added.

Examples

The following example resets the time stamps on RLM group 1:

```
Router# clear rlm group 1 link
!
02:48:17: rlm 1: [State_Up, rx ACTIVE_LINK_BROKEN] over link [10.1.1.1(Loopback1),
10.1.4.1]
02:48:17: rlm 1: link [10.1.1.2(Loopback2), 10.1.4.2] requests activation
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.4.1] is deactivated
02:48:17: rlm 1: [State_Recover, rx LINK_BROKEN] over link [10.1.1.2(Loopback2), 10.1.4.2]
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.4.1] = socket[10.1.1.1, 10.1.4.1]
02:48:17: rlm 1: [State_Recover, rx USER_SOCKET_OPENED] over link [10.1.1.1(Loopback1),
10.1.4.1] for user RLM_MGR
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.4.1] is opened
02:48:17: rlm 1: link [10.1.1.2(Loopback2), 10.1.4.2] = socket[10.1.1.2, 10.1.4.2]
02:48:17: rlm 1: [State_Recover, rx USER_SOCKET_OPENED] over link [10.1.1.2(Loopback2),
10.1.4.2] for user RLM_MGR
02:48:17: rlm 1: link [10.1.1.2(Loopback2), 10.1.4.2] is opened
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.5.1] = socket[10.1.1.1, 10.1.5.1]
02:48:17: rlm 1: [State_Recover, rx USER_SOCKET_OPENED] over link [10.1.1.1(Loopback1),
10.1.5.1] for user RLM_MGR
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.5.1] is opened
02:48:17: rlm 1: link [10.1.1.2(Loopback2), 10.1.5.2] = socket[10.1.1.2, 10.1.5.2]
02:48:17: rlm 1: [State_Recover, rx USER_SOCKET_OPENED] over link [10.1.1.2(Loopback2),
10.1.5.2] for user RLM_MGR
02:48:17: rlm 1: link [10.1.1.2(Loopback2), 10.1.5.2] is opened
02:48:17: rlm 1: [State_Recover, rx LINK_OPENED] over link [10.1.1.1(Loopback1), 10.1.4.1]
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.4.1] requests activation
02:48:17: rlm 1: [State_Recover, rx LINK_OPENED] over link [10.1.1.2(Loopback2), 10.1.4.2]
02:48:17: rlm 1: [State_Recover, rx START_ACK] over link [10.1.1.1(Loopback1), 10.1.4.1]
02:48:17: rlm 1: link [10.1.1.1(Loopback1), 10.1.4.1] is activated
```

Related Commands

Command	Description
clear interface	Resets the hardware logic on an interface.
interface	Defines the IP addresses of the server, configures an interface type, and enters interface configuration mode.
link (**RLM**)	Specifies the link preference.
protocol rlm port	Reconfigures the port number for the basic RLM connection for the whole RLM group.
retry keepalive	Allows consecutive keepalive failures a certain amount of time before the link is declared down.
server (**RLM**)	Defines the IP addresses of the server.
show rlm group statistics	Displays the network latency of the RLM group.
show rlm group status	Displays the status of the RLM group.
show rlm group timer	Displays the current RLM group timer values.
timer	Overwrites the default setting of timeout values.

clear rpms-proc counters

To clear statistics counters for the number of leg 3 authentication, authorization, and accounting (AAA) preauthentication requests, successes, and rejects, use the **clear rpms-proc counters** command in privileged EXEC mode.

clear rpms-proc counters

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)T	This command was introduced.

Examples

The following example clears statistics counters for leg 3 AAA preauthentication requests, successes, and rejects:

```
Router# clear rpms-proc counters
```

Related Commands

Command	Description
show rpms-proc counters	Displays statistics for the number of leg 3 AAA preauthentication requests, successes, and rejects.

clear rudpv0 statistics

To clear the counters that track RUDP statistics, enter the **clear rudpv0 statistics** command in privileged EXEC mode.

clear rudpv0 statistics

Syntax Description This command has no arguments or keywords.

Command Default The statistical information accumulates.

Command Modes Privileged EXEC

Command History

Release	Modification
12.0(7)XR	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Examples The following example shows how to clear RUDP statistics on a Cisco 2611 (Cisco SLT):

```
clear rudpv0 statistics
```

Related Commands

Command	Description
show rudpv0 failures	Displays RUDP information about failed connections and the reasons for them.
show rudpv0 statistics	Displays RUDP information about number of packets sent, received, and so forth.

clear rudpv1 statistics

To clear the counters that track Reliable User Datagram Protocol (RUDP) statistics, use the **clear rudpv1 statistics** command in privileged EXEC mode.

clear rudpv1 statistics

Syntax Description This command has no arguments or keywords.

Command Default The statistical information accumulates.

Command Modes Privileged EXEC

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on Cisco 7200.
12.2(4)T	This command was implemented on the Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on Cisco IAD2420 series.
12.2(11)T	This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850 in this release.

Examples The following example clears all RUDP statistics for all available session groups:

```
Router# clear rudpv1 statistics
```

Related Commands

Command	Description
debug rudpv1	Displays debugging information for RUDP.
show rudpv1	Displays RUDP information.

clear sccp server statistics

To clear the counts displayed under the **show sccp server statistics** command, use the **clear sccp server statistics** command in privileged EXEC mode.

clear sccp server statistics

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
15.0(1)M	This command was integrated into a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows the Skinny Client Control Protocol (SCCP) server statistics counts being cleared, followed by verification that the counters are reset to zero with the **show sccp server statistics** command. The field descriptions are self-explanatory.

```
Router# show sccp server statistics

Failure type              Error count
------------------------  -----------
Send queue enqueue        0
Socket send               0
Msg discarded upon error  0
```

Related Commands

Command	Description
show sccp server statistics	Displays the number of SCCP messages sent and received by the SCCP server.

clear sdspfarm counters

To reset the server counts of the digital signal processor farms that are registered to the Skinny Client Control Protocol (sdspfarm) displayed under the **server show sdspfarm message statistics** command to zero, use the **clear sdspfarm counters** command in privileged EXEC mode.

clear sdspfarm counters

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(15)XY	This command was introduced.

Examples

The following example shows the sdspfarm counters being cleared and verification that the counters are reset to zero with the **show sdspfarm sessions state** command:

```
Router# clear sdspfarm counters

Router# show sdspfarm sessions state

Call state      Num of sessions
----------      ---------------
IDLE            1022
ALERTING        0
SEIZE           0
PROGRESS        0
CONNECTED       0
DIGITS          0
BUSY            0
RINGING         0
ERROR           0
HOLD            0
END             0
STOP            0
START           2
RESTART         0
UNKNOWN         0
DELAYED-SMT     0
```

Field descriptions should be self-explanatory.

Related Commands

Command	Description
show sdspfarm message statistics	Displays the number of SCCP messages sent and received by the SCCP server.
show sdspfarm sessions state	Displays the number of sessions in each SCCP call state.

clear sgcp statistics

To clear all Simple Gateway Control Protocol (SGCP) statistics, use the **clear sgcp statistics** command in privileged EXEC mode.

clear sgcp statistics

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Privileged EXEC

Command History

Release	Modification
12.0(5)T	This command was introduced in a private release on the Cisco AS5300 only and was not generally available.
12.0(7)XK	This command was implemented on the Cisco MC3810 and the Cisco 3600 series (except for the Cisco 3620) in a private release that was not generally available.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines None

Examples The following example shows all SGCP statistics being cleared:

```
Router# clear sgcp statistics
```

Related Commands

Command	Description
show sgcp statistics	Displays global statistics for SGCP packet counts.

clear sip-ua statistics

To reset the Session Initiation Protocol (SIP) user-agent (UA) statistical counters, use the **clear sip-ua statistics** command in privileged EXEC mode.

clear sip-ua statistics

Syntax Description This command has no arguments or keywords.

Command Modes Privileged EXEC

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines Use this command to clear all SIP statistics counters that are displayed by the **show sip-ua statistics** command.

Examples The following example shows all SIP-UA statistics being cleared:

```
Router# clear sip-ua statistics
```

Related Commands

Command	Description
show sip-ua statistics	Displays response, traffic, and retry SIP statistics.

clear sip-ua tcp connection

To clear a session initiation protocol (SIP) TCP connection, use the **clear sip-ua tcp connection** command in privileged EXEC mode.

clear sip-ua tcp connection {**id** *connection-id* [**target ipv4:***address***:***port*] | [**id** *connection-id*] **target ipv4:***address***:***port*}

Syntax Description

id *connection-id*	Specifies the ID of the connection that needs to be closed in the SIP TCP process. The *connection-id* argument represents the connection ID. The range is from 1 to 2048.
target ipv4:*address***:***port*	Specifies the target address for the connection that needs to be closed in the SIP transport layer.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(6)T	This command was replaced by the **clear sip-ua tcp tls connection** command.

Usage Guidelines

Inappropriate usage of the **clear sip-ua tcp connection** command can lead to erroneous call behavior, inappropriate usage of connections, and failure of calls.

Examples

To cear the connection entry only at the upper transport layer, assign the target IP address and port:

```
Router# clear sip-ua tcp connection target ipv4:172.18.194.183:5060
```

To clear the connection entry only at the lower TCP or User Datagram Protocol (UDP) layer, specify the connection:

```
Router# clear sip-ua tcp connection id 1
```

To completely clear a valid connection to target 172.18.194.183, port 5060, consider the following output example from the **show sip-ua connections** command:

```
Router# show sip-ua connections tcp detail

Total active connections : 1
No. of send failures : 0
No. of remote closures : 0
No. of conn. failures : 0
No. of inactive conn. ageouts : 0
Max. tcp send msg queue size of 1, recorded for 172.18.194.183:5060
---------Printing Detailed Connection Report---------
Note:
** Tuples with no matching socket entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port>'
to overcome this error condition
++ Tuples with mismatched address/port entry
```

```
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port> id <connid>'
to overcome this error condition
Remote-Agent:172.18.194.183, Connections-Count:1
Remote-Port Conn-Id Conn-State WriteQ-Size
=========== ======= =========== ===========
5060 1 Established 0
```

Then execute the **clear sip-ua tcp connection** command:

```
Router# clear sip-ua tcp connection id 1 target ipv4:172.18.194.183:5060

Purging the entry from sip tcp process
Purging the entry from reusable global connection table
```

The result is that all connections are cleared after inputting the **clear sip-ua tcp connection** command:

```
Router# show sip-ua connections tcp detail

Total active connections : 0
No. of send failures : 0
No. of remote closures : 0
No. of conn. failures : 0
No. of inactive conn. ageouts : 0
Max. tcp send msg queue size of 1, recorded for 172.18.194.183:5060
---------Printing Detailed Connection Report---------
Note:
** Tuples with no matching socket entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port>'
to overcome this error condition
++ Tuples with mismatched address/port entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port> id <connid>'
to overcome this error condition
Remote-Agent:172.18.194.183, Connections-Count:0
```

Related Commands

Command	Description
clear sip-ua udp connection	Clears a SIP UDP connection.
show sip-ua connections	Displays SIP UA transport connection tabless.
timers connection aging	Sets the time before the SIP UA ages out a TCP and UDP connection.

clear sip-ua tcp tls connection

To clear a session initiation protocol (SIP) TCP connection, use the **clear sip-ua tcp tls connection** command in privileged EXEC mode.

clear sip-ua tcp tls connection {**id** *connection-id* [**target ipv4:***address***:***port*] | [**id** *connection-id*] **target ipv4:***address***:***port*}

Syntax Description

id *connection-id*	Specifies the ID of the connection that needs to be closed in the SIP TCP process. The *connection-id* argument represents the connection ID. The range is from 1 to 2048.
target ipv4:*address***:***port*	Specifies the target address for the connection that needs to be closed in the SIP transport layer.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(6)T	This command was introducted to replace the **clear sip-ua tcp connection** command.

Usage Guidelines

Inappropriate usage of the **clear sip-ua tcp tls connection** command can lead to erroneous call behavior, inappropriate usage of connections, and failure of calls.

Examples

To cear the connection entry only at the upper transport layer, assign the target IP address and port:

```
Router# clear sip-ua tcp tls connection target ipv4:172.18.194.183:5060
```

To clear the connection entry only at the lower TCP or User Datagram Protocol (UDP) layer, specify the connection:

```
Router# clear sip-ua tcp tls connection id 1
```

To completely clear a valid connection to target 172.18.194.183, port 5060, consider the following output example from the **show sip-ua connections** command:

```
Router# show sip-ua connections tcp tls detail

Total active connections : 1
No. of send failures : 0
No. of remote closures : 0
No. of conn. failures : 0
No. of inactive conn. ageouts : 0
Max. tcp send msg queue size of 1, recorded for 172.18.194.183:5060
---------Printing Detailed Connection Report---------
Note:
** Tuples with no matching socket entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port>'
to overcome this error condition
++ Tuples with mismatched address/port entry
```

```
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port> id <connid>'
to overcome this error condition
Remote-Agent:172.18.194.183, Connections-Count:1
Remote-Port Conn-Id Conn-State WriteQ-Size
=========== ======= =========== ===========
5060 1 Established 0
```

Then execute the **clear sip-ua tcp connection** command:

```
Router# clear sip-ua tcp tls connection id 1 target ipv4:172.18.194.183:5060

Purging the entry from sip tcp process
Purging the entry from reusable global connection table
```

The result is that all connections are cleared after inputting the **clear sip-ua tcp connection** command:

```
Router# show sip-ua connections tcp tls detail

Total active connections : 0
No. of send failures : 0
No. of remote closures : 0
No. of conn. failures : 0
No. of inactive conn. ageouts : 0
Max. tcp send msg queue size of 1, recorded for 172.18.194.183:5060
---------Printing Detailed Connection Report---------
Note:
** Tuples with no matching socket entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port>'
to overcome this error condition
++ Tuples with mismatched address/port entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port> id <connid>'
to overcome this error condition
Remote-Agent:172.18.194.183, Connections-Count:0
```

Related Commands

Command	Description
clear sip-ua udp connection	Clears a SIP UDP connection.
show sip-ua connections	Displays SIP UA transport connection tabless.
timers connection aging	Sets the time before the SIP UA ages out a TCP and UDP connection.

clear sip-ua udp connection

To clear a SIP UDP connection, use the **clear sip-ua udp connection** command in privileged EXEC mode.

clear sip-ua udp connection {**id** *value* [**target** *ip-address*] | [**id** *value*] **target** *ip-address*}

Syntax Description

id *value*	Specifies the ID of the connection that needs to be closed in the SIP UDP process. The *value* argument represents the value of the connection ID. The range is from 1 to 2048.
target ip-address	Specifies the target address for the connection that needs to be closed in the SIP transport layer. The *ip-address* argument is the target address in the form of **ipv4:***address***:***port*.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Inappropriate usage of the **clear sip-ua udp connection** command without understanding the issue or the implications can lead to erroneous call behavior, inappropriate usage of connections, and failure of calls.

Examples

To purge the connection entry only at the upper transport layer, assign the target IP address and port.

```
Router# clear sip-ua udp connection target ipv4:172.18.194.183:5060
```

To purge the connection entry only at the lower TCP/UDP layer, assign the connection ID.

```
Router# clear sip-ua udp connection id 1
```

Note Inappropriate usage of the **clear** command without understanding the issue or the implications would lead to erroneous call behavior, inappropriate usage of connections, and failure of calls.

To completely purge a valid connection to target 172.18.194.183, port 5060, consider the following example.

Before executing the **clear sip-ua udp connection** command, running the **show sip-ua connections** command gave the following output.

```
Router# show sip-ua connections udp detail

Total active connections : 1
No. of send failures : 0
No. of remote closures : 0
No. of conn. failures : 0
No. of inactive conn. ageouts : 0
Max. udp send msg queue size of 1, recorded for 172.18.194.183:5060
```

```
---------Printing Detailed Connection Report---------
Note:
** Tuples with no matching socket entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port>'
to overcome this error condition
++ Tuples with mismatched address/port entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port> id <connid>'
to overcome this error condition
Remote-Agent:172.18.194.183, Connections-Count:1
Remote-Port Conn-Id Conn-State WriteQ-Size
=========== ======= =========== ===========
5060 1 Established 0
```

Then execute the **clear sip-ua udp connection** command:

```
Router# clear sip-ua udp connection id 1 target ipv4:172.18.194.183:5060

Purging the entry from sip udp process
Purging the entry from reusable global connection table
```

The final result is that all connections are cleared after executing the **clear sip-ua udp connection** command:

```
Router# show sip-ua connections udp detail

Total active connections : 0
No. of send failures : 0
No. of remote closures : 0
No. of conn. failures : 0
No. of inactive conn. ageouts : 0
Max. udp send msg queue size of 1, recorded for 172.18.194.183:5060
---------Printing Detailed Connection Report---------
Note:
** Tuples with no matching socket entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port>'
to overcome this error condition
++ Tuples with mismatched address/port entry
- Do 'clear sip <tcp/udp> conn t ipv4:<addr>:<port> id <connid>'
to overcome this error condition
Remote-Agent:172.18.194.183, Connections-Count:0
```

Related Commands

Command	Description
clear sip-ua tcp connection	Clears a SIP TCP connection.
show sip-ua connections	Displays SIP UA transport connections.
timers connection aging	Sets the time before the SIP UA ages out a TCP and UDP connection.

clear ss7 sm-stats

To clear the counters that track session manager statistics, use the **clear ss7 sm-stats** command in privileged EXEC mode.

clear ss7 sm-stats [**session-set** *number*]

Syntax Description

session-set	(Optional) Specifies the session set.
number	(Optional) Specifies the session-set number. The range is from 0 to 3.

Command Default The statistical information accumulates.

Command Modes Privileged EXEC (#)

Command History

Release	Modification
12.0(7)XR	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **session-set** keyword and *number* argument were added.

Examples The following example shows how to clear session manager statistics:

```
Router# clear ss7 sm-stats session-set 2
```

Related Commands

Command	Description
show ss7 sm stats	Displays session manager information about number of packets queued, received, and so forth.

clear statistics dial-peer voice

To reset voice call counters and recent call details stored in a dial peer, use the **clear statistics dial-peer voice** command in privileged EXEC mode.

clear statistics dial-peer voice [*tag*| **busy-trigger-counter**]

Syntax Description

tag	(Optional) Identification tag number of a specific dial peer. A valid entry is any integer that identifies a specific dial peer. Range is from 1 to 2147483647.
busy-trigger-counter	(Optional) Specifies to clear the dial peer busy trigger call counter.

Command Default

If the *tag* argument is not used, counters in all the configured voice dial peers are cleared.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(8)T	This command was introduced on the Cisco AS5300.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **busy-trigger-counter** keyword was added.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

The **clear statistics dial-peer voice** command resets the following statistical information about calls:

- Time elapsed since last clearing of statistics
- Connect time
- Charged units
- Accepted calls
- Refused calls
- Successful calls
- Failed calls
- Incomplete calls
- Last disconnect cause
- Last disconnect text
- Last setup time

Examples

The following example shows how to clear voice dial peer statistics using tag 1234:

```
Router# clear statistics dial-peer voice 1234
Clear voice call statistics stored in this voice dial-peer [confirm]y
```

The following example shows how to clear statistics in all the configured voice dial peers:

```
Router# clear statistics dial-peer voice

Clear voice call statistics stored in all voice dial-peers [confirm]y
```

Related Commands

Command	Description
dial-peer voice	Enters dial peer configuration mode and specifies the method of voice encapsulation.
show call history voice record	Displays CDR events in the call history table.
show dial-peer voice	Displays configuration information for dial peers.

clear stcapp statistics

To clear SCCP Telephony Control Application (STCAPP) statistics, use the **clear stcapp statistics** command in privileged EXEC mode.

clear stcapp statistics {**all** | **port** *slot-number*}

Syntax Description

all	Clears all STCAPP statistics.
port	Clears port-level STCAPP statistics.
slot-number	Voice interface slot number. The range is from 0 to 2147483647.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example show how to clear all STCAPP statistics:

```
Router# clear stcapp statistics all
```

Related Commands

Command	Description
stcapp	Enables the STCAPP.

clear subscription

To clear all active subscriptions or a specific subscription, use the **clear subscription** command in privileged EXEC mode.

clear subscription {**all** | **session-id** *session-id* | **statistics**}

Syntax Description

all	All active subscriptions.
session-id *session-id*	Subscription session to be cleared.
statistics	Global subscription statistics and all subscription history records.

Command Default No default behavior or values

Command Modes Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines To cancel a specific subscription, use the *session-id* argument. You can obtain the session ID by viewing **show subscriptions** output. When this command is used, the applications associated with subscriptions receive the ev_subscribe_cleanup event. On receiving this event, the script closes the subscription.

Examples The following example shows global statistics and history records being cleared:

```
Router# clear subscription statistics
```

Related Commands

Command	Description
retry subscribe	Configures the number of retries for SUBSCRIBE messages.
show subscription sip	Displays active SIP subscriptions.
subscription maximum	Specifies the maximum number of outstanding subscriptions to be accepted or originated by the gateway.

clear tgrep counters

To clear Telephony Gateway Registration Protocol (TGREP) counters, use the **clear tgrep counters** command in privileged EXEC mode.

clear tgrep counters {***** | **carrier** *string* | **csr** | **dial-peer** *tag* | **trunk-group** *label*} [**csr**] [**ac**]

Syntax Description

*****	Clears all TGREP counters.
carrier	Clears available circuit counters.
string	Carrier ID.
dial-peer	Clears dial-peer.
tag	Dial peer tag. The range is from 1 to 2147483647.
trunk-group *label*	Clears the trunk-group counters.
csr	(Optional) Clears the call success rate counters.
ac	(Optional) Clears all the available circuit counters.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example show how to clear all tgrep counter information:

```
Router# clear tgrep counters *
```

Related Commands

Command	Description
clear tgrep neighbor	Clears all neighbor sessions.

clear tgrep neighbor

To clear Telephony Gateway Registration Protocol (TGREP) neighbor sessions, use the **clear tgrep neighbor** command in privileged EXEC mode.

clear tgrep neighbor {***** | *ip-address*}

Syntax Description

*****	Clears all neighbor sessions.
ip-address	IP addresses of neighbor sessions.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows how to clear neighbor sessions:

```
Router# clear tgrep neighbor *
```

Related Commands

Command	Description
clear tgrep counters	Clears TGREP counters.

clear voice accounting method

To clear VoIP AAA accounting statistics for a specific accounting method on the gateway, use the **clear voice accounting method** command in privileged EXEC mode.

clear voice accounting method *method-list-name*

Syntax Description

method-list-name	Name of the method list.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples

The following example clears accounting statistics for method list “h323”:

```
Router# clear voice accounting method h323
```

Related Commands

Command	Description
voice statistics type csr	Configures the collection of signaling and VoIP AAA accounting statistics.

clear voice dsp

To "cold-start" one or more digital signal processor (DSP) voice channels, use the **clear voice dsp** command in privileged EXEC mode.

clear voice dsp {**channels** | **error**} [*slot*[*/dsp*][*/channel*]] [*slot*[*/dsp*][*/channel*]]

Syntax Description

channels	Clears DSP calls on a specific channel or a range of channels.
error	Clears DSP error statistics.
slot	(Optional) Specifies either a single slot or the first slot in a range. To specify a range of slots, you can enter a **second slot in the syntax of this argument. The second slot specifies the end of the range.** All slots in the range are affected by the command.
/dsp	(Optional) Specifies either a single DSP on the slot or the first DSP in a range. To specify a range of DSPs, you can enter a **second DSP in the syntax of this argument. The second DSP specifies the end of the range.** All DSPs in the range are affected by the command.
/channel	(Optional) Specifies either a single channel on the DSP or the first channel in a range. To specify a range of channels, you can enter a **second channel in the syntax of this argument. The second channel specifies the end of the range.** All channels in the range are affected by the command.

Command Default

If this command is not used, active calls continue on the DSP voice channels.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(4)XC	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines

The **clear voice dsp** command allows you to cold-start DSPs. Execution of this command causes the configured firmware to be downloaded to the specified DSP or a range of DSPs. This command can be executed irrespective of the state of the DSPs. All the active channels of the DSPs are prematurely terminated.

Examples

The following example clears all active calls on slot 2, DSP 1:

```
Router# clear voice dsp 2/1
```

The following example clears the active calls on slot 2, DSP 1, channel 1:

```
Router# clear voice dsp 2/1/1
```

Related Commands

Command	Description
show voice dsp	Displays the current status or selective statistics of DSP voice channels

clear voice statistics

To clear voice-statistic collection settings on the gateway to reset the statistics collection, use the **clear voice statistics** command in privileged EXEC mode.

clear voice statistics [**csr** [**accounting** | **signaling**]] | [**iec**]

Syntax Description

csr	(Optional) All accounting and signaling statistics are cleared, but Cisco VoIP internal error codes (IECs) are not cleared.
accounting	(Optional) Only accounting statistics are cleared.
signaling	(Optional) Only signaling statistics are cleared.
iec	(Optional) Only Cisco VoIP IECs are cleared.

Command Default

If no keywords are specified, all accounting and signaling statistics, and all IECs are cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples

The following example clears all accounting and signaling statistics, and all Cisco VoIP IECs:

```
Router# clear voice statistics
```

The following example clears all accounting and signaling statistics:

```
Router# clear voice statistics csr
```

The following example clears only accounting statistics:

```
Router# clear voice statistics csr accounting
```

The following example clears only signaling statistics:

```
Router# clear voice statistics csr signaling
```

The following example clears only Cisco VoIP IECs:

```
Router# clear voice statistics iec
```

Related Commands

Command	Description
voice statistics type csr	Configures the collection of signaling and VoIP AAA accounting statistics.

clear vsp statistics

To clear all Voice Streaming Processing (VSP) statistics that are displayed when using the **show vsp** command is used, use the **clear vsp statistics** command in privileged EXEC mode.

clear vsp statistics

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Privileged EXEC

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.

Usage Guidelines This command resets all cumulative VSP statistics to 0. Use the **show vsp statistics** command to display the current statistics.

Examples The following example resets the statistics for VSP sessions:

```
Router# clear vsp statistics
```

Related Commands

Command	Description
show vsp	Displays cumulative information about VSP sessions.

clid

To preauthenticate calls on the basis of the Calling Line Identification (CLID) number, use the **clid** command in AAA preauthentication configuration mode. To remove the **clid** command from your configuration, use the **no** form of this command.

clid [**if-avail | required**] [**accept-stop**] [**password** *password*]

no clid [**if-avail | required**] [**accept-stop**] [**password** *password*]

Syntax Description

if-avail	(Optional) Implies that if the switch provides the data, RADIUS must be reachable and must accept the string in order for preauthentication to pass. If the switch does not provide the data, preauthentication passes.
required	(Optional) Implies that the switch must provide the associated data, that RADIUS must be reachable, and that RADIUS must accept the string in order for preauthentication to pass. If these three conditions are not met, preauthentication fails.
accept-stop	(Optional) Prevents subsequent preauthentication elements such as **ctype** or **dnis** from being tried once preauthentication has succeeded for a call element.
password *password*	(Optional) Defines the password for the preauthentication element.

Command Default

The **if-avail** and **required** keywords are mutually exclusive. If the **if-avail** keyword is not configured, the preauthentication setting defaults to **required**.

The default password string is cisco.

Command Modes

AAA preauthentication configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines

You may configure more than one of the authentication, authorization and accounting (AAA) preauthentication commands (**clid**, **ctype**, **dnis**) to set conditions for preauthentication. The sequence of the command configuration decides the sequence of the preauthentication conditions. For example, if you configure **dnis**, then **clid**, then **ctype**, in this order, then this is the order of the conditions considered in the preauthentication process.

In addition to using the preauthentication commands to configure preauthentication on the Cisco router, you must set up the preauthentication profiles on the RADIUS server.

Examples

The following example specifies that incoming calls be preauthenticated on the basis of the CLID number:

```
aaa preauth
 group radius
 clid required
```

Related Commands

Command	Description
ctype	Preauthenticates calls on the basis of the call type.
dnis (RADIUS)	Preauthenticates calls on the basis of the DNIS number.
dnis bypass (AAA preauthentication configuration)	Specifies a group of DNIS numbers that will be bypassed for preauthentication.
group (RADIUS)	Specifies the AAA RADIUS server group to use for preauthentication.

clid (dial peer)

To control the presentation and use of calling-line ID (CLID) information, use the **clid** command in dial peer configuration mode. To remove CLID controls, use the **no** form of this command.

clid {**network-number** *number* [**second-number** strip] | **network-provided** | **override rdnis** | **restrict** | **strip** [**name** | **pi-restrict** [**all**]] | **substitute name**}

no clid {**network-number** *number* [**second-number** strip] | **network-provided** | **override rdnis** | **restrict** | **strip** [**name** | **pi-restrict** [**all**]] | **substitute name**}

Syntax Description

network-number *number*	Network number. Establishes the calling-party network number in the CLID for this router.
network-provided	Allows you to set the screening indicator to reflect the number that was provided by the network.
override rdnis	Supported for POTS dial peers only Overrides the CLID with the redirected dialed number identification service (RDNIS) if available.
pi-restrict	Restricted progress indicator (PI). Causes removal of the calling-party number from the CLID when the PI is restricted.
restrict	Restricts presentation of the caller ID in the CLID.
second-number strip	(Optional) Removes a previously configured second network number from the CLID.
strip	Strips the calling-party number from the CLID. • **name**—(Optional) Calling-party name. Causes removal of the calling-party name from the CLID. • **pi-restrict** [**all**]—(Optional) Restricted PI. Causes removal of all calling-party names and numbers from the CLID when the PI is restricted.
substitute name	Copies the calling number into the display name if PI allows it (and the calling name is empty).

Command Default

No default behavior or values

Command Modes

Dial Peer configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.
12.2(13)T	The **override rdnis** keywords were added.
12.4(4)T	The following keywords were added: **network-provided**, **pi-restrict all**, and **substitute name**.

Usage Guidelines

The **override rdnis** keywords are supported only for POTS dial peers.

CLID is the collection of information about the billing telephone number from which a call originated. The CLID value might be the entire phone number, the area code, or the area code plus the local exchange. It is also known as caller ID. The various keywords to this command manage the presentation, restriction, or stripping of the various CLID elements.

The **clid network-number** command sets the presentation indicator to "y" and the screening indicator to "network-provided." The **second-number strip** keyword strips from the H.225 source-address field the original calling-party number, and is valid only if a network number was previously configured.

The **clid override rdnis** command overrides the CLID with the RDNIS if it is available.

The **clid restrict** command causes the calling-party number to be present in the information element, but the presentation indicator is set to "n" to prevent its presentation to the called party.

The **clid strip** command causes the calling-party number to be null in the information element, and the presentation indicator is set to "n" to prevent its presentation to the called party.

Examples

The following example sets the calling-party network number to 98765 for POTS dial peer 4321:

```
Router(config)# dial-peer voice 4321 pots
Router(config-dial-peer)# clid network-number 98765
```

An alternative method of accomplishing this result is to enter the **second-number strip** keywords as part of the **clid network-number** command. The following example sets the calling-party network number to 56789 for VoIP dial peer 1234 and also prevents the second network number from being sent:

```
Router(config)# dial-peer voice 1234 voip
Router(config-dial-peer)# clid network-number 56789 second-number strip
```

The following example overrides the calling-party number with RDNIS if available:

```
Router(config-dial-peer)# clid override rdnis
```

The following example prevents the calling-party number from being presented:

```
Router(config-dial-peer)# clid restrict
```

The following example removes the calling-party number from the CLID information and prevents the calling-party number from being presented:

```
Router(config-dial-peer)# clid strip
```

The following example strips the name from the CLID information and prevents the name from being presented:

```
Router(config-dial-peer)# clid strip name
```

The following example strips the calling party number when PI is set to restrict clid strip from the CLID information and prevents the calling party number from being presented:

```
Router(config-dial-peer)# clid strip pi-restrict
```

The following example strips calling party name and number when the PI is set to the restrict all clid strip from the CLID information and prevents the calling party name and number from being presented:

```
Router(config-dial-peer)# clid strip pi-restrict all
```

The following example substitutes the calling party number into the display name:

```
Router(config-dial-peer)# clid substitute name
```

The following example allows you to set the screening indicator to reflect that the number was provided by the network:

```
Router(config-dial-peer)# clid network-provided
```

Related Commands

Command	Description
clid (voice-service-voip)	Passes the network provided ISDN numbers in an ISDN calling party information element screening indicator field, removes the calling party name and number from the calling-line identifier in voice service voip configuration mode, or allows a presentation of the calling number by substituting for the missing Display Name field in the Remote-Party-ID and From headers.

clid (voice-service-voip)

To pass the network-provided ISDN numbers in an ISDN calling party information element screening indicator field, and remove the calling party name and number from the calling-line identifier in voice service voip configuration mode, or allow a presentation of the calling number by substituting for the missing Display Name field in the Remote-Party-ID and From headers use the **clid** command in voice service voip configuration mode. To return to the default configuration, use the **no** form of this command.

clid {**network-provided | strip pi-restrict all | substitute name**}

no clid {**network-provided | strip pi-restrict all | substitute name**}

Syntax Description

network-provided	Sets the screen indicator as network-provided.
strip pi-restrict all	Removes the CLID when the progress indicator (PI) is restricted for PSTN to SIP operations and removes the calling party name and number when the PI is restricted for PSTN to SIP operations.
substitute name	Copies the calling number to the display name if unavailable for PSTN to SIP operations.

Command Default

The **clid** command passes along user-provided ISDN numbers in an ISDN calling party information element screening indicator field.

Command Modes

Voice-service-VoIP configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

Use the **clid network-provided** keyword to pass along network-provided ISDN numbers in an ISDN calling party information element screening indicator field.

Use the **clid strip pi-restrict all** keyword to remove the Calling Party Name and Calling Party Number from the CLID.

Use the **clid substitute name** keyword to allow a presentation of the Display Name field in the Remote-Party-ID and From headers. The Calling Number is substituted for the Display Name field.

Examples

The following example passes along network-provided ISDN numbers in an ISDN calling party information element screening indicator field:

```
Router(conf-voi-serv)# clid network-provided
```

The following example passes along user-provided ISDN numbers in an ISDN calling party information element screening indicator field:

```
Router(conf-voi-serv)# no clid network-provided
```

The following example removes the calling party name and number from the calling-line identifier (CLID):

```
Router(conf-voi-serv)# clid strip pi-restrict all
```

The following example does not remove the calling party name and number from the CLID:

```
Router(conf-voi-serv)# no clid strip pi-restrict all
```

The following example allows the presentation of the calling number to be substituted for the missing Display Name field in the Remote-Party-ID and From headers:

```
Router(conf-voi-serv)# clid substitute name
```

The following example disallows the presentation of the calling number to be substituted for the missing Display Name field in the Remote-Party-ID and From headers:

```
Router(conf-voi-serv)# no clid substitute name
```

Related Commands

Command	Description
clid (dial-peer)	Controls the presentation and use of CLID information in dial peer configuration mode.

clid strip

To remove the calling-party number from calling-line-ID (CLID) information and to prevent the calling-party number from being presented to the called party, use the **clid strip** command in dial peer configuration mode. To remove the restriction, use the **no** form of this command.

clid strip [**name**]

no clid strip [**name**]

Syntax Description

name	(Optional) Removes the calling-party name for both incoming and outgoing calls.

Command Default

Calling-party number and name are included in the CLID information.

Command Modes

Dial peer configuration

Command History

Cisco IOS Release	Cisco CME Version	Modification
12.2(11)T	2.01	This command was introduced.
12.2(15)ZJ1	3.0	The **name** keyword was added.
12.3(4)T	3.0	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

If the **clid strip** command is issued, the calling-party number is null in the information element, and the presentation indicator is set to "n" to prevent the presentation of the number to the called party.

If you want to remove both the number and the name, you must issue the command twice, once with the **name** keyword.

Examples

The following example removes the calling-party number from the CLID information and prevents the calling-party number from being presented:

```
Router(config-dial-peer)# clid strip
```

The following example removes both the calling-party number and the calling-party name from the caller-ID display:

```
Router(config-dial-peer)# clid strip
Router(config-dial-peer)# clid strip name
```

Related Commands

Command	Description
clid network-number	Configures a network number in the router for CLID and uses it as the calling-party number.
clid restrict	Prevents the calling-party number from being presented by CLID.
clid second-number strip	Prevents the second network number from being sent in the CLID information.

clid strip reason

To remove the calling-line ID (CLID) reason code and to prevent it from being displayed on the phone, use the **clid strip reason** command in dial peer voice configuration mode. To disable the configuration, use the **no** form of this command.

clid strip reason

no clid strip reason

Syntax Description

This command has no arguments or keywords.

Command Default

The CLID reason code is not removed.

Command Modes

Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

When the **caller-id enable** command is enabled on the gateway so that the gateway forwards information depending on the preference of the caller, client layer interface port (CLIP), or calling line identification restriction (CLIR), an "unavailable" message is displayed on the terminating phone. An "unavailable" message is a standard message that indicates the reason for the absence of calling party name.

You can use the **clid strip reason** command to remove the message and have only the call parameters forwarded.

Examples

The following example shows how to remove the CLID reason code:

```
Router# configure terminal
Router(config)# dial-peer voice 88 voip
Router(config-dial-peer)# clid strip reason
```

Related Commands

Command	Description
caller-id enable	Allows the sending or receiving of caller-ID information.
clid strip	Removes the calling-party number from CLID information and prevents the calling-party number from being presented to the called party.
dial-peer voice	Defines a particular dial peer, specifies the method of voice encapsulation, and enters dial peer configuration mode.

clock-rate (codec-profile)

To set the clock rate, in Hz, for the codec, use the **clock-rate** command in codec-profile configuration mode. To return to the default value, use the **no** form of this command.

clock-rate *clock-rate*

no clock-rate

Syntax Description

clock-rate	Number in the range of 1 to 1000000.

Command Default

The default clock rate is 0.

Command Modes

Codec-profile configuration (config-codec-profile)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

The clock-rate must be set to 90000 for H.263/H.264.

Examples

The following example shows:

```
codec profile 116 h263
    clock-rate 500000
    fmtp "fmtp "fmtp:120 SQCIF=1;QCIF=1;CIF=1;CIF4=2;MAXBR=3840;I=1""
!
```

Related Commands

Command	Description
codec profile	Defines video capabilities needed for video endpoints.

clock-select

To establish the sources and priorities of the requisite clocking signals for the OC-3/STM-1 ATM Circuit Emulation Service network module, use the **clock-select** command in CES configuration mode.

clock-select *priority-number interface slot/port*

Syntax Description

priority-number	Priority of the clock source. Range is from 1 (high priority) to 4 (low priority). There is no default value.
interface	Specifies the interface to supply the clock source.
slot/port	Backplane slot number and port number on the interface.

Command Default

No default behavior or values

Command Modes

CES configuration

Command History

Release	Modification
12.1(2)T	This command was introduced on the Cisco 3600 series.

Usage Guidelines

This command is used on Cisco 3600 series routers that have OC-3/STM-1 ATM CES network modules.

To support synchronous or synchronous residual time stamp (SRTS) clocking modes, you must specify a primary reference source to synchronize the flow of constant bit rate (CBR) data from its source to its destination.

You can specify up to four clock priorities. The highest priority active interface in the router supplies primary reference source to all other interfaces that require network clock synchronization services. The fifth priority is the local oscillator on the network module.

Use the **show ces clock-select** command to display the currently configured clock priorities on the router.

Examples

The following example defines two clock priorities on the router:

```
clock-select 1 cbr 2/0
clock-select 2 atm 2/0
```

Related Commands

Command	Description
channel-group	Configures the timing recovery clock for the CES interface.
clock source	Configures a transmit clock source for the CES interface.
show ces clock	Displays which ports are designated as network clock sources.

codec (dial peer)

To specify the voice coder rate of speech for a dial peer, use the **codec** command in dial peer voice configuration mode. To reset command settings to the default value, use the **no** form of this command.

Cisco 1750 and Cisco 1751 Modular Access Routers, Cisco AS5300 and AS5800 Universal Access Servers, and Cisco MC3810 Multiservice Concentrators

codec *codec* [**bytes** *payload-size*] [**fixed-bytes**] [**mode** {**independent** | **adaptive**} [**bit-rate** *value*] [**framesize** {**30** | **60**} [**fixed**]]

no codec *codec* [**bytes** *payload-size*] [**fixed-bytes**] [**mode** {**independent** | **adaptive**} [**bit-rate** *value*] [**framesize** {**30** | **60**} [**fixed**]]

Cisco 2600, 3600, 7200, and 7500 Series Routers

codec {*codec* [**bytes** *payload-size*] | **transparent**} [**fixed-bytes**] [**mode** {**independent** | **adaptive**} [**bit-rate** *value*] [**framesize** {**30** | **60**} [**fixed**]]

no codec {*codec* [**bytes** *payload-size*] | **transparent**} [**fixed-bytes**] [**mode** {**independent** | **adaptive**} [**bit-rate** *value*] [**framesize** {**30** | **60**} [**fixed**]]

Syntax Description

codec	Specifies the voice coder rate for speech. Codec options available for various platforms are described in Table 11.
bytes	(Optional) Precedes the argument that specifies the number of bytes in the voice payload of each frame.
payload-size	(Optional) Number of bytes in the voice payload of each frame. See Table 12 for valid entries and default values.
transparent	Enables codec capabilities to be passed transparently between endpoints in a Cisco Unified Border Element. **Note** The **transparent** keyword is available only on the Cisco 2600, 3600, 7200, and 7500 series router platforms.
fixed-bytes	(Optional) Indicates that the codec byte size is fixed and non-negotiable.
mode	(Optional) For iSAC codec only. Specifies the iSAC operating frame mode that is encapsulated in each packet.
independent | **adaptive**	(Optional) For iSAC codec only. Determines whether configuration mode (VBR) is **independent** (value 1) or **adaptive** (value 0).
bit rate *value*	(Optional) For iSAC codec only. Configures the target bit rate. The range is 10 to 32 kbps.
frame-size	(Optional) For iSAC codec only. Specifies the operating frame in milliseconds (ms). Valid entries are: • **30**—30-ms frames • **60**—60-ms frames • **fixed**—This keyword is applicable only for adaptive mode.

Command Default

g729r8, 30-byte payload for VoFR and VoATM.
g729r8, 20-byte payload for VoIP.
See Table 12 for valid entries and default values for codecs.

Command Modes

Dial peer configuration (config-dialpeer)

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(3)T	This command was implemented on the Cisco 2600 series.
12.0(3)T	This command was implemented on the Cisco AS5300. This release does not support the **clear-channel** keyword.
12.0(4)T	This command was implemented on the Cisco 3600 series, Cisco 7200 series, and Cisco MC3810, and the command was modified for VoFR dial peers.
12.0(5)XE	Additional *codec* choices and other options were implemented.
12.0(5)XK	The **g729br8** and **pre-ietf** codec choices were added for the Cisco 2600 and Cisco 3600 series.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0.(7)T and implemented on the Cisco AS5800. Voice coder rates of speech were added. This release does not support the **clear-channel** keyword were added on this platform.
12.0(7)XK	**g729abr8** and **g729ar8** codec choices were for the Cisco MC3810, and the keyword **pre-ietf** was deleted.
12.1(1)T	This command was integrated in Cisco IOS Release 12.1(1)T.
12.1(5)T	**gsmefr** and **gsmfr** codec keywords were added.
12.2(8)T	The command was implemented on the Cisco 1750 and Cisco 1751.
12.2(13)T3	The **transparent** keyword was added for use with H.323 to H.323 connections. This keyword is available only in js2 images.
12.4(11)XJ2	**gsmefr** and **gsmfr** keywords were removed as configurable codec options for all platforms with the exception of the **gsmfr** codec on the Cisco AS5400 and AS5350 with MSAv6 DSPs. The **transparent** keyword now supports H.323 to SIP connections.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
12.4(15)XY	The **g722-64** keyword was added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.
15.0(1)M	The **fixed-bytes** keyword was added.
15.1(1)T	This command was modified. The **isac** keyword was added as a codec type, and the **mode**, **independent**, **adaptive**, **bit rate**, and **fixed** keywords were added as configurable parameters.

Usage Guidelines

Use this command to define a specific voice coder rate of speech and payload size for a VoIP or VoFR dial peer. This command is also used for VoATM.

Table 11 Codec Support by Platform

Codec	Cisco 1750 and Cisco 1751 Modular Access Routers	Cisco 2600 and 3600 Series Routers and Cisco 7200 and 7500 Series Routers	Cisco AS5300 and AS5800 Universal Access Servers	Cisco MC3810 Multiservice Concentrators
clear-channel—Clear channel at 64,000 bits per second (bps)	Yes	Yes	—	Yes
g711alaw—G.711 A-Law at 64,000 bps	Yes	Yes	Yes	Yes
g711ulaw—G.711 mu-Law at 64,000 bps	Yes	Yes	Yes	Yes
g722-64—G.722-64 at 64,000 bps	Yes	Yes	Yes	—
g723ar53—G.723.1 Annex A at 5300 bps	—	Yes	Yes	Yes
g723ar63—G.723.1 Annex A at 6300 bps	—	Yes	Yes	Yes
g723r53—G.723.1 at 5300 bps	—	Yes	Yes	Yes
g723r63—G.723.1 at 6300 bps	—	Yes	Yes	Yes
g726r16—G.726 at 16,000 bps	Yes	Yes	Yes	Yes
g726r24—G.726 at 24,000 bps	Yes	Yes	Yes	Yes
g726r32—G.726 at 32,000 bps	Yes	Yes	Yes	Yes
g726r53—G.726 at 53,000 bps	Yes	Yes	Yes	—
g726r63—G.726 at 63,000 bps	Yes	Yes	Yes	—
g728—G.728 at 16,000 bps	—	Yes	Yes	Yes
g729abr8—G.729 Annex A and B at 8000 bps	Yes	Yes	Yes	Yes
g729ar8—G.729 Annex A at 8000 bps	Yes	Yes	Yes	Yes
g729br8—G.729 Annex B at 8000 bps	Yes	Yes	Yes	Yes
g729r8—G.729 at 8000 bps. This is the default codec.	Yes	Yes	Yes	Yes
isac—Cisco internet Speech Audio Codec (iSAC) codec.	Yes	Yes	Yes	Yes

A specific codec type can be configured on the dial peer as long as the codec is supported by the setting used with the **codec complexity** voice-card configuration command. The **codec complexity** command is voice-card specific and platform specific. The **codec complexity** voice-card configuration command is set to either high or medium.

If the **codec complexity** command is set to high, the following keywords are available: **g711alaw**, **g711ulaw**, **g722-64**, **g723ar53**, **g723ar63**, **g723r53**, **g723r63**, **g726r16**, **g726r24**, **g726r32**, **g728**, **g729r8**, and **g729br8**.

If the **codec complexity** command is set to medium, the following keywords are available: **g711alaw**, **g711ulaw**, **g726r16**, **g726r24**, **g726r32**, **g729r8**, and **g729br8**.

The **codec** dial peer configuration command is particularly useful when you must change to a small-bandwidth codec. Large-bandwidth codecs, such as G.711, do not fit in a small-bandwidth link. However, the g711alaw and g711ulaw codecs provide higher quality voice transmission than other codecs. The g729r8 codec provides near-toll quality with considerable bandwidth savings.

The **transparent** keyword is available with H.323 to H.323 call connections beginning in Cisco IOS Release 12.2(13)T3. Support for the keyword in H.32 to SIP call connections begins in Cisco IOS Release 12.4(11)XJ2.

If codec values for the dial peers of a connection do not match, the call fails.

You can change the payload of each VoIP frame by using the **bytes** keyword; you can change the payload of each VoFR frame by using the **bytes** keyword with the *payload-size* argument. However, increasing the payload size can add processing delay for each voice packet.

Table 12 describes the voice payload options and default values for the codecs and packet voice protocols.

Table 12 Voice Payload-per-Frame Options and Defaults

Codec	Protocol	Voice Payload Options (in Bytes)	Default Voice Payload (in Bytes)
g711alaw **g711ulaw**	VoIP VoFR VoATM	80, 160 40 to 240 in multiples of 40 40 to 240 in multiples of 40	160 240 240
g722-64	VoIP	80, 160, 240	160
g723ar53 **g723r53**	VoIP VoFR VoATM	20 to 220 in multiples of 20 20 to 240 in multiples of 20 20 to 240 in multiples of 20	20 20 20
g723ar63 **g723r63**	VoIP VoFR VoATM	24 to 216 in multiples of 24 24 to 240 in multiples of 24 24 to 240 in multiples of 24	24 24 24
g726r16	VoIP VoFR VoATM	20 to 220 in multiples of 20 10 to 240 in multiples of 10 10 to 240 in multiples of 10	40 60 60
g726r24	VoIP VoFR VoATM	30 to 210 in multiples of 30 15 to 240 in multiples of 15 30 to 240 in multiples of 15	60 90 90
g726r32	VoIP VoFR VoATM	40 to 200 in multiples of 40 20 to 240 in multiples of 20 40 to 240 in multiples of 20	80 120 120
g728	VoIP VoFR VoATM	10 to 230 in multiples of 10 10 to 240 in multiples of 10 10 to 240 in multiples of 10	40 60 60
g729abr8 **g729ar8** **g729br8** **g729r8**	VoIP VoFR VoATM	10 to 230 in multiples of 10 10 to 240 in multiples of 10 10 to 240 in multiples of 10	20 30 30
isac	VoIP	10 to 230 in multiples of 10	30 60

Note If you are configuring G.729r8 or G.723 as the *codec-type*, the maximum value for the *payload-size* argument is 60 bytes.

For toll quality, use the **g711alaw** or **g711ulaw** keyword. These values provide high-quality voice transmission but use a significant amount of bandwidth. For nearly toll quality (and a significant savings in bandwidth), use the **g729r8** keyword.

Note The G.723 and G.728 codecs are not supported on the Cisco 1700 platform for Cisco Hoot and Holler applications.

Note The **clear-channel** keyword is not supported on the Cisco AS5300.

Note The G.722-64 codec is supported only for H.323 and SIP.

Examples

The following example shows how to configure a voice coder rate that provides toll quality voice with a payload of 120 bytes per voice frame on a router that acts as a terminating node. The sample configuration begins in global configuration mode and is for VoFR dial peer 200.

```
dial-peer voice 200 vofr
 codec g711ulaw bytes 240
```

The following example shows how to configure a voice coder rate for VoIP dial peer 10 that provides toll quality but uses a relatively high amount of bandwidth:

```
dial-peer voice 10 voip
 codec g711alaw
```

The following example shows how to configure the transparent codec used by the Cisco Unified Border Element:

```
dial-peer voice 1 voip
 incoming called-number .T
 destination-pattern .T
 session target ras
 codec transparent
```

Related Commands

Command	Description
codec (DSP interface dsp farm)	Specifies call density and codec complexity.
codec (voice port)	Specifies voice compression.
codec complexity	Specifies call density and codec complexity based on the codec used.
show dial peer voice	Displays the codec setting for dial peers.

codec (dsp)

To specify call density and codec complexity based on a particular codec standard, use the **codec** command in DSP interface DSP farm configuration mode. To reset the card type to the default, use the **no** form of the command.

codec {**high** | **med**}

no codec {**high** | **med**}

Syntax Description

high	Specifies high complexity: two channels of any mix of codec.
med	Specifies medium complexity: four channels of g711/g726/g729a/fax.

Command Default Medium complexity

Command Modes DSP interface DSP farm

Command History

Release	Modification
12.0(5)XE	This command was introduced on the Cisco 7200 series.
12.1(1)T	This command was integrated into Cisco Release 12.1(1)T.
12.1(3)T	This command was implemented on the Cisco 7500 series.

Usage Guidelines This command is supported on only the Cisco 7200 series and Cisco 7500 series routers.

Codec complexity refers to the amount of processing required to perform compression. Codec complexity affects the number of calls, referred to as call density, that can take place on the DSPfarm interfaces. The greater the codec complexity, the fewer the calls that are handled. For example, G.711 requires less DSP processing than G.728, so as long as the bandwidth is available, more calls can be handled simultaneously by using the G.711 standard than by using G.728.

The DSPinterface dspfarm **codec** complexity setting affects the options available for the **codec** dial peer configuration command.

To change codec complexity, you must first remove any configured channel associated signaling (CAS) or DS0 groups and then reinstate them after the change.

Note On the Cisco 2600 series routers, and 3600 series codec complexity is configured using the **codec complexity** command in voice-card configuration mode.

Examples The following example configures the DSPfarm interface 1/0 on the Cisco 7200 series routers to support high compression:

```
dspint DSPFarm 1/0
 codec high
```

Related Commands

Command	Description
codec (dial peer)	Specifies the voice codec rate of speech for a dial peer.
codec complexity	Specifies call density and codec complexity based on the codec standard you are using.

codec (DSP farm profile)

To specify the codecs that are supported by a digital signal processor (DSP) farm profile, use the **codec** command in DSP farm profile configuration mode. To remove the codec, use the **no** form of this command.

codec {*codec-type* [*resolution*] | [**frame-rate** *framerate*] | [**bitrate** *bitrate*] | [**rfc-2190**] | **pass-through**}

no codec {*codec-type* [*resolution*] | [**frame-rate** *framerate*] | [**bitrate** *bitrate*] | [**rfc-2190**] | **pass-through**}

Syntax Description

codec-type	Specifies the codec preferred. • **g711alaw**—G.711 a-law 64,000 bits per second (bps) • **g711ulaw**—G.711 mu-law 64,000 bps • **g722r-64**—G.722-64 at 64,000 bps • **g729abr8**—G.729 ANNEX A and B 8000 bps • **g729ar8**—G.729 ANNEX A 8000 bps • **g729br8**—G.729 ANNEX B 8000 bps • **g729r8**—G.729 8000 bps • **h263**—H.263 video codec • **h264**—H.264 video codec • **ilbc**—Internet Low Bitrate Codec (iLBC) • **isac**—Cisco internet Speech Audio Codec (iSAC) codec
resolution	Specifies the supported video resolution. The valid entries are: • For H.263—**qcif** and **cif** • For H.264—**qcif**, **cif, vga, w360p**, **w448p, 4cif,** and **720p** **Note** 720p option applies only to homogeneous video conferences.
frame-rate *framerate*	Specifies the frame rate. The valid entries are 15 fps or 30 fps. This option applies to homogeneous conferences only.
bitrate *bitrate*	Specifies the bitrate. This option applies to homogeneous conferences only.
rfc-2190	Specifies the payload format follow RFC-2190.
pass-through	Enables codec pass-through. Supported for transcoding and media termination point (MTP) profiles.

Command Default

The following transcoding default apply when you are configuring audio profiles only. When you configure video transcoding, you must specify the audio codecs.

Transcoding

- **g711alaw**

- **g711ulaw**
- **g729abr8**
- **g729ar8**

Conferencing

- **g711alaw**
- **g711ulaw**
- **g729abr8**
- **g729ar8**
- **g729br8**
- **g729r8**

MTP

- **g711ulaw**

Command Modes

DSP farm profile configuration (config-dspfarm-profile)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(4)T	The **pass-through** keyword was added.
12.4(11)XJ2	The **gsmefr** and **gsmfr** keywords were removed as configurable codec options for all platforms.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
12.4(15)XY	The **g722r-64** keyword was added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.
12.4(22)T	Support for IPv6 was added.
15.1(1))T	This command was modified. The **isac** keyword was added.
15.1(4)M	This command was modified. The **frame-rate, bitrate, rfc-2190, and pass-through** keywords were added and codec support was added for **ilbc**, **h.263** and **h.264**.

Usage Guidelines

Only one codec is supported for each MTP profile. To support multiple codecs, you must define a separate MTP profile for each codec.

For homogeneous video profiles, only one video format is supported

For heterogeneous and heterogeneous guaranteed-audio video profiles, multiple video formats and audio codecs are supported.

To change the configured codec in the profile, you must first enter a **no maximum session** command.

Table 13 shows the relationship between DSP farm functions and codecs.

Table 13 DSP Farm Functions and Codec Relationships

DSP Farm Function	Supported Codec
Transcoding	• **g711alaw** • **g711ulaw** • **g729abr8** • **g729ar8** • **iSAC** • **h263** • **h264**
Conferencing	• **g711alaw** • **g711ulaw** • **g722r-64** • **g729abr8** • **g729ar8** • **g729br8** • **g729r8** • **h263** • **h264** • **ilbc**
MTP	• **g711ulaw** • **iSAC**

Hardware MTPs support only G.711 a-law and G.711 mu-law. If you configure a profile as a hardware MTP and you want to change the codec to other than G.711, you must first remove the hardware MTP by using the **no maximum sessions hardware** command.

The **pass-through** keyword is supported for transcoding and MTP profiles only; the keyword is not supported for conferencing profiles. To support the Resource Reservation Protocol (RSVP) agent on a Skinny Client Control Protocol (SCCP) device, you must use the **codec pass-through** command. In the pass-through mode, the SCCP device processes the media stream by using a pure software MTP, regardless of the nature of the stream, which enables video and data streams to be processed in addition to audio streams. When the pass-through mode is set in a transcoding profile, no transcoding is done for the session; the transcoding device performs a pure software MTP function. The pass-through mode can be used for secure Real-Time Transport Protocol (RTP) sessions.

Examples

The following example shows how to set the call density and codec complexity to g729abr8:

```
Router(config)# dspfarm profile 123 transcode
Router(config-dspfarm-profile)# codec g729abr8
```

The following example shows how to set up a video conference with guaranteed-audio.

```
Router(config)# dspfarm profile 99 conference video guaranteed-audio
Router(config-dspfarm-profile)# codec h264 4cif
Router(config-dspfarm-profile)# codec h264 cif
Router(config-dspfarm-profile)# maximum conference-participants 8
```

Related Commands

Command	Description
associate application	Associates the SCCP protocol to the DSP farm profile.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
maximum sessions (DSP Farm profile)	Specifies the maximum number of sessions that are supported by the profile.
rsvp	Enables RSVP support on a transcoding or MTP device.
maximum conference-participants (DSP Farm profile)	Specifies the maximum number of conference participants that are supported by this profile.
shutdown (DSP Farm profile)	Disables a DSP farm profile.

codec (voice-card)

To specify call density and codec complexity according to the codec standard that is being used or to increase processing frequency for the G.711 codec, use the **codec** command in voice-card configuration mode. To reset the flex complexity default or to disable configured values, use the **no** form of this command.

codec {**complexity** {**flex** [**reservation-fixed** {**high** | **medium**}] | **high** | **medium** | **secure**} | **sub-sample**}

no codec complexity

Syntax Description

complexity	Manages the complexity and density of codecs used in voice processing.
flex	When the **flex** keyword is used, up to 16 calls can be completed per digital signal processor (DSP). The number of supported calls varies from 6 to 16, depending on the codec used for a call. In this mode, reservation for analog voice interface cards (VICs) may be needed for certain applications such as Central Automatic Message Accounting (CAMA) E-911 calls because oversubscription of DSPs is possible. If this is true, enable the **reservation-fixed** keyword. There is no reservation by default.
reservation-fixed	(Optional) If you have specified the **flex** keyword, the **reservation-fixed** keyword ensures that sufficient DSP resources are available to handle a call. If you enter the **reservation-fixed** keyword, set the complexity for **high** or **medium**. (See the guidelines following to understand the effects of the keywords.) This option appears only when there is an analog VIC present.
high	If you specify the **high** keyword to define the complexity, each DSP supports two voice channels encoded in any of the following formats: • g711alaw—G.711 a-law 64,000 bps. • g711ulaw—G.711 mu-law 64,000 bps. • g723ar53—G.723.1 Annex A 5300 bps. • g723ar63—G.723.1 Annex A 6300 bps. • g723r53—G.723.1 5300 bps. • g723r63—G.723.1 6300 bps. • g726r16—G.726 16,000 bps. • g726r24—G726 24,000 bps. • g726r32—G.726 32,000 bps. • g728—G.728 16,000 bps. • g729r8—G.729 8000 bps. This is the default. • g729br8—G.729 Annex B 8000 bps. • fax relay—2400 bps, 4800 bps, 7200 bps, 9600 bps, 12 kbps, and 14.4 kbps. **Note** Codecs G.723.1 and G.728 are not supported on Cisco 1750 and Cisco 1751 modular access routers for Cisco Hoot and Holler over IP applications.

medium	If you specify the **medium** keyword to define the complexity, each DSP supports four voice channels encoded in any of the following formats: • g711alaw—G.711 a-law 64,000 bps. • g711ulaw—G.711 mu-law 64,000 bps. • g726r16—G.726 16,000 bps. • g726r24—G.726 24,000 bps. • g726r32—G.726 32,000 bps. • g729r8—G.729 Annex A 8000 bps. • g729br8—G.729 Annex B with Annex A 8000 bps. • fax relay—2400 bps, 4800 bps, 7200 bps, 9600 bps, 12 kbps, and 14.4 kbps. Fax relay is the default.
secure	If you specify the **secure** keyword to define complexity, each DSP on an NM-HDV network module supports two voice channels encoded in any of the following formats: • g711alaw—G.711 a-law 64,000 bps. • g711ulaw—G.711 mu-law 64,000 bps. • g729—G.729 8000 bps. • g729A—G.729 8000 bps.
sub-sample	Increases the processing frequency for the G.711 codec with reduced 5510 DSP density.

Defaults

The default type of codec complexity is **flex**. The default value for the G.711 codec is 10 milliseconds (ms).

Command Modes

Voice-card configuration (config-voice-card)

Command History

Release	Modification
12.0(5)XK	This command was introduced as the codec complexity on the Cisco 2600 and Cisco 3600 series.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.
12.0(7)XK	This command was implemented on the Cisco MC3810 for use with the high-performance compression module (HCM).
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.2(8)T	This command was implemented on the Cisco 1750 and Cisco 1751.
12.2(13)T	The **ecan-extended** keyword was added.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T with support for the Cisco 2600 series, Cisco 2600XM, Cisco 3660, Cisco 3725, and Cisco 3745 routers. High codec complexity is supported for DSP processing on these platforms.

Release	Modification
12.2(15)ZJ	This command was integrated into Cisco IOS Release 12.2(15)ZJ and the **flex** keyword was added. The **ecan-extended** keyword was removed and G.168 echo-cancellation compliance became the default.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T and the **reservation-fixed** keyword was added.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T and the **secure** keyword was added to provide secure codec complexity for TI-549 DSP processing on the NM-HDV network module.
12.4(22)T1	The **codec complexity** command was changed to the **codec** (voice-card) command and the **sub-sample** keyword was added for the 5510 DSP.

Usage Guidelines

Codec complexity refers to the amount of processing required to perform voice compression. Codec complexity affects the call density—the number of calls reconciled on the DSPs. With higher codec complexity, fewer calls can be handled. Select a higher codec complexity if that is required to support a particular codec or combination of codecs. Select a lower codec complexity to support the greatest number of voice channels, provided that the lower complexity is compatible with the particular codecs in use.

For codec complexity to change, all of the DSP voice channels must be in the idle state.

When you have specified the **flex** keyword, you can connect (or configure in the case of DS0 groups and PRI groups) more voice channels to the module than the DSPs can accommodate. If all voice channels should go active simultaneously, the DSPs become oversubscribed, and calls that are unable to allocate a DSP resource fail to connect. The **flex** keyword allows the DSP to process up to 16 channels. In addition to continuing support for configuring a fixed number of channels per DSP, the **flex** keyword enables the DSP to handle a flexible number of channels. The total number of supported channels varies from 6 to 16, depending on which codec is used for a call. Therefore, the channel density varies from 6 per DSP (high-complexity codec) to 16 per DSP (g.711 codec).

The **high** keyword selects a higher codec complexity if that is required to support a particular codec or combination of codecs. When you use the **codec complexity high** command to change codec complexity, the system prompts you to remove all existing DS0 or PRI groups using the specified voice card, then all DSPs are reset, loaded with the specified firmware image, and released.

The **medium** keyword selects a lower codec complexity to support the greatest number of voice channels, provided that the lower complexity is compatible with the particular codecs in use.

The **secure** keyword restricts the number of TI-549 DSP channels to 2, which is the lower codec complexity required to support Secure Real-Time Transport Protocol (SRTP) package capability on the NM-HDV and enable media authentication and encryption. If the **secure** command is not configured then the gateway will not advertise secure capability to Cisco CallManager, resulting in nonsecure calls. You do not need to use any command to specify secure codec complexity for TI-5510 DSPs, which support SRTP capability in all modes. Use the **mgcp package-capability** *srtp-package* command to enable MGCP gateway capability to process SRTP packages. Use the **show voice dsp** command to display codec complexity status.

Voice quality issues may occur when there are more than 15 G.711 channels on one 5510 DSP. To resolve the voice-quality issue, change the processing period (or segment size) of the G.711 codec from 5 ms to 10 ms. (The segment size of most voice codecs is 10 ms.) However, a voice call with 10-ms segment size has longer end-to-end delay (+ 5ms to 10 ms) than a call with 5-ms segment size.

Beginning in Cisco IOS Release 12.4(22)T1, the **sub-sample** keyword is added for applications that have strict requirements for round-trip delay times for VoIP. You can now accept the default G.711 (10 ms with lower MIPS) or enter the **codec sub-sample** command to select 5-ms G.711 (lower delay with higher MIPS). The **sub-sample** keyword is enabled only for the 5510 DSP.

The **codec sub-sample** command enables 5-ms processing for the G.711 codec inside the DSP to reduce the delay. However, this reduces the channel density of G.711 channels from 16 to 14. There is no difference in secure channel density when this mode is enabled.

Examples

The following example sets the codec complexity to high on voice card 1 installed on a router, and configures local calls to bypass the DSP:

```
voice-card 1
 codec complexity high
local-bypass
```

The following example sets the codec complexity to secure on voice card 1 installed on the NM-HDV, and configures it to support SRTP package processing, media authentication, and encryption:

```
voice-card 1
 codec complexity secure
```

The following example shows how to enable 5-ms processing for the G.711 codec inside the 5510 DSP:

```
voice-card 1
 codec sub-sample
```

Related Commands

Command	Description
ds0-group	Defines T1/E1 channels for compressed voice calls and the CAS method by which the router connects to the PBX or PSTN.
mgcp package-capability	Enables MGCP gateway capability to process SRTP packages.
show voice dsp	Displays the current status of all DSP voice channels.

codec aal2-profile

To set the codec profile for a digital signal processor (DSP) on a per-call basis, use the **codec aal2-profile** command in dial peer configuration mode. To restore the default codec profile, use the **no** form of this command.

codec aal2-profile {**itut** | **custom** | **atmf**} *profile-number codec*

no codec aal2-profile

Syntax Description

itut	The *profile-number* as an ITU-T type.
custom	The *profile-number* as a custom type.
atmf	The *profile-number* as an Asynchronous Transfer Mode Forum (ATMF) type.
profile-number	The available *profile-number* selections depend on the profile type. For ITU-T: • **1** = G.711 mu-law • **2** = G.711 mu-law with silence insertion descriptor (SID) • **7** = G.711 mu-law and G.729ar8 For ATMF: **9** = Broadband Loop Emulation Services (BLES) support for VoAAL2 For custom: • **100** = G.711 mu-law and G.726r32 • **110** = G.711 mu-law, G.726r32, and G.729ar8
codec	Enter one codec for the DSP. The possible *codec* entries depend on the *profile-number* value. The valid entries are as follows: • For ITU 1—**g711 mu-law** • For ITU 2—**g711 mu-law** • For ITU 7—**g711 mu-law** or **g729ar8** • For ATMF—**g711 mu-law** • For custom 100—**g711 mu-law** or **g726r32** • For custom 110—**g711 mu-law** or **g726r32** or **g729ar8** • For lossless compression—**llcc**

Command Default ITU-T profile 1 (G.711 mu-law)

Command Modes Dial peer configuration

Command History

Release	Modification
12.1(1)XA	This command was introduced on the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.2(2)T	This command was implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco IAD2420 series.
12.3(4)XD	The lossless compression codec (**llcc**) keyword was added.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

Use this command to configure the DSP to operate with a specified profile type and codecs.

You must enter the **session protocol aal2-trunk** command before configuring the codec ATM adaptation Layer 2 (AAL2) profile.

This command is used instead of the **codec (dial peer)** command for AAL2 trunk applications.

Examples

The following example sets the codec AAL2 profile type to ITU-T and configures a profile number of 7, enabling codec G.729ar8:

```
dial-peer voice 100 voatm
 session protocol aal2-trunk
 codec aal2-profile itut 7 g729ar8
```

The following example sets the codec AAL2 profile type to custom and configures a profile number of 100, enabling codec G.726r32:

```
dial-peer voice 200 voatm
 session protocol aal2-trunk
 codec aal2-profile custom 100 g726r32
```

Related Commands

Command	Description
session protocol (dial peer)	Establishes a session protocol for calls between the local and remote routers via the packet network.

codec gsmamr-nb

To specify the Global System for Mobile Adaptive Multi-Rate Narrow Band (GSMAMR-NB) codec for a dial peer, use the **codec gsmamr-nb** command in dial peer voice configuration mode. To disable the GSMAMR-NB codec, use the **no** form of this command.

codec gsmamr-nb [**packetization-period 20**] [**encap rfc3267**] [**frame-format** {**bandwidth-efficient** | **octet-aligned** [**crc** | **no-crc**]}] [**modes** *modes-value*]

no codec gsmamr-nb

Syntax Description

packetization-period 20	(Optional) Sets the packetization period at 20 ms.
encap rfc3267	(Optional) Sets the encapsulation value to comply with RFC 3267.
frame-format	(Optional) Specifies a frame format. Supported values are octet-aligned and bandwidth-efficient. The default is octet-aligned.
crc | **no-crc**	(Optional) CRC is applicable only for octet-aligned frame format. If you enter bandwidth-efficient frame format, the crc | no-crc options will not be available because they are inapplicable.
modes	(Optional) The eight speech-encoding modes (bit rates between 4.75 and 12.2 kbps) available in the GSMAMR-NB codec.
modes-value	(Optional) Valid values are from 0 to 7. You can specify modes as a range (for example, 0-2), or individual modes separated by commas (for example, 2,4,6), or a combination of the two (for example, 0-2,4,6-7).

Command Default

Packetization period is **20** ms.
Encapsulation is **rfc3267**.
Frame format is **octet-aligned**.
CRC is **no-crc**.
Modes value is **0-7**.

Command Modes

Dial peer voice configuration

Command History

Release	Modification
12.4(4)XC	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines

The **codec gsmamr-nb** command configures the GSMAMR-NB codec and its parameters on the Cisco AS5350XM and Cisco AS5400XM platforms.

Examples

The following example sets the codec to **gsmamr-nb** and sets parameters:

```
Router(config-dial-peer)# codec gsmamr-nb packetization-period 20 encap rfc3267
frame-format octet-aligned crc
```

Related Commands

Command	Description
codec complexity	Specifies call density and codec complexity based on the codec used.
show dial peer voice	Displays the codec setting for dial peers.

codec ilbc

To specify the voice coder rate of speech for a dial peer using the internet Low Bandwidth Codec (iLBC), use the **codec ilbc** command in dial peer configuration mode. To reset the default value, use the **no** form of this command.

codec ilbc [**mode** *frame_size* [**bytes** *payload_size*]]

no codec ilbc [**mode** *frame_size* [**bytes** *payload_size*]]

Syntax Description

mode	(Optional) Specifies the iLBC operating frame mode that is encapsulated in each packet.
frame_size	(Optional) iLBC operating frame in milliseconds (ms). Valid entries are: • 20—20ms frames for 15.2kbps bit rate • 30—30ms frames for 13.33 kbps bit rate Default is 20.
bytes	(Optional) Specifies the number of bytes in the voice payload of each frame.
payload_size	(Optional) Number of bytes in the voice payload of each frame. Valid entries are: • For **mode 20**—38, 76, 114, 152, 190, 228. Default is 38. • For **mode 30**—50, 100, 150, 200. Default is 50.

Command Default

20ms frames with a 15.2kbps bit rate.

Command Modes

Dial peer configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.
IOS Release XE 2.5	This command was integrated into Cisco IOS XE Release 2.5.

Usage Guidelines

Use this command to define a specific voice coder rate of speech and payload size for a VoIP dial peer using an iLBC codec.

If codec values for the dial peers of a connection do not match, the call fails.

You can change the payload of each VoIP frame by using the **bytes** keyword. However, increasing the payload size can add processing delay for each voice packet.

Examples

The following example shows how to configure the iLBC codec on an IP-to-IP Gateway:

```
dial-peer voice 1 voip
 rtp payload-type cisco-codec-ilbc 100
 codec ilbc mode 30 bytes 200
```

Related Commands

Command	Description
show dial peer voice	Displays the codec setting for dial peers.

codec preference

To specify a list of preferred codecs to use on a dial peer, use the **codec preference** command in voice-class configuration mode. To disable this functionality, use the **no** form of this command.

codec preference *value codec-type* [**mode** {**independent** | **adaptive**}] [**frame-size** {**20** | **30** | **60** | **fixed**] [**bit rate** *value*] [**bytes** *payload-size*] [**packetization-period 20**] [**encap rfc3267**] [**frame-format** {**bandwidth-efficient** | **octet-aligned** [**crc** | **no-crc**]}] [**modes** *modes-value*]

no codec preference *value codec-type*

Syntax Description

value	The order of preference; 1 is the most preferred and 14 is the least preferred.
codec-type	The codec preferred. Values are as follows: • **clear-channel**—Clear Channel 64,000 bps. • **g711alaw**—G.711 a-law 64,000 bps. • **g711ulaw**—G.711 mu-law 64,000 bps. • **g722r-64**—G.722-64 at 64,000 bps. • **g723ar53**—G.723.1 Annex-A 5300 bps. • **g723ar63**—G.723.1 Annex-A 6300 bps. • **g723r53**—G.723.1 5300 bps. • **g723r63**—G.723.1 6300 bps. • **g726r16**—G.726 16,000 bps • **g726r24**—G.726 24,000 bps • **g726r32**—G.726 32,000 bps. • **g728**—G.728 16,000 bps. • **g729abr8**—G.729 ANNEX-A and B 8000 bps. • **g729br8**—G.729 ANNEX-B 8000 bps. • **g729r8**—G.729 8000 bps. • **gsmamr-nb**—Enables GSMAMR-NB codec capability. • **gsmfr**—Global System for Mobile Communications Full Rate (GSMFR) 13,200 bps. **Note** The **gsmfr** keyword is configurable only on the Cisco AS5350 and AS5400 with MSAv6 digital signal processors (DSPs). • **ilbc**—internet Low Bitrate Codec (iLBC) at 13,330 bps or 15,200 bps. • **isac**—Cisco internet Speech Audio Codec (iSAC) codec. • **transparent**—Enables codec capabilities to be passed transparently between endpoints. **Note** The **transparent** keyword is not supported when the **call-start** command is configured.
mode	(Optional) For iLBC and iSAC codecs only. Specifies the iLBC or iSAC operating frame mode that is encapsulated in each packet.

independent	(Optional) For iSAC codec only. Specifies that the configuration mode variable bit rate (VBR) is independent (value 1).
adaptive	(Optional) For iSAC codec only. Specifies that the configuration mode VBR is adaptive (value 0).
frame-size	(Optional) For iLBC and iSAC codecs only. Specifies the operating frame in milliseconds (ms). Valid entries are: • **20**—20-ms frames (iLBC only) • **30**—30-ms frames (iLBC or iSAC) • **60**—60-ms frames (iLBC or iSAC) • **fixed**—This keyword is applicable only for adaptive mode.
bit rate *value*	(Optional) Configures the target bit rate in kilobits per second. The range is 10 to 32.
bytes	(Optional) Specifies that the size of the voice frame is in bytes.
payload-size	(Optional) Number of bytes that you specify as the voice payload of each frame. Values depend on the codec type and the packet voice protocol.
packetization-period 20	(Optional) Sets the packetization period at 20 ms. This keyword is applicable only to GSMAMR-NB codec support.
encap rfc3267	(Optional) Sets the encapsulation value to comply with RFC 3267. This keyword is applicable only to GSMAMR-NB codec support.
frame-format	(Optional) Specifies a frame format. Supported values are **octet-aligned** and **bandwidth-efficient**. The default is **octet-aligned**. This keyword is applicable only to GSMAMR-NB codec support.
crc | no-crc	(Optional) Cyclic Redundancy Check (CRC) is applicable only for octet-aligned frame format. If you enter bandwidth-efficient frame format, the **crc | no-crc** options are not available because they are inapplicable. This keyword is applicable only to GSMAMR-NB codec support.
modes *modes-values*	(Optional) Valid values are from 0 to 7. You can specify modes as a range (for example, 0-2), or individual modes separated by commas (for example, 2,4,6), or a combination of the two (for example, 0-2,4,6-7). This argument is applicable only to GSMAMR-NB codec support.

Command Default

If this command is not entered, no specific types of codecs are identified with preference.

If you enter the **gsmamr-nb** keyword, the default values are as follows:

Packetization period is 20 ms.
Encap is **rfc3267**.
Frame format is **octet-aligned**.
CRC is **no-crc**.
Modes value is **0-7**.

If you enter the **isac** keyword, the default values are as follows:

Mode is **independent**.
Target bit-rate is **32000 bps**.
Framesize is **30ms**.

Command Modes Voice-class configuration (config-voice-class)

Command History

Release	Modification
12.0(2)XH	This command was introduced on the Cisco AS5300.
12.0(7)T	This command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.0(7)XK	This command was implemented on the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco Release IOS Release 12.1(2)T.
12.1(5)T	This command was modified. The **gsmefr** and **gsmfr** keywords were added.
12.2(13)T3	This command was modified.The **transparent** keyword was added.
12.4(4)XC	This command was extended to include GSMAMR-NB codec parameters on the Cisco AS5350XM and Cisco AS5400XM platforms.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.
12.4(11)T	This command was modified. The **ilbc** and **mode** keywords were added.
12.4(11)XJ2	This command was modified. The **gsmefr** and **gsmfr** keywords were removed as configurable codec options for all platforms with the exception of the **gsmfr** codec on the Cisco AS5400 and AS5350 with MSAv6 dsps.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
12.4(15)XY	This command was modified. The **g722r-64** keyword was added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.
IOS Release XE 2.5	This command was integrated into Cisco IOS XE Release 2.5.
15.1(1)T	This command was modified. The **isac** keyword was added as a codec type, and the **independent**, **adaptive**, **bit rate**, and **fixed** keywords were added as configurable parameters.

Usage Guidelines The routers at opposite ends of the WAN may have to negotiate the codec selection for the network dial peers. The **codec preference** command specifies the order of preference for selecting a negotiated codec for the connection. Table 14 describes the voice payload options and default values for the codecs and packet voice protocols.

Note The **transparent** keyword is not supported when the **call start** command is configured.

Table 14 Voice Payload-per-Frame Options and Defaults

Codec	Protocol	Voice Payload Options (in Bytes)	Default Voice Payload (in Bytes)
g711alaw **g711ulaw**	VoIP VoFR VoATM	80, 160 40 to 240 in multiples of 40 40 to 240 in multiples of 40	160 240 240
g722r-64	VoIP	80, 160, 240	160

Table 14 Voice Payload-per-Frame Options and Defaults (continued)

Codec	Protocol	Voice Payload Options (in Bytes)	Default Voice Payload (in Bytes)
g723ar53 **g723r53**	VoIP VoFR VoATM	20 to 220 in multiples of 20 20 to 240 in multiples of 20 20 to 240 in multiples of 20	20 20 20
g723ar63 **g723r63**	VoIP VoFR VoATM	24 to 216 in multiples of 24 24 to 240 in multiples of 24 24 to 240 in multiples of 24	24 24 24
g726r16	VoIP VoFR VoATM	20 to 220 in multiples of 20 10 to 240 in multiples of 10 10 to 240 in multiples of 10	40 60 60
g726r24	VoIP VoFR VoATM	30 to 210 in multiples of 30 15 to 240 in multiples of 15 30 to 240 in multiples of 15	60 90 90
g726r32	VoIP VoFR VoATM	40 to 200 in multiples of 40 20 to 240 in multiples of 20 40 to 240 in multiples of 20	80 120 120
g728	VoIP VoFR VoATM	10 to 230 in multiples of 10 10 to 240 in multiples of 10 10 to 240 in multiples of 10	40 60 60
g729abr8 **g729ar8** **g729br8** **g729r8**	VoIP VoFR VoATM	10 to 230 in multiples of 10 10 to 240 in multiples of 10 10 to 240 in multiples of 10	20 30 30
ilbc	VoIP	For the **mode 20** keyword, 38, 76, 114, 152, 190, 228 For the **mode 30** keyword, 50, 100, 150, 200	38 50
iSAC	VoIP	—	—

Examples

The following example show how to set the codec preference to the GSMAMR-NB codec and specify parameters:

```
Router(config-voice-class)# codec preference 1 gsmamr-nb packetization-period 20 encap
rfc3267 frame-format octet-aligned crc
```

The following example shows how to create codec preference list 99 and applies it to dial peer 1919:

```
voice class codec 99
codec preference 1 g711alaw
codec preference 2 g711ulaw bytes 80
codec preference 3 g723ar53
codec preference 4 g723ar63 bytes 144
codec preference 5 g723r53
codec preference 6 g723r63 bytes 120
codec preference 7 g726r16
codec preference 8 g726r24
codec preference 9 g726r32 bytes 80
codec preference 10 g729br8
codec preference 11 g729r8 bytes 50
end
```

```
dial-peer voice 1919 voip
 voice-class codec 99
```

The following example shows how to configure the transparent codec used by the Cisco Unified Border Element:

```
voice class codec 99
codec preference 1 transparent
```

Note You can assign a preference value of 1 only to the transparent codec. Additional codecs assigned to other preference values are ignored if the transparent codec is used.

The following example shows how to configure the iLBC codec used by the Cisco Unified Border Element:

```
voice class codec 99
codec preference 1 ilbc mode 30 bytes 200
```

Related Commands

Command	Description
call-start	Forces an H.323 Version 2 gateway to use fast connect or slow connect procedures for a dial peer.
voice class codec	Enters voice-class configuration mode and assigns an identification tag number to a codec voice class.
voice-class codec (dial peer)	Assigns a previously configured codec selection preference list to a dial peer.

codec profile

To define video capabilities needed for video endpoints, use the **codec profile** command in telephony-service configuration mode. To disable the codec profile, use the **no** form of this command.

codec profile *tag profile*

no codec profile

Syntax Description

tag	A number in the range of 1 to 1000000.
profile	The name of the audio or video codec profile: • aacld • h263 • h263+ • h264

Command Default No codec profile is configured.

Command Modes Global configuration (config)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines For the Cisco Unified Customer Voice Portal solution, only h263 and h263+ are supported profile options.

Examples The following example shows the codec tagged 116 assigned to the H263 profile.

```
codec profile 116 H263
    clockrate 90000
    fmtp "fmtp:120 SQCIF=1;QCIF=1;CIF=1;CIF4=2;MAXBR=3840;I=1"
```

The codec profile can then be added to a voice class codec list, or the VoIP dial peer:

```
voice class codec 998
 codec preference 1 g711ulaw
 video codec h263 profile 116
```

Related Commands

Command	Description
clockrate	Sets the clock rate for the codec.
fmtp	Defines a string for video endpoints.

comfort-noise

To generate background noise to fill silent gaps during calls if voice activity detection (VAD) is activated, use the **comfort-noise** command in voice-port configuration mode. To provide silence when the remote party is not speaking and VAD is enabled at the remote end of the connection, use the **no** form of this command.

comfort-noise

no comfort-noise

Syntax Description

This command has no arguments or keywords.

Command Default

Background noise is generated by default.

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T and was implemented on the Cisco 2600 series, the Cisco 7200 series, and the Cisco 7500 series using the extended echo canceller.

Usage Guidelines

Use the **comfort-noise** command to generate background noise to fill silent gaps during calls if VAD is activated. If the **comfort-noise** command is not enabled, and VAD is enabled at the remote end of the connection, the user hears dead silence when the remote party is not speaking.

The configuration of the **comfort-noise** command affects only the silence generated at the local interface; it does not affect the use of VAD on either end of the connection or the silence generated at the remote end of the connection.

Examples

The following example enables background noise on voice port 1/0/0:

```
voice-port 1/0/0
 comfort-noise
```

Related Commands

Command	Description
vad (dial peer configuration)	Enables VAD for the calls using a particular dial peer.
vad (voice-port configuration)	Enables VAD for the calls using a particular voice port.

compand-type

To specify the companding standard used to convert between analog and digital signals in pulse code modulation (PCM) systems, use the **compand-type** command in voice-port configuration mode. To disable the compand type, use the **no** form of this command.

compand-type {**u-law** | **a-law**}

no compand-type {**u-law** | **a-law**}

Syntax Description

u-law	Specifies the North American mu-law ITU-T PCM encoding standard.
a-law	Specifies the European a-law ITU-T PCM encoding standard.

Command Default

mu-law (T1 digital)
a-law (E1 digital)

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced.

Usage Guidelines

The Cisco 2660 and the Cisco 3640 routers do not require configuration of the **compand-type a-law** command. However, if you request a list of commands, the **compand-type a-law** command displays.

Note On the Cisco 3600 series routers router, the mu-law and a-law settings are configured using the **codec** dial peer configuration command.

Note This command is not supported on the Cisco AS 5300/5350/5400 and 5850 Universal Gateway series which use the Nextport DSP.

Examples

The following example configures a-law encoding on voice port 1/1:

```
voice-port 1/1
 compand-type a-law
```

Related Commands

Command	Description
codec (voice-port configuration)	Configures voice compression.

conference

To define a Feature Access Code (FAC) to initiate a three-party conference in feature mode on analog phones connected to FXS ports, use the **conference** command in STC application feature-mode call-control configuration mode. To return the code to its default, use the **no** form of this command.

conference *keypad-character*

no conference

Syntax Description

keypad-character	Character string of one to four characters that can be dialed on a telephone keypad (0—9, *, #). Default is #3.

Command Default

The default value is #3.

Command Modes

STC application feature-mode call-control configuration (config-stcapp-fmcode)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command changes the value of the FAC for the Call Conference feature from the default (#3) to the specified value.

If you attempt to configure this command with a value that is already configured for another FAC in feature mode, you receive a message. This message will not prevent you from configuring the feature code. If you configure a duplicate FAC, the system implements the first feature it matches in the order of precedence as determined by the value for each FAC (#1 to #5).

If you attempt to configure this command with a value that precludes or is precluded by another FAC in feature mode, you receive a message. If you configure a FAC to a value that precludes or is precluded by another FAC in feature mode, the system always executes the call feature with the shortest code and ignores the longer code. For example, 1 will always preclude 12 and 123. These messages will not prevent you from configuring the feature code. You must configure a new value for the precluded code in order to enable phone user access to that feature.

Examples

The following example shows how to change the value of the feature code for Call Conference from the default (#3). With this configuration, a phone user presses hook flash to get the first dial tone, then dials an extension number to connect to a second call. When the second call is established, the user presses hook flash to get the feature tone and then dials 33 to initiate a three-party conference.

```
Router(config)# stcapp call-control mode feature
Router(config-stcapp-fmcode)# conference 33
Router(config-stcapp-fmcode)# exit
```

Related Commands

Command	Description
drop-last-conferee	Defines FAC in feature mode to use to drop last active call during a three-party conference.
hangup-last-active-call	Defines FAC in feature mode to drop last active call during a three-party conferencee.
toggle-between-two-calls	Defines FAC in feature mode to toggle between two active calls.
transfer	Defines FAC in feature mode to connect a call to a third party that the phone user dials.

conference-join custom-cptone

To associate a custom call-progress tone to indicate joining a conference with a DSP farm profile, use the **conference-join custom-cptone** command in DSP farm profile configuration mode. To remove the custom call-progress tone association and disable the tone for the conference profile, use the **no** form of this command.

conference-join custom-cptone *cptone-name*

no conference-join custom-cptone *cptone-name*

Syntax Description

cptone-name	Descriptive identifier for this custom call-progress tone that indicates joining a conference.

Command Default

No custom call-progress tone to indicate joining a conference is associated with the DSP farm profile.

Command Modes

DSP farm profile configuration

Command History

Cisco IOS Release	Version	Modification
12.4(11)XJ2	Cisco Unified CME 4.1	This command was introduced.
12.4(15)T	Cisco Unified CME 4.1	This command was integrated into Cisco IOS Release 12.4(15)T

Usage Guidelines

To have a tone played when a party joins a conference, define the join tone, then associate it with the DSP farm profile for that conference.

- Use the **voice class custom-cptone** command to create a voice class for defining custom call-progress tones to indicate joining a conference.
- Use the **cadence** and **frequency** commands to define the characteristics of the join tone.
- Use the **conference-join custom-cptone** command to associate the join tone to the DSP farm profile for that conference. Use the **show dspfarm profile command** to display the DSP farm profile.

Examples

The following example defines a custom call-progress tone to indicate joining a conference and associates that join tone to a DSP farm profile defined for conferencing. Note that the custom call-progress tone names in the **voice class custom-cptone** and **conference-join custom-cptone** commands must be the same.

```
Router(config)# voice class custom-cptone jointone
Router(cfg-cptone)# dualtone conference
Router(cfg-cp-dualtone)# frequency 500 500
Router(cfg-cp-dualtone)# cadence 100 100 100 100 100
!
Router(config)# dspfarm profile 1 conference
Router(config-dspfarm-profile)# conference-join custom-cptone jointone
```

Related Commands

Command	Description
cadence	Defines the tone-on and tone-off durations for a call-progress tone.
conference-leave	Associates a custom call-progress tone to indicate leaving a conference with a DSP farm profile.
daultone conference	Enters cp-dualtone configuration mode for specifying a custom call-progress tone.
frequency	Defines the frequency components for a call-progress tone.
show dspfarm profile	Display configured digital signal processor (DSP) farm profile information.
voice class custom-cptone	Creates a voice class for defining custom call-progress tones to be detected.

conference-leave custom-cptone

To associate a custom call-progress tone to indicate leaving a conference with a DSP farm profile, use the **conference-leave custom-cptone** command in DSP farm profile configuration mode. To remove the custom call-progress tone association and disable the tone for the conference profile, use the **no** form of this command.

conference-leave custom-cptone *cptone-name*

no conference-leave custom-cptone *cptone-name*

Syntax Description

cptone-name	Descriptive identifier for this custom call-progress tone that indicates leaving a conference.

Command Default

No custom call-progress tone to indicate leaving a conference is is associated with the DSP farm profile.

Command Modes

DSP farm profile configuration

Command History

Cisco IOS Release	Version	Modification
12.4(11)XJ2	Cisco Unified CME 4.1	This command was introduced.
12.4(15)T	Cisco Unified CME 4.1	This command was integrated into Cisco IOS Release 12.4(15)T

Usage Guidelines

For a tone to be played when a party leaves a conference, define the leave tone, then associate it with the DSP farm profile for that conference.

Use the **voice class custom-cptone** command to create a voice class for defining custom call-progress tones to indicate leaving a conference.

Use the **cadence** and **frequency** commands to define the characteristics of the leave tone.

Use the **conference-join custom-cptone** command to associate the leave tone to the DSP farm profile for that conference. Use the **show dspfarm profile command** to display the DSP farm profile.

Examples

The following example defines a custom call-progress tone to indicate leaving a conference and associates that leave tone to a DSP farm profile defined for conferencing. Note that the custom call-progress tone names in the **voice class custom-cptone** and **conference-join custom-cptone** commands must be the same.

```
Router(config)# voice class custom-cptone leavetone
Router(cfg-cptone)# dualtone conference
Router(cfg-cp-dualtone)# frequency 500 500
Router(cfg-cp-dualtone)# cadence 100 100 100 100 100
!
Router(config)# dspfarm profile 1 conference
Router(config-dspfarm-profile)# conference-join custom-cptone leavetone
```

Related Commands

Command	Description
cadence	Defines the tone-on and tone-off durations for a call-progress tone.
conference-join	Associates a custom call-progress tone to indicate joining a conference with a DSP farm profile.
dualtone conference	Enters cp-dualtone configuration mode for specifying a custom call-progress tone.
frequency	Defines the frequency components for a call-progress tone.
show dspfarm profile	Display configured digital signal processor (DSP) farm profile information.
voice class custom-cptone	Creates a voice class for defining custom call-progress tones to be detected.

condition

To manipulate the signaling format bit-pattern for all voice signaling types, use the **condition** command in voice-port configuration mode. To turn off conditioning on the voice port, use the **no** form of this command.

condition {**tx-a-bit** | **tx-b-bit**| **tx-c-bit**| **tx-d-bit**} {**rx-a-bit** | **rx-b-bit**| **rx-c-bit**| **rx-d-bit**} {**on** | **off** | **invert**}

no condition {**tx-a-bit** | **tx-b-bit**| **tx-c-bit**| **tx-d-bit**} {**rx-a-bit** | **rx-b-bit**| **rx-c-bit**| **rx-d-bit**} {**on** | **off** | **invert**}

Syntax Description

tx-a-bit	Sends A bit.
tx-b-bit	Sends B bit.
tx-c-bit	Sends C bit.
tx-d-bit	Sends D bit.
rx-a-bit	Receives A bit.
rx-b-bit	Receives B bit.
rx-c-bit	Receives C bit.
rx-d-bit	Receives D bit.
on	Forces the bit state to 1.
off	Forces the bit state to 0.
invert	Inverts the bit state.

Command Default

The signaling format is not manipulated (for all sent or received A, B, C, and D bits).

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on the Cisco 2600 series and 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

Use the **condition** command to manipulate the sent or received bit patterns to match expected patterns on a connected device. Be careful not to destroy the information content of the bit pattern. For example, forcing the a-bit on or off prevents Foreign Exchange Office (FXO) interfaces from being able to generate both an on-hook and off-hook state.

The **condition** command is applicable to digital voice ports only.

Examples

The following example manipulates the signaling format bit pattern on digital voice port 0:5:

```
voice-port 0:5
 condition tx-a-bit invert
 condition rx-a-bit invert
```

The following example manipulates the signaling format bit pattern on voice port 1/0:0:

```
voice-port 1/0:0
 condition tx-a-bit invert
 condition rx-a-bit invert
```

Related Commands

Command	Description
define	Defines the transmit and receive bits for North American E&M and E&M MELCAS voice signaling.
ignore	Configures the North American E&M or E&M MELCAS voice port to ignore specific receive bits.

connect (channel bank)

To define connections between T1 or E1 controller ports for the channel bank feature, use the **connect** command in global configuration mode. To restore default values, use the **no** form of this command.

connect *connection-id* **voice-port** *voice-port-number* {**t1** | **e1**} *controller-number ds0-group-number*

no connect *connection-id* **voice-port** *voice-port-number* {**t1** | **e1**} *controller-number ds0-group-number*

Syntax Description

connection-id	A name for this connection.
voice-port	Specifies that a voice port is used in the connection.
voice-port-number	The voice port slot number and port number.
t1	Specifies a T1 port.
e1	Specifies an E1 port.
controller-number	The location of the first T1 or E1 controller to be connected. Valid values for the slot and port are 0 and 1.
ds0-group-number	The number identifier of the DS0 group associated with the first T1 or E1 controller port. The number is created by using the **ds0-group** command. Valid values are from 0 to 23 for T1 and from 0 to 30 for E1.

Command Default

There is no drop-and-insert connection between the ports.

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)XK	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.
12.2(15)ZJ	The **voice-port** keyword was added.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines

The **connect** command creates a named connection between two DS0 groups associated with voice ports on T1 or E1 interfaces where the groups have been defined by the **ds0-group** command.

Examples

The following example shows how to configure a channel bank connection for FXS loop-start signaling:

```
Router(config)# controller t1 1/0
Router(config-controller)# ds0-group 1 timeslot 0 type fxo-loop-start
Router(config-controller)# exit
Router(config)# voice-port 1/1/0
Router(config-voiceport)# signal-type fxs-loop-start
Router(config-voiceport)# exit

Router(config)# connect connection1 voice-port 1/1/0 t1 1/0 0
```

Related Commands

Command	Description
ds0-group	Specifies the DS0 time slots that make up a logical voice port on a T1 or E1 controller and the signaling type by which the router communicates with the PBX or PSTN.
show connect	Displays configuration information about drop-and-insert connections that have been configured on a router.

connect (drop-and-insert)

To define connections among T1 or E1 controller ports for drop-and-insert (also called TDM cross-connect), use the **connect** command in global configuration mode. To restore default values, use the **no** form of this command.

connect *connection-id* {**t1** | **e1**} *slot*/*port-1 tdm-group-no-1* {**t1** | **e1**} *slot*/*port-2 tdm-group-no-2*

no connect *connection-id* {**t1** | **e1**} *slot*/*port-1 tdm-group-no-1* {**t1** | **e1**} *slot*/*port-2 tdm-group-no-2*

Syntax Description

connection-id	A name for this connection.
t1	Specifies a T1 port.
e1	Specifies an E1 port.
slot/*port-1*	The location of the first T1 or E1 controller to be connected. Range for *slot* and *port* is 0 and 1.
tdm-group-no-1	The number identifier of the TDM) group associated with the first T1 or E1 controller port and created by using the **tdm-group** command. Range is from 0 to 23 for T1 and from 0 to 30 for E1.
slot/*port-2*	The location of the second T1 or E1 controller port to be connected. Range for *slot* is from 0 to 5, depending on the platform. Range for *port* is from 0 to 3, depending on the platform and the presence of a network module.
tdm-group-no-2	The number identifier of the TDM group associated with the second T1 or E1 controller and created by using the **tdm-group** command. Range is from 0 to 23 for T1 and from 0 to 30 for E1.

Command Default There is no drop-and-insert connection between the ports.

Command Modes Global configuration

Command History

Release	Modification
12.0(5)XK	The command was introduced on the Cisco 2600 series and Cisco 3600 series.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.
12.1(1)T	The command was modified to accommodate two channel groups on a port for 1- and 2-port T1/E1 multiflex voice/WAN interface cards (VWICs) on the Cisco 3600 series.

Usage Guidelines The **connect** command creates a named connection between two TDM groups associated with drop-and-insert ports on T1 or E1 interfaces where you have already defined the groups by using the **tdm-group** command.

Once TDM groups are created on two different physical ports, use the **connect** command to start the passage of data between the ports. If a crosspoint switch is provided in the AIM slot, the connections can extend between ports on different cards. Otherwise, the connection is restricted to ports on the same VWIC.

The VWIC can make a connection only if the number of time slots at the source and destination are the same. For the connection to be error-free, the two ports must be driven by the same clock source; otherwise, slips occur.

Examples

The following example shows a fractional T1 terminated on port 0 using time slots 1 through 8, a fractional T1 is terminated on port 1 using time slots 2 through 12, and time slots 13 through 20 from port 0 are connected to time slots 14 through 21 on port 1 by using the **connect** command:

```
controller t1 0/0
 channel-group 1 timeslots 1-8
 tdm-group 1 timeslots 13-20
 exit
controller t1 0/1
 channel-group 1 timeslots 2-12
 tdm-group 2 timeslot 14-21
 exit
 connect exampleconnection t1 0/0 1 t1 0/1 2
```

Related Commands

Command	Description
show connect	Displays configuration information about drop-and-insert connections that have been configured on a router.
tdm-group	Configures a list of time slots for creating clear channel groups (pass-through) for TDM cross-connect.

connect atm

To define connections between T1 or E1 controller ports and the ATM interface, enter the **connect atm** command in global configuration mode. Use the **no** form of this command to restore the default values.

connect *connection-id* **atm** *slot/port-1 virtual-circuit-name* | *vpi/vci* {**atm** | **T1** | **E1**} *slot/port-2 TDM-group-number* | {*virtual-circuit-name* | *vpi/vci*}

no connect *connection-id* **atm** *slot/port-1 virtual-circuit-name* | *vpi/vci* {**atm** | **T1** | **E1**} *slot/port-2 TDM-group-number* | {*virtual-circuit-name* | *vpi/vci*}

Syntax Description

connection-id	A name for this connection.
atm	Specifies the first ATM interface.
slot/port-1	The location of the ATM controller to be connected.
virtual-circuit- name	Specifies the permanent virtual circuit (PVC) or switched virtual circuit (SVC).
vpi/vci	Specifies a virtual path identifier (VPI) and virtual channel identifier (VCI).
atm	Specifies the second ATM interface.
T1	Specifies a T1 port.
E1	Specifies an E1 port.
slot/port-2	The location of the T1 or E1 controller to be connected.
TDM-group-number	The number identifier of the time-division multiplexing (TDM) group associated with the T1 or E1 controller port and created by using the **tdm-group** command. Range is 0 to 23 for T1 and 0 to 30 for E1.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.1(2)T	This command was introduced for ATM interfaces on the Cisco 2600 series and Cisco 3600 series.
12.3(4)XD	ATM-to-ATM connections are allowed.
12.3(7)T	Support for ATM-to-ATM connections was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

This command is used on Cisco 2600, Cisco 3600, and Cisco 3700 series routers to provide connections between T1/E1 and ATM interfaces. This command is used after all interfaces are configured.

After TDM groups are created on two different physical ports, you can use the **connect atm** command to start the passage of data between the ports. If a crosspoint switch is provided in the advanced integration module (AIM) slot, the connections can extend between ports on different cards. Otherwise, the connection is restricted to ports on the same VWIC card.

The VWIC can make a connection only if the number of time slots at the source and destination are the same. For the connection to be error free, the two ports must be driven by the same clock source; otherwise, slips occur.

Examples

The following example shows how the ATM permanent virtual circuit (PVC) and T1 TDM group are set up and then connected:

```
interface atm 1/0
 pvc pvc1 10/100 ces
 exit
controller T1 1/1
 tdm-group 3 timeslots 13-24 type e&m
 exit
connect tdm1 atm 1/0 pvc1 10/100 T1 1/1 3
```

Related Commands

Command	Description
tdm-group	Creates TDM groups that can be connected.
pvc	Creates a private virtual circuit.

connect interval

To specify the amount of time that a given digital signal processor (DSP) farm profile waits before attempting to connect to a Cisco Unified CallManager when the current Cisco Unified CallManager fails to connect, use the **connect interval** command in SCCP Cisco Unified CallManager configuration mode. To reset to the default value, use the **no** form of this command.

connect interval *seconds*

no connect interval

Syntax Description

seconds	Timer value, in seconds. Range is 1 to 3600. Default is 60.

Command Default

60 seconds

Command Modes

SCCP Cisco Unified CallManager configuration (config-sccp-ccm)

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

The optimum setting for this command depends on the platform and your individual network characteristics. Adjust the connect interval value to meet your needs.

Examples

The following example specifies that the profile attempts to connect to another Cisco Unified CallManager after 1200 seconds (20 minutes) when the current Cisco Unified CallManager connection fails:

```
Router(config-sccp-ccm)# connect interval 1200
```

Related Commands

Command	Description
associate ccm	Associates a Cisco Unified CallManager with a Cisco Unified CallManager group and establishes its priority within the group.
associate profile	Associates a DSP farm profile with a Cisco Unified CallManager group.
bind interface	Binds an interface to a Cisco Unified CallManager group.
connect retries	Specifies the number of times that a DSP farm attempts to connect to a Cisco Unified CallManager when the current Cisco Unified CallManager connections fails.
sccp ccm group	Creates a Cisco Unified CallManager group and enters SCCP Cisco Unified CallManager configuration mode.

connect retries

To specify the number of times that a digital signal processor (DSP) farm attempts to connect to a Cisco Unified CallManager when the current Cisco Unified CallManager connections fails, use the **connect retries** command in SCCP Cisco CallManager configuration mode. To reset this number to the default value, use the **no** form of this command.

connect retries *number*

no connect retries

Syntax Description

number	Number of connection attempts. Range is 1 to 32. Default is 3.

Command Default

3 connection attempts

Command Modes

SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

The value of this command specifies the number of times that the given DSP farm attempts to connect to the higher-priority Cisco Unified CallManager before it gives up and attempts to connect to the next Cisco Unified CallManager.

Note The optimum setting for this command depends on the platform and your individual network characteristics. Adjust the connect retries value to meet your needs.

Examples

The following example allows a DSP farm to make 5 attempts to connect to the Cisco Unified CallManager before giving up and attempting to connect to the next Cisco Unified CallManager specified in the group:

```
Router(config-sccp-ccm)# connect retries 5
```

Related Commands

Command	Description
associate ccm	Associates a Cisco Unified CallManager with a Cisco CallManager group and establishes its priority within the group.
associate profile	Associates a DSP farm profile with a Cisco CallManager group.
bind interface	Binds an interface to a Cisco CallManager group.

Command	Description
connect interval	Specifies how many times a given profile attempts to connect to the specific Cisco Unified CallManager.
sccp ccm group	Creates a Cisco CallManger group and enters SCCP Cisco CallManager configuration mode.

connection

To specify a connection mode for a voice port, use the **connection** command in voice-port configuration mode. To disable the selected connection mode, use the **no** form of this command.

connection {**plar** | **tie-line** | **plar opx** [**cut-through-wait** | **immediate**]} *phone-number* | {**trunk** *phone-number* [**answer-mode**]}

connection {**plar** | **tie-line** | **plar opx** [**cut-through-wait** | **immediate**]} *phone-number* | {**trunk** *phone-number* [**answer-mode**]}

Syntax Description

plar	Specifies a private line automatic ringdown (PLAR) connection. PLAR is an autodialing mechanism that permanently associates a voice interface with a far-end voice interface, allowing call completion to a specific telephone number or PBX without dialing. When the calling telephone goes off-hook, a predefined network dial peer is automatically matched, which sets up a call to the destination telephone or PBX.
tie-line	Specifies a connection that emulates a temporary tie-line trunk to a private branch exchange (PBX). A tie-line connection is automatically set up for each call and torn down when the call ends.
plar opx	Specifies a PLAR off-premises extension (OPX) connection. Using this option, the local voice port provides a local response before the remote voice port receives an answer. On Foreign Exchange Office (FXO) interfaces, the voice port does not answer until the remote side has answered.
cut-through-wait	(Optional) Specifies that the router waits for the off-hook signal before cutting through the audio path. **Note** This keyword suppresses the subtle clicking sound that is heard when a phone goes off-hook. Users may have difficulty perceiving when the local FXO port has gone off-hook.
immediate	(Optional) Configures the FXO port to set up calls immediately (without waiting for Caller ID information) so the ring-cycle perception is identical for the caller and the called party. When the Caller ID is available, it is forwarded to the called number if the called party has not already answered the call. **Note** This option cannot be configured on an FXO port that is configured as a Centralized Automatic Message Accounting (CAMA) port.
phone-number	Specifies the destination telephone number. Valid entries are any series of digits that specify the E.164 telephone number.
trunk	Specifies a connection that emulates a permanent trunk connection to a PBX. A trunk connection remains permanent in the absence of any active calls.
answer-mode	(Optional) Specifies that the router does not initiate a trunk connection but waits for an incoming call before establishing the trunk. Use only with the **trunk** keyword.

Command Default

No connection mode is specified, and the standard session application outputs a dial tone when the interface goes off-hook until enough digits are collected to match a dial peer and complete the call.

Command Modes

Voice-port configuration (config-voiceport)

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(1)MA1	This command was implemented on the Cisco MC3810, and the **tie-line** keyword added.
11.3(1)MA5	The **plar opx** keyword was implemented on the Cisco MC3810 as the **plar-opx-ringrelay** keyword. The keyword was shortened in a subsequent release.
12.0(2)T	This command was integrated into Cisco IOS Release 12.0(2)T.
12.0(3)XG	The **trunk** keyword was implemented on the Cisco MC3810. The **trunk answer-mode** option was added.
12.0(4)T	This command was integrated in Cisco IOS Release 12.0(4)T.
12.0(7)XK	This command was unified across the Cisco 2600, Cisco 3600, and Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.3(8)T	The **cut-through-wait** keyword was added.
12.4(11)XW	The **immediate** keyword was added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

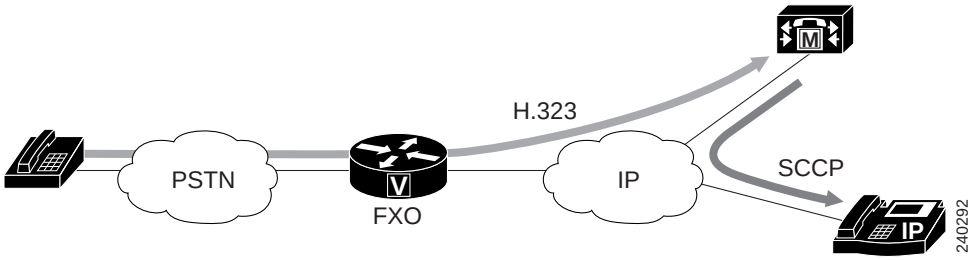
Usage Guidelines

Use the **connection** command to specify a connection mode for a specific interface. For example, use the **connection plar** command to specify a PLAR interface. The string you configure for this command is used as the called number for all incoming calls over this connection. The destination peer is determined by the called number.

The **connection plar opx immediate** option enables FXO ports to set up calls with no ring discrepancy for Caller ID between the caller and the called party. To implement the FXO Delayed Caller ID Delivery feature, you must have a configured network with a Cisco 2800 or Cisco 3800 series integrated services router running Cisco IOS Release 12.4(11)XW. The integrated services router must have at least one voice interface card. Cisco CallManager Release 4.2.3 SR1 or later releases must be installed on the network to support this feature.

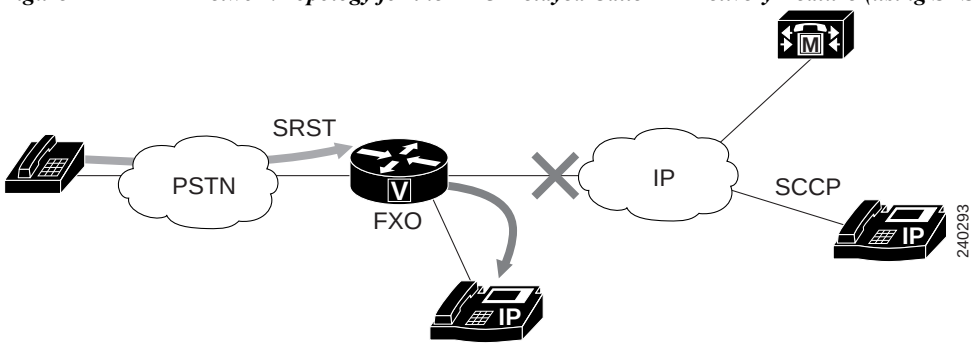
Figure 3 and Figure 4 show the network topology and call flow for the FXO Delayed Caller ID feature. The caller is in the PSTN, and the call arrives via an FXO port at the gateway. In Figure 3, the gateway is connected via H.323 to Cisco CallManager. Cisco CallManager extends the call to the called party which is a SCCP-based IP phone (Cisco 7941).

Figure 3 Network Topology for the FXO Delayed Caller ID Delivery Feature



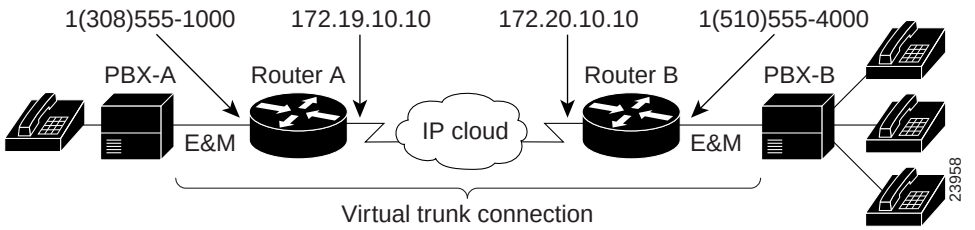
In Figure 4, the gateway is on the same router, and Survivable Remote Site Telephony (SRST) is active. SRST extends the call to the called party, which is a Skinny Client Control Protocol (SCCP)-based IP phone (Cisco 7941).

Figure 4 Network Topology for the FXO Delayed Caller ID Delivery Feature (using SRST)



Use the **connection trunk** command to specify a permanent tie-line connection to a PBX. VoIP simulates a trunk connection by creating virtual trunk tie lines between PBXs connected to Cisco devices on each side of a VoIP connection (see Figure 5). In this example, two PBXs are connected using a virtual trunk. PBX-A is connected to Router A via an E&M voice port; PBX-B is connected to Router B via an E&M voice port. The Cisco routers spoof the connected PBXs into believing that a permanent trunk tie line exists between them.

Figure 5 Virtual Trunk Connection



When configuring virtual trunk connections in VoIP, the following restrictions apply:

- You can use the following voice port combinations:
  - E&M to E&M (same type)
  - Foreign Exchange Station (FXS) to Foreign Exchange Office (FXO)
  - FXS to FXS (with no signaling)
- Do not perform number expansion on the destination pattern telephone numbers configured for trunk connection.
- Configure both end routers for trunk connections.

Note Because virtual trunk connections do not support number expansion, the destination patterns on each side of the trunk connection must match exactly.

To configure one of the devices in the trunk connection to act as slave and only receive calls, use the **answer-mode** option with the **connection trunk** command when configuring that device.

Note When using the **connection trunk** command, you must enter the **shutdown** command followed by the **no shutdown** command on the voice port.

VoIP establishes the trunk connection immediately after configuration. Both ports on either end of the connection are dedicated until you disable trunking for that connection. If for some reason the link between the two switching systems goes down, the virtual trunk reestablishes itself after the link comes back up.

Use the **connection tie-line** command when the dial plan requires you to add digits in front of any digits dialed by the PBX, and the combined set of digits is used to route the call onto the network. The operation is similar to the **connection plar** command operation, but in this case, the tie-line port waits to collect thedigits from the PBX. Tie-line digits are automatically stripped by a terminating port.

Examples

The following example shows PLAR as the connection mode with a destination telephone number of 555-0100:

```
voice-port 1/0/0
 connection trunk 5550100
```

The following example shows the tie-line as the connection mode with a destination telephone number of 555-0100:

```
voice-port 1/1
 connection tie-line 5550100
```

The following example shows a PLAR off-premises extension connection with a destination telephone number of 555-0100:

```
voice-port 1/0/0
 connection plar-opx 5550100
```

The following example shows a trunk connection configuration that is established only when the trunk receives an incoming call:

```
voice-port 1/0/0
 connection trunk 5550100 answer-mode
```

The following example shows a PLAR off-premises extension connection with a destination telephone number of 0199. The router waits for the off-hook signal before cutting through the audio path:

```
voice-port 2/0/0
 connection plar opx 0199 cut-through-wait
```

The following examples show configuration of the routers on both sides of a VoIP connection (as illustrated in Figure 5) to support trunk connections.

Router A

```
voice-port 1/0/0
 connection trunk +15105550190
dial-peer voice 10 pots
 destination-pattern +13085550181
 port 1/0/0
dial-peer voice 100 voip
 session-target ipv4:172.20.10.10
 destination-pattern +15105550190
```

Router B

```
voice-port 1/0/0
 connection trunk +13085550180
dial-peer voice 20 pots
 destination-pattern +15105550191
 port 1/0/0
dial-peer voice 200 voip
 session-target ipv4:172.19.10.10
 destination-pattern +13085550180
```

Related Commands

Command	Description
destination-pattern	Specifies the prefix or the full E.164 telephone number for a dial peer.
dial peer voice	Enters dial peer configuration mode and specifies the voice encapsulation type.
session-protocol	Establishes a session protocol for calls between the local and remote routers via the packet network.
session-target	Configures a network-specific address for a dial peer.
shutdown	Takes a specific voice port or voice interface card offline.
voice-port	Enters voice-port configuration mode.

connection-timeout

To configure the time in seconds for which a connection is maintained after completion of a communication exchange, use the **connection-timeout** command in settlement configuration mode. To return to the default value, use the **no** form of this command.

connection-timeout *seconds*

no connection-timeout *seconds*

Syntax Description

seconds	Time, in seconds, for which a connection is maintained after the communication exchange is completed. Range is from 0 to 86400; 0 means that the connection does not time out. The default is 3600 (1 hour).

Command Default

3600 seconds (1 hour)

Command Modes

Settlement configuration

Command History

Release	Modification
12.0(4)XH1	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.

Usage Guidelines

The router maintains the connection for the configured period in anticipation of future communication exchanges to the same server.

Examples

The following example shows a connection configured to be maintained for 3600 seconds after completion of a communications exchange:

```
settlement 0
 connection-timeout 3600
```

Related Commands

Command	Description
customer-id	Sets the customer identification.
device-id	Sets the device identification.
encryption	Specifies the encryption method.
max-connection	Sets the maximum simultaneous connections.
response-timeout	Sets the response timeout.
retry-delay	Sets the retry delay.
retry-limit	Sets the connection retry limit.

Command	Description
session-timeout	Sets the session timeout.
settlement	Enters settlement configuration mode.
show settlement	Displays the configuration for all settlement server transactions.
shutdown	Brings up or shuts down the settlement provider.
type	Specifies the provider type.
url	Specifies the Internet service provider address.

copy flash vfc

To copy a new version of VCWare from the Cisco AS5300 universal access server motherboard to voice feature card (VFC) flash memory, use the **copy flash vfc** command in privileged EXEC mode.

copy flash vfc *slot-number*

Syntax Description

slot-number	Slot on the Cisco AS5300 in which the VFC is installed. Range is from 0 to 2.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3NA	This command was introduced on the Cisco AS5300.

Usage Guidelines

Use the **copy flash vfc** command to use the standard copy user interface in order to copy a new version of VCWare from the Cisco AS5300 universal access server motherboard to VFC flash memory. The VFC is a plug-in feature card for the Cisco AS5300 universal access server and has its own Flash memory storage for embedded firmware. For more information about VFCs, refer to *Voice-over-IP Card*.

Once the VCWare file has been copied, use the **unbundle vfc** command to uncompress and install VCWare.

Examples

The following example copies a new version of VCWare from the Cisco AS5300 universal access server motherboard to VFC flash memory:

```
Router# copy flash vfc 0
```

Related Commands

Command	Description
copy tftp vfc	Copies a new version of VCWare from a TFTP server to VFC flash memory.
unbundle vfc	Unbundles the current running image of VCWare or DSPWare into separate files.

copy tftp vfc

To copy a new version of VCWare from a TFTP server to voice feature card (VFC) flash memory, use the **copy tftp vfc** command in privileged EXEC mode.

copy tftp vfc *slot-number*

Syntax Description

slot-number	Slot on the Cisco AS5300 in which the VFC is installed. Range is from 0 to 2. There is no default.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3NA	This command was introduced on the Cisco AS5300.

Usage Guidelines

Use the **copy tftp vfc** command to copy a new version of VCWare from a TFTP server to VFC flash memory. The VFC is a plug-in feature card for the Cisco AS5300 universal access server and has its own flash storage for embedded firmware. For more information about VFCs, refer to *Voice-over-IP Card*.

Once the VCWare file has been copied, use the **unbundle vfc** command to uncompress and install VCWare.

Examples

The following example copies a file from the TFTP server to VFC flash memory:

```
Router# copy tftp vfc 0
```

Related Commands

Command	Description
copy flash vfc	Copies a new version of VCWare from the Cisco AS5300 motherboard to VFC flash memory.
unbundle vfc	Unbundles the current running image of VCWare or DSPWare into separate files.

corlist incoming

To specify the class of restrictions (COR) list to be used when a specified dial peer acts as the incoming dial peer, use the **corlist incoming** command in dial peer configuration mode. To clear the previously defined incoming COR list in preparation for redefining the incoming COR list, use the **no** form of this command.

corlist incoming *cor-list-name*

no corlist incoming *cor-list-name*

Syntax Description

cor-list-name	Name of the dial peer COR list that defines the capabilities that the specified dial peer has when it is used as an incoming dial peer.

Command Default No default behavior or values.

Command Modes Dial peer configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.

Usage Guidelines The **dial-peer cor list** and **member** commands define a set of capabilities (a COR list). These lists are used in dial peers to indicate the capability set that a dial peer has when it is used as an incoming dial peer (the **corlist incoming** command) or to indicate the capability set that is required for an incoming dial peer to make an outgoing call through the dial peer (the **corlist outgoing** command). For example, if dial peer 100 is the incoming dial peer and its incoming COR list name is list100, dial peer 200 has list200 as the outgoing COR list name. If list100 does not include all the members of list200 (that is, if list100 is not a superset of list200), it is not possible to have a call from dial peer 100 that uses dial peer 200 as the outgoing dial peer.

Examples In the following example, incoming calls from 526.... are blocked from being switched to outgoing calls to 1900.... because the COR list for the incoming dial peer (list2) is not a superset of the COR list for the outgoing dial peer (list1):

```
dial-peer list list1
 member 900call

dial-peer list list2
 member 800call
 member othercall

dial-peer voice 526 pots
 answer-address 408555....
 corlist incoming list2
 direct-inward-dial
```

```
dial-peer voice 900 pots
 destination pattern 1900.......
 direct-inward-dial
 trunkgroup 101
 prefix 333
 corlist outgoing list1
```

Related Commands

Command	Description
corlist outgoing	Specifies the COR list to be used by outgoing dial peers.
dial-peer cor list	Defines a COR list name.
member	Adds a member to a dial peer COR list.

corlist outgoing

To specify the class of restrictions (COR) list to be used by outgoing dial peers, use the **corlist outgoing** command in dial peer configuration mode. To clear the previously defined outgoing COR list in preparation for redefining the outgoing COR list, use the **no** form of this command.

corlist outgoing *cor-list-name*

no corlist outgoing *cor-list-name*

Syntax Description

cor-list-name	Required name of the dial peer COR list for outgoing calls to the configured number using this dial peer.

Command Default No default behavior or values.

Command Modes Dial peer configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.

Usage Guidelines If the COR list for the incoming dial peer is not a superset of the COR list for the outgoing dial peer, calls from the incoming dial peer cannot use that outgoing dial peer.

Examples In the following example, incoming calls from 526.... are blocked from being switched to outgoing calls to 1900.... because the COR list for the incoming dial peer (list2) is not a superset of the COR list for the outgoing dial peer (list1):

```
dial-peer list list1
member 900call

dial-peer list list2
 member 800call
 member othercall

dial-peer voice 526 pots
 answer-address 408555....
 corlist incoming list2
 direct-inward-dial

dial-peer voice 900 pots
 destination pattern 1900.......
 direct-inward-dial
 trunk group 101
 prefix 333
 corlist outgoing list1
```

cptone

To specify a regional analog voice-interface-related tone, ring, and cadence setting for a voice port, use the **cptone** command in voice-port configuration mode. To disable the selected tone, use the **no** form of this command.

cptone *locale*

no cptone *locale*

Syntax Description

locale	Country-specific voice-interface-related default tone, ring, and cadence setting (for ISDN PRI and E1 R2 signaling). Keywords are shown in Table 15. The default keyword is **us** in Cisco IOS Release 12.0(4)T and later releases.

Command Default

The default keyword is **us** for all supported gateways and interfaces in Cisco IOS Release 12.0(4)T and later releases.

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(1)MA	This command was modified. The full keyword names for the countries were first added on the Cisco MC3810.
12.0(4)T	This command was modified. ISO 3166 two-letter country codes were added on the Cisco MC3810.
12.1(5)XM	This command was modified. The following keywords were added: **eg**, **gh**, **jo**, **ke**, **lb**, **ng, np**, **pa, pk**, **sa**, and **zw**.
12.2(2)T	This command was implemented on the Cisco 1750 and integrated into Cisco IOS Release 12.2(2)T.
12.2(15)ZJ	This command was modified. The **c1** and **c2** keywords were added for the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3640A, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.4(15)T	This command was modified. The following keywords were added: **ae**, **kw**, and **om**.
15.0(1)M	This command was modified. The **cl** keyword was added.
15.1(3)T	This command was modified. The **mt** keyword was added.

Usage Guidelines

This command defines the detection of call-progress tones generated at the local interface. It does not affect any information passed to the remote end of a connection, and it does not define the detection of tones generated at the remote end of a connection. Use the **cptone** command to specify a regional analog voice interface-related default tone, ring, and cadence setting for a specified voice port.

If your device is configured to support E1 R2 signaling, the E1 R2 signaling type (whether ITU, ITU variant, or local variant as defined by the **cas-custom** command) must match the appropriate pulse code modulation (PCM) encoding type as defined by the **cptone** command. For countries for which a **cptone** value has not yet been defined, you can try the following:

- If the country uses a-law E1 R2 signaling, use the **gb** value for the **cptone** command.
- If the country uses mu-law E1 R2 signaling, use the **us** value for the **cptone** command.

Table 15 lists valid entries for the *locale* argument.

Table 15 Valid Command Entries for* locale *Argument

Country	cptone *locale* Command Entry	Country	cptone *locale* Command Entry
Argentina	**ar**	Lebanon	**lb**

1. Automatically configured the first time the XML file is downloaded to the gateway.

Examples

The following example configures United States as the call-progress tone locale:

```
voice-port 1/0/0
 cptone us
```

The following example configures Brazil as the call-progress tone locale on a Cisco universal access server:

```
voice-port 1:0
 cptone br
 description Brasil Tone
```

Related Commands

Command	Description
voice-port	Enters voice-port configuration mode.
cas-custom	Customizes signaling parameters for a particular E1 or T1 channel group on a channelized line.

cptone call-waiting repetition interval

To set the call-waiting alert pattern on analog endpoints that are connected to Foreign Exchange Station (FXS) ports, use the **cptone call-waiting repetition interval** command in supplementary-service voice-port configuration mode. To return to the default behavior, use the **no** form of this command.

cptone call-waiting repetition interval *second*

no cptone call-waiting repetition interval

Syntax Description

second	Length of time, in seconds for the tone repetition interval. Range: 0 to 30. Default: 0.

Command Default

A single-beep tone is the default behavior.

Command Modes

Supplementary-service voice-port configuration (config-stcapp-suppl-serv-port)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use the **cptone call-waiting repetition interval** command to set the call-waiting alert pattern on analog endpoints that are connected to FXS ports on a Cisco IOS voice gateway, such as a Cisco Integrated Services Router (ISR) or Cisco VG224 Analog Phone Gateway.

When configured, the ringtone periodically repeats with configured interval until either the user switches to the new call or the calling party hangs up.

Examples

The following example shows how to set the call-waiting alert pattern on analog endpoints connected to port 2/0 on a Cisco VG224:

```
Router(config)# stcapp supplementary-services
Router(config-stcapp-suppl-serv)# port 2/0
Router(config-stcapp-suppl-serv-port)# cptone call-waiting repetition interval 20
Router(config-stcapp-suppl-serv-port)# end
```

Related Commands

Command	Description
stcapp supplementary-services	Enters supplementary-service configuration mode for configuring STCAPP supplementary-service features on an FXS port.

credential load

To reload a credential file into flash memory, use the **credential load** command in privileged EXEC mode.

credential load *tag*

Syntax Description

tag	Number that identifies the credential (.csv) file to load. Range: 1 to 5. This is the number that was defined with the **authenticate credential** command.

Command Default The credential file is not reloaded.

Command Modes Privileged EXEC

Command History

Release	Modification
12.4(11)XJ	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines This command provides a shortcut to reload credential files that were defined with the **authenticate credential** command.

Up to five .csv files can be configured and loaded into the system. The contents of these five files are mutually exclusive, that is, the username/password pairs must be unique across all the files. For Cisco Unified CME, these username/password pairs cannot be the same ones defined for SCCP or SIP phones with the **username** command.

Examples The following example shows how to reload credential file 3:

```
credential load 3
```

Related Commands

Command	Description
authenticate (voice register global)	Defines the authenticate mode for SIP phones in a Cisco Unified CME or Cisco Unified SRST system.
username (ephone)	Defines a username and password for SCCP phones.
username (voice register pool)	Defines a username and password for authenticating SIP phones.

credentials (SIP UA)

To configure a Cisco IOS Session Initiation Protocol (SIP) time-division multiplexing (TDM) gateway, a Cisco Unified Border Element (Cisco UBE), or Cisco Unified Communications Manager Express (Cisco Unified CME) to send a SIP registration message when in the UP state, use the **credentials** command in SIP UA configuration mode. To disable SIP digest credentials, use the **no** form of this command.

credentials {**dhcp** | **number** *number* **username** *username*} **password** [**0** | **7**] *password* **realm** *realm*

no credentials {**dhcp** | **number** *number* **username** *username*} **password** [**0** | **7**] *password* **realm** *realm*

Syntax Description

dhcp	(Optional) Specifies the Dynamic Host Configuration Protocol (DHCP) is to be used to send the SIP message.
number *number*	(Optional) A string representing the registrar with which the SIP trunk will register (must be at least four characters).
username *username*	A string representing the username for the user who is providing authentication (must be at least four characters). This option is only valid when configuring a specific registrar using the **number** keyword.
password	Specifies password settings for authentication.
0	(Optional) Specifies the encryption type as cleartext (no encryption). This is the default.
7	(Optional) Specifies the encryption type as encrypted.
password	A string representing the password for authentication. If no encryption type is specified, the password will be cleartext format. The string must be between 4 and 128 characters.
realm *realm*	(Optional) A string representing the domain where the credentials are applicable.

Command Default

SIP digest credentials are disabled.

Command Modes

SIP UA configuration (sip-ua)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(22)T	This command was integrated into Cisco IOS Release 12.4(22)T.
12.4(22)YB	This command was modified. The **dhcp** keyword was added and the **username** keyword and *username* argument were removed.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.
15.0(1)XA	This command was modified. The **number** keyword and *number* argument were added and the **username** keyword and *username* argument reintroduced to configure credentials for a given registrar when multiple registrars are configured.
15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines

The following configuration rules are applicable when credentials are enabled:

- Only one password is valid for all domain names. A new configured password overwrites any previously configured password.
- The password will always be displayed in encrypted format when the **credentials** command is configured and the **show running-config** command is used.

The **dhcp** keyword in the command signifies that the primary number is obtained via DHCP and the Cisco IOS SIP TDM gateway, Cisco UBE, or Cisco Unified CME on which the command is enabled uses this number to register or unregister the received primary number.

Examples

The following example shows how to configure SIP digest credentials without specifying the password encryption type:

```
Router> enable
Router# configure terminal
Router(config)# sip-ua
Router(config-sip-ua)# credentials dhcp password MyPassword realm example.com
```

The following example shows how to configure SIP digest credentials using the encrypted format:

```
Router> enable
Router# configure terminal
Router(config)# sip-ua
Router(config-sip-ua)# credentials dhcp password 7 095FB01AA000401 realm example.com
```

The following example shows how to disable SIP digest credentials where the encryption type was specified:

```
Router> enable
Router# configure terminal
Router(config)# sip-ua
Router(config-sip-ua)# no credentials dhcp password 7 095FB01AA000401 realm example.com
```

The following example shows how to configure SIP digest credentials for two different realms without specifying the encryption type:

```
Router> enable
Router# configure terminal
Router(config)# sip-ua
Router(config-sip-ua)# credentials number 1111 username MyUser password MyPassword realm
MyLocation1.example.com
Router(config-sip-ua)# credentials number 1111 username MyUser password MyPassword realm
MyLocation2.example.com
```

Related Commands

Command	Description
authentication (dial peer)	Enables SIP digest authentication on an individual dial peer.
authentication (SIP UA)	Enables SIP digest authentication.
localhost	Configures global settings for substituting a DNS localhost name in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages.
registrar	Enables Cisco IOS SIP TDM gateways to register E.164 numbers for FXS, EFXS, and SCCP phones on an external SIP proxy or SIP registrar.
voice-class sip localhost	Configures settings for substituting a DNS localhost name in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages on an individual dial peer, overriding the global setting.

Cisco IOS Voice Commands: D

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order beginning with the letter D. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the master index of commands or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Library.*

default (auto-config application)

To configure an auto-config application configuration command to its default value, use the **default** command in auto-config application configuration mode.

default *command*

Syntax Description

command	One of the auto-config application configuration commands. Valid choices are as follows: • **retries** • **server** • **shutdown** • **timeout**

Command Default No default behavior or values

Command Modes Auto-config application configuration

Command History

Release	Modification
12.3(8)XY	This command was introduced on the Communication Media Module.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T.

Examples The following example shows the **default** command used to set the number of download retry attempts for an auto-configuration application to its default value.

```
Router(auto-config-app)# default retries
```

Related Commands

Command	Description
auto-config	Enables auto-configuration or enters auto-config application configuration mode for the SCCP application.
show auto-config	Displays the current status of auto-config applications.

default (MGCP profile)

To configure a Media Gateway Control Protocol (MGCP profile) command to its default value, use the **default** command in MGCP profile configuration mode. To disable the default command, use the **no** form of the command for that profile parameter.

default *command*

no default *command*

Syntax Description

command	One of the MGCP profile commands. Valid choices are as follows: • call-agent • description (MGCP profile) • max1 lookup • max1 retries • max2 lookup • max2 retries • package persistent • timeout tcrit • timeout tdinit • timeout tdmax • timeout tdmin • timeout thist • timeout tone busy • timeout tone cot1 • timeout tone cot2 • timeout tone dial • timeout tone dial stutter • timeout tone mwi • timeout tone network congestion • timeout tone reorder • timeout tone ringback • timeout tone ringback connection • timeout tone ringing • timeout tone ringing distinctive • timeout tpar • timeout tsmax • voice-port (MGCP profile)

Command Default No default behaviors or values

Command Modes MGCP profile configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines This command is used when configuring values for an MGCP profile.

The **default (MGCP profile)** command instructs the MGCP profile to use the default value of the specified command whenever the profile is called. This has the same effect as using the **no** form of the specified command, but the **default** command clearly specifies which commands are using their default values.

To use the default values for more than one command, enter each command on a separate line.

Examples The following example shows how to configure the default values for three MGCP profile commands:

```
Router(config)# mgcp profile newyork
Router(config-mgcp-profile)# default max1 retries
Router(config-mgcp-profile)# default timeout tdinit
Router(config-mgcp-profile)# default timeout tone mwi
```

Related Commands

Command	Description
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints or to configure the default profile.

default (SIP)

To reset a SIP command to its default value, use the **default** command in SIP configuration mode.

default *command*

Syntax Description

command	One of the SIP configuration commands. Valid choices are: • **bind**: Configures the source address of signaling and media packets to a specific interface's IP address. • **rel1xx**: Enables all SIP provisional responses (other than 100 Trying) to be sent reliably to the remote SIP endpoint. • **session-transport**: Configures the underlying transport layer protocol for SIP messages to TCP or UDP. • **url**: Configures URLs to either the SIP or TEL format for your voip sip calls.

Defaults

The default is that binding is disabled (**no bind**).

Command Modes

SIP configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco AS5300, Cisco AS5350, and Cisco AS5400 platforms.
12.2(2)XB2	This command was implemented on the Cisco AS5850 platform.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and support was added for the Cisco 3700 series. Cisco AS5300, Cisco AS5350, Cisco AS5850, and Cisco AS5400 platforms were not supported in this release.
12.2(11)T	Support was added for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 platforms.
Cisco IOS XE Release 2.5	This command was integrated into Cisco IOS XE Release 2.5.

Examples

The following example shows how to reset the value of the SIP **bind** command:

```
Router(config)# voice serv voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# default bind
```

Related Commands

Command	Description
sip	Enter SIP configuration mode from voice-service VoIP configuration mode.

default-file vfc

To specify an additional (or different) file from the ones in the default file list and stored in voice feature card (VFC) Flash memory, use the **default-file vfc** command in global configuration mode. To delete the file from the default file list, use the **no** form of this command.

default-file *filename* **vfc** *slot*

no default-file *filename* **vfc** *slot*

Syntax Description

filename	Indicates the file to be retrieved from VFC Flash memory and used to boot up the system.
slot	Indicates the slot on the Cisco AS5300 in which the VFC is installed. Range is to 2. There is no default value.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
11.3(1)NA	This command was introduced on the Cisco AS5300.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines

When VCWare is unbundled, it automatically adds DSPWare to Flash memory, creates both the capability and default file lists, and populates these lists with the default files for that version of VCWare. The default file list includes the files that is used to boot up the system.

Use the **default-file vfc** command to add a specified file to the default file list, replacing the existing default for that extension type.

Examples

The following example specifies that the bas-vfc-1.0.14.0.bin file, which is stored in VFC Flash memory, be added to the default file list:

```
default-file bas-vfc-1.0.14.0.bin vfc 0
```

Related Commands

Command	Description
cap-list vfc	Adds a voice codec overlay file to the capability file list.
delete vfc	Deletes a file from VFC Flash memory.

define

To define the transmit and receive bits for North American ear and mouth (E&M), E&M Mercury Exchange Limited Channel-Associated Signaling (MELCAS), and Land Mobile Radio (LMR) voice signaling, use the **define** command in voice-port configuration mode. To restore the default value, use the **no** form of this command.

define {**tx-bits** | **rx-bits**} {**seize** | **idle**} {**0000** | **0001** | **0010** | **0011** | **0100** | **0101** | **0110** | **0111** | **1000** | **1001** | **1010** | **1011** | **1100** | **1101** | **1110** | **1111**}

no define {**tx-bits** | **rx-bits**} {**seize** | **idle**} {**0000** | **0001** | **0010** | **0011** | **0100** | **0101** | **0110** | **0111** | **1000** | **1001** | **1010** | **1011** | **1100** | **1101** | **1110** | **1111**}

Syntax Description

tx-bits	The bit pattern applies to the transmit signaling bits.
rx-bits	The bit pattern applies to the receive signaling bits.
seize	The bit pattern defines the seized state.
idle	The bit pattern defines the idle state.
0000 through **1111**	Specifies the bit pattern.

Command Default

The default is to use the preset signaling patterns as defined in American National Standards Institute (ANSI) and European Conference of Postal and Telecommunications Administrations (CEPT) standards, as follows:

- For North American E&M:
  - tx-bits idle 0000 (0001 if on E1 trunk)
  - tx-bits seize 1111
  - rx-bits idle 0000
  - rx-bits seize 1111
- For E&M MELCAS:
  - tx-bits idle 1101
  - tx-bits seize 0101
  - rx-bits idle 1101
  - rx-bits seize 0101
- For LMR:
  - tx-bits idle 0000
  - tx-bits seize 1111
  - rx-bits idle 0000
  - rx-bits seize 1111

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)MA3	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.1(2)T	The command was integrated into Cisco IOS Release 12.1(2)T.
12.3(4)XD	The LMR signaling type was added to the signaling types to which this command applies.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(14)T	This command was implemented on the Cisco 2800 series and Cisco 3800 series.
12.4(2)T	This command was integrated into Cisco IOS Release 12.4(2)T.

Usage Guidelines

The **define** command applies to E&M digital voice ports associated with T1/E1 controllers.

Use the **define** command to match the E&M bit patterns with the attached telephony device. Be careful not to define invalid configurations, such as all 0000 on E1, or identical seized and idle states. Use this command with the **ignore** command.

In LMR signaling, the **define** command is used to define polarity on E&M analog and digital voice ports.

Examples

To configure a voice port on a Cisco 2600 or Cisco 3600 series router that is sending traffic in North American E&M signaling format to convert the signaling to MELCAS format, enter the following commands:

```
voice-port 1/0/0
 define rx-bits idle 1101
 define rx-bits seize 0101
 define tx-bits idle 1101
 define tx-bits seize 0101
```

In this example, reverse polarity is configured on a voice port on a Cisco 3700 series router that is sending traffic in LMR signaling format:

```
voice-port 1/0/0
 define rx-bits idle 1111
 define rx-bits seize 0000
 define tx-bits idle 1111
 define tx-bits seize 0000
```

Related Commands

Command	Description
condition	Manipulates the signaling bit-pattern for all voice signaling types.
ignore	Configures a North American E&M or E&M MELCAS voice port to ignore specific receive bits.

delete vfc

To delete a file from voice feature card (VFC) Flash memory, use the **delete vfc** command in privileged EXEC mode.

delete *filename* **vfc** *slot*

Syntax Description

filename	Specifies the file in VFC Flash memory to be deleted.
slot	Specifies the slot on the Cisco AS5300 in which the specified VFC resides. Range is from 0 to 2.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3(1)NA	This command was introduced on the Cisco AS5300.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines

Use the **delete vfc** command to delete a specific file from VFC Flash memory and to remove the file from the default list or capability list if the specified file is included in those lists.

Note Deleting a file from VFC Flash memory does not free the VFC Flash memory space that the file occupied. To free VFC Flash memory space, use the **erase vfc** command.

Examples

The following example deletes the bas-vfc-1.0.14.0.bin file, which is stored in VFC Flash memory of the VFC located in slot 0:

```
Router# delete bas-vfc-1.0.14.0.bin vfc 0
```

Related Commands

Command	Description
default-file vfc	Specifies an additional (or different) file from the ones in the default file list and stored in VFC Flash memory.
erase vfc	Erases the Flash memory of a specified VFC.
show vfc directory	Displays the list of all files that reside on this VFC.

description

To specify a description of the digital signal processor (DSP) interface, use the **description** command in voice-port or DSP farm interface configuration mode. To describe a MGCP profile that is being defined, use the **description** command in MGCP profile configuration mode. To specify the name or a brief description of a charging profile, use the **description** command in charging profile configuration mode. To delete a configured description, use the **no** form of the command in the appropriate configuration mode.

description *string*

no description

Syntax Description

string	Character string from 1 to 80 characters for DSP interfaces and MGCP profiles, or from 1 to 99 characters for charging profiles.

Command Default

Enabled with a null string.
The MGCP profile has no default description.
Charging profiles have no default description.

Command Modes

Voice-port configuration
DSP farm interface configuration
MGCP profile configuration
Charging profile configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series and Cisco 7200.
11.3(1)MA	This command in voice-port configuration mode was implemented on the Cisco MC3810.
12.0(5)XE	This command in DSP farm interface configuration mode was modified.
12.1(1)T	The DSP farm interface configuration mode modification was integrated into Cisco IOS Release 12.1(1)T.
12.2(2)XA	This command was implemented on the Cisco AS5300.
12.2(11)T	Support for the Cisco AS5300 and Cisco AS5850 was added.
12.3(8)XU	This command was introduced in charging profile configuration mode.
12.3(11)YJ	This command in charging profile configuration mode was integrated into Cisco IOS Release 12.3(11)YJ.
12.3(14)YQ	This command in charging profile configuration mode was integrated into Cisco IOS Release 12.3(14)YQ.
12.4(9)T	This command in charging profile configuration mode was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines

Use the **description** command to describe the DSP interface connection or a defined MGCP profile. The information is displayed when a **show** command is used, and it does not affect the operation of the interface in any way.

Examples

The following example identifies voice port 1/0/0 as being connected to the purchasing department:

```
voice-port 1/0/0
 description purchasing_dept
```

The following example identifies DSP farm interface 1/0 as being connected to the marketing department:

```
dspint dspfarm 1/0
 description marketing_dept
```

The following example shows a description for an MGCP profile:

```
mgcp profile newyork
 description This is the head sales office in New York.
 dot ...(socket=0)
 S:.
 R:250 NAA09092 Message accepted for delivery
 S:QUIT
 R:221 madeup@abc.com closing connection
 Freeing SMTP ctx at 0x6121D454
 returned from work_routine, context freed
```

Related Commands

Command	Description
category	Identifies the subscriber category to which a charging profile applies.
cdr suppression	Specifies that CDRs be suppressed as a charging characteristic in a charging profile.
charging profile	
content dcca profile	Defines a DCCA client profile in a GGSN charging profile.
content postpaid time	Specifies, as a trigger condition for postpaid users in a charging profile, the time duration limit that when exceeded causes the GGSN to collect upstream and downstream traffic byte counts and close and update the G-CDR for a particular PDP context.
content postpaid validity	Specifies, as a trigger condition in a charging profile, that the amount of time quota granted to a postpaid user is valid.
content postpaid volume	Specifies, as a trigger condition for postpaid users in a charging profile, the maximum number of bytes that the GGSN maintains across all containers for a particular PDP context before closing and updating the G-CDR.
content rulebase	Associates a default rule-base ID with a charging profile.
gprs charging characteristics reject	Specifies that create PDP context requests for which no charging profile can be selected be rejected by the GGSN.
gprs charging container time-trigger	
gprs charging profile	Creates a new charging profile (or modifies an existing one) and enters charging profile configuration mode.

Command	Description
limit duration	Specifies, as a trigger condition in a charging profile, the time duration limit that when exceeded causes the GGSN to collect upstream and downstream traffic byte counts and close and update the G-CDR for a particular PDP context.
limit sgsn-change	Specifies, as a trigger condition in a charging profile, the maximum number of GGSN changes that can occur before closing and updating the G-CDR for a particular PDP context.
limit volume	Specifies, as a trigger condition in a charging profile, the maximum number of bytes that the GGSN maintains across all containers for a particular PDP context before closing and updating the G-CDR.
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints or to configure the default profile.
tariff-time	Specifies that a charging profile use the tariff changes configured using the **gprs charging tariff-time** global configuration command.

description (dial peer)

To add a description to a dial peer, use the **description** command in dial peer configuration mode. To remove the description, use the **no** form of this command.

description *description*

no description

Syntax Description

description	Text string up to 64 alphanumeric characters.

Command Default Disabled

Command Modes Dial peer configuration

Command History

Release	Modification
12.2(2)T	This command was introduced.

Usage Guidelines Use this command to include descriptive text about the dial peer. The description displays in **show** command output and does not affect the operation of the dial peer.

Examples The following example shows a description included in a dial peer:

```
dial-peer voice 1 pots
 description inbound PSTN calls
```

Related Commands

Command	Description
dial-peer voice	Defines a dial peer.
show dial-peer voice	Displays configuration information for dial peers.

description (DSP Farm profile)

To include a description about the digital signal processor (DSP) farm profile, use the **description** command in DSP farm profile configuration mode. To remove a description, use the **no** form of this command.

description *text*

no description

Syntax Description

text	Character string from 1 to 80 characters.

Command Default No default behavior or values

Command Modes DSP farm profile configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines Use this command to include descriptive text about this DSP farm profile. This information displays in **show** commands and does not affect the operation of the interface.

Examples The following example identifies the DSP farm profile as being designated to the art department:

```
Router(config-dspfarm-profile)# description art_dept
```

Related Commands

Command	Description
codec (DSP Farm profile)	Specifies the codecs supported by a DSP farm profile.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
maximum sessions (DSP Farm profile)	Specifies the maximum number of sessions that need to be supported by the profile.
shutdown (DSP Farm profile)	Allocates DSP farm resources and associates with the application.

description (dspfarm)

To include a specific description about the digital signal processor (DSP) interface, use the **description** command in DSPfarm interface configuration mode. To disable this feature, use the **no** form of this command.

description *string*

no description *string*

Syntax Description

string	Character string from 1 to 80 characters.

Command Default Enabled with a null string.

Command Modes DSPfarm interface configuration

Command History

Release	Modification
11.3(1)T	This command was introduced for the Cisco 7200 series routers.
12.0(5)XE	This command was modified to reduce the maximum number of allowable characters in a text string from 255 to 80.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Usage Guidelines Use the **description** command to include descriptive text about this DSP interface connection. This information is displayed when you issue a **show** command and does not affect the operation of the interface in any way.

Examples The following example identifies DSPfarm interface 1/0 on the Cisco 7200 series routers router as being connected to the marketing department:

```
dspint dspfarm 1/0
description marketing_dept
```

description (SCCP Cisco CallManager)

To include a description about the Cisco CallManager group, use the **description** command in SCCP Cisco CallManager configuration mode. To remove a description, use the **no** form of this command.

description *text*

no description

Syntax Description

text	Character string from 1 to 80 characters.

Command Default No default behavior or values

Command Modes SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines Use this command to include descriptive text about a Cisco CallManager group. This information is displayed in **show** commands and does not affect the operation of the interface.

Examples The following example identifies SCCP as being designated to the Boston office:

```
Router(config-sccp-ccm)# description boston office
```

Related Commands

Command	Description
associate ccm	Associates a Cisco CallManager with a Cisco CallManager group and establishes its priority within the group.
connect retries	Specifies the number of times that a DSP farm attempts to connect to a Cisco CallManager when the current Cisco CallManager connections fails.
sccp ccm group	Creates a Cisco CallManager group and enters SCCP Cisco CallManager configuration mode.

description (trunk group)

To add a description to a trunk group, use the **description** command in trunk group configuration mode. To delete the description, use the **no** form of this command.

description *text*

no description *text*

Syntax Description

text	Trunk group description. Maximum length is 63 alphanumeric characters.

Command Default No default behavior or values

Command Modes Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Examples The following example shows a description for a trunk group:

```
Router(config)# trunk group alpha1
Router(config-trunk-group)# description carrierAgroup1
```

Related Commands

Command	Description
trunk group	Initiates the definition of a trunk group.

description (voice source group)

To add a description to a voice source group, use the **description** command in voice source-group configuration mode. To delete the description, use the **no** form of this command.

description *text*

no description *text*

Syntax Description

text	Describes a voice source group, Maximum length of the voice source group description is 63 alphanumeric characters.

Command Default No default behavior or values

Command Modes Voice source-group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Examples The following example shows a description for a voice source group:

```
Router(config)# voice source-group northern1
Router(cfg-source-grp)# description carrierBgroup3
```

Related Commands

Command	Description
voice source-group	Defines a source group for voice calls.

destination uri

To specify the voice class used to match a dial peer to the destination uniform resource identifier (URI) of an outgoing call, use the **destination uri** command in dial peer configuration mode. To remove the URI voice class, use the **no** form of this command.

destination uri *tag*

no destination uri

Syntax Description

tag	Alphanumeric label that uniquely identifies the voice class. This tag must be configured with the **voice class uri** command.

Command Default

No default behavior or values

Command Modes

Dial peer configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

- Before you use this command, configure the voice class by using the **voice class uri** command.
- This command applies new rules for dial-peer matching. Table 16 shows the rules and the order in which they are applied when the **destination uri** command is used. The gateway compares the dial-peer command to the call parameter in its search to match an outbound call to a dial peer. All dial peers are searched based on the first match criteria. Only if no match is found does the gateway move on to the next criteria.

Table 16 Dial-Peer Matching Rules for Outbound URI

Match Order	Cisco IOS Command	Outgoing Call Parameter
1	**destination uri** and **carrier-id target**	Application-provided URI and target carrier ID associated with the call
2	**destination-pattern** and **carrier-id target**	Called number and target carrier ID associated with the call
3	**destination uri**	Application-provided URI
4	**destination-pattern**	Called number
5	**carrier-id target**	Target carrier ID associated with the call

Note Calls whose destination is an E.164 number, rather than a URI, use the previously existing dial-peer matching rules. For information, see the *Dial Peer Configuration on Voice Gateway Routers* document, Cisco IOS Voice Library.

Examples

The following example matches the destination URI in the outgoing call by using voice class ab100:

```
dial-peer voice 100 voip
 destination uri ab100
```

Related Commands

Command	Description
answer-address	Specifies calling number to match for a dial peer.
debug voice uri	Displays debugging messages related to URI voice classes.
destination-pattern	Specifies telephone number to match for a dial peer.
dial-peer voice	Enters dial peer configuration mode to create or modify a dial peer.
incoming uri	Specifies the voice class that a VoIP dial peer uses to match the URI of an incoming call.
pattern	Matches a call based on the entire SIP or TEL URI.
session protocol	Specifies a session protocol for calls between local and remote routers using the packet network.
show dialplan uri	Displays which outbound dial peer is matched for a specific destination URI.
voice class uri	Creates or modifies a voice class for matching dial peers to calls containing a SIP or TEL URI.

destination-pattern

To specify either the prefix or the full E.164 telephone number to be used for a dial peer, use the **destination-pattern** command in dial peer configuration mode. To disable the configured prefix or telephone number, use the **no** form of this command.

destination-pattern [**+**]*string*[**T**]

no destination-pattern [**+**]*string*[**T**]

Syntax Description

+	(Optional) Character that indicates an E.164 standard number.
string	Series of digits that specify a pattern for the E.164 or private dialing plan telephone number. Valid entries are the digits 0 through 9, the letters A through D, and the following special characters: • The asterisk (*) and pound sign (#) that appear on standard touch-tone dial pads. • Comma (,), which inserts a pause between digits. • Period (.), which matches any entered digit (this character is used as a wildcard). • Percent sign (%), which indicates that the preceding digit occurred zero or more times; similar to the wildcard usage. • Plus sign (+), which indicates that the preceding digit occurred one or more times. **Note** The plus sign used as part of a digit string is different from the plus sign that can be used preceding a digit string to indicate that the string is an E.164 standard number. • Circumflex (^), which indicates a match to the beginning of the string. • Dollar sign ($), which matches the null string at the end of the input string. • Backslash symbol (\), which is followed by a single character, and matches that character. Can be used with a single character with no other significance (matching that character). • Question mark (?), which indicates that the preceding digit occurred zero or one time. • Brackets ([ ]), which indicate a range. A range is a sequence of characters enclosed in the brackets; only numeric characters from 0 to 9 are allowed in the range. • Parentheses (( )), which indicate a pattern and are the same as the regular expression rule.
T	(Optional) Control character that indicates that the **destination-pattern** value is a variable-length dial string. Using this control character enables the router to wait until all digits are received before routing the call.

Command Default The command is enabled with a null string.

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(1)MA	This command was implemented on the Cisco MC3810.
12.0(4)XJ	This command was modified for store-and-forward fax.
12.1(1)	The command was integrated into Cisco IOS Release 12.1(1).
12.0(7)XR	This command was implemented on the Cisco AS5300 and modified to support the plus sign, percent sign, question mark, brackets, and parentheses symbols in the dial string.
12.0(7)XK	This command was modified. Support for the plus sign, percent sign, question mark, brackets, and parentheses in the dial string was added to the Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T and implemented on the Cisco 1750, Cisco 7200 series, and Cisco 7500 series. The modifications for the Cisco MC3810 in Cisco IOS Release12.0(7)XK are not supported in this release.
12.1(2)T	The modifications made in Cisco IOS Release 12.0(7)XK for the Cisco MC3810 were integrated into Cisco IOS Release 12.1(2)T.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series and Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T and implemented on the Cisco 2600XM, the Cisco ICS7750, and the Cisco VG200.
12.4(22)T	Support for IPv6 was added.

Usage Guidelines Use the **destination-pattern** command to define the E.164 telephone number for a dial peer.

The pattern you configure is used to match dialed digits to a dial peer. The dial peer is then used to complete the call. When a router receives voice data, it compares the called number (the full E.164 telephone number) in the packet header with the number configured as the destination pattern for the voice-telephony peer. The router then strips out the left-justified numbers that correspond to the destination pattern. If you have configured a prefix, the prefix is prepended to the remaining numbers, creating a dial string that the router then dials. If all numbers in the destination pattern are stripped out, the user receives a dial tone.

There are areas in the world (for example, certain European countries) where valid telephone numbers can vary in length. Use the optional control character **T** to indicate that a particular **destination-pattern** value is a variable-length dial string. In this case, the system does not match the dialed numbers until the interdigit timeout value has expired.

Note Cisco IOS software does not verify the validity of the E.164 telephone number; it accepts any series of digits as a valid number.

Examples

The following example shows configuration of the E.164 telephone number 555-0179 for a dial peer:

```
dial-peer voice 10 pots
 destination-pattern +5550179
```

The following example shows configuration of a destination pattern in which the pattern “43” is repeated multiple times preceding the digits “555”:

```
dial-peer voice 1 voip
 destination-pattern 555(43)+
```

The following example shows configuration of a destination pattern in which the preceding digit pattern is repeated multiple times:

```
dial-peer voice 2 voip
 destination-pattern 555%
```

The following example shows configuration of a destination pattern in which the possible numeric values are between 5550109 and 5550199:

```
dial-peer voice 3 vofr
 destination-pattern 55501[0-9]9
```

The following example shows configuration of a destination pattern in which the possible numeric values are between 5550439, 5553439, 5555439, 5557439, and 5559439:

```
dial-peer voice 4 voatm
 destination-pattern 555[03579]439
```

The following example shows configuration of a destination pattern in which the digit-by-digit matching is prevented and the entire string is received:

```
dial-peer voice 2 voip
 destination-pattern 555T
```

Related Commands

Command	Description
answer-address	Specifies the full E.164 telephone number to be used to identify the dial peer of an incoming call.
dial-peer terminator	Designates a special character to be used as a terminator for variable-length dialed numbers.
incoming called-number (dial peer)	Specifies a digit string that can be matched by an incoming call to associate that call with a dial peer.
prefix	Specifies the prefix of the dialed digits for a dial peer.
timeouts interdigit	Configures the interdigit timeout value for a specified voice port.

destination-pattern (interface)

To specify the ISDN directory number for the telephone interface, use the **destination-pattern** command in interface configuration mode. To disable the specified ISDN directory number, use the **no** form of this command.

destination-pattern *isdn*

no destination-pattern

Syntax Description

isdn	Local ISDN directory number assigned by your telephone service provider.

Command Default

A default ISDN directory number is not defined for this interface.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(3)T	This command was introduced on the Cisco 800 series.

Usage Guidelines

This command is applicable to the Cisco 800 series routers.

You must specify this command when creating a dial peer. This command does not work if it is not specified within the context of a dial peer. For information on creating a dial peer, refer to the *Cisco 800 Series Routers Software Configuration Guide*.

Do not specify an area code with the local ISDN directory number.

Examples

The following example specifies 555-0101 as the local ISDN directory number:

```
destination-pattern 5550101
```

Related Commands

Command	Description
dial-peer voice	Enters dial peer configuration mode, defines the type of dial peer, and defines the tag number associated with a dial peer.
no call-waiting	Disables call waiting.
port (dial peer)	Enables an interface on a PA-4R-DTR port adapter to operate as a concentrator port.
ring	Sets up a distinctive ring for telephones, fax machines, or modems connected to a Cisco 800 series router.
show dial-peer voice	Displays configuration information and call statistics for dial peers.

detect v54 channel-group

To enable V.54 loopback detection for the command sent from the remote device, use the **detect v54 channel-group command in** controller configuration mode. To disable the V.54 loopback detection, use the **no** form of this command.

detect v54 channel-group *channel-number*

no detect v54 channel-group *channel-number*

Syntax Description

channel-number	Channel number from 1 to 24 (T1) or from 1 to 31 (E1).

Command Default

V.54 loopback detection is disabled.

Command Modes

Controller configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco 2600 series and Cisco 3600 series.

Usage Guidelines

Use the **detect v54 channel-group** controller configuration command to enable V.54 loopback detection. The remote device sends a loopup inband payload command sequence in fractional T1 (FT1).

Examples

The following example sets the loopback detection for channel-group 1; then the loopback detection is disabled for channel-group 1.

```
detect v54 channel-group 1
no detect v54 channel-group 1
```

Related Commands

Command	Description
loopback remote v54 channel-group	Activates a remote V.54 loopback for the channel group on the far end.

device-id

To identify a gateway associated with a settlement provider, use the **device-id** command in settlement configuration mode. To reset to the default value, use the **no** form of this command.

device-id *number*

no device-id *number*

Syntax Description

number	Device ID number as provided by the settlement server. Range is from 0 to 2147483647.

Command Default The default device ID is 0

Command Modes Settlement configuration

Command History

Release	Modification
12.0(4)XH1	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Usage Guidelines It is optional to identify a gateway associated with a settlement provider.

Examples The following example sets the device ID to 1000:

```
settlement 0
 device-id 1000
```

Related Commands

Command	Description
customer-id	Identifies a carrier or Internet service provider with the settlement provider.
settlement	Enters settlement configuration mode.

dhcp interface

To configure an interface type for Dynamic Host Configuration Protocol (DHCP) provisioning of Session Initiation Protocol (SIP) parameters, use the **dhcp interface** command in SIP user-agent configuration mode.

dhcp interface *type number*

Syntax Description

type	Type of interface to be configured.
number	Port, connector, or interface card number. **Note** The number format varies depending on the network module or line card type and the router's chassis slot it is installed in. The numbers are assigned at the factory at the time of installation or when they are added to a system; they can be displayed with the **show interfaces** command.

Command Default

No interface type is configured for DHCP provisioning of SIP parameters.

Command Modes

SIP user-agent configuration (sip-ua)

Command History

Release	Modification
12.4(22)YB	This command was introduced.
15.0(1)M	This command was integrated in Cisco IOS Release 15.0(1)M.

Usage Guidelines

Multiple interfaces on the Cisco Unified Border Element can be configured with DHCP. The **dhcp interface** command specifies which one is the DHCP interface used with SIP.

This command does not have a **no** form.

Table 17 displays the keywords that represent the types of interfaces that can be configured with the **dhcp interface** command. Replace the *type* argument with the appropriate keyword from the table.

Table 17 Interface Type Keywords

Keyword	Interface Type
ethernet	Ethernet IEEE 802.3 interface.
fastethernet	100-Mbps Ethernet interface. In RITE configuration mode, specifies the outgoing (monitored) interface for exported IP traffic.
gigabitethernet	1000-Mbps Ethernet interface.
tengigabitethernet	10-Gigabit Ethernet interface.

Examples

The following example configures the Gigabit Ethernet interface of slot 0 port 0 as the DHCP interface for DHCP provisioning of SIP parameters:

```
Router> enable
Router# configure terminal
Router(config)# interface gigabitethernet 0/0
Router(config-if)# ip address dhcp
Router(config-if)# sip-ua
Router(sip-ua)# dhcp interface gigabitethernet 0/0
```

Related Commands

Command	Description
show interfaces	Displays information about interfaces.
sip-ua	Enters SIP user-agent configuration mode.

dial-control-mib

To specify attributes for the call history table, use the **dial-control-mib** command in global configuration mode. To restore the default maximum size or retention time of the call history table, use the **no** form of this command.

dial-control-mib {**max-size** *number* | **retain-timer** *number*}

no dial-control-mib {**max-size** *number* | **retain-timer** *number*}

Syntax Description

max-size *number*	Specifies the maximum size of the call history table. Range is from 0 to 1200 table entries. **Note** Specifying a value of 0 prevents any further entries from being added to the table. Any existing table entries will be preserved for the duration specified with the **retain-timer** keyword.
retain-timer *number*	Specifies the duration, in minutes, for entries to remain in the call history table. Range is from 0 to 35791. **Note** Specifying a value of 0 prevents any further table entries from being retained, but does not affect any timer currently in effect. Therefore, any existing table entries will remain for the duration previously specified with the **retain-timer** keyword.

Command Default

The default call history table length is 50 table entries. The default retain timer is 15 minutes.

Command Modes

Global configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series routers.
12.0(1)XA	This command was first applied to the CDR feature on the Cisco MC3810.
12.0(2)T	The command was integrated into Cisco IOS Release 12.0(2)T.
12.3T	The maximum value for the *number* argument following the **max-size** keyword was increased to 1200 entries.
12.3(8)T	The maximum value of the *number* argument following the **retain-timer** keyword was decreased to 35791 minutes.

Examples

The following example configures the call history table to hold 400 entries, with each entry remaining in the table for 10 minutes:

```
dial-control-mib max-size 400
dial-control-mib retain-timer 10
```

dial-peer cor custom

To specify that named class of restrictions (COR) apply to dial peers, use the **dial-peer cor custom** command in global configuration mode.

dial-peer cor custom

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or keywords.

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.

Usage Guidelines You must use the **dial-peer cor custom** command and the **name** command to define the names of capabilities before you can specify COR rules and apply them to specific dial peers.

Examples of possible names might include the following: call1900, call527, call9, and call911.

Note You can define a maximum of 64 COR names.

Examples The following example defines two COR names:

```
dial-peer cor custom
 name 900blackhole
 name CatchAll
```

Related Commands

Command	Description
name (dial peer cor custom)	Provides a name for a custom COR.

dial-peer cor list

To define a class of restrictions (COR) list name, use the **dial-peer cor list** command in global configuration mode. To remove a previously defined COR list name, use the **no** form of this command.

dial-peer cor list *list-name*

no dial-peer cor list *list-name*

Syntax Description

list-name	List name that is applied to incoming or outgoing calls to specific numbers or exchanges.

Command Default

No default behavior or keywords.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.

Usage Guidelines

A COR list defines a capability set that is used in the COR checking between incoming and outgoing dial peers.

Examples

The following example adds two members to the COR list named list1:

```
dial-peer cor list list1
 member 900block
 member 800_call
```

Related Commands

Command	Description
dial-peer cor custom	Specifies that named COR apply to dial peers.
member (dial peer cor list)	Adds a member to a dial peer COR list.
name (dial peer cor custom)	Provides a name for a custom COR.

dial-peer data

To create a data dial peer and to enter dial-peer configuration mode, use the **dial-peer data** command in global configuration mode. To remove a data dial peer, use the **no** form of this command.

dial-peer data *tag* **pots**

no dial-peer data *tag*

Syntax Description

tag	Specifies the dial-peer identifying number. Range is from 1 to 2147483647.
pots	Specifies an incoming POTS dial peer.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.4(4)XC	This command was implemented on the Cisco 2600XM series, Cisco 2800 series, Cisco 3700 series, and Cisco 3800 series.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines A data dial peer should be defined only for incoming data calls. The **incoming called-number** and **shutdown** commands on the data dial peer are allowed. However, the following POTS dial-peer commands are disabled on a data dial peer:

- **answer-address**
- **carrier-id**
- **destination-pattern**
- **information-type**
- **port**
- **trunk-group-label**

Examples The following example is a data dial peer configuration:

```
dial-peer data 100 pots
 incoming called-number 100
```

The following example is a voice dial peer configuration:

```
dial-peer voice 2001 pots
 destination-pattern 2001
 no digit-strip
 port 3/1:1
```

Related Commands

Command	Description
dial-peer search	Optimizes voice or data dial-peer searches.
incoming called-number	Specifies an incoming called number of an MMoIP or POTS dial peer.
shutdown (dial peer)	Changes the administrative state of a selected dial peer from up to down.

dial-peer hunt

To specify a hunt selection order for dial peers, use the **dial-peer hunt command in** global configuration mode. To restore the default selection order, use the **no** form of this command.

dial-peer hunt *hunt-order-number*

no dial-peer hunt

Syntax Description

hunt-order-number	A number from 0 to 7 that selects a predefined hunting selection order: 0—Longest match in phone number, explicit preference, random selection. This is the default hunt order number. 1—Longest match in phone number, explicit preference, least recent use. 2—Explicit preference, longest match in phone number, random selection. 3—Explicit preference, longest match in phone number, least recent use. 4—Least recent use, longest match in phone number, explicit preference. 5—Least recent use, explicit preference, longest match in phone number. 6—Random selection. 7—Least recent use.

Command Default

The default is the longest match in the phone number, explicit preference, random selection (hunt order number 0).

Command Modes

Global configuration

Command History

Release	Modification
12.0(7)XK	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco MC3810, and Cisco AS5300.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

Use the **dial-peer hunt** dial peer configuration command if you have configured hunt groups. “Longest match in phone number” refers to the destination pattern that matches the greatest number of the dialed digits. “Explicit preference” refers to the **preference** setting in the dial peer configuration. “Least recent use” refers to the destination pattern that has waited the longest since being selected. “Random selection” weights all of the destination patterns equally in a random selection mode.

This command applies to POTS, VoIP, Voice over Frame Relay (VoFR), Voice over ATM (VoATM), and Multimedia Mail over Internet Protocol (MMOIP) dial peers.

Examples

The following example configures the dial peers to hunt in the following order: (1) longest match in phone number, (2) explicit preference, (3) random selection.

```
dial-peer hunt 0
```

Related Commands

Command	Description
destination-pattern	Specifies the prefix or the complete telephone number for a dial peer.
preference	Specifies the preferred selection order of a dial peer within a hunt group.
show dial-peer voice	Displays configuration information for dial peers.

dial-peer inbound selection sip-trunk

To enable incoming SIP line-side calls to use the same dial-peer matching rules as SIP trunk-side calls, use the **dial-peer inbound selection sip-trunk** command in global configuration mode. To revert to the default behavior, use the **no** form of this command.

dial-peer inbound selection sip-trunk

no dial-peer inbound selection sip-trunk

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled (SIP line-side and SIP trunk-side calls use different dial-peer matching rules).

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(11)T2	This command was introduced.

Usage Guidelines

This command applies the same dial-peer matching rules used for calls from SIP trunks to incoming calls from SIP phones (line side). Table 18 shows the rules and the order in which they are applied by default to SIP line-side calls. Table 19 shows the rules and the order in which they are applied to SIP trunk-side calls and to SIP line-side calls when the **dial-peer inbound selection sip-trunk** command is used.

The router compares the dial-peer configuration to the call parameter in its search to match an inbound call to a dial peer. All dial peers are searched based on the first match criteria. The router moves on to the next criteria only if no match is found.

Table 18 Dial-Peer Matching Rules for Inbound Calls from SIP Phones (Line Side)

Match Order	Cisco IOS Command	Incoming Call Parameter
1	**destination-pattern**	Calling number
2	**answer-address**	Calling number
3	**incoming called-number**	Called number
4	**incoming uri request**	Request-URI
5	**incoming uri to**	To URI
6	**incoming uri from**	From URI
7	**carrier-id source**	Carrier-is associated with the call

Table 19 Dial-Peer Matching Rules for Inbound Calls from SIP Trunks

Match Order	Cisco IOS Command	Incoming Call Parameter
1	**incoming uri request**	Request-URI
2	**incoming uri to**	To URI
3	**incoming uri from**	From URI
4	**incoming called-number**	Called number
5	**answer-address**	Calling number
6	**destination-pattern**	Calling number
7	**carrier-id source**	Carrier-is associated with the call

Examples

The following example shows SIP line-side calls use the same matching rules as trunk-side calls:

```
dial-peer inbound selection sip-trunk
```

Related Commands

Command	Description
answer-address	Specifies calling number to match for a dial peer.
destination-pattern	Specifies telephone number to match for a dial peer.
dial-peer voice	Defines a specific dial peer.
incoming called-number	Incoming called number matched to a dial peer.
incoming uri	Specifies the voice class used to match a VoIP dial peer to the uniform resource identifier (URI) of an incoming call.
show dial-peer voice	Displays configuration information for voice dial peers.

dial-peer no-match disconnect-cause

To disconnect the incoming ISDN or channel associated signaling (CAS) call when no inbound voice or modem dial peer is matched, use the **dial-peer no-match disconnect-cause** command in global configuration mode. To restore the default incoming call state (call is forwarded to the dialer), use the **no** form of this command.

dial-peer no-match disconnect-cause *cause-code-number*

no dial-peer no-match disconnect-cause *cause-code-number*

Syntax Description

cause-code-number	An ISDN cause code number. Range is from 1 to 127.

Command Default

The call is forwarded to the dialer to handle as a modem call.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines

By default, calls are forwarded to the dialer to handle as a modem call when no inbound dial peer is matched. The **dial-peer no-match disconnect-cause** command changes that behavior to disconnect the incoming ISDN or CAS calls when no inbound voice or modem dial peer is matched.

Refer to the ISDN Cause Values table in the *Cisco IOS Debug Command Reference*, for a list of ISDN cause codes.

Examples

The following example shows that ISDN cause code 47 has been specified to match inbound voice or modem dial peers:

```
dial-peer no-match disconnect-cause 47
```

Related Commands

Command	Description
show dial-peer voice	Displays configuration information for dial peers.

dial-peer outbound status-check pots

To check the status of outbound POTS dial peers during call setup and to disallow, for that call, any whose status is down, use the **dial-peer outbound status-check pots** command in privileged EXEC mode. To disable status checking, use the **no** form of this command.

dial-peer outbound status-check pots

no dial-peer outbound status-check pots

Command Default None

Command Modes Privileged EXEC

Command History

Release	Modification
12.3	This command was introduced.

Usage Guidelines Use this command to disallow, during call setup, outbound POTS dial peers (except those for e-phones) whose endpoints (voice ports or trunk groups) are down.

When the **dial-peer outbound status-check pots** command is configured, if the voice-port configured under an outbound POTS dial-peer is down, that dial-peer is excluded while matching the corresponding destination-pattern. Therefore, if there are no other matching outbound POTS dial-peers for the specified destination-pattern, the gateway will disconnect the call with a cause code of 1 (Unallocated/unassigned number), which is mapped to the "404 Not Found" SIP response by default. When the **no** form of this command is configured, the outbound POTS dial-peer is matched even if the voice-port configured under is down and the gateway disconnects the call with a cause code of 34 (No circuit/channel available), which is mapped to the "503 Service Unavailable" SIP response by default.

Note "503 Service Unavailable" was the default behavior before the **dial-peer outbound status-check pots** command was introduced. Users who need the original behavior should configure the **no** form of this command.

Table 20 shows conditions under which an outbound POTS dial peer may be up or down.

Table 20 Conditions Under Which an Outbound POTS Dial Peer Is Up or Down

If a Dial Peer's,,,	And If...	Then the Dial Peer Is...
Operational state is up	Its voice port is up	Up
	Its trunk groups and any associated trunks are up	
Operational state is down	—	Down
Voice port is down		
Trunk groups are down	All associated trunks are down	

To show or verify the status (up or down) of all or selected dial peers, use the **show dial-peer voice** command.

Examples

The following examples of output for the related **show dial-peer voice** command show the status of all or selected dial peers. You can use the **dial-peer outbound status-check pots** command to disallow the outbound POTS dial peers that are down.

The following example shows a short summary status for all dial peers. Outbound status is displayed in the OUT STAT field. POTS dial peers 31 and 42 are shown as down.

```
Router# show dial-peer voice summary

dial-peer hunt 0
              AD                                      PRE PASS                OUT
TAG    TYPE   MIN  OPER PREFIX    DEST-PATTERN       FER THRU SESS-TARGET    STAT PORT
444    voip   up   up                                 0
22     voip   up   up                                 0   syst
12     pots   up   up             5550123 0                        up   4/0:15
311    voip   up   up                                 0   syst
31     pots   up   up             5550111            0                       down 4/1:15
421    voip   up   up             5550199 0  syst ipv4:1.8.56.2
42     pots   up   up                                 0                       down
```

The following example shows the status for dial peer 12. Outbound status is displayed in the Outbound state field. The dial peer is shown as up.

```
Router# show dial-peer voice 12

VoiceEncapPeer12
        peer type = voice, information type = voice,
        description = `',
        tag = 12, destination-pattern = `5550123',
        answer-address = `', preference=0,
        CLID Restriction = None
        CLID Network Number = `'
        CLID Second Number sent
        source carrier-id = `', target carrier-id = `',
        source trunk-group-label = `',  target trunk-group-label = `',
        numbering Type = `unknown'
        group = 12, Admin state is up, Operation state is up,
        Outbound state is up,                                  <------- display status
        incoming called-number = `', connections/maximum = 0/unlimited,
        DTMF Relay = disabled,
        huntstop = disabled,
        in bound application associated: 'DEFAULT'
        out bound application associated: ''
        dnis-map =
        permission :both
        incoming COR list:maximum capability
        outgoing COR list:minimum requirement
        Translation profile (Incoming):
        .
        .
        .
```

The following example shows the status for dial peer 31. Outbound status is displayed in the Outbound state field. The dial peer is listed as down.

```
Router# show dial-peer voice 31

VoiceEncapPeer31
        peer type = voice, information type = voice,
        description = `',
        tag = 31, destination-pattern = `5550111',

        outgoing COR list:minimum requirement
        Translation profile (Incoming):
        .
        .
        .
```

For descriptions of other significant fields shown in these outputs, see the **show dial-peer voice** command.

Related Commands

Command	Description
show dial-peer voice	Displays information for voice dial peers.

dial-peer search type

To optimize voice or data dial-peer searches, use the **dial-peer search type** command in global configuration mode. To disable the search parameters, use the **no** form of this command.

dial-peer search *type* {**data voice** | **voice data** | **none**}

no dial-peer search *type*

Syntax Description

data	Searches for data dial peers.
none	Searches for all dial peers by order of input.
voice	Searches for voice dial peers.

Command Default **data** and **voice**

Command Modes Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.4(4)XC	This command was implemented on the Cisco 2600XM series, Cisco 2800 series, Cisco 3700 series, and Cisco 3800 series.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines The search defines the search preference explicitly. If the **data** and **voice** keywords are specified, data dial peers are searched first. If no data dial peers are found, the voice dial peers are searched.

Examples The following is sample output that shows that data dial peers are searched first. Then voice dial peers are searched if no data dial peers can be matched for an incoming call:

```
dial-peer search type data voice
```

The following is sample output that shows that voice dial peers are searched first. Then data dial peers are searched if no voice dial peers can be matched for an incoming call:

```
dial-peer search type voice data
```

Related Commands

Command	Description
dial-peer data	Enable a gateway to process incoming data calls first by assigning the POTS dial peer as data.

dial-peer terminator

To change the character used as a terminator for variable-length dialed numbers, use the **dial-peer terminator command in** global configuration mode. To restore the default terminating character, use the **no** form of this command.

dial-peer terminator *character*

no dial-peer terminator

Syntax Description

character	Designates the terminating character for a variable-length dialed number. Valid numbers and characters are #, *, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, a, b, c, and d. The default is #.

Command Default

The default terminating character is #

Command Modes

Global configuration

Command History

Release	Modification
12.0	This command was introduced.
12.0(7)XK	Usage was restricted to variable-length dialed numbers. The command was implemented on the Cisco 2600 series and Cisco 3600 series, and Cisco MC3810.
12.1(2)T	The command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

There are certain areas in the world (for example, in certain European countries) where telephone numbers can vary in length. When a dialed-number string has been identified as a variable length dialed-number, the system does not place a call until the configured value for the **timeouts interdigits** command has expired or until the caller dials the terminating character. Use the **dial-peer terminator** global configuration command to change the terminating character.

Examples

The following example shows that “9” has been specified as the terminating character for variable-length dialed numbers:

```
dial-peer terminator 9
```

Related Commands

Command	Description
answer-address	Specifies the full E.164 telephone number to be used to identify the dial peer of an incoming call.
destination-pattern	Specifies the prefix or the complete telephone number for a dial peer.
timeouts interdigit	Configures the interdigit timeout value for a specified voice port.
show dial-peer voice	Displays configuration information for dial peers.

dial-peer video

To define a video ATM dial peer for a local or remote video codec, to specify video-related encapsulation, and to enter dial peer configuration mode use the **dial-peer video** command in global configuration mode. To remove the video dial peer, use the **no** form of this command.

dial-peer video *tag* {**videocodec** | **videoatm**}

no dial-peer video *tag* {**videocodec** | **videoatm**}

Syntax Description

tag	Digits that define a particular dial peer. Defines the dial peer and assigns the protocol type to the peer. Range is from 1 to 10000. The tag must be unique on the router.
videocodec	Specifies a local video codec connected to the router.
videoatm	Specifies a remote video codec on the ATM network.

Command Default

No video dial peer is configured

Command Modes

Global configuration

Command History

Release	Modification
12.0(5)XK	This command was introduced for ATM interface configuration on the Cisco MC3810.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.

Usage Guidelines

The *tag* value must be unique to the device.

Examples

The following example sets up a local video dial peer designated as 10:

```
dial-peer video 10 videocodec
```

Related Commands

Command	Description
show dial-peer video	Displays dial peer video configuration.

dial-peer voice

To define a particular dial peer, to specify the method of voice encapsulation, and to enter dial peer configuration mode, use the **dial-peer voice** command in global configuration mode. To delete a defined dial peer, use the **no** form of this command.

Cisco 1750 and Cisco 1751 Modular Access Routers

dial-peer voice *tag* {**pots** | **vofr** | **voip**}

no dial-peer voice *tag* {**pots** | **vofr** | **voip**}

Cisco 2600 Series, Cisco 2600XM, Cisco 3600 Series, and Cisco 3700 Series

dial-peer voice *tag* {**pots** | **voatm** | **vofr** | **voip**}

no dial-peer voice *tag* {**pots** | **voatm** | **vofr** | **voip**}

Cisco 7200 Series

dial-peer voice *tag* **vofr**

no dial-peer voice *tag* **vofr**

Cisco 7204VXR and Cisco 7206VXR

dial-peer voice *tag* {**pots** | **voatm** | **vofr** | **voip**}

no dial-peer voice *tag* {**pots** | **voatm** | **vofr** | **voip**}

Cisco AS5300

dial-peer voice *tag* {**mmoip** | **pots** | **vofr** | **voip**}

no dial-peer voice *tag* {**mmoip** | **pots** | **vofr** | **voip**}

Syntax Description

tag	Digits that define a particular dial peer. Range is from 1 to 2147483647.
pots	Indicates that this is a POTS peer that uses VoIP encapsulation on the IP backbone.
vofr	Specifies that this is a Voice over Frame Relay (VoFR) dial peer that uses FRF.11 encapsulation on the Frame Relay backbone network.
voip	Indicates that this is a VoIP peer that uses voice encapsulation on the POTS network.
voatm	Specifies that this is a Voice over ATM (VoATM) dial peer that uses real-time ATM adaptation layer 5 (AAL5) voice encapsulation on the ATM backbone network.
mmoip	Indicates that this is a multimedia mail peer that uses IP encapsulation on the IP backbone.

Command Default

No dial peer is defined.
No method of voice encapsulation is specified.

Command Modes

Global configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(1)MA	This command was implemented on the Cisco MC3810, with support for the **pots**, **voatm**, **vofr**, and **vohdlc** keywords.
12.0(3)T	This command was implemented on the Cisco AS5300, with support for the **pots** and **voip** keywords.
12.0(3)XG	The **vofr** keyword was added for the Cisco 2600 series and Cisco 3600 series.
12.0(4)T	The **vofr** keyword was added to the Cisco 7200 series.
12.0(4)XJ	The **mmoip** keyword was added for the Cisco AS5300. The **dial-peer voice** command was implemented for store-and-forward fax.
12.0(7)XK	The **voip** keyword was added for the Cisco MC3810, and the **voatm** keyword was added for the Cisco 3600 series. Support for the **vohdlc** keyword on the Cisco MC3810 was removed.
12.1(1)	The **mmoip** keyword addition in Cisco IOS Release 12.0(4)XJ was integrated into Cisco IOS Release 12.1(1). The **dial-peer voice** implementation for store-and-forward fax was integrated into this mainline release.
12.1(2)T	The keyword changes in Cisco IOS Release 12.0(7)XK were integrated into Cisco IOS Release 12.1(2)T.
12.1(5)T	This command was implemented on the Cisco AS5300 and integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(2)XN	Support for enhanced Media Gateway Control Protocol (MGCP) voice gateway interoperability was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2. This command was implemented on the Cisco IAD2420 series.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T and implemented on the Cisco 2600XM, Cisco ICS7750, and Cisco VG200.
12.4(22)T	Support for IPv6 was added.

Usage Guidelines

Use the **dial-peer voice** global configuration command to switch to dial peer configuration mode from global configuration mode and to define a particular dial peer. Use the **exit** command to exit dial peer configuration mode and return to global configuration mode.

After you have created a dial peer, that dial peer remains defined and active until you delete it. To delete a dial peer, use the **no** form of this command. To disable a dial peer, use the **no shutdown** command in dial peer configuration mode.

In store-and-forward fax on the Cisco AS5300, the POTS dial peer defines the inbound faxing line characteristics from the sending fax device to the receiving Cisco AS5300 and the outbound line characteristics from the sending Cisco AS5300 to the receiving fax device. The Multimedia Mail over Internet Protocol (MMoIP) dial peer defines the inbound faxing line characteristics from the Cisco AS5300 to the receiving Simple Mail Transfer Protocol (SMTP) mail server. This command works with both on-ramp and off-ramp store-and-forward fax functions.

Note On the Cisco AS5300, MMoIP is available only if you have modem ISDN channel aggregation (MICA) technologies modems.

Examples

The following example shows how to access dial peer configuration mode and configure a POTS peer identified as dial peer 10 and an MMoIP dial peer identified as dial peer 20:

```
dial-peer voice 10 pots
dial-peer voice 20 mmoip
```

The following example deletes the MMoIP peer identified as dial peer 20:

```
no dial-peer voice 20 mmoip
```

The following example shows how the **dial-peer voice** command is used to configure the extended echo canceller. In this instance, **pots** indicates that this is a POTS peer using VoIP encapsulation on the IP backbone, and it uses the unique numeric identifier tag 133001.

```
Router(config)# dial-peer voice 133001 pots
```

Related Commands

Command	Description
codec (dial-peer)	Specifies the voice coder rate of speech for a VoFR dial peer.
destination-pattern	Specifies the prefix, the full E.164 telephone number, or an ISDN directory number to be used for a dial peer.
dtmf-relay (Voice over Frame Relay)	Enables the generation of FRF.11 Annex A frames for a dial peer.
preference	Indicates the preferred order of a dial peer within a rotary hunt group.
sequence-numbers	Enables the generation of sequence numbers in each frame generated by the DSP for VoFR applications.
session protocol	Establishes a session protocol for calls between the local and remote routers via the packet network.
session target	Specifies a network-specific address for a specified dial peer or destination gatekeeper.
shutdown	Changes the administrative state of the selected dial peer from up to down.

dial-type

To specify the type of out-dialing for voice port interfaces, use the **dial-type** command in voice-port configuration mode. To disable the selected type of dialing, use the **no** form of this command.

dial-type {**dtmf** | **pulse** | **mf**}

no dial-type

Syntax Description

dtmf	Dual tone multifrequency (DTMF) touch-tone dialing.
pulse	Pulse (rotary) dialing.
mf	Multifrequency tone dialing.

Command Default DTMF touch-tone dialing

Command Modes Voice-port configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(1)MA3	This command was implemented on the Cisco MC3810, and the **pulse** keyword was added.
12.0(7)XK	The **mf** keyword was added.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.1(5)XM	This command was extended to the merged SGCP/MGCP software image.
12.2(2)T	This command was implemented on the Cisco 7200 series and integrated into Cisco IOS Release 12.2(2)T.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines Use the **dial-type** command to specify an out-dialing type for a Foreign Exchange Office (FXO) or E&M voice port interface. This command specifies the tone type for digit detection and out-pulsing. This command is not applicable to Foreign Exchange Station (FXS) voice ports because the ports do not generate out-dialing. This command also specifies the detection direction. Multifrequency tone dialing is not supported for FXS and FXO.

Voice ports can always detect DTMF and pulse signals. This command does not affect voice port dialing detection.

The **dial-type** command affects out-dialing as configured for the dial peer.

If you are using the **dial-type** command with E&M Wink Start signaling, use the **dtmf** or **mf** option.

SGCP 1.1+ does not support pulse dialing.

Examples

The following example shows a voice port configured to support a rotary (pulse tone) dialer:

```
Router(config)# voice-port 1/1
Router(config-voice-port)# dial-type pulse
```

The following example shows a voice port configured to support a DTMF (touch-tone) dialer:

```
Router(config)# voice-port 1/1
Router(config-voice-port)# dial-type dtmf
```

The following example shows a voice port configured to support a multifrequency tone dialer:

```
Router(config)# voice-port 1/1
Router(config-voice-port)# dial-type mf
```

Related Commands

Command	Description
sgcp	Starts and allocates resources for the SGCP daemon.
sgcp call-agent	Defines the IP address of the default SGCP call agent.

dialer extsig

To configure an interface to initiate and terminate calls using an external signaling protocol, use the **dialer extsig** command in interface configuration mode. To discontinue control of the interface by the external signaling protocol, use the **no** form of this command.

dialer extsig

no dialer extsig

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Interface configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(11)T	The command was integrated into Cisco IOS Release 12.2(11)T and implemented on the Cisco AS5850.

Usage Guidelines

This command is used with the Network Access Server Package for Media Gateway Control Protocol feature. Configuring the **dialer in-band** command is a prerequisite to using this command. The configuration is blocked for profile dialers.

Examples

The following example shows output from the **dialer extsig** command:

```
Router(config)# interface Dialer1
Router(config-if)# dialer extsig
```

Related Commands

Command	Description
debug dialer	Provides debugging information for two types of dialer information: dial-on-demand events and dial-on-demand traffic.
dialer in-band	Specifies that DDR is to be supported.
extsig mgcp	Configures external signaling control by MGCP for a T1 or E1 trunk controller card.
show dialer	Displays dialer-related information for DNIS, interface, maps, and sessions.

dialer preemption level

To set the precedence for voice calls to be preempted by a dial-on demand routing (DDR) call for the dialer map, use the **dialer preemption level** command in map-class dialer configuration mode. To remove the preemption setting, use the **no** form of this command.

dialer preemption level {**flash-override | flash | immediate | priority | routine**}

no dialer preemption level {**flash-override | flash | immediate | priority | routine**}

Syntax Description

flash-override	Sets the precedence for DDR calls to preemption level 0 (highest).
flash	Sets the precedence for DDR calls to preemption level 1.
immediate	Sets the precedence for DDR calls to preemption level 2.
priority	Sets the precedence for DDR calls to preemption level 3.
routine	Sets the precedence for DDR calls to preemption level 4 (lowest). This is the default.

Command Default

The preemption level default is **routine** (lowest).

Command Modes

Map-class dialer configuration

Command History

Release	Modification
12.4(4)XC	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Examples

The following example sets a preemption level of *priority* (level 3) for the dialer map-class *dial1*.

```
Router(config)# map-class dialer dial1
Router(config-map-class)# dialer preemption level priority
```

Related Commands

Command	Description
dialer map	Configures a serial interface or ISDN interface to call one or multiple sites or to receive calls from multiple sites.
dialer trunkgroup	Defines the dial-on-demand trunk group label for the dialer interface.
map-class dialer	Defines a class of shared configuration parameters associated with the **dialer map** command for outgoing calls from an ISDN interface and for PPP callback.
preemption enable	Enables preemption capabilities on a trunk group.

Command	Description
preemption level	Sets the preemption level of the selected outbound dial peer. Voice calls can be preempted by a DDR call with higher preemption level.
preemption tone timer	Defines the expiry time for the preemption tone for the outgoing call being preempted by a DDR backup call.

dialer trunkgroup

To define the dial-on-demand trunk group label for the dialer interface, use the **dialer trunkgroup** command in map-class dialer configuration mode. To remove the trunk group label, use the **no** form of this command.

dialer trunkgroup *label*

no dialer trunkgroup *label*

Syntax Description

label	Unique name for the dialer interface trunk group. Valid names contain a maximum of 63 alphanumeric characters.

Command Default No dialer trunk group is defined.

Command Modes Map-class dialer configuration

Command History

Release	Modification
12.4(4)XC	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Examples The following example creates a trunk group named 20 for dialer map-class *dial1*.

```
Router(config)# map-class dialer dial1
Router(config-map-class)# dialer trunkgroup 20
```

Related Commands

Command	Description
dialer map	Configures a serial interface or ISDN interface to call one or multiple sites or to receive calls from multiple sites.
map-class dialer	Defines a class of shared configuration parameters associated with the **dialer map** command for outgoing calls from an ISDN interface and for PPP callback.
show dialer	Displays general diagnostic information for interfaces configured for dial-on-demand routing (DDR).
trunk group	Defines a trunk group (global configuration) and enters trunk group configuration mode.

digit

To designate the number of digits for SCCP telephony control (STC) application feature speed-dial codes, use the **digit** command in STC application feature speed-dial configuration mode. To reset to the default, use the **no** form of this command.

digit *number*

no digit

Syntax Description

number	Number of digits for speed-dial codes. Values are 1 or 2. Default is 1.

Command Default

The default number of digits is 1.

Command Modes

STC application feature speed-dial configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

This command is used with the STC application, which enables features on analog FXS endpoints that use Skinny Client Control Protocol (SCCP) for call control.

This command determines the number of digits that can be configured for speed-dial codes using the **speed dial** and **voicemail** commands. Use this command only if you want to change the number of digits from its default, which is 1. If you modify the value of this command, the **speed dial** and **voicemail** commands are reset to their defaults. If you set the value to 2 and then try to configure a single-digit speed-dial code, the system converts the speed-dial code into two digits.

Note that the phone numbers that are stored with various speed-dial codes are configured on the call-control device, such as Cisco CallManager or a Cisco CallManager Express router.

Examples

The following example sets the number of digits for speed-dial codes to two. It also sets a speed-dial prefix of one pound sign (#) and a speed-dial code range from 5 to 25. After these values are configured, a phone user presses #10 on the keypad to dial the number that was stored with code 10.

```
Router(config)# stcapp feature speed-dial
Router(stcapp-fsd)# prefix #
Router(stcapp-fsd)# digit 2
Router(stcapp-fsd)# speed dial from 5 to 25
```

Related Commands

Command	Description
prefix (stcapp-fsd)	Designates a prefix to precede the dialing of an STC application feature speed-dial code.
show stcapp feature codes	Displays configured and default STC application feature access codes.
speed dial	Designates a range of STC application feature speed dial codes.
voicemail	Designates an STC application feature speed-dial code to dial the voice-mail number.

digit-strip

To enable digit stripping on a plain old telephone service (POTS) dial-peer call leg, use the **digit-strip** command in dial peer configuration mode. To disable digit stripping on the dial-peer call leg, use the **no** form of this command.

digit-strip

no digit-strip

Syntax Description

This command has no arguments or keywords.

Command Default

Digit stripping is enabled.

Command Modes

Dial peer configuration

Command History

Release	Modification
12.0(7)XR1	This command was introduced for VoIP on the Cisco AS5300.
12.0(7)XK	This command was first supported for the following voice technologies on the following platforms: • VoIP (Cisco 2600 series, Cisco 3600 series, Cisco MC3810) • Voice over Frame Relay (VoFR)—Cisco 2600 series, Cisco 3600 series, Cisco MC3810) • Voice over ATM (VoATM)—Cisco 3600 series and Cisco MC3810.
12.1(1)T	This command was integrated in Cisco IOS Release 12.1(1)T
12.1(2)T	This command was first implemented in Cisco IOS Release 12.1(2)T for the following voice technologies on the following platforms: • VoIP (Cisco MC3810) • VoFR (Cisco 2600 series, Cisco 3600 series, and Cisco MC3810) • VoATM (Cisco 3600 series, Cisco MC3810)

Usage Guidelines

The **digit-strip** command is supported on POTS dial peers only.

When a called number is received and matched to a POTS dial peer, the matched digits are stripped and the remaining digits are forwarded to the voice interface.

Table 21 lists a series of dial peers configured with a specific destination pattern and shows the longest matched number after the digit is stripped based on the dial string 408 555-3048.

Table 21 Dial Peer Configurations with Longest Matched Number

Dial Peer	Destination Pattern	Preference	Session Target	Longest Matched Number
1	4085553048	0 (highest)	100-voip	10
2	408[0-9]553048	0	200-voip	9
3	408555	0	300-voip	6
4	408555	1(lower)	400-voip	6
5	408%	1	500-voip	3
6	.....	0	600-voip	0
7	.....	1	1:D (interface)	0

Table 22 lists a series of dial peers configured with a specific destination pattern and shows the number after the digit strip based on the dial string 408 555-3048 and the different dial-peer symbols applied.

Table 22 Dial Peer Configurations with Digits Stripped

Dial Peer	Destination Pattern	Number After the Digit Strip
1	408555....	3048
2	408555.%	3048
3	408525.+	3048
4	408555.?	3048
5	408555+	3048
6	408555%	53048
7	408555?	53048
8	408555[0-9].%	3048
9	408555(30).%	3048
10	408555(30)%	3048
11	408555..48	3048

Examples

The following example disables digit stripping on a POTS dial peer:

```
dial-peer voice 100 pots
 no digit-strip
```

Related Commands

Command	Description
numbering-type	Specifies number type for the VoIP or POTS dial peer.
rule	Applies a translation rule to a calling party number or a called party number for both incoming and outgoing calls.
show translation-rule	Displays the contents of all the rules that have been configured for a specific translation name.
test translation-rule	Tests the execution of the translation rules on a specific name-tag.

Command	Description
translation-rule	Creates a translation name and enters translation-rule configuration mode.
voip-incoming translation-rule	Captures calls that originate from H.323-compatible clients.

digital-filter

To specify the digital filter to be used before the voice packet is sent from the digital signal processor (DSP) to the network, use the **digital-filter** command in voice-class configuration mode. To remove the digital filter, use the **no** form of this command.

digital-filter {**1950hz** | **2175hz**}

no digital-filter {**1950hz** | **2175hz**}

Syntax Description

1950hz	Filter out 1950 Hz frequency.
2175hz	Filter out 2175 Hz frequency.

Command Default Digital filtering is disabled.

Command Modes Voice-class configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines The **digital-filter** command has an effect on an ear and mouth (E&M) voice port only if the signal type for that port is Land Mobile Radio (LMR). The digital filter improves voice quality by preventing transmission of the guard tone with the voice packet from the LMR system to the VoIP network. The guard tone is configured with the **inject guard-tone** command. The digital filter can be configured to filter out either 2175 Hz or 1950 Hz. Only one of these frequencies can be filtered out at a time. Filtering is performed by the DSP.

Examples The following example specifies that 1950 Hz guard tone be filtered out of the voice packet before it is sent from the DSP to the network:

```
voice class tone-signal mytones
 digital-filter 1950hz
```

Related Commands

Command	Description
inject guard-tone	Plays out a guard tone with the voice packet.

direct-inward-dial

To enable the direct inward dialing (DID) call treatment for an incoming called number, use the **direct-inward-dial command in** dial peer configuration mode. To disable DID on the dial peer, use the **no** form of this command.

direct-inward-dial

no direct-inward-dial

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Dial peer configuration

Command History

Release	Modification
11.3(1)NA	This command was introduced.
12.0(4)T	This command was modified for store-and-forward fax.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

Use the **direct-inward-dial** command to enable the DID call treatment for an incoming called number. When this feature is enabled, the incoming call is treated as if the digits were received from the DID trunk. The called number is used to select the outgoing dial peer. No dial tone is presented to the caller.

Use the **no** form of this command to disable DID on the dial peer. When disabled, the called number is used to select the outgoing dial peer. The caller is prompted for a called number via dial tone.

This command is applicable only to plain old telephone service (POTS) dial peers. This command applies to on-ramp store-and-forward fax functions.

Examples

The following example enables DID call treatment for the incoming called number:

```
dial-peer voice 10 pots
  direct-inward-dial
```

disable-early-media 180

To specify which call treatment, early media or local ringback, is provided for 180 responses with 180 responses with Session Description Protocol (SDP), use the **disable-early-media 180** command in sip-ua configuration mode. To enable early media cut-through for 180 messages with SDP, use the **no** form of this command.

disable-early-media ***180***

no disable-early-media ***180***

Syntax Description

This command has no arguments or keywords.

Command Default

Early media cut-through for 180 responses with SDP is enabled.

Command Modes

SIP-UA configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
IOS Release XE 2.5	This command was integrated into Cisco IOS XE Release 2.5.

Usage Guidelines

This command provides the ability to enable or disable early media cut-through on Cisco IOS gateways for Session Initiation Protocol (SIP) 180 responses with SDP. Use the **disable-early-media 1*80*** *command to configure the gateway to ignore the SDP message and provide local ringback.* To restore the default treatment, early media cut-through, use the **no disable-early-media** ***180*** *command.*

Examples

The following example disables early media cut-through for SIP 180 responses with SDP:

```
Router(config-sip-ua)# disable-early-media 180
```

Related Commands

Command	Description
show sip-ua retry	Displays SIP retry statistics.
show sip-ua statistics	Displays response, traffic, and retry SIP statistics.
show sip-ua timers	Displays the current settings for SIP-UA timers.
sip-ua	Enables the SIP-UA configuration commands.

disc_pi_off

To enable an H.323 gateway to disconnect a call when it receives a disconnect message with a progress indicator (PI) value, use the **disc_pi_off** command in voice-port configuration mode. To restore the default state, use the **no** form of this command.

disc_pi_off

no disc_pi_off

Syntax Description

This command has no arguments or keywords.

Command Default

The gateway does not disconnect a call when it receives a disconnect message with a PI value.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.1(5)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco 7500 series, Cisco AS5300, Cisco AS5800, and Cisco MC3810.
12.2(2)XA	This command was implemented on the Cisco AS5400 and Cisco AS5350.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into the Cisco IOS Release 12.2(11)T.

Usage Guidelines

The **disc_pi_off** voice-port command is valid only if the disconnect with PI is received on the inbound call leg. For example, if this command is enabled on the voice port of the originating gateway, and a disconnect message with PI is received from the terminating switch, the disconnect message is converted to a disconnect message. But if this command is enabled on the voice port of the terminating gateway, and a disconnect message with PI is received from the terminating switch, the disconnect message is not converted to a standard disconnect message because the disconnect message is received on the outbound call leg.

Note The **disc_pi_off** voice-port configuration command is valid only for the default session application; it does not work for interactive voice response (IVR) applications.

Examples

The following example handles a disconnect message with a PI value in the same way as a standard disconnect message for voice port 0:23:

```
voice-port 0:D
 disc_pi_off
```

Related Commands

Command	Description
isdn t306	Sets a timer for Disconnect messages.

disconnect-ack

To configure a Foreign Exchange Station (FXS) voice port to return an acknowledgment upon receipt of a disconnect signal, use the **disconnect-ack** command in voice-port configuration mode. To disable the acknowledgment, use the **no** form of this command.

disconnect-ack

no disconnect-ack

Syntax Description This command has no arguments or keywords.

Command Default FXS voice ports return an acknowledgment upon receipt of a disconnect signal

Command Modes Voice-port configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines The **disconnect-ack** command configures an FXS voice port to remove line power if the equipment on an FXS loop-start trunk disconnects first.

Examples The following example, which begins in global configuration mode, turns off the disconnect acknowledgment signal on voice port 1/1/0:

```
voice-port 1/0/0
 no disconnect-ack
```

Command History

Command	Description
show voice port	Displays voice port configuration information.

dnis (DNIS group)

To add a dialed number identification service (DNIS) number to a DNIS map, use the **dnis** command in DNIS-map configuration mode. To delete a DNIS number, use the **no** form of this command.

dnis *number* [**url** *url*]

no dnis

Syntax Description

number	Adds a user-selected DNIS number to a DNIS map.
url *url*	(Optional) URL that links a DNIS number to a specific VoiceXML document. If a URL is not entered, the DNIS number is linked to the VoiceXML application in the dial peer, which must be configured using the **application** command. This keyword is not valid for Tool Command Language (TCL) applications.

Command Default

If no URL is entered, the DNIS number links to the VoiceXML application that is configured in the dial peer with the **application** command.

Command Modes

DNIS-map configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines

To enter DNIS-map configuration mode for the **dnis** command, use the **voice dnis-map** command.

Enter the **dnis** command once for each telephone number that you want to map to a voice application. A separate entry must be made for each telephone number in a DNIS map. Wildcards are not supported.

URLs in DNIS entries are used only by VoiceXML applications. When an incoming called number matches a DNIS entry, it loads the VoiceXML document that is specified by the URL, provided that a VoiceXML application is configured in the dial peer using the **application** command.

Non-VoiceXML applications, such as TCL applications, ignore the URLs in DNIS maps and link a call to the TCL application that is configured in the dial peer using the **application** command.

For a DNIS map to be applied to an outbound dial peer, a VoiceXML application must be configured by using the **application** command with the **out-bound** keyword. Otherwise, the call is not handed off to the application that is specified in the URL of the DNIS map.

The number of allowable DNIS entries is limited by the amount of available configuration memory on the gateway. As a guideline, DNIS maps that contain more than several hundred DNIS entries should be maintained in an external text file.

To associate a DNIS map with a dial peer, use the **dnis-map** command.

Examples

The first line in the following example shows how the **voice dnis-map** command is used to create a DNIS map named "dmap1". The last two lines show how the **dnis** command is used to enter DNIS entries.

The first DNIS entry specifies the location of a VoiceXML document. The second DNIS entry does not specify a URL. A DNIS number without a URL is, by default, matched to the URL of the application that is configured in the dial peer by using the **application** command.

```
voice dnis-map dmap1
 dnis 5553305 url tftp://blue/sky/test.vxml
 dnis 5558888
```

Related Commands

Command	Description
dnis-map	Associates a DNIS map with a dial peer.
show voice dnis-map	Displays configuration information about DNIS maps.
voice dnis-map	Enters DNIS map configuration mode to create a DNIS map.
voice dnis-map load	Reloads a DNIS map that has changed since the previous load.

dnis-map

To associate a dialed number identification service (DNIS) map with a dial peer, use the **dnis-map** command in dial peer configuration mode. To remove a DNIS map from the dial peer, use the **no** form of this command.

dnis-map *map-name*

no dnis-map

Syntax Description

map-name	Name of the configured DNIS map.

Command Default No default behavior or values

Command Modes Dial peer configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines A DNIS map is a table of destination numbers with optional URLs that link to specific VoiceXML documents. When configured in a dial peer, a DNIS map enables you to link multiple called numbers to a single Tool Command Language (TCL) application or to individual VoiceXML documents.

The **dnis-map** command must be used with the **application** command.

Only one DNIS map can be configured in each dial peer.

To create a DNIS map, use the **voice dnis-map** command to enter DNIS-map configuration mode, and then use the **dnis** command to add entries to the DNIS map. Or you can create an external text file of DNIS entries and link to its URL by using the **voice dnis-map** command.

To view the configuration information for DNIS maps, use the **show voice dnis-map** command.

A URL configured for a DNIS number is ignored by a TCL application; the TCL script that is configured for the application is used instead.

Note For a DNIS map to be applied to an outbound dial peer, the call application must be configured as an outbound application. That is, a VoiceXML application must be configured by using the **application** command with the **out-bound** keyword. Otherwise, the call is not handed off to the application that is specified in the URL of the DNIS map.

Examples

In the following example the DNIS map named “dmap1” is associated with the VoIP dial peer 3. The outbound application “vapptest1” is associated through this dial peer with DNIS map “dmap1”.

```
dial-peer voice 3 voip
 dnis-map dmap1
 application vapptest1 outbound
```

Related Commands

Command	Description
dnis	Adds a DNIS number to a DNIS map.
show voice dnis-map	Displays configuration information about DNIS maps.
voice dnis-map	Enters DNIS map configuration mode to create a DNIS map.
voice dnis-map load	Reloads a DNIS map that has changed since the previous load.

domain-name (annex G)

To set the domain name that is reported in service relationships, use the **domain-name** command in annex G neighbor configuration mode. To remove the domain name, use the **no** form of this command.

domain-name *id*

no domain-name *id*

Syntax Description

id	Domain name that is reported in service relationships.

Command Modes

Annex G neighbor configuration mode

Command Default

No default behavior or values

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

Use this command to set the domain name reported that is reported in service relationships.

Examples

The following example shows how to set a domain name to “boston1”:

```
Router(config-annexg-neigh)# domain-name boston1
```

Related Commands

Command	Description
access-policy	Requires that a neighbor be explicitly configured.

drop-last-conferee

To define a Feature Access Code (FAC) to access the Drop Last Conferee feature in feature mode on analog phones controlled by Cisco Unified Communications Manager Express (CME), use the **drop-last-conferee** command in STC application feature-mode call-control configuration mode. To return the code to its default, use the **no** form of this command.

drop-last-conferee *keypad-character*

no drop-last-conferee

Syntax Description

keypad-character	Character string of one to four characters that can be dialed on a telephone keypad (0—9, *, #). Default is #4.

Command Default

The default value is #4.

Command Modes

STC application feature-mode call-control configuration (config-stcapp-fmcode)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command changes the value of the FAC for the Drop Last Conferee feature from the default (#4) to the specified value.

If you attempt to configure this command with a value that is already configured for another FAC in feature mode, you receive a message. This message will not prevent you from configuring the feature code. If you configure a duplicate FAC, the system implements the first feature it matches in the order of precedence as determined by the value for each FAC (#1 to #5).

If you attempt to configure this command with a value that precludes or is precluded by another FAC in feature mode, you receive a message. If you configure a FAC to a value that precludes or is precluded by another FAC in feature mode, the system always executes the call feature with the shortest code and ignores the longer code. For example, 1 will always preclude 12 and 123. These messages will not prevent you from configuring the feature code. You must configure a new value for the precluded code in order to enable phone user access to that feature.

Note This command does not change the user experience for Drop Last Conferee if the Cisco call-control system is Cisco Unified Communications Manager.

Examples

The following example shows how to change the value of the feature code for the Drop Last Conferee feature from the default (#4). With this configuration, a phone user in a three-party conference on an analog phone controlled by Cisco Unified CME presses hook flash to get the feature tone and then dials 44 to drop the last active party. The conference becomes a basic call to the second call party.

```
Router(config)# stcapp call-control mode feature
Router(config-stcapp-fmcode)# drop-last-conferee 44
Router(config-stcapp-fmcode)# exit
```

Related Commands

Command	Description
conference	Defines FAC in Feature Mode to initiate a three-party conference.
hangup-last-active-call	Defines FAC in feature mode to drop last active call during a three-party conferencee.
toggle-between-two-calls	Defines FAC in feature mode to toggle between two active calls.
transfer	Defines FAC in feature mode to connect a call to a third party that the phone user dials.

ds0 busyout (voice)

To force a DS0 time slot on a controller into the busyout state, use the **ds0 busyout command in** controller configuration mode. To remove the DS0 time slot from the busyout state, use the **no** form of this command.

ds0 busyout *ds0-time-slot*

no ds0 busyout *ds0-time-slot*

Syntax Description

ds0-time-slot	DS0 time slots to be forced into the busyout state. Range is from 1 to 24 and can include any combination of time slots.

Command Default DS0 time slots are not in busyout state.

Command Modes Controller configuration

Command History

Release	Modification
12.0(7)XK	This command was introduced on Cisco MC3810 and Cisco 2600 series and Cisco 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines The **ds0 busyout** command affects only DS0 time slots that are configured into a DS0 group and that function as part of a digital voice port. If multiple DS0 groups are configured on a controller, any combination of DS0 time slots can be busied out, provided that each DS0 time slot to be busied out is part of a DS0 group.

If a DS0 time slot is in the busyout state, only the **no ds0 busyout** command can restore the DS0 time slot to service.

To avoid conflicting command-line interface (CLI) commands, do not use the **ds0 busyout** command and the **busyout forced** command on the same controller.

Examples The following example configures DS0 time slot 6 on controller T1 0 to be forced into the busyout state:

```
controller t1 0
 ds0 busyout 6
```

The following example configures DS0 time slots 1, 3, 4, 5, 6, and 24 on controller E1 1 to be forced into the busyout state:

```
controller e1 1
 ds0 busyout 1,3-6,24
```

Related Commands

Command	Description
busyout seize	Changes the busyout seize procedure for a voice port.
show running configuration	Determines which DS0 time slots have been forced into the busyout state.

ds0-group (E1)

To specify the DS0 time slots that make up a logical voice port on an E1 controller, specify the signaling type by which the router communicates with the PBX or PSTN, and define E1 channels for compressed voice calls and the channel-associated signaling (CAS) method by which the router connects to the PBX or PSTN, use the **ds0-group** command in controller configuration mode. To remove the group and signaling setting, use the **no** form of this command.

Cisco IOS Release 12.2 and Later Releases

Cisco 1750 and Cisco 1751

ds0-group *ds0-group-number* **timeslots** *timeslot-list {*[**service** *service-type*] | [**type** **e&m-fgb | e&m-fgd | e&m-immediate-start | fgd-eana | fgd-os | fxs-ground-start | fxs-loop-start | none | r1-itu | r1-modified | r1-turkey**]}

ds0-group *ds0-group-number* **timeslots** *timeslot-list* **type** {**e&m-delay-dial** | **e&m-immediate-start** | **e&m-wink-start** | **fxs-ground-start** | **fxs-loop-start** | **fxo-ground-start** | **fxo-loop-start**}

no ds0-group *ds0-group-number*

Cisco AS5300 and the Cisco AS5400

ds0-group *ds0-group-number* **timeslots** *timeslot-list* **type** {**none** | **p7** | **r2-analog** | **r2-digital** | **r2-lsv181-digital** | **r2-pulse**}

no ds0-group *ds0-group-number*

Note This command does not support the extended echo canceller (EC) feature on the Cisco AS5x00 series.

Syntax Description

ds0-group-number	A value that identifies the DS0 group. Range is from 0 to 14 and 16 to 30; 15 is reserved.
timeslots *timeslot-list*	Lists time slots in the DS0 group. The *timeslot-list* argument is a single time-slot number, a single range of numbers, or multiple ranges of numbers separated by commas. Range is from 1 through 31. Examples are as follows: • 2 • 1-15,17-24 • 1-23 • 2,4,6-12
type	Specifies the type of signaling for the DS0 group. The signaling method selection for the **type** keyword depends on the connection that you are making. The ear and mouth (E&M) interface allows connection for PBX trunk lines (tie lines) and telephone equipment. The Foreign Exchange Station (FXS) interface allows connection of basic telephone equipment and PBX. The Foreign Exchange Office (FXO) interface is for connecting the central office (CO) to a standard PBX interface where permitted by local regulations; it is often used for off-premise extensions (OPXs). Types are as follows: • **e&m-delay-dial**—The originating endpoint sends an off-hook signal and then waits for an off-hook signal followed by an on-hook signal from the destination. • **e&m-fgb**—E&M Type II Feature Group B. • **e&m-fgd**—E&M Type II Feature Group D. • **e&m-immediate-start**—E&M immediate start. • **e&m-lmr**—E&M Land Mobile Radio (LMR). • **e&m-melcas-delay**—E&M MELCAS delay-start signaling support. • **e&m-melcas-immed**—E&M MELCAS immediate-start signaling support.

	• **e&m-melcas-wink**—E&M MELCAS wink-start signaling support. • **e&m-wink-start**—The originating endpoint sends an off-hook signal and waits for a wink-start from the destination. • **fgd-eana—Feature Group D exchange access North American.** • **fgd-os**—Feature Group D operator services. • **fxo-ground-start—FXO ground-start signaling.** • **fxo-loop-start—FXO loop-start signaling.** • **fxo-melcas—FXO MELCAS signaling.** • **fxs-ground-start—FXS ground-start signaling.** • **fxs-loop-start—FXS loop-start signaling.** • **fxs-melcas—FXS MELCAS signaling.** • **none**—Null signaling for external call control. • **p7**—Specifies the p7 switch type. • **r1-itu**—Line signaling based on international signaling standards. • **r1-modified**—An international signaling standard that is common to channelized T1/E1 networks. • **r1-turkey**—A signaling standard used in Turkey. • **r2-analog—R2 analog line signaling.** • **r2-digital—R2 digital line signaling.** • **r2-lsv181-digital**—Specifies a specific R2 digital line. • **r2-pulse—7-pulse line signaling, a transmitted pulse that indicates a change in the line state.** • **sas-ground-start—Single attachment station (SAS) ground-start.** • **sas-loop-start—SAS loop-start.**
service *service-type*	(Optional) Specifies the type of service. • **data**—data service • **fax**— store-and-forward fax service • **voice**—voice service (for FGD-OS service) • **mgcp**—Media Gateway Control Protocol service

Command Default There is no DS0 group. Calls are allowed in both directions.

Command Modes Controller configuration

Command History

Release	Modification
11.2	This command was introduced for the Cisco AS5300 as the **cas-group** command.
11.3(1)MA	The command was introduced as the **voice-group** command for the Cisco MC3810.
12.0(1)T	This command was integrated into Cisco IOS Release 12.0(1)T, and the **cas-group** command was implemented on the Cisco 3600 series routers.
12.0(5)T	The command was renamed **ds0-group** on the Cisco AS5300 and Cisco 2600 series and Cisco 3600 series routers. Some keyword modifications were implemented.
12.0(5)XE	This command was implemented on the Cisco 7200 series.
12.0(7)XK	Support for this command was implemented on the Cisco MC3810. When the **ds0-group** command became available on the Cisco MC3810, the **voice-group** command was removed and no longer supported. The **ext-sig** keyword replaced the **ext-sig-master** and **ext-sig-slave** keywords that were available with the **voice-group** command.
12.0(7)XR	The **mgcp** service type was added.
12.1(2)XH	The **e&m-fgd** and **fgd-eana** keywords were added for Feature Group D signaling.
12.1(5)XM	The **sgcp** keyword was removed.
12.1(3)T	This command was modified for Cisco 7500 series routers. The **fgd-os** signaling type and the **voice** service type were added.
12.2	The command was modified to exclude **sas** keywords**.** The Single Attachment Station (SAS) CAS options of **sas-loop-start** and **sas-ground-start** are not supported as a type of signaling for the DS0 group.
12.2(2)XA	This command was implemented on the Cisco AS5300.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(4)T	Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on Cisco 1750 and Cisco 1751 routers. Support for other Cisco platforms is not included in this release.
12.2(2)XN	Support for the **mgcp** keyword was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was supported with Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2. This command is supported on the Cisco IAD2420 series, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5850 in this release.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T. The Cisco 1750 and Cisco 1751 do not support T1 and E1 voice and data cards in Cisco IOS Release 12.2(13)T. The Cisco 17xx platforms can support only HC DSP firmware images in this release.

Release	Modification
12.3(8)T	Documentation of the **ds0-group** command was divided into the individual **ds0-group (E1)** and **ds0-group (T1)** commands.
12.4(2)T1	Support was added for the **e&m-lmr** signaling type on the Cisco 2691, Cisco 2600XM series, Cisco 2800 series (except Cisco 2801), Cisco 3660, Cisco 3700 series, and Cisco 3800 series.

Usage Guidelines

The **ds0-group** command automatically creates a logical voice port that is numbered as follows:

- Cisco 2600 series, Cisco 2600XM, Cisco 3660, Cisco 3725, and Cisco 3745, and Cisco 7200 series:
  - *slot*/*port*:*ds0-group-number*

Although only one voice port is created for each group, applicable calls are routed to any channel in the group.

Be sure you take the following into account when you are configuring DS0 groups:

- Channel groups, CAS voice groups, DS0 groups, and time-division multiplexing (TDM) groups all use group numbers. All group numbers configured for channel groups, CAS voice groups, DS0 groups, and TDM groups must be unique on the local router. For example, you cannot use the same group number for a channel group and for a TDM group.
- The keywords available for the **ds0-group** command are dependent upon the Cisco IOS software release that you are using. For the most current information, go to the Cisco Feature Navigator home page at the following URL:
  http://www.cisco.com/go/fn
- When you are using command-line interface (CLI) help, the keywords for the **ds0-group** command are configuration specific. For example, if Media Gateway Control Protocol (MGCP) is configured, you see the **mgcp** keyword. If you are not using MGCP, you do not see the **mgcp** keyword.
- Cisco IOS Releases later than 12.2 do not support the Single Attachment Station (SAS) CAS options of sas-loop-start and sas-ground-start.

Examples

The following example shows ranges of E1 controller time slots configured for FXS ground-start and FXO loop-start signaling:

```
E1 1/0
 framing esf
 linecode b8zs
 ds0-group 1 timeslots 1-10 type fxs-ground-start
 ds0-group 2 timeslots 11-24 type fxo-loop-start
```

The following example shows ranges of T1 controller time slots configured for FXS ground-start signaling:

```
controller E1 1/0
 ds0-group 1 timeslots 1-4 type fxs-ground-start
```

The following example illustrates setting the E1 channels for Signaling System 7 (SS7) service on any trunking gateway using the **mgcp** keyword:

```
Router(config-controller)# ds0-group 0 timeslots 1-24 type none service mgcp
```

In the following example, the time slot maximum is 12 and the time slot is 1, so two voice-ports are created successfully.

```
controller E1 0/0
 ds0-group 0 timeslots 1-4 type e&m-immediate-start
 ds0-group 1 timeslots 6-12 type e&m-immediate-start
```

If a third DS0 group is added, the voice-port is rejected even though the total number of voice channels is less than 16.

```
 ds0-group 2 timeslots 17-18 type e&m-immediate-start
```

In the following example, the signaling type is set to e&m-lmr:

```
ds0-group 0 timeslots 1-10 type e&m-lmr
```

Related Commands

Command	Description
cas-group	Configures channelized T1 time slots with robbed bit signaling.
codec	Specifies the voice coder rate of speech for a dial peer.
codec complexity	Specifies call density and codec complexity based on the codec standard that you are using.

ds0-group (T1)

To specify the DS0 time slots that make up a logical voice port on a T1 controller, to specify the signaling type by which the router communicates with the PBX or PSTN, and to define T1 channels for compressed voice calls and the channel-associated signaling (CAS) method by which the router connects to the PBX or PSTN, use the **ds0-group** command in controller configuration mode. To remove the group and signaling setting, use the **no** form of this command.

no ds0-group *ds0-group-number*

Syntax Description

ds0-group-number	A value that identifies the DS0 group. Range is from 0 to 23.
timeslots *timeslot-list*	Lists time slots in the DS0 group. The *timeslot-list* argument is a single time-slot number, a single range of numbers, or multiple ranges of numbers separated by commas. Range is from 1 to 24. Examples are as follows: • 2 • 1-15,17-24 • 1-23 • 2,4,6-12
• **typenone**—Null signaling for external call control.	Specifies the type of signaling for the DS0 group. The signaling method selection for the **type** keyword depends on the connection that you are making. The ear and mouth (E&M) interface allows connection for PBX trunk lines (tie lines) and telephone equipment. The Foreign Exchange Station (FXS) interface allows connection of basic telephone equipment and PBX. The Foreign Exchange Office (FXO) interface is for connecting the central office (CO) to a standard PBX interface where permitted by local regulations; it is often used for off-premise extensions (OPXs). Types are as follows: • **e&m-delay-dial**—The originating endpoint sends an off-hook signal and then waits for an off-hook signal followed by an on-hook signal from the destination. • **e&m-fgb**—E&M Type II Feature Group B. • **e&m-fgd**—E&M Type II Feature Group D. • **e&m-immediate-start**—E&M immediate start. • **e&m-lmr**—E&M Land Mobile Radio (LMR). • **e&m-wink-start**—The originating endpoint sends an off-hook signal and waits for a wink-start from the destination. • **ext-sig**—The external signaling interface specifies that the signaling traffic comes from an outside source. • **fgd-eana—Feature Group D exchange access North American.** • **fgd-emf—**FGD Enhanced MF. • **fgd-os**—Feature Group D operator services. • **fxo-ground-start—FXO ground-start signaling.** • **fxo-loop-start—FXO loop-start signaling.** • **fxs-ground-start—FXS ground-start signaling.** • **fxs-loop-start—FXS loop-start signaling.** • **none**—Null signaling for external call control. • **r1-itu**—Line signaling based on international signaling standards. (This signaling type is not supported on the Cisco AS5300, Cisco AS5350, and Cisco AS5400 platforms.) • **r1-modified**—An international signaling standard that is common to channelized T1/E1 networks.

	• **r1-turkey**—A signaling standard used in Turkey. • **sas-ground-start**—Single attachment station (SAS) ground-start. • **sas-loop-start**—SAS loop-start.
service *service-type*	(Optional) Specifies the type of service. • **data**—Data service. • **fax**— Store-and-forward fax service. • **mgcp**[1]—Media Gateway Control Protocol service. • **sccp**[1]—Simple Gateway Control Protocol service. • **voice**—Voice service (for FGD-OS service).
dtmf	(Optional) Specifies dual tone multifrequency (DTMF) tone signaling.
mf	(Optional) Specifies multifrequency (MF) tone signaling
ani	(Optional) Provisions ANI address information.
ani-dnis	(Optional) Specifies automatic number identification (ANI) and dialed number identification service (DNIS) address information provisioning for FGD OS.
ani-pani	(Optional) Provisions ANI and PANI address information.
dnis-ani	(Optional) Specifies ANI and DNIS address information provisioning for FGD EANA.
dnis	(Optional) Specifies DNIS address information provisioning.
info-digits-no-strip	(Optional) Retains info digits on the Cisco AS5x00 platforms.

1. Used only with the **type none** keywords on the Cisco AS5x00 platforms.

Command Default There is no DS0 group. Calls are allowed in both directions.

Command Modes Controller configuration

Command History

Release	Modification
11.2	This command was introduced for the Cisco AS5300 as the **cas-group** command.
11.3(1)MA	The command was introduced as the **voice-group** command for the Cisco MC3810.
12.0(1)T	This command was integrated into Cisco IOS Release 12.0(1)T, and the **cas-group** command was implemented on the Cisco 3600 series routers.
12.0(5)T	The command was renamed **ds0-group** on the Cisco AS5300 and Cisco 2600 series and Cisco 3600 series routers. Some keyword modifications were implemented.
12.0(5)XE	This command was implemented on the Cisco 7200 series.

Release	Modification
12.0(7)XK	Support for this command was implemented on the Cisco MC3810. When the **ds0-group** command became available on the Cisco MC3810, the **voice-group** command was removed and no longer supported. The **ext-sig** keyword replaced the **ext-sig-master** and **ext-sig-slave** keywords that were available with the **voice-group** command.
12.0(7)XR	The **mgcp** service type was added.
12.1(2)XH	The **e&m-fgd** and **fgd-eana** keywords were added for Feature Group D signaling.
12.1(5)XM	The **sgcp** keyword was removed.
12.1(3)T	This command was modified for Cisco 7500 series routers. The **fgd-os** signaling type and the **voice** service type were added.
12.2(2)XA	This command was implemented on the Cisco AS5300.
12.2	The command was modified to exclude **sas** keywords**.** The Single Attachment Station (SAS) CAS options of **sas-loop-start** and **sas-ground-start** are not supported as a type of signaling for the DS0 group.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(4)T	Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)XM	This command was implemented on Cisco 1750 and Cisco 1751 routers. Support for other Cisco platforms is not included in this release.
12.2(2)XN	Support for the **mgcp** keyword was added to Cisco CallManager Version 3.1 for the Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was supported in Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2. This command is supported on the Cisco IAD2420 series, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5850 in this release.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T. The Cisco 1750 and Cisco 1751 do not support T1 and E1 voice and data cards in Cisco IOS Release 12.2(13)T. The Cisco 17xx platforms can support only HC DSP firmware images in this release.
12.2(15)T	This command was implemented on the Cisco 2600XM, Cisco 3725, and Cisco 3745.
12.3(4)XD	This command was modified for the Cisco 3725 and Cisco 3745. The **e&m-lmr** signaling type was added.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T	Documentation of the **ds0-group** command was divided into the individual **ds0-group (E1)** and **ds0-group (T1)** commands.

Release	Modification
12.3(10)	The **info-digits-no-strip** keyword was added for use on the Cisco AS5x00 platforms.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T. The **fgd-emf**, **ani-pani**, and **ani** keywords were added for the Cisco 2800 and Cisco AS5x00 platforms.

Usage Guidelines

The **ds0-group** command automatically creates a logical voice port that is numbered as follows:

- Cisco 2600 series, Cisco 2600XM, Cisco 3660, Cisco 3725, Cisco 3745, and Cisco 7200 series:
  - *slot*/*port*:*ds0-group-number*
- Cisco AS5300, Cisco AS5350, and Cisco AS5400 with a T1 controller:
  - *slot*/*port*
- Cisco AS5850 with a T1 controller:
  - *slot*/*port*:*ds0-group-number*

Although only one voice port is created for each group, applicable calls are routed to any channel in the group.

Be sure that you take the following into account when you are configuring DS0 groups:

- Channel groups, CAS voice groups, DS0 groups, and time-division multiplexing (TDM) groups all use group numbers. All group numbers configured for channel groups, CAS voice groups, DS0 groups, and TDM groups must be unique on the local router. For example, you cannot use the same group number for a channel group and for a TDM group.
- The keywords available for the **ds0-group** command are dependent upon the Cisco IOS software release that you are using. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

  http://www.cisco.com/go/fn
- When you are using command-line interface (CLI) help, the keywords for the **ds0-group** command are configuration specific. For example, if Media Gateway Control Protocol (MGCP) is configured, you see the **mgcp** keyword. If you are not using MGCP, you do not see the **mgcp** keyword.

Note This command does not support the extended echo canceller (EC) feature on the Cisco AS5x00 series.

Note The signaling type R1-ITU is not supported on the Cisco AS5300, Cisco AS5350, and Cisco AS5400 platforms.

Examples

The following example shows ranges of T1 controller time slots configured for FXS ground-start and FXO loop-start signaling:

```
controller T1 1/0
 framing esf
 linecode b8zs
 ds0-group 1 timeslots 1-10 type fxs-ground-start
 ds0-group 2 timeslots 11-24 type fxo-loop-start
```

The following example shows ranges of T1 controller time slots configured for FXS ground-start signaling:

```
controller T1 1/0
 ds0-group 1 timeslots 1-4 type fxs-ground-start
```

The following example illustrates setting the T1 channels for Signaling System 7 (SS7) service on any trunking gateway using the **mgcp** keyword:

```
ds0-group 0 timeslots 1-24 type none service mgcp
```

In the following example, the time slot maximum is 12 and the time slot is 1, so two voice-ports are created successfully.

```
controller T1 0/0
 ds0-group 0 timeslots 1-4 type e&m-immediate-start
 ds0-group 1 timeslots 6-12 type e&m-immediate-start
```

If a third DS0 group is added, the voice port is rejected even though the total number of voice channels is less than 16.

```
 ds0-group 2 timeslots 17-18 type e&m-immediate-start
```

In the following example, the signaling type is set to E&M LMR:

```
 ds0-group 0 timeslots 1-10 type e&m-lmr
```

You have the option to retain info digits when you are configuring E&M Type II Feature Group D with MF signaling and ANI/DNIS for calls being sent over IP. Info digits denote the subscriber type, and the info-digits keyword prepends info digits to the calling number.

On inbound calls from a T1 FGD voice-port with MF ANI-DNIS, when ANI information is obtained, it is passed unaltered to the next matching dial peer, either POTS or VoIP. The addition of the **info-digits-no-strip** keyword allows you to retain the info digits portion of the ANI information; the modified ANI is then passed to the next matching dial peer. Ordinarily, info digits are not valid for calls going over IP and are, therefore, stripped off. The ability to retain info digits is particularly useful for calls that are not leaving the PSTN network and are just being hairpinned back.

In the following example, the E&M Type II Feature Group D is configured with MF signaling and ANI/DNIS over IP while retaining info digits:

```
 ds0-group 0 timeslots 1-24 type e&m-fgd mf ani-dnis info-digits-no-strip
```

The following example enables FGD EMF:

```
 ds0-group 11 timeslots 11 type fgd-emf ani
 ds0-group 11 timeslots 11 type fgd-emf ani-pani
```

Related Commands

Command	Description
cas-group	Configures channelized T1 time slots with robbed bit signaling.
codec	Specifies the voice coder rate of speech for a dial peer.
codec complexity	Specifies call density and codec complexity based on the codec standard that you are using.

ds0-num

To add B-channel information in outgoing Session Initiation Protocol (SIP) messages, use the **ds0-num** command in SIP voice service configuration mode. To return to the default setting, use the **no** form of this command.

ds0-num

no ds0-num

Syntax Description

This command has no arguments or keywords.

Command Default

B channel information is disabled.

Command Modes

SIP voice service configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

This command enables the SIP application to receive B-channel information of incoming ISDN calls. The B-channel information appears in the Via header of an Invite request and information acquired from the Via header can be used during call transfer or to route a call.

Examples

The following example adds B-channel information to outgoing SIP messages:

```
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# ds0-num
```

Related Commands

Command	Description
sip	Enables SIP voice service configuration commands.
voice service voip	Specifies the voice encapsulation type as VoIP.

dsn

To specify that a delivery status notice (DSN) be delivered to the sender, use the **dsn** command in dial peer configuration mode. To cancel a specific DSN option, use the **no** form of this command.

dsn {**delay** | **failure** | **success**}

no dsn {**delay** | **failure** | **success**}

Syntax Description

delay	Defines the delay for each mailer.
failure	Requests that a failed message be sent to the FROM address. This is a default.
success	Requests that message be sent to the FROM address that the message was delivered successfully to the recipient.

Note In the absence of any other DSN settings (for example, **no dsn**, or a mailer in the path that does not support the DSN extension), a failure to deliver message always causes a nondelivery message to be generated. This nondelivery message is called a *bounce*.

Command Default The default is to send a nondelivery message in the event of a failure

Command Modes Dial peer configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series and Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines When the **delay** keyword is selected, the next-hop mailer sends a message to the FROM address saying that the mail message was delayed. The definition of the **delay** keyword is made by each mailer and is not controlled by the sender. Each mailer in the path to the recipient that supports the DSN extension receives the same request.

When the **failur**e keyword is selected, the next-hop mailer sends a message to the FROM address that the mail message delivery failed. Each mailer in the path to the recipient that supports the DSN extension receives the same request.

When the **success** keyword is selected, the next-hop mailer sends a message to the FROM address saying that the mail message was successfully delivered to the recipient. Each mailer in the path to the recipient that supports the DSN extension receives the same request.

This command is applicable to Multimedia Mail over Internet Protocol (MMoIP) dial peers.

DSNs are messages or responses that are automatically generated and sent to the sender or originator of an e-mail message by the Simple Mail Transfer Protocol (SMTP) server, notifying the sender of the status of the e-mail message. Specifications for DSN are described in RFC 1891, RFC 1892, RFC 1893, and RFC 1894.

The on-ramp DSN request is included as part of the fax-mail message sent by the on-ramp gateway when the matching MMoIP dial peer has been configured. The on-ramp DSN response is generated by the SMTP server when the fax-mail message is accepted. The DSN is sent back to the user defined by the **mta send mail-from** command. The off-ramp DSN is requested by the e-mail client. The DSN response is generated by the SMTP server when it receives a request as part of the fax-mail message.

Note DSNs are generated only if the mail client on the SMTP server is capable of responding to a DSN request.

Because the SMTP server generates the DSNs, you need to configure both **mail from:** and **rcpt to:** on the server for the DSN feature to work. For example:

```
mail from: <user@mail-server.company.com>
rcpt to: <fax=555-1212@company.com> NOTIFY=SUCCESS,FAILURE,DELAY
```

There are three different states that can be reported back to the sender:

- Delay—Indicates that the message was delayed in being delivered to the recipient or mailbox.
- Success—Indicates that the message was successfully delivered to the recipient or mailbox.
- Failure—Indicates that the SMTP server was unable to deliver the message to the recipient or mailbox.

Because these delivery states are not mutually exclusive, you can configure store-and-forward fax to generate these messages for all or any combination of these events.

DSN messages notify the sender of the status of a particular e-mail message that contains a fax TIFF image. Use the **dsn** command to specify which notification messages are sent to the user.

The **dsn** command allows you to select more than one notification option by reissuing the command and specifying a different notification option each time. To discontinue a specific notification option, use the **no** form of the command for that specific keyword.

If the **failure** keyword is not included when DSN is configured, the sender receives no notification of message delivery failure. Because a failure is usually significant, care should be taken to always include the **failure** keyword as part of the **dsn** command configuration.

This command applies to on-ramp store-and-forward fax functions.

Examples

The following example specifies that a DSN message be returned to the sender when the e-mail message that contains the fax has been successfully delivered to the recipient or if the message that contains the fax has failed to be delivered:

```
dial-peer voice 10 mmoip
 dsn success
 dsn failure
```

Related Commands

Command	Description
mta send mail-from hostname	Specifies the originator (host-name portion) of the e-mail fax message.
mta send mail-from username	Specifies the originator (username portion) of the e-mail fax message.

dsp allocation signaling dspid

To change the digital signal processor (DSP) selection for signaling channel allocation from the default (DSP weight-based) to the DSP ID number, use the **dsp allocation signaling dspid** command in voice-card configuration mode. To return to the default behavior, use the **no** form of this command.

dsp allocation signaling dspid

no dsp allocation signaling dspid

Syntax Description

This command has no arguments or keywords.

Command Default

Selection of a DSP for signaling channel allocation is based on the internal weighted value assigned to the DSPs.

Command Modes

Voice-card configuration (config-voicecard)

Command History

Release	Modification
12.4(15)T9	This command was introduced.

Usage Guidelines

The **dsp allocation signaling dspid** command takes effect only after a reload of the router. The command should be enabled and saved into the startup-config file.

The default signal channel allocation method (by weight) may not be suitable for some network implementations. The default allocation method selects the DSPs based on the DSP weight, and you cannot control the selection of the DSP for specific configuration even if the order of the packet voice data modules (PVDMs) is changed. Enable the **dsp allocation signaling dspid** command to change the selection order to the DSP ID number. This command is more useful when there is a PVDM2-8 module in the network configuration.

Examples

The following example shows how to change the default for DSP allocation from the DSP weight to the DSP ID number:

```
voice card 1
 dsp allocation signaling dspid
```

Related Commands

Command	Description
show voice dsp	Displays the current status or selective statistics of DSP voice channels.
voice-card	Enters voice-card configuration mode.

dsp services dspfarm

To enable digital-signal-processor (DSP) farm services for a particular voice network module, use the **dsp services dspfarm** command in voice card configuration mode. To disable services, use the **no** form of this command.

dsp services dspfarm

no dsp services dspfarm

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Voice-card configuration (config-voicecard)

Command History

Release	Modification
12.2(13)T	This command was introduced.
Cisco IOS XE Release 3.2S	Support for this command was added on Cisco ASR 1000 Series Routers.

Usage Guidelines The router must be equipped with one or more voice network modules that provide DSP resources. DSP resources are used only if this command is configured under the particular voice card.

The number of voice network modules that must be enabled for DSP-farm services depends on the number of DSPs on the module and on the maximum number of transcoding and conferencing sessions configured for the DSP farm.

Note Use this command before enabling DSP-farm services with the **dspfarm** command for an NM-HDV or NM-HDV-FARM.

Cisco ASR 1000 Series Router

The SPA-DSPs on a Cisco ASR 1000 Series Routers are installed in a subslot on a SIP. Hence, when referring to a SPA-DSP the **voice-card** command is used.

Examples The following example enables DSP-farm services on an NM-HDV2 or NM-HD-1V/2V/2VE:

```
Router(config)# voice-card 2
Router(config-voicecard)# dsp services dspfarm
Router(config-voicecard)# exit
```

The following example enables DSP-farm services on an NM-HDV or NM-HDV-FARM:

```
Router(config)# voice-card 2
Router(config-voicecard)# dsp services dspfarm
Router(config-voicecard)# exit
```

The following example enables DSP-farm services on SPA-DSP for a Cisco ASR 1000 Series Router:

```
Router(config)# voice-card 1/1
Router(config-voicecard)# dsp services dspfarm
Router(config-voicecard)# exit
```

Related Commands

Command	Description
dsp services dspfarm	Enables the DSP farm services.
dspfarm profile	Enters the DSP farm profile configuration mode, and defines a profile for the DSP farm services.
show voice dsp (SPA-DSP)	Displays the DSP current status or the selective statistics of the DSP voice channels.

dspfarm (DSP farm)

To enable digital-signal-processor (DSP) farm service, use the **dspfarm** command in global configuration mode. To disable the service, use the **no** form of this command.

dspfarm

no dspfarm

Syntax Description

This command has no arguments or keywords.

Command Default

DSP-farm service is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)YH	This command was introduced on the Cisco VG200.
12.2(13)T	This command was implemented on the Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, and Cisco 3700 series.

Usage Guidelines

The router on which this command is used must be equipped with one or more digital T1/E1 packet voice trunk network modules (NM-HDVs) or high-density voice (HDV) transcoding/conferencing DSP farms (NM-HDV-FARMs) to provide DSP resources.

Before enabling DSP-farm services, you must configure the NM-HDV or NM-HDV-FARM on which DSP-farm services are to be enabled using the **dsp service dspfarm** command. You must also specify the maximum number of transcoding sessions to be supported by the DSP farm using the **dspfarm transcoder maximum sessions** command.

This command causes the system to download new firmware into the DSPs, start up the required subsystems, and wait for a service request from the transcoding and conferencing applications.

Examples

The following example configures an NM-HDV or NM-HDV-FARM, specifies the maximum number of transcoding sessions, and enables DSP-farm services:

```
Router# configure terminal
Router(config)# no dspfarm
Router(config)# voice-card 2
Router(config-voicecard)# dsp services dspfarm
Router(config-voicecard)# exit
Router(config)# dspfarm transcoder maximum sessions 15
Router(config)# dspfarm
```

Related Commands

Command	Description
dsp services dspfarm	Specifies the NM-HDV or NM-HDV-FARM on which DSP-farm services are to be enabled.
dspfarm transcoder maximum sessions	Specifies the maximum number of transcoding sessions to be supported by a DSP farm.
show dspfarm	Displays summary information about DSP resources.

dspfarm (voice-card)

To add a specified voice card to those participating in a digital signal processor (DSP) resource pool, use the **dspfarm** command in voice-card configuration mode. To remove the specified card from participation in the DSP resource pool, use the **no** form of this command.

dspfarm

no dspfarm

Syntax Description

This command has no arguments or keywords.

Command Default

A card participates in the DSP resource pool

Command Modes

Voice-card configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced for the Cisco 3660.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(2)XB	This command was implemented on the Cisco 2600 series routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(15)T	This command was implemented on the Cisco 2600XM, Cisco 3725, and Cisco 3745.

Usage Guidelines

DSP mapping occurs when DSP resources on one AIM or network module are available for processing of voice time-division multiplexing (TDM) streams on a different network module or on a voice/WAN interface card (VWIC). This command is used on Cisco 3660 routers with multiservice interchange (MIX) modules installed or on Cisco 2600 series routers with AIMs installed.

To reach voice-card configuration mode for a particular voice card, from global configuration mode enter the **voice-card** command and the slot number for the AIM or network module that you want to add to the pool. See the **voice-card** command reference for details on slot numbering.

The assignment of DSP pool resources to particular TDM streams is based on the order in which the streams are configured with the **ds0-group** command for T1/E1 channel-associated signaling (CAS) or with the **pri-group** command for ISDN PRI.

The assignment of DSP pool resources does not occur dynamically during call signaling.

Examples

The following example adds to the DSP resource map the DSP resources on the network module in slot 5 on a Cisco 3660 with a MIX module:

```
voice-card 5
 dspfarm
```

The following example makes available the DSP resources on an AIM on a modular access router:

```
voice-card 0
 dspfarm
```

Related Commands

Command	Description
ds0-group	Specifies the DS0 time slots that make up a logical voice port on a T1 or E1 controller, to specify the signaling type by which the router communicates with the PBX or PSTN, and to define T1or E1 channels for compressed voice calls and the channel-associated signaling (CAS) method by which the router connects to the PBX or PSTN.
pri-group	Specifies ISDN Primary Rate Interface (PRI) on a channelized T1 or E1 controller.
voice-card	Enters voice-card configuration mode.

dspfarm confbridge maximum sessions

To specify the maximum number of concurrent conference sessions for which digital-signal-processor (DSP) farm resources should be allocated, use the **dspfarm confbridge maximum sessions** command in global configuration mode. To reset to the default, use the **no** form of this command.

dspfarm confbridge maximum sessions *number*

no dspfarm confbridge maximum sessions

Syntax Description

number	Number of conference sessions. A single DSP supports 1 conference session with up to 6 participants.

Command Default 0 sessions

Command Modes Global configuration

Command History

Release	Modification
12.1(5)YH	This command was introduced on the Cisco VG200.
12.2(13)T	This command was implemented on the Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, and Cisco 3700 series.

Usage Guidelines The router on which this command is used must be equipped with one or more digital T1/E1 packet voice trunk network modules (NM-HDVs) or high-density voice (HDV) transcoding/conferencing DSP farms (NM-HDV-FARMs) to provide DSP resources.

Before using this command, you must disable DSP-farm service using the **no dspfarm** command.

The maximum number of conference sessions depends upon DSP availability in the DSP farm. A single DSP supports one conference session with up to six participants. However, you may need to allocate additional DSP resources for transcoding to support conferences. If all participants use G.711 or G.729 codecs, you need not allocate any additional DSP resources because transcoding is done in the conferencing DSP.

When you use this command, take into consideration the number of DSPs allocated for transcoding services with the **dspfarm transcoder maximum sessions** command.

Examples The following example sets the maximum number of conferencing sessions to 8:

```
Router# dspfarm confbridge maximum sessions 8
```

Related Commands

Command	Description
dspfarm (DSP farm)	Enables DSP-farm service.
dspfarm transcoder maximum sessions	Specifies the maximum number of transcoding sessions to be supported by a DSP farm.
show dspfarm	Displays summary information about DSP resources.

dspfarm connection interval

To specify the time interval during which to monitor Real-Time Transport Protocol (RTP) inactivity before deleting an RTP stream, use the **dspfarm connection interval** command in global configuration mode. To reset to the default, use the **no** form of this command.

dspfarm connection interval *seconds*

no dspfarm connection interval

Syntax Description

seconds	Interval, in seconds, during which to monitor RTP inactivity. Range is from 60 to 10800. Default is 600.

Command Default

600 seconds

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)YH	This command was introduced on the Cisco VG200.
12.2(13)T	This command was implemented on the Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, and Cisco 3700 series.

Usage Guidelines

The router on which this command is used must be equipped with one or more digital T1/E1 packet voice trunk network modules (NM-HDVs) or high-density voice (HDV) transcoding/conferencing DSP farms (NM-HDV-FARMs) to provide digital-signal-processor (DSP) resources.

After each interval, RTP streams are checked for inactivity. If all RTP streams for a particular call are inactive, the RTP timer, as set with the **dspfarm rtp timeout** command, is started. When the RTP timer expires, the call is deleted.

Examples

The following example sets the connection interval to 60 seconds:

```
Router(config)# dspfarm connection interval 60
```

Related Commands

Command	Description
dspfarm rtp timeout	Specifies the RTP timeout interval used to clear hanging connections.

dspfarm profile

To enter DSP farm profile configuration mode and define a profile for digital signal processor (DSP) farm services, use the **dspfarm profile** command in global configuration mode. To delete a disabled profile, use the **no** form of this command.

Cisco Unified Border Element

dspfarm profile *profile-identifier* {**conference** | **mtp** | **transcode**} [**security**]

no dspfarm profile *profile-identifier*

Cisco Unified Border Element (Enterprise) Cisco ASR 1000 Series Router

dspfarm profile *profile-identifier* {**transcode**}

no dspfarm profile *profile-identifier*

Cisco Integrated Services Routers Generation 2 (Cisco ISR G2)

dspfarm profile *profile-identifier* {**conference** [**video** [**homogeneous** | **heterogeneous** | **guaranteed-audio**]] | **mtp** | **transcode** [**video** | **universal**] } [**security**]

no dspfarm profile *profile-identifier*

Syntax Description

profile-identifier	Number that uniquely identifies a profile. Range is 1 to 65535. There is no default.
conference	Enables a profile for conferencing.
mtp	Enables a profile for Media Termination Point (MTP).
transcode	Enables a profile for transcoding.
security	Enables a profile for secure DSP farm services.
video	(Optional) Enables a profile for video conferencing or transcoding.
homogeneous	(Optional) Specifies that all video participants use the one video format that is configured in this profile. DSP resources are reserved to support the conference at configuration time. **Note** The homogeneous profiles only support one video codec.
heterogeneous	(Optional) Specifies that video participants can use the different video formats that are configured in the profile. You can configure up to 10 video codecs in the heterogeneous profile. DSP resources are reserved to support the different configurations at configuration time.
guaranteed-audio	(Optional) Specifies that video participants in a heterogeneous conference will at least have an audio connection. You can configure up to 10 video codecs in the guaranteed-audio profile. The DSP resources for audio streams are reserved at configuration time, but DSP resources to support video conferences are not reserved. If the video endpoint supports the video format specified in the profile and DSP resources are available when the participant joins the conference, the participant joins as a video conferee in the video conference.

Command Default If this command is not entered, no profiles are defined for the DSP farm services.

Command Modes Global configuration (config)

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(11)XW	The **security** keyword was added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.
12.4(22)T	Support for IPv6 was added.
15.0(1)M2 15.1(1)T	Support was modified for the Cisco IAD 2430, IAD 2431, IAD 2432, and IAD 2435, and the Cisco VG 202, VG 204, and VG 224 platforms.
Cisco IOS XE Release 3.2S	This command was modified. Support was added to the Cisco ASR 1000 Series Router. The **conference**, **mtp** & **security** keywords are not supported on the Cisco ASR 1000 Series Router in this release.
15.1(4)M	This command was modified. The **video** keyword was added.

Usage Guidelines Use this command to create a new profile or delete a disabled profile. After you create a new profile in dspfarm profile configuration mode, use the **no shutdown** command to enable the profile configuration, allocate resources and associate the profile with the application(s). If the profile cannot be enabled due to lack of resources, the system prompts you with a message "Can not enable the profile due to insufficient resources, resources available to support X sessions; please modify the configuration and retry."

If the DSP farm profile is successfully created, you enter the DSP farm profile configuration mode. You can configure multiple profiles for the same service.

Use the **no dspfarm profile** command to delete a profile from the system. If the profile is active, you cannot delete it; you must first disable it using the **shutdown** command. To modify a DSP farm profile, use the **shutdown** command in dspfarm profile configuration mode before you begin configuration.

The *profile identifier* uniquely identifies a profile. If the service type and *profile identifier* are not unique, the user is prompted with a message to choose a different profile identifier.

You must use the **security** keyword in order to enable secure DSP farm services such as secure transcoding.

Effective with Cisco IOS Releases 15.0(1)M2 and 15.1(1)T, platform support for the Cisco IAD 2430, IAD 2431, IAD 2432, and IAD 2435, and the Cisco VG 202, VG 204, and VG 225 is modified. These platforms are designed as TDM-IP devices and are not expandable to install extra DSP resources. So even though the **conference** keyword appears in the command syntax, this DSP service is not configurable on these platforms. If you try to configure conferencing on these platforms, the command-line interface displays the following message: "`%This platform does not support Conferencing feature.`"

The **transcode** keyword also appears in the command syntax, but this DSP service is not available on the Cisco VG 202, VG 204, and VG 224 platforms. If you try to configure transcoding on these platforms, the CLI displays the following message: "`%This platform does not support Transcoding feature.`"

Cisco ASR 1000 Series Router

The support for dspfarm profile command was added on Cisco ASR 1000 Series Router from Cisco IOS XE Release 3.2 and later releases. The command is used to create a dspfarm profile for different services.

Note The secure DSP farm services is always enabled for SPA-DSP on Cisco ASR 1000 Series Router. Only **transcode** keyword is supported on Cisco ASR 1000 Series Router for Cisco IOS XE Release 3.2s. The **conference**, **media**, and **security** keywords are not supported on Cisco ASR 1000 Series Router for Cisco IOS XE Release 3.2s.

In order to configure a video dspfarm profile, you must set **voice-service dsp-reservation** to be less than 100 percent.

To enable dspfarm profiles for voice services, you must use the **dsp services dspfarm command** under the voice-card submode.

Examples

The following example enables DSP farm services profile 20 for conferencing:

```
Router(config)# dspfarm profile 20 conference
```

Note the response if the profile is already being used:

```
Router(config)# dspfarm profile 6 conference

Profile id 6 is being used for service TRANSCODING
 please select a different profile id
```

The following example enables DSP farm services profile 1 for transcoding:

```
Router(config)# dspfarm profile 1 transcode
```

Video Conferences

The following example enables DSP farm services profile 99 for homogeneous video. The conference supports four participants under one format (Video codec H.263, qcif resolution, and a frame-rate of 15 f/s).

```
Router(config)# dspfarm profile 99 conference video homogeneous
Router(config-dspfarm-profile)# codec h263 qcif frame-rate 15
Router(config-dspfarm-profile)# maximum conference-participant 4
```

Related Commands

Command	Description
dsp service dspfarm	Configures the DSP farm services for a specified voice card.
shutdown (DSP farm profile)	Disables the DSP farm profile.
voice-card	Enters voice card configuration mode
voice-service dsp-reservation	Configures the percentage of DSP resources are reserved for voice services and enables video services to use the remaining DSP resources. This command is required to enable video services.

dspfarm rtp timeout

To specify the Real-Time Transport Protocol (RTP) timeout interval used to clear hanging connections, use the **dspfarm rtp timeout** command in global configuration mode. To reset to the default, use the **no** form of this command.

dspfarm rtp timeout *seconds*

no dspfarm rtp timeout

Syntax Description

seconds	RTP timeout interval, in seconds. Range is from 10 to 7200. Default is 1200.

Command Default

1200 seconds (20 minutes)

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)YH	This command was introduced on the Cisco VG200.
12.2(13)T	This command was implemented on the Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, and Cisco 3700 series.

Usage Guidelines

The router on which this command is used must be equipped with one or more digital T1/E1 packet voice trunk network modules (NM-HDVs) or high-density voice (HDV) transcoding/conferencing DSP farms (NM-HDV-FARMs) to provide digital-signal-processor (DSP) resources.

Use this command to set the RTP timeout interval for when the error condition “RTP port unreachable” occurs.

Examples

The following example sets the RTP timeout value to 600 seconds (10 minutes):

```
Router# dspfarm rtp timeout 600
```

Related Commands

Command	Description
dspfarm (DSP farm)	Enables DSP-farm service.
dspfarm connection interval	Specifies the time interval during which to monitor RTP inactivity before deleting an RTP stream.
show dspfarm	Displays summary information about DSP resources.

dspfarm transcoder maximum sessions

To specify the maximum number of transcoding sessions to be supported by the digital-signal-processor (DSP) farm, use the **dspfarm transcoder maximum sessions** command in global configuration mode. To reset to the default, use the **no** form of this command.

dspfarm transcoder maximum sessions *number*

no dspfarm transcoder maximum sessions

Syntax Description

number	Number of transcoding sessions.

Command Default 0 sessions

Command Modes Global configuration

Command History

Release	Modification
12.1(5)YH	This command was introduced on the Cisco VG200.
12.2(13)T	This command was implemented on the Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, and Cisco 3700 series.

Usage Guidelines The router on which this command is used must be equipped with one or more digital T1/E1 packet voice trunk network modules (NM-HDVs) or high-density voice (HDV) transcoding/conferencing DSP farms (NM-HDV-FARMs) to provide DSP resources.

Before using this command, you must disable DSP-farm service using the **no dspfarm** command.

Use this command in conjunction with the **dspfarm confbridge maximum sessions** commands.

The maximum number of transcoding sessions depends upon DSP availability in the DSP farm. A single DSP supports four transcoding sessions transmission to and from G.711 and G.729 codecs.

Examples The following example configures an NM-HDV or NM-HDV-FARM, specifies the maximum number of transcoding sessions, and enables DSP-farm services:

```
Router# configure terminal
Router(config)# no dspfarm
Router(config)# voice-card 2
Router(config-voicecard)# dsp services dspfarm
Router(config-voicecard)# exit
Router(config)# dspfarm transcoder maximum sessions 15
Router(config)# dspfarm
```

Related Commands

Command	Description
dspfarm (DSP farm)	Enables DSP-farm service.
dspfarm confbridge maximum sessions	Specifies the maximum number of conferencing sessions to be supported by a DSP farm.
dsp services dspfarm	Specifies the NM-HDV or NM-HDV-FARM on which DSP-farm services are to be enabled.
show dspfarm	Displays summary information about DSP resources.

dspint dspfarm

To enable the digital signal processor (DSP) interface, use the **dspint dspfarm** command in global configuration mode. This command does not have a no form.

dspint dspfarm *slot*/*port*

Syntax Description

slot	Slot number of the interface.
port	Port number of the interface.

Command Default Enabled

Command Modes Global configuration

Command History

Release	Modification
12.0(5)XE	This command was introduced on the Cisco 7200 series routers.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(13)T	This command was implemented on the Cisco 7200 series.

Usage Guidelines DSP mapping occurs when DSP resources on one advanced interface module (AIM) or network module are available for processing of voice time-division multiplexing (TDM) streams on a different network module or on a voice/WAN interface card (VWIC). This command is used on Cisco 3660 routers with multiservice interchange (MIX) modules installed or on Cisco 2600 series routers with AIMs installed.

To reach voice-card configuration mode for a particular voice card, from global configuration mode enter the **voice-card** command and the slot number for the AIM or network module that you want to add to the pool. See the **voice-card** command reference for details on slot numbering.

The assignment of DSP pool resources to particular TDM streams is based on the order in which the streams are configured using the **ds0-group** command for T1/E1 channel-associated signaling (CAS) or using the **pri-group** command for ISDN PRI.

The assignment of DSP pool resources does not occur dynamically during call signaling.

To disable the interface use the **no shutdown** command.

Examples The following example creates a DSP farm interface with a slot number of 1 and a port number of 0.

```
dspint dspfarm 1/0
```

To change codec complexity on the Cisco 7200 series, you must enter the following commands:

```
Router# configure terminal
Router(config)# dspint dspfarm 2/0
Router(config-dspfarm)# codec medium | high ecan-extended
```

Related Commands

Command	Description
ds0-group	Specifies the DS0 time slots that make up a logical voice port on a T1 or E1 controller
no shutdown	Disables the interface.
pri-group	Specifies an ISDN PRI on a channelized T1 or E1 controller
show interfaces dspfarm dsp	Displays information about the DSP interface.
voice-card	Enters voice-card configuration mode.

dtmf-interworking rtp-nte

To enable a delay between the dtmf-digit begin and dtmf-digit end events in the RFC 2833 packets sent from Cisco Unified Border Element (Cisco UBE) or Cisco Unified Communications Manager Express (Cisco Unified CME), use the **dtmf-interworking rtp-nte** command in voice-service or dial-peer configuration mode. To remove the delay amount, use the no form of this command.

dtmf-interworking rtp-nte

no dtmf-interworking rtp-nte

Syntax Description

This command has no arguments or keywords.

Command Default

RFC 2833 packet is sent in a single burst of three dtmf-digit begin events, one duration equaling 50ms, and three dtmf-digit end events with a duration of 100ms.

Command Modes

Voice-service configuration (config-voi-serv)
Dial-peer configuration (config-dial-peer)

Command History

Cisco IOS Release	Modification
12.4(15)XZ	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

If your system is configured for RFC 2833 DTMF interworking and if the remote system cannot handle RFC 2833 packets sent in a single burst, use this command to introduce a delay between the dtmf-digit begin and end events in the RFC 2833 packet.

Examples

The following example shows a delay between the dtmf-digit and events being configured.

```
Router(config-voi-serv) dtmf-interworking rtp-nte
```

Related Commands

Command	Description
nte-end-digit-delay	Specifies length of delay for each digit in dtmf-digit end event.
keypad-normalize	Ensures that the delay configured for a dtmf-end event is always honored.

dtmf timer inter-digit

To configure the dual tone multifrequency (DTMF) interdigit timer for a DS0 group, use the **dtmf timer inter-digit** command in T1 controller configuration mode. To restore the timer to its default value, use the **no** form of this command.

dtmf timer inter-digit *milliseconds*

no dtmf timer inter-digit

Syntax Description

milliseconds	DTMF interdigit timer duration, in milliseconds. Range is from 250 to 3000. The default is 3000.

Command Default 3000 milliseconds

Command Modes T1 controller configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco AS5300.

Usage Guidelines Use the **dtmf timer inter-digit** command to specify the duration in milliseconds the router waits to detect the end of DTMF digits. After this period, the router expects no more digits to arrive and establishes the call.

Examples The following example, beginning in global configuration mode, sets the DTMF interdigit timer value to 250 milliseconds:

```
controller T1 2
 ds0-group 2 timeslots 4-10 type e&m-fgb dtmf dnis
 cas-custom 2
 dtmf timer inter-digit 250
```

Related Commands

Command	Description
cas-custom	Customizes E1 R2 signaling parameters for a particular E1 channel group on a channelized E1 line.
ds0-group	Configures channelized T1 time slots, which enables a Cisco AS5300 modem to answer and send an analog call.

dtmf-relay (Voice over Frame Relay)

To enable the generation of FRF.11 Annex A frames for a dial peer, use the **dtmf-relay** command in dial peer configuration mode. To disable the generation of FRF.11 Annex A frames and return to the default handling of dial digits, use the **no** form of this command.

dtmf-relay

no dtmf-relay

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Dial peer configuration

Command History

Release	Modification
12.0(3)XG	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T, and implemented on the Cisco 7200 series router.

Usage Guidelines

Cisco recommends that this command be used with low bit-rate codecs.

When **dtmf-relay** (VoFR) is enabled, the digital signal processor (DSP) generates Annex A frames instead of passing a dual-tone multifrequency (DTMF) tone through the network as a voice sample. For information about the payload format of FRF.11 Annex A frames, see the *Cisco IOS Wide-Area Networking Configuration Guide*.

Examples

The following example shows how to enable FRF.11 Annex A frames for VoFR dial peer 200, starting from global configuration mode:

```
dial-peer voice 200 vofr
 dtmf-relay
```

Related Commands

Command	Description
called-number (dial peer)	Enables an incoming VoFR call leg to get bridged to the correct POTS call leg when using a static FRF.11 trunk connection.
codec (dial peer)	Specifies the voice coder rate of speech for a VoFR dial peer.
connection	Specifies a connection mode for a voice port.
cptone	Specifies a regional analog voice interface-related tone, ring, and cadence setting.

Command	Description
destination-pattern	Specifies the prefix, the full E.164 telephone number, or an ISDN directory number (depending on the dial plan) to be used for a dial peer.
preference	Indicates the preferred order of a dial peer within a rotary hunt group.
session protocol	Establishes a session protocol for calls between the local and remote routers via the packet network.
session target	Specifies a network-specific address for a specified dial peer or destination gatekeeper.
signal-type	Sets the signaling type to be used when connecting to a dial peer.

dtmf-relay (Voice over IP)

To specify how an H.323 or Session Initiation Protocol (SIP) gateway relays dual tone multifrequency (DTMF) tones between telephony interfaces and an IP network, use the **dtmf-relay** command in dial peer voice configuration mode. To remove all signaling options and send the DTMF tones as part of the audio stream, use the **no** form of this command.

dtmf-relay {[**cisco-rtp**] [**h245-alphanumeric**] [**h245-signal**] [**rtp-nte** [**digit-drop**]] [**sip-notify**]}

no dtmf-relay

Syntax Description

cisco-rtp	Forwards DTMF tones by using Real-Time Transport Protocol (RTP) with a Cisco proprietary payload type.
h245-alphanumeric	Forwards DTMF tones by using the H.245 "alphanumeric" User Input Indication method. Supports tones from 0 to 9, *, #, and from A to D.
h245-signal	Forwards DTMF tones by using the H.245 "signal" User Input Indication method. Supports tones from 0 to 9, *, #, and from A to D.
rtp-nte	Forwards DTMF tones by using RTP with the Named Telephone Event (NTE) payload type.
digit-drop	Passes digits out-of-band and drops in-band digits are dropped. **Note** The **digit-drop** keyword is only available when the **rtp-nte** keyword is configured.
sip-notify	Forwards DTMF tones using SIP NOTIFY messages. This keyword is available only if the VoIP dial peer is configured for SIP.

Command Default

DTMF tones are disabled and sent in-band. That is, they are left in the audio stream.

Command Modes

Dial peer voice configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on the Cisco AS5300.
12.0(2)XH	The **cisco-rtp**, **h245-alphanumeric**, and **h245-signal** keywords were added.
12.0(5)T	This command was integrated into Cisco IOS Release 12.0(5)T.
12.0(7)XK	This command was first supported for VoIP on the MC3810.
12.1(2)T	Changes made in Cisco IOS Release 12.0(7)XK were integrated into Cisco IOS Release 12.1(2)T.
12.2(8)T	This command was implemented on the Cisco 1751, Cisco 2600 series and Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 was not included in this release.

Release	Modification
12.2(2)XB1	This command was implemented on the Cisco AS5850 platform.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.2(15)ZJ	The **sip-notify** keyword was added.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(11)T	The **digit-drop** keyword was added.

Usage Guidelines

DTMF is the tone generated when you press a button on a touch-tone phone. This tone is compressed at one end of a call; when the tone is decompressed at the other end, it can become distorted, depending on the codec used. The DTMF relay feature transports DTMF tones generated after call establishment out-of-band using either a standard H.323 out-of-band method or a proprietary RTP-based mechanism. For SIP calls, the most appropriate method to transport DTMF tones is RTP-NTE or SIP-NOTIFY.

This command specifies how an H.323 or SIP gateway relays DTMF tones between telephony interfaces and an IP network.

You must include one or more keywords when using this command.

To avoid sending both in-band and out-of band tones to the outgoing leg when sending IP-to-IP gateway calls in-band (rtp-nte) to out-of band (h245-alphanumeric), configure the **dtmf-relay** command using the **rtp-nte** and **digit-drop** keywords on the incoming SIP dial peer. On the H.323 side, and for H.323 to SIP calls, configure this command using either the **h245-alphanumeric** or **h245-signal** keyword.

The SIP-NOTIFY method sends NOTIFY messages bidirectionally between the originating and terminating gateways for a DTMF event during a call. If multiple DTMF relay mechanisms are enabled on a SIP dial peer and are negotiated successfully, the SIP-NOTIFY method takes precedence.

SIP NOTIFY messages are advertised in an invite message to the remote end only if the **dtmf-relay** command is set.

For SIP, the gateway chooses the format according to the following priority:

1. sip-notify (highest priority)
2. rtp-nte
3. None—DTMF sent in-band

The gateway sends DTMF tones only in the format that you specify if the remote device supports it. If the H.323 remote device supports multiple formats, the gateway chooses the format according to the following priority:

1. cisco-rtp (highest priority)
2. h245-signal
3. h245-alphanumeric
4. rtp-nte
5. None—DTMF sent in-band

The principal advantage of the **dtmf-relay** command is that it sends DTMF tones with greater fidelity than is possible in-band for most low-bandwidth codecs, such as G.729 and G.723. Without the use of DTMF relay, calls established with low-bandwidth codecs may have trouble accessing automated DTMF-based systems, such as voice mail, menu-based Automatic Call Distributor (ACD) systems, and automated banking systems.

Note

- The **cisco-rtp** keyword supports a proprietary Cisco implementation and operates only between two Cisco 2600 series or Cisco 3600 series routers running Cisco IOS Release 12.0(2)XH or later. Otherwise, the DTMF relay feature does not function, and the gateway sends DTMF tones in-band.
- The **cisco-rtp** keyword is supported on Cisco 7200 series routers.
- The **sip-notify** keyword is available only if the VoIP dial peer is configured for SIP.
- The **digit-drop** keyword is available only when the **rtp-nte** keyword is configured.

Examples

The following example configures DTMF relay with the **cisco-rtp** keyword when DTMF tones are sent to dial peer 103:

```
dial-peer voice 103 voip
 dtmf-relay cisco-rtp
```

The following example configures DTMF relay with the **cisco-rtp** and **h245-signal** keywords when DTMF tones are sent to dial peer 103:

```
dial-peer voice 103 voip
 dtmf-relay cisco-rtp h245-signal
```

The following example configures the gateway to send DTMF in-band (the default) when DTMF tones to are sent dial peer 103:

```
dial-peer voice 103 voip
 no dtmf-relay
```

The following example configures DTMF relay with the **digit-drop** keyword to avoid both in-band and out-of band tones being sent to the outgoing leg on H.323 to H.323 or H.323 to SIP calls:

```
dial-peer voice 1 voip
 session protocol sipv2
 dtmf-relay h245-alphanumeric rtp-nte digit-drop
```

The following example configures DTMF relay with the **rtp-nte** keyword when DTMF tones are sent to dial peer 103:

```
dial-peer voice 103 voip
 dtmf-relay rtp-nte
```

The following example configures the gateway to send DTMF tones using SIP NOTIFY messages to dial peer 103:

```
dial-peer voice 103 voip
 session protocol sipv2
 dtmf-relay sip-notify
```

Related Commands

Command	Description
notify telephone-event	Configures the maximum interval between two consecutive NOTIFY messages for a particular telephone event.

dualtone

To enter cp-dualtone configuration mode for specifying a custom call-progress tone, use the **dualtone** command in custom-cptone voice-class configuration mode. To configure the custom-cptone voice class not to detect a call-progress tone, use the **no** form of this command.

dualtone {**busy** | **conference** | **disconnect** | **number-unobtainable** | **out-of-service** | **reorder** | **ringback**}

no dualtone {**busy** | **conference** | **disconnect** | **number-unobtainable** | **out-of-service** | **reorder** | **ringback**}

Syntax Description

busy	Configure busy tone.
conference	Configure conference join and leave tones.
disconnect	Configure disconnect tone.
number-unobtainable	Configure number-unavailable tone.
out-of-service	Configure out-of-service tone.
reorder	Configure reorder tone.
ringback	Configure ringback tone.

Command Default

No call-progress tones are defined within the custom-cptone voice class

Command Modes

Custom-cptone voice-class configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced on the Cisco 2600 and Cisco 3600 series and on the Cisco MC3810.
12.2(2)T	This command was implemented on the Cisco 1750 router and integrated into Cisco IOS Release 12.2(2)T.
12.4(11)XJ2	The **conference** keyword was added.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

The **dualtone** command enters cp-dualtone configuration mode and specifies a call-progress tone to be detected. You can specify additional call-progress tones without exiting cp-dualtone configuration mode.

Any call-progress tones that are not specified are not detected.

To delete a call-progress tone from this custom-cptone voice class, use the **no** form of this command and the keyword for the tone that should not be detected; for example, **no dualtone busy**.

You must associate the class of custom call-progress tones with a voice port for this command to affect tone detection.

Use the **dualtone conference** command to define custom join and leave tones for hardware conferences.

Examples

The following example enters cp-dualtone configuration mode and specifies busy tone and ringback tone in the custom-cptone voice class country-x.

```
Router(config)# voice class custom-cptone country-x
Router(cfg-cptone)# dualtone busy
Router(cfg-cp-dualtone)# frequency 440 480
Router(cfg-cp-dualtone)# cadence 500 500
Router(cfg-cp-dualtone)# exit
Router(cfg-cptone)# dualtone ringback
Router(cfg-cp-dualtone)# frequency 400 440
Router(cfg-cp-dualtone)# cadence 2000 4000
```

The following example deletes ringback tone from the custom-cptone voice class country-x.

```
Router(config)# voice class custom-cptone country-x
Router(cfg-cptone)# no dualtone ringback
```

The following example configures a conference leave tone. The configured leave tone must be associated with a digital signal processor (DSP) farm profile.

```
Router(config)# voice class custom-cptone leavetone
Router(cfg-cptone)# dualtone conference
Router(cfg-cp-dualtone)# frequency 500 500
Router(cfg-cp-dualtone)# cadence 100 100 100 100 100
```

Related Commands

Command	Description
cadence	Defines the tone on and off durations for a call-progress tone.
conference-join custom-cptone	Defines a custom call-progress tone to indicate joining a conference.
conference-leave custom-cptone	Defines a custom call-progress tone to indicate leaving a conference.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
frequency	Defines the frequency components for a call-progress tone.
supervisory custom-cptone	Associates a class of custom call-progress tones with a voice port.
voice class custom-cptone	Creates a voice class for defining custom call-progress tones.

Cisco IOS Voice Commands: E

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Guide*.

e911

To enable E911 system services for SIP on the VoIP dial peer, use the **e911** command in voice service VoIP configuration mode. To disable SIP E911 functionality, use the **no** form of this command.

e911

no e911

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Voice service VoIP (dial peer) configuration mode.

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

The **no** form of the command disables E911 functionality from a global perspective. Output from the **show running-config** command shows whether E911 is configured. See also the **voice-class sip e911** and **debug csm neat** commands.

Examples

The following example enables E911 services in voice service VoIP SIP configuration mode:

```
Router# configure terminal
Router(config-term)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# e911
```

The following example disables E911 functionality:

```
Router(conf-serv-sip)# no e911
```

Related Commands

Command	Description
debug csm neat	Turns on debugging for all Call Switching Module (CSM) Voice over IP (VoIP) calls.
show running-config	Displays the current configuration information.
voice-class sip e911	Configures e911 services on the voice dial peer.

early-offer

To force a Cisco Unified Border Element (Cisco UBE) to send a SIP invite with Early-Offer (EO) on the Out-Leg (OL), use the **early-offer** command in SIP or dial peer configuration mode. To disable Early-Offer, use the **no** form of this command.

early-offer forced

no early-offer forced

Syntax Description

forced	Forcefully sends Early-Offer on the SIP Out-Leg.

Command Default

Disabled. The Cisco UBE does not distinguish SIP Delayed-Offer to Early-Offer call flows.

Command Modes

SIP configuration (conf-serv-sip)
Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use this command to forcefully configure a Cisco UBE to send a SIP invite with EO on the Out-Leg (OL), Delayed-Offer to Early-Offer for all VoIP calls, SIP audio calls, or individual dial peers.

Examples

The following example shows SIP Early-Offer invites being configured globally:

```
Router(conf-serv-sip)# early-offer forced
```

The following example shows SIP Early-Offer invites being configured per dial peer:

```
Router(config-dial-peer)# voice-class sip early-offer forced
```

echo-cancel comfort-noise

To specify that background noise be generated, use the **echo-cancel comfort-noise** command in controller configuration mode. To disable this feature, use the **no** form of this command.

echo-cancel comfort-noise

no echo-cancel comfort-noise

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Controller configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines Use the **echo-cancel comfort-noise** command to generate background noise to fill silent gaps during calls if voice activated dialing (VAD) is activated. If comfort noise is not enabled and VAD is enabled at the remote end of the connection, the user hears nothing or silence when the remote party is not speaking.

The configuration of comfort noise affects only the silence generated at the local interface; it does not affect the use of VAD on either end of the connection or the silence generated at the remote end of the connection.

For the OC-3/STM-1 ATM Circuit Emulation Service network module, echo cancellation must be enabled.

Examples The following example enables comfort noise on a T1 controller:

```
controller T1 0/0
 echo-cancel enable
 echo-cancel comfort-noise
```

Related Commands

Command	Description
echo-cancel enable (controller)	Enables echo cancellation on a voice port.
voice port	Specifies which port is used for voice traffic.

echo-cancel compensation

To set attenuation for loud signals, use the **echo-cancel compensation** command in controller configuration mode. To disable this feature, use the **no** form of this command.

echo-cancel compensation

no echo-cancel compensation

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Controller configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines Use the **echo-cancel compensation** command to add attenuation control to the T1 or E1 controller. When this command is enabled, 6 decibels of attenuation are inserted if the signal level from the receive direction is loud. When loud signals are not received, the attenuation is removed.

For the OC-3/STM-1 ATM Circuit Emulation Service network module, echo cancellation must be enabled.

Examples The following example enables attenuation control on a T1 controller:

```
controller T1 0/0
 echo-cancel enable
 echo-cancel compensation
```

Related Commands

Command	Description
echo-cancel enable (controller)	Enables echo cancellation on a voice port.
voice port	Specifies which port is used for voice traffic.

echo-cancel coverage

To adjust the size of the echo canceller (EC) and to select the extended EC when the Cisco default EC is present, use the **echo-cancel coverage** command in voice-port configuration mode. To reset this command to the default value (64 ms), use the **no** form of this command.

echo-cancel coverage {**8** | **16** | **24** | **32** | **48** | **64**}

no echo-cancel coverage

Syntax Description

8	EC size of 8 ms.
16	EC size of 16 ms.
24	EC size of 24 ms.
32	EC size of 32 ms.
48	EC size of 48 ms.
64	EC size of 64 ms. This is the default.

Command Default 64 ms

Command Modes Voice-port configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3(1)MA	This command was implemented on the Cisco MC3810.
12.0(5)XK	The command was modified to add the 8-ms option.
12.0(5)XE	The command was implemented on the Cisco 7200 series.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(13)T	This command was modified to provide a new set of size options when the extended EC is configured. This command is supported on all T1 Digital Signal Processor (DSP) platforms.
12.3(11)T	This command was modified for use on NextPort platforms for use with the dual-filter G.168 echo canceller.

Usage Guidelines Use the **echo-cancel coverage** command to adjust the coverage size of the EC. This command enables cancellation of voice that is sent out the interface and received on the same interface within the configured amount of time. If the local loop (the distance from the interface to the connected equipment that is producing the echo) is greater than this amount of time, the configured value of this command should be increased.

If you configure a greater value for this command, the EC takes longer to converge. In this case, you might hear a slight echo when the connection is initially set up. If the configured value for this command is too short, you might hear some echo for the duration of the call because the EC is not canceling the longer delay echoes.

There is no echo or echo cancellation on the network side (for example, the non-POTS side) of the connection.

Note This command is valid only if the echo cancellation feature has been enabled. For more information, see the **echo-cancel enable** command.

The NextPort dual-filter G.168 echo canceller feature supports echo tails from 8 to 64 ms in 8-ms increments. Use the **echo-cancel coverage** command to limit the echo canceller coverage to 64 ms on NextPort platforms. Tail length values greater than 64 ms are not accepted with the NextPort dual-filter G.168 echo canceller feature. For more information about the NextPort dual0filter G.168 echo canceller, see *NextPort Voice Tuning and Background Noise Statistics with NextPort Dual-Filter G.168 Echo Cancellation*.

Examples

The following example enables the extended echo cancellation feature and adjusts the size of the echo canceller to 16 milliseconds:

```
Router (config-voiceport)# echo-cancel coverage 16
```

Related Commands

Command	Description
echo-cancel enable (controller)	Enables echo cancellation on a controller.
echo-cancel enable	Enables echo cancellation on a voice port.

echo-cancel enable

To enable the cancellation of voice that is sent out the interface and received back on the same interface, use the **echo-cancel enable** command in voice-port configuration mode or global configuration mode. To disable echo cancellation, use the **no** form of this command.

echo-cancel enable type [**hardware** | **software**]

no echo-cancel enable

Syntax Description

hardware	(Optional) Specifies that echo cancellation is enabled via the hardware on the network module.
software	(Optional) Specifies that echo cancellation is enabled via command-line interface entries.

Note The **hardware** and **software** keywords are available only when the optional hardware echo cancellation module is installed on the multiflex VWIC.

Command Default

The Cisco-proprietary G.168 echo canceller (EC) is enabled with the echo suppressor turned off.

Command Modes

Voice-port configuration
Global configuration

Command History

Release	Modification
11.3(1)T	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T. This command is supported on all TI Digital Signal Processor (DSP) platforms.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T and the optional **hardware** and **software** keywords were added.

Usage Guidelines

The **echo-cancel enable** command enables cancellation of voice that is sent out the interface and received back on the same interface; sound that is received back in this manner is perceived by the listener as an echo. Disabling echo cancellation might cause the remote side of a connection to hear an echo. Because echo cancellation is an invasive process that can minimally degrade voice quality, this command should be disabled if it is not needed.

Typically a hybrid circuit can provide greater than 6 decibels (dB) echo return loss (ERL), so the extended EC is configured to handle 6 dB worst case by default. However, if a measurement shows that a circuit can provide only 6 dB ERL or less, the extended EC can be configured to use this lower rate.

The Cisco G.168 EC is enabled by default with the echo suppressor turned off. The echo suppressor can be turned on only when the default Cisco G.168 EC is used. The **echo-cancel suppressor** command used with the Cisco default EC is still visible when the extended EC is selected, but it does not do anything.

The **echo-cancel enable** command does not affect the echo heard by the user on the analog side of the connection.

There is no echo path for a 4-wire recEive and transMit interface (also called ear and mouth and abbreviated as E&M). The echo canceller should be disabled for that interface type.

Note This command is valid only when the **echo-cancel coverage** command has been configured.

Examples

The following example enables the extended echo cancellation feature in voice-port configuration mode:

```
Router (config-voiceport)# echo-cancel enable
```

The following example enables the extended echo cancellation feature on the Cisco 1700 series or Cisco ICS7750 in global configuration mode:

```
Router (config)# echo-cancel enable
```

Related Commands

Command	Description
echo-cancel coverage	Specifies the amount of coverage for echo cancellation.
echo-cancel enable (controller)	Enables echo cancellation on a controller.
echo-cancel suppressor	Enables echo suppression to reduce initial echo before the echo canceller converges.
non-linear	Enables nonlinear processing in the echo canceler.

echo-cancel enable (controller)

To enable the echo cancel feature, use the **echo-cancel enable** command in controller configuration mode. To disable this feature, use the **no** form of this command.

echo-cancel enable

no echo-cancel enable

Syntax Description This command has no arguments or keywords.

Command Default Enabled for all interface types

Command Modes Controller configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines The **echo-cancel enable** command enables cancellation of voice that is sent out of the interface and received back on the same interface. Disabling echo cancellation might cause the remote side of a connection to hear an echo. Because echo cancellation is an invasive process that can minimally degrade voice quality, this command should be disabled if it is not needed.

The **echo-cancel enable** command does not affect the echo heard by the user on the analog side of the connection.

Note This command is valid only if the **echo-cancel coverage** command has been configured.

The following example enables the echo cancel feature on a T1 controller:

```
controller T1 0/0
 echo-cancel enable
 echo-cancel coverage 32
```

Related Commands

Command	Description
echo-cancel coverage	Specifies the amount of coverage for echo cancellation.
echo-cancel enable	Enables echo cancellation on a voice port.
non-linear	Enables nonlinear processing in the echo canceler.
voice port	Configures the voice port.

echo-cancel erl worst-case

To determine worst-case Echo Return Loss (ERL) in decibels (dB), use the **echo-cancel erl worst-case** command in voice-port configuration mode. To disable the command, use the **no** form.

echo-cancel erl worst-case {**6** | **3** | **0**}

no echo-cancel erl worst-case {**6** | **3** | **0**}

Syntax Description

6 | **3** | **0**	Values of 6, 3, or 0 dB ERL in the extended echo canceller (EC). The default is 6.

Command Default Enabled at 6 dB when the extended G.168 EC is used

Command Modes Voice-port configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines This command is used only when the extended EC is present and is not supported with the Cisco proprietary-G.165 EC. This command predicts the worst-case ERL that the EC might encounter.

Examples The following example shows a worst-case ERL of 3:

```
Router(config-voiceport)# echo-cancel erl worst-case 3
```

To check the configuration, enter the **show voice port** command in privileged EXEC mode:

```
Router# show voice port
.
.
Echo Cancel worst case ERL is set to 6 dB
Playout-delay Mode is set to adaptive
.
.
```

Related Commands

Command	Description
echo-cancel enable	Enables the cancellation of voice that is sent out and received on the same interface.

echo-cancel loopback

To place the echo cancellation processor in loopback mode, use the **echo-cancel loopback** command in controller configuration mode. To disable loopback of the echo cancellation processor, use the **no** form of this command.

echo-cancel loopback

no echo-cancel loopback

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Controller configuration

Command History

Release	Modification
12.1(2)T	This command was introduced.

Usage Guidelines Use an **echo-cancel loopback** test on lines to detect and distinguish equipment malfunctions caused by either the line or the interface. If correct echo cancellation is not possible when an interface is in loopback mode, the interface is the source of the problem.

Examples The following example sets up echo cancellation loopback diagnostics:

```
controller T1 0/0
 echo-cancel enable
 echo-cancel coverage 32
 echo-cancel loopback
```

Related Commands

Command	Description
echo-cancel enable (controller)	Enables echo cancellation on a controller.

echo-cancel mode

To enable echo cancel mode on the extended G.168 echo canceller, use the **echo-cancel mode** command in voice-port configuration mode. To reset to the default, use the **no** form of this command.

echo-cancel mode {**1** | **2**}

no echo-cancel mode

Syntax Description

1	Enables fast convergence for multiple echo reflectors and applies 0 dB Sin gain and 0 dB Sout gain.
2	Enables fast convergence for multiple echo reflectors and improves double-talk detection by applying 6 dB Sin gain and -6 dB Sout gain.

Command Default Disabled

Command Modes Voice-port configuration

Command History

Release	Modification
12.3(7)	This command was introduced.

Usage Guidelines This command enables an operation mode to improve echo canceller (EC) performance in systems that have multiple echo reflectors and double-talk caused by low volume. When this command is enabled, the extended EC cancels the echo better in multiple echo reflector scenarios, which occur most often in analog interfaces.

Note

- This command is available only if the extended G.168 echo canceller is enabled for the voice port.
- If you select mode **2**, set the **echo-cancel erl worst-case** command to 0.

Examples The following example sets the extended G.168 EC mode to 1 on a Cisco 1700 series router:

```
Router(config)# voice-port 1/0/1
Router(config-voiceport)# echo-cancel mode 1
```

Related Commands

Command	Description
echo-cancel coverage	Adjusts the size of the echo canceller.
echo-cancel enable	Enables echo cancellation for voice that is sent and received on the same interface.
echo-cancel erl worst-case	Determines worst-case Echo Return Loss (ERL).

echo-cancel suppressor

To enable echo suppression to reduce initial echo before the echo canceller converges, use the **echo-cancel suppressor** command in voice-port configuration mode. To disable echo suppression, use the **no** form of this command.

echo-cancel s uppressor *seconds*

no echo-cancel suppressor

Syntax Description

seconds	Suppressor coverage, in seconds. Range is from 1 to 10. Default is 7.

Command Default Disabled

Command Modes Voice-port configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines This command is used only when the echo canceller is enabled. In case of double-talk in the first number of seconds, the code automatically disables the suppressor.

Examples The following example shows echo suppression configured for a suppression coverage of 9 seconds:

```
Router(config-voiceport)# echo-cancel suppressor 9
```

Related Commands

Command	Description
echo-cancel enable	Enables the cancellation of voice that is sent out and received on the same interface.

element

To define component elements of local or remote clusters, use the **element** command in gatekeeper configuration mode. To disable component elements of local or remote clusters, use the **no** form of this command.

element *gatekeeper-name ip-address* [*port*]

no element *gatekeeper-name ip-address* [*port*]

Syntax Description

gatekeeper-name	Name of the gatekeeper component to be added to the local or remote cluster.
ip-address	IP address of the gatekeeper to be added to the local or remote cluster.
port	(Optional) Registration, Admission, and Status (RAS) signaling port number for the remote zone. Range is from 1 to 65535. Default is the well-known RAS port number 1719.

Command Default No default behavior or values

Command Modes Gatekeeper configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Examples The following example places the GenevaGK gatekeeper into the specified local or remote cluster:

```
element GenevaGK 172.16.204.158 1719
```

Related Commands

Command	Description
zone cluster local	Defines a local grouping of gatekeepers, including the gatekeeper that you are configuring.
zone cluster remote	Defines a remote grouping of gatekeepers, including the gatekeeper that you are configuring.

emptycapability

To eliminate the need for identical codec capabilities for all dial peers in the rotary group, use the **emptycapability** command in h.323 voice-service configuration mode. To return to the default configuration, use the **no** form of this command.

emptycapability

no emptycapability

Syntax Description

There are no keywords or arguments for this command.

Command Default

Identical codec capabilities are required on all dial peers.

Command Modes

H.323 voice-service configuration mode

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

The default dial-peer configuration requires that all members of a hunt group must have the same codec configured to complete calls. Configuring **emptycapability** on the IP-to-IP gateway (IPIPGW) eliminates the need for identical codec capabilities for all dial peers in the rotary group, and allows the IPIPGW to restart the codec negotiation end-to-end.

Note If extended caps (DTMF or T.38) are configured on the outgoing gateway or the trunking gateway, extended caps must be configured in both places.

Examples

The following example shows emptycapability being configured to allow the IPIPGW to restart codec negotiation from end-to-end regardless of codec configured on each endpoint:

```
Router(conf-serv-h323)# emptycapability
```

Related Commands

Command	Description
h323	Enters H.323 voice service configuration mode.

emulate cisco h323 bandwidth

To instruct the H.323 gateway to use H.323 version 2 behavior for bandwidth management, use the **emulate cisco h323 bandwidth** command in gateway configuration mode. To instruct the gateway to use H.323 version 3 behavior for bandwidth management, use the **no** form of the command.

emulate cisco h323 bandwidth

no emulate cisco h323 bandwidth

Syntax Description

This command has no keywords or arguments.

Command Default

No default behaviors or values

Command Modes

Gateway configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

Prior to Cisco IOS Release 12.2(2)XA, gateway calls were always reported to require a bandwidth of 64 kbps, the unidirectional bandwidth for a Cisco G.711 codec. If the endpoints in the call chose to use a more efficient codec, this was not reported to the Cisco gatekeeper.

In the version of the Cisco H.323 gateway in Cisco IOS Release 12.2(2)XA or later (which conforms with H.323 version 3), the reported bandwidth is bidirectional. Initially, 128 kbps is reserved. If the endpoints in the call select a more efficient codec, the Cisco gatekeeper is notified of the bandwidth change.

For backward compatibility, the **emulate cisco h323 bandwidth** command allows devices running Cisco IOS Release 12.2(2)XA and later to conform to the H.323 version 2 bandwidth reporting implementation.

Examples

The following example shows that the router emulates the behavior of a Cisco H.323 Version 2 gateway.

```
Router(config-gateway)# emulate cisco h323 bandwidth
```

Related Commands

Command	Description
bandwidth	Specifies the maximum aggregate bandwidth for H.323 traffic from a zone to another zone, within a zone, or for a session in a zone.
bandwidth remote	Specifies the total bandwidth for H.323 traffic between this gatekeeper and any other gatekeeper.
gateway	Enables gateway configuration commands.

encap clear-channel standard

To globally enable RFC 4040-based clear-channel codec negotiation for Session Initiation Protocol (SIP) calls on a Cisco IOS voice gateway or Cisco Unified Border Element (Cisco UBE), use the **encap clear-channel standard** command in voice service SIP configuration mode. To disable RFC 4040-based clear-channel codec negotiation for SIP calls globally on a Cisco IOS voice gateway or Cisco UBE, use the **no** form of this command.

encap clear-channel standard

no encap clear-channel standard

Syntax Description

standard	Specifies standard RFC 4040 encapsulation.

Command Default

Disabled—legacy encapsulation [X-CCD/8000] is used for clear-channel codec negotiation.

Command Modes

Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
15.0(1)XA	This command was introduced.
15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.

Usage Guidelines

Use the **encap clear-channel standard** command in voice service SIP configuration mode to globally enable RFC 4040-based clear-channel codec negotiation [CLEARMODE/8000] for SIP calls on a Cisco IOS voice gateway or Cisco UBE. RFC 4040-based clear-channel codec negotiation allows Cisco IOS voice gateways and Cisco UBEs to successfully interoperate with third-party SIP gateways that do not support legacy Cisco IOS clear-channel codec encapsulation [X-CCD/8000].

When the **encap clear-channel standard** command is enabled on a Cisco IOS voice gateway or Cisco UBE, calls using the Cisco IOS clear channel codec are translated into calls that use CLEARMODE/8000 so that the calls do not get rejected when they reach third-party SIP gateways.

To enable RFC 4040-based clear-channel codec negotiation for SIP calls on an individual dial peer, overriding the global configuration for the Cisco IOS voice gateway or Cisco UBE, use the **voice-class sip encap clear-channel standard** command in dial peer voice configuration mode. To globally disable RFC 4040-based clear-channel codec negotiation on a Cisco IOS voice gateway or Cisco UBE, use the **no encap clear-channel standard** command in voice service SIP configuration mode.

Examples

The following example shows how to enable RFC 4040-based clear-channel code negotiation globally for all dial peers on a Cisco IOS voice gateway or Cisco UBE:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# encap clear-channel standard
```

Related Commands

Command	Description
voice-class sip encap clear-channel	Enables RFC 4040-based clear-channel codec negotiation for SIP calls on an individual dial peer on a Cisco IOS voice gateway or Cisco UBE.

encapsulation atm-ces

To enable circuit emulation service (CES) ATM encapsulation, use the **encapsulation atm-ces** command in interface configuration mode. To disable CES ATM encapsulation, use the **no** form of this command.

encapsulation atm-ces

no encapsulation atm-ces

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Interface configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0	This command was integrated into Cisco IOS Release 12.0.

Usage Guidelines This command is supported only on serial ports 0 and 1.

Examples The following example enables CES ATM encapsulation on serial port 0:

```
interface serial 0
 encapsulation atm-ces
```

Related Commands

Command	Description
ces cell-loss-integration-period	Sets the CES cell-loss integration period.
ces clockmode synchronous	Configures the ATM CES synchronous clock mode.
ces connect	Maps the CES service to an ATM PVC.
ces initial-delay	Configures the size of the receive buffer of a CES circuit.
ces max-buf-size	Configures the send buffer of a CES circuit.
ces partial-fill	Configures the number of user octets per cell for the ATM CES.
ces service	Configures the ATM CES type.

encoding h450 call-identity

To set the Abstract Syntax Notation (ASN) Packed Encoding Rules (PER) format used for encoding and decoding the H.450 protocol data units (PDUs), use the **encoding h450 call-identity** command in voice-class configuration mode. To reset to the default, use the **no** form of this command.

encoding h450 call-identity{**cisco** | **itu**}

no encoding h450 call-identity

Syntax Description

cisco	Gateway uses a PER encoding format that is not compliant with ITU X.691 for encoding or decoding the H.450.2 callIdentity field.
itu	Gateway uses a PER encoding format that is compliant with ITU X.691 for encoding or decoding the H.450.2 callIdentity field.

Command Default Cisco encoding is enabled at the global (voice-service configuration) level.

Command Modes Voice-class configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.
12.3(7)T3	This command was integrated into Cisco IOS release 12.3(7)T3.

Usage Guidelines Use this command to set the encoding format in the voice-class assigned to individual dial peers. By default, Cisco encoding is enabled globally. However, Cisco encoding for the H.450.2 callIdentity field is not compliant with ITU X.691 and can cause interoperability problems with third-party devices during H.450.2 call transfer with consultation. Use the **itu** keyword to configure ITU X.691 encoding in the dial peer.

Note This command takes precedence over the **encoding h450 call-identity itu** command in voice-service configuration mode.

Examples The following example enables X.691-compliant encoding for the H.450-2 PDUs for calls on dial-peer 4:

```
voice class h323 1
 encoding h450 call-identity itu

dial-peer voice 4 voip
 voice-class h323 1
```

The following example enables Cisco encoding, which is not compliant with ITU X.691, on dial-peer 5:

```
voice class h323 1
 encoding h450 call-identity cisco

dial-peer voice 5 voip
 voice-class h323 1
```

By entering the **no encoding h450 call-identity** command under the voice-class configuration mode, the following example sets the encoding for calls only on dial-peer 7 to reset to the global configuration. However, the **no encoding h450 call-identity** configuration is not displayed in the running configuration:

```
voice class h323 1
 no encoding h450 call-identity

dial-peer voice 7 voip
 voice-class h323 1
```

The following example illustrates a typical use case when the ITU encoding is configured for all the dial peers except dial-peer 4; dial-peer 4 uses Cisco encoding:

```
voice service voip
 h323
  encoding h450 call-identity itu

voice class h323 1
   encoding h450 call-identity cisco

dial-peer voice 1 voip
 destination-pattern 1..

dial-peer voice 2 voip
 destination-pattern 2..

dial-peer voice 3 voip
 destination-pattern 3..

dial-peer voice 4 voip
 destination-pattern 4..
 voice-class h323 1
```

Related Commands

Command	Description
encoding h450 call-identity itu	Sets the Abstract Syntax Notation (ASN) Packed Encoding Rules (PER) format used for encoding and decoding the H.450 protocol data units (PDUs).
voice class h323	Enters voice-class configuration mode and creates a voice class for H.323 attributes.

encoding h450 call-identity itu

To set the Abstract Syntax Notation (ASN) Packed Encoding Rules (PER) format used for encoding and decoding the H.450 protocol data units (PDUs), use the **encoding h450 call-identity itu** command in voice-service configuration mode. To reset to the default, use the **no** form of this command.

encoding h450 call-identity itu

no encoding h450 call-identity

Syntax Description

This command has no argument or keywords.

Command Default

Cisco encoding enabled globally

Command Modes

Voice-service configuration

Command History

Release	Modification
12.3(11)T	This command was introduced on Cisco voice gateways.
12.3(7)T3	This command was integrated into Cisco IOS release 12.3(7)T3.

Usage Guidelines

Use this command to set ITU X.691 encoding globally on the Cisco voice gateway. By default, Cisco encoding is enabled. However, Cisco encoding for the H.450.2 callIdentity field is not compliant with ITU X.691 and could cause interoperability problems with third-party devices during H.450.2 call transfer with consultation.

Note The **encoding h450 call-identity** command in voice-class configuration mode takes precedence over this command.

Examples

The following example globally configures all dial-peers with the ITU X.691:

```
voice service voip
 h323
 encoding h450 call-identity itu
```

Related Commands

Command	Description
encoding h45 call-identity	Sets the Abstract Syntax Notation (ASN) Packed Encoding Rules (PER) format used for encoding and decoding the H.450 protocol data units (PDUs).
voice service voip	Enters voice-service configuration mode.

encryption

To set the algorithm to be negotiated with the provider, use the **encryption** command in settlement configuration mode. To reset to the default encryption method, use the **no** form of this command.

encryption {**des-cbc-sha** | **des40-cbc-sha** | **dh-des-cbc-sha** | **dh-des40-cbc-sha** | **null-md5** | **null-sha** | **all**}

no encryption {**des-cbc-sha** | **des40-cbc-sha** | **dh-des-cbc-sha** | **dh-des40-cbc-sha** | **null-md5** | **null-sha** | **all**}

Syntax Description

des-cbc-sha	Encryption type ssl_rsa_with_des_cbc_sha cipher suite.
des40-cbc-sha	Encryption type ssl_rsa_export_with_des40_cbc_sha cipher suite.
dh-des-cbc-sha	Encryption type ssl_dh_rsa_with_des_cbc_sha cipher suite.
dh-des40-cbc-sha	Encryption type ssl_dh_rsa_export_with_des40_cbc_sha cipher suite.
null-md5	Encryption type ssl_rsa_with_null_md5 cipher suite.
null-sha	Encryption type ssl_rsa_with_null_sha cipher suite.
all	All encryption methods are used in the Secure Socket Layer (SSL).

Command Default

The default encryption method is **all**. If none of the encryption methods is configured, the system uses all of the encryption methods in the SSL session negotiation.

Command Modes

Settlement configuration

Command History

Release	Modification
12.0(4)XH1	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Usage Guidelines

For Cisco IOS Release 12.0(4)XH1, only one encryption method is allowed for each provider.

Examples

The following example sets the algorithm to be negotiated with the provider, using the **encryption** command:

```
settlement 0
     encryption des-cbc-sha
```

Related Commands

Command	Description
connection-timeout	Sets the connection timeout.
customer-id	Sets the customer identification.

Command	Description
device-id	Sets the device identification.
max-connection	Sets the maximum number of simultaneous connections.
response-timeout	Sets the response timeout.
retry-delay	Sets the retry delay.
retry-limit	Sets the connection retry limit.
session-timeout	Sets the session timeout.
settlement	Enters settlement configuration mode.
show settlement	Displays the configuration for all settlement server transactions.
shutdown	Disables the settlement provider.
type	Specifies the provider type.
url	Specifies the ISP address.

endpoint alt-ep collect

To configure the collection of alternate routes to endpoints, use the **endpoint alt-ep collect** command in gatekeeper configuration mode. To disable alternate route collection, use the **no** form of this command.

endpoint alt-ep collect *value* [**distribute**]

no endpoint alt-ep collect

Syntax Description

value	Number of alternate routes to endpoints for the gatekeeper to collect before ending the collection process and sending the Location Confirmation (LCF) message to the requesting endpoint. Range for the *value* argument is from 1 to 20. The default is 0, which indicates that alternate route collection is not enabled.
distribute	(Optional) Causes the gatekeeper to include alternate routes from as many LCF messages as possible in the consolidated list. Use of this keyword allows the gatekeeper to give fairness to the information of alternate routes present in various LCF messages. **Note** Identical alternate endpoints are removed from the list. That is, if an alternate endpoint received in an LCF message has an identical IP address or trunk group label or carrier ID as any alternate endpoints received in previous LCF messages, the previous duplicate alternate endpoints are removed from the consolidated list.

Command Default

The default value for the *value* argument is 0, which indicates that alternate route collection is not enabled.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(8)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	Duplicate alternate endpoints received in an LCF message were removed from the consolidated list of endpoints. This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.

Usage Guidelines

Use this command to force the gatekeeper to collect a specified number of alternate routes to endpoints and to create a consolidated list of those alternate routes to report back to the requesting endpoint.

Examples

The following example shows that 15 alternate routes to endpoints should be collected:

```
Router(config-gk)# endpoint alt-ep collect 15
```

Related Commands

Command	Description
endpoint alt-ep h323id	Configures an alternate endpoint on a gatekeeper, including endpoint ID, IP address, port, and trunk group label or carrier-ID information.
show gatekeeper endpoints alternates	Displays information about alternate endpoints.

endpoint alt-ep h323id

To configure alternate endpoints, use the **endpoint alt-ep h323id command in** gatekeeper configuration mode. To disable alternate endpoints, use the **no** form of this command.

endpoint alt-ep h323id *h323-id ip-address* [*port-number*] [**carrier-id** *carrier-name*]

no endpoint alt-ep h323id

Syntax Description

h323-id	H.323 name (ID) of the endpoint for which an alternate address is being supplied. This ID is used by a gateway when the gateway communicates with the gatekeeper. Usually, this H.323 ID is the name given to the gateway, with the gatekeeper domain name appended to the end.
ip-address	IP address of an alternate for this endpoint.
port-number	(Optional) Port number associated with the address of the alternate. Default is 1720.
carrier-id *carrier-name*	(Optional) Trunk group label or carrier ID of the alternate endpoint. It may be added in addition to the IP address of the alternate endpoint. The *carrier-name* argument is the name of the trunk group label or circuit ID.

Command Default

The default port number is 1720.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and the **carrier-id** keyword and *carrier-name* argument were added.

Usage Guidelines

This command defines the IP address for an alternate endpoint for the primary endpoint identified by its H.323 ID. The IP address is returned in the alternate endpoint field whenever the primary endpoint is returned in an Admission Confirmation (ACF) or Location Confirmation (LCF) message. The alternate endpoint provides an alternate address to which a call can be placed if a call to the primary endpoint fails.

This command provides a failover mechanism if a gateway becomes disabled for a period of time before the gatekeeper becomes aware of the problem. After receiving an ACF message from the gatekeeper with an alternate endpoint list, the Cisco gateway may attempt to use an alternate address if a SETUP message results in no reply from the destination. This command causes the alternate endpoints specified in the *h323-id* argument to be sent in all subsequent ACF and LCF messages. Gatekeepers that support the **endpoint alt-ep h323id** command can also send alternate endpoint information in Registration, Admissions, and Status (RAS) messages. The gatekeeper accepts IP, port call signal address, and trunk

group ID and carrier ID information in endpoint Registration Request (RRQ) messages. The gatekeeper list of alternates for a given endpoint includes the configured alternates and the alternates received in RRQ messages from that endpoint and any alternate endpoints received in incoming RAS LCF messages.

Examples

The following example shows that the endpoint at 172.16.53.15 1719 has been configured as an alternate for "GW10". There are no carrier IDs:

```
endpoint alt-ep h323id GW10 172.16.53.15 1719
```

The following example shows that an alternate endpoint list with different carrier IDs (CARRIER_ABC, CARRIER_DEF, and CARRIER_GHI) has been configured for "gwid":

```
endpoint alt-ep h323id gwid 1.1.1.1 carrier-id CARRIER_ABC
endpoint alt-ep h323id gwid 2.2.2.2 carrier-id CARRIER_DEF
endpoint alt-ep h323id gwid 1.1.1.1 carrier-id CARRIER_GHI
```

Related Commands

Command	Description
show gatekeeper endpoints	Displays information about alternate endpoints.

endpoint circuit-id h323id

To associate a circuit with a non-Cisco endpoint or on using a Cisco IOS Release older than that on the gatekeeper, use the **endpoint circuit-id h323id** command in gatekeeper configuration mode. To delete the association, use the **no** form of this command.

endpoint circuit-id h323id *endpoint-h323id circuit-id* [**max-calls** *number*]

no endpoint circuit-id h323id *endpoint-h323id descriptor* [**max-calls** *number*]

Syntax Description

endpoint-h323id	ID of the H.323 endpoint.
circuit-id	Circuit assigned to the H.323 endpoint.
max-calls *number*	(Optional) Maximum number of calls that this endpoint can handle. Range is from 1 to 10000. There is no default.

Command Default

No default behavior or values

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The **endpoint circuit-id h323id** command allows the gatekeeper and GKTMP server application to work with Cisco gateways that are running non-Cisco gateways or Cisco IOS versions that cannot identify incoming circuits. This command permits only one circuit to be associated with the endpoint.

Examples

The following example associates a non-Cisco endpoint **first** with a circuit **westcoast**, and assigns a maximum of 2750 calls to the endpoint:

```
Router(config)# gatekeeper
Router(config-gk)# endpoint circuit-id h323-id first westcoast maxcalls 2750
```

Related Commands

Command	Description
show gatekeeper endpoint circuits	Displays information about all registered endpoints for a gatekeeper.

endpoint max-calls h323id

To set the maximum number of calls that are allowed for an endpoint, use the **endpoint max-calls h323id** command in gatekeeper configuration mode. To disable the set number, use the **no** form of this command.

endpoint max-calls h323id *endpoint-h323id max-number*

no endpoint max-calls h323id

Syntax Description

endpoint-h323id	H.323 ID of the endpoint.
max-number	Maximum number of calls that the endpoint can handle. The range is from 1 to 100000.

Command Default

This command is not configured by default.

Command Modes

Gatekeeper configuration (config-gk)

Command History

Release	Modifications
12.3(1)	This command was introduced.
12.3(10)	This command was modified to reject the limit set by the endpoints.
12.3(14)T	This command was modified to reject the limit set by the endpoints.

Usage Guidelines

You must use the **endpoint resource-threshold** command and the **arq reject-resource-low** command to start resource monitoring on a gatekeeper before you can use this command. The **endpoint resource-threshold** command sets the call-capacity threshold of a gateway in the gatekeeper. The **arq reject-resource-low** command allows the endpoint to reject the limit of automatic repeat request message-packet (ARQs) when the endpoint reaches its configured maximum number of calls.

Examples

The following example shows how to set the maximum number of calls that GW-1 can handle to 1000:

```
gatekeeper
 endpoint max-calls h323id GW-1 1000
```

Related Commands

Command	Description
arq reject-resource-low	Enables the gatekeeper to send an ARQ to the requesting gateway if destination resources are low.
endpoint resource-threshold	Sets the call capacity threshold of a gateway in the gatekeeper.

endpoint naming

To customize the T3 endpoint naming convention on a per-MGCP-profile basis, use the **endpoint naming** command in MGCP profile configuration mode. To disable endpoint naming, use the **no** form of this command.

endpoint naming {**t1** | **t3**}

no endpoint naming

Syntax Description

t1	Flat-T3-endpoint naming convention.
t3	Hierarchical-T3-endpoint naming convention.

Command Default t1

Command Modes MGCP profile configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines The option to select between a flat-endpoint naming convention and a hierarchical-T3-endpoint naming convention gives call agents flexibility without enforcing one naming convention. Signaling, backhauling, and trunks using SS7 are supported. T3 naming conventions on XCC signaling types, SS7, and ISDN are not supported.

Examples The following example shows the T3 endpoint naming convention on an MGCP profile:

```
Router# configure terminal
Router(config)# mgcp profile default
Router(config-mgcp-profile)# endpoint naming t3
Router(config-mgcp-profile)# end
```

Related Commands

Command	Description
show mgcp	Displays MGCP configuration information.

endpoint resource-threshold

To set a gateway's call capacity thresholds in the gatekeeper, use the **endpoint resource threshold** command in gatekeeper configuration mode. To delete the thresholds, use the **no** form of this command.

endpoint resource-threshold [**onset** *high-water-mark* | **abatement** *low-water-mark*]

no endpoint resource-threshold [**onset** *high-water-mark*] [**abatement** *low-water-mark*]

Syntax Description

onset *high-water-mark*	(Optional) Maximum call volume usage for the gateway, as a percent. Range is from 1 to 99. The default is 90.
abatement *low-water-mark*	(Optional) Minimum call volume usage for the gateway, as a percent. Range is from 1 to 99. The default is 70.

Command Default

High-water-mark: 90 percent
Low-water-mark: 70 percent

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The gatekeeper monitors the call volume in each of its gateways. If the call capacity usage in a particular gateway exceeds the high-water-mark threshold, the gatekeeper stops sending calls to that gateway. When the gateway's active call volume falls below the low-water-mark threshold, the gatekeeper resumes sending new calls to the gateway. These thresholds are global values and affect all gateways registered with a given gatekeeper.

If neither threshold is set, the gatekeeper uses the default values.

Examples

The following example sets the high and low call-volume thresholds for all of its gateways:

```
Router(config)# gatekeeper
Router(config-gk)# endpoint resource-threshold onset 85 abatement 65
```

Related Commands

Command	Description
show gatekeeper endpoint circuits	Displays the information of all registered endpoints for a gatekeeper.

endpoint ttl

To enable the gatekeeper to assign a time-to-live (TTL) value to the endpoint when it registers with the gatekeeper, use the **endpoint ttl** *command in* gatekeeper configuration mode. To disable the TTL value, use the **no** form of this command.

endpoint ttl *time-to-live*

no endpoint ttl *time-to-live*

Syntax Description

time-to-live	TTL value, in seconds. Range is from 60 to 3600. The default is 1800.

Command Default

1800 seconds

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Usage Guidelines

This command specifies endpoint registration. Use this command to set the interval that the gatekeeper requires of an endpoint that does not supply its own value. Use a lower value to make the gatekeeper clear the registration of an unresponsive endpoint more quickly.

When an endpoint registers with the gatekeeper and does not provide a TTL value, the gatekeeper assigns this value as the time to live. When the TTL expires, the endpoint becomes subject to removal. However, the endpoint is queried a few times in an attempt to communicate with the device. If the device appears active, the registration does not expire. If the device is unresponsive after a few communication attempts, the endpoint is removed.

Examples

The following example enables a time to live value of 60 seconds:

```
endpoint ttl 60
```

Related Commands

Command	Description
timer cluster-element announce	Specifies the announcement period.
timer lrq seq delay	Specifies the timer for sequential LRQs.
timer lrq window	Specifies the window timer for LRQs.

erase vfc

To erase the Flash memory of a specified voice feature card (VFC), use the **erase vfc** command in privileged EXEC mode.

erase vfc *slot*

Syntax Description

slot	Slot on the Cisco AS5300 in which the specified VFC resides. Range is from 0 to 2. There is no default.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco AS5300.

Usage Guidelines

Use the **erase vfc** command to erase the contents of Flash memory for a specified VFC (thereby freeing space in VFC Flash memory) including the default file list and the capability file list.

Examples

The following example erases the Flash memory on the VFC located in slot 0:

```
Router# erase vfc 0
```

Related Commands

Command	Description
delete vfc	Deletes a file from VFC Flash memory.

error-category

To specify Q.850 cause code mapping, use the **error-category** command in voice cause-code configuration mode. To disable Q.850 cause code mapping, use the **no** form of this command.

error-category *number* **q850-cause** *number*

no error-category *number* **q850-cause** *number*

Syntax Description

number	Specifies error category value to be mapped to a configured Q850 cause code value. Values range from 128 to 278.
q850-cause *number*	Specifies the default Q.850 cause code value. Values range from 1 to 127.

Command Default The IEC mechanism defaults to the assigned Q.850 cause codes.

Command Modes Voice cause-code configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines Only the Session Initiation Protocol (SIP) and H.323 subsystems use the category and Q.850 mapping tables to determine the disconnect cause code when releasing a call due to an internal error.

To disable all mappings, use the no voice cause-code command. To disable a single mapping, use the voice cause-code command, followed by the no error-category *number* command.

Examples The following example sets error category 128 to map to Q.850 cause code 27:

```
Router(config)# voice cause code
Router(conf-voice-cause)# error-category 128 q850-cause 27
```

The following example defines two mappings for categories 128 and 129:

```
Router(config)# voice cause-code
Router(conf-voice-cause)# error-category 128 q850-cause 27
Router(conf-voice-cause)# error-category 129 q850-cause 38
Router(conf-voice-cause)# exit
```

The following example removes the mapping for category 128 only, leaving 129 defined:

```
Router(config)# voice cause-code
Router(conf-voice-cause)# no error-category 128
Router(conf-voice-cause)# exit
```

The following example removes all configured mappings:

```
Router(config)# no voice cause-code
```

Related Commands

Command	Description
show voice cause-code	Displays internal error category to q.850 cause code mapping.
voice cause-code	Enables voice cause-code configuration mode.

error-code-override

To configure the Session Initiation Protocol (SIP) error code to use at the dial peer for the call spike failure, use the **error-code-override** command in voice service SIP or dial peer voice configuration mode. To disable the SIP error code configuration, use the **no** form of this command.

error-code-override {**options-keepalive failure | call spike failure**} *sip-status-code-number*

no error-code-override {**options-keepalive failure | call spike failure**}

Syntax Description

options-keepalive failure	(Optional) Configures the SIP error code for options-keepalive failures.
call spike failure	(Optional) Configures the SIP error code for call spike failures.
sip-status-code-number	The SIP response error codec that is sent for the options-keepalive or call spike failure that happened at the dial peer. The range is from 400 to 699. The default value is 500. Table 1 in the "Usage Guidelines" section describes these error codes.

Command Default

The SIP error code is not configured.

Command Modes

Voice service SIP configuration (conf-ser-sip)
Dial peer voice configuration (conf-dial-peer)

Command History

Release	Modification
15.0(1)XA	This command was introduced.
15.1(1)T	This command was integrated into Cisco IOS Release 15.1(1)T.
15.1(3)T	This command was modified. The **call spike failure** keyword was introduced.

Usage Guidelines

The **error-code-override** command in voice service SIP or dial peer voice configuration mode configures the error code response for options-keepalive or call spike failures. The **voice-class sip error-code-override** command in voice service SIP or dial peer voice configuration mode configures the error code responses for call spike failures.

Table 1 describes the SIP error codes.

Table 23 SIP Error Codes

Error Code Number	Description
400	Bad Request
401	Unauthorized
402	Payment Required

Table 23 SIP Error Codes (continued)

Error Code Number	Description
403	Forbidden
404	Not Found
408	Request Timed Out
416	Unsupported URI
480	Temporarily Unavailable
482	Loop Detected
484	Address Incomplete
486	Busy Here
487	Request Terminated
488	Not Acceptable Here
500–599	SIP 5xx—Server/Service Failure
500	Internal Server Error
502	Bad Gateway
503	Service Unavailable
600–699	SIP 6xx—Global Failure

Examples

The following example shows how to configure the SIP error code using the **error-code-override** command for options-keepalive failures in voice service SIP configuration mode:

```
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(config-ser-sip)# error-code-override options-keepalive failure 503
```

The following example shows how to configure the SIP error code using the **error-code-override** command for call spike failures in dial peer voice configuration mode:

```
Router(config)# dial-peer voice 400
Router(conf-dial-peer)# error-code-override call spike failure 503
```

Related Commands

Command	Description
voice-class sip error-code-override	To configure the Session Initiation Protocol (SIP) error code that a dial peer uses for options-keepalive failures or call spike failures.

error-correction

To set error correction for the Signaling System 7 (SS7) signaling link when the SS7 Message Transfer Part Layer 2 (MTP2) variant is Bellcore or ITU-white, use the error-correction command in ITU configuration mode. To disable error correction, use the **no** form of this command.

error-correction [**basic** | **pcr** [**forced-retransmission** *parameters*]]

no error-correction

Syntax Description

basic	(Optional) Sets SS7 signaling link error correction to basic mode for configurations in which one-way propagation delay is less than 40 ms.
pcr	(Optional) Sets intercontinental SS7 signaling link error correction to Preventive Cyclic Retransmission (PCR) mode for configurations that are transmitted over satellite connections and for configurations in which one-way propagation delay is greater than 40 ms.
forced-retransmission	(Optional) Enables forced retransmission when the **pcr** keyword is selected. To disable forced retransmission, use the **no** form of the command.
parameters	(Optional) Sets the error-correction method for an SS7 signaling link. The following types of error correction are configurable: • **pcr-enabled**—Tracks the error-correction method on the SS7 signaling channel. The error-correction method can be either PCR or basic. PCR is disabled by default. • **forced-retransmission-enabled**—Tracks forced retransmission on the SS7 signaling channel. **Note** Forced retransmission is enabled only if PCR is enabled. • **n2** *octets*—The maximum number of N2 octets that can be queued in the RTB for an SS7 signaling channel before forced retransmission procedures are initiated. The number of octets can range from 200 to 4000. The default is 450. **Note** This parameter is ignored if forced retransmission is not enabled.

Command Default Error correction is set to basic.

Command Modes ITU configuration

Command History

Release	Modification
12.3(2)T	This command was introduced on the Cisco 2600 series, Cisco AS5350, and Cisco AS5400 Cisco signaling link terminals (SLTs).

Usage Guidelines

The maximum supported signaling link loop (round trip) delay is 670 ms (the time between the sending of a message signal unit [MSU] and the reception of the acknowledgment for this MSU in undisturbed operation).

Examples

The following example sets the error-correction method to PCR and enables forced retransmission with the N2 parameter set and 1000 octets selected:

```
Router(config-ITU)# error-correction pcr forced-retransmission n2 1000
```

Related Commands

Command	Description
ss7 mtp2-variant	Configures an SS7 signaling link.

event-log

To enable event logging for applications, use the **event-log** command in application configuration monitor configuration mode. To disable event logging, use the **no** form of this command.

event-log [**size** [*number-of-events*]] [**one-shot**] [**pause**]

no event-log

Syntax Description

size [*number-of-events*]	(Optional) Maximum number of OSPF events in the event log.
one-shot	(Optional) Mode that enables the logging of new events at one specific point in time. The event logging mode is cyclical by default, meaning that all new events are logged as they occur.
pause	(Optional) Enables the user to pause the logging of any new events at any time, while keeping the current events in the log.

Command Default

By default, event logging is not enabled.
When event logging is enabled, it is cyclical by default.

Command Modes

Application configuration monitor configuration mode
OSPF for IPv6 router configuration mode

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application event-log** command.
12.2(33)SRC	Support for IPv6 was added.
12.2(33)SB	This command was integrated into Cisco IOS Release 12.2(33)SB.

Usage Guidelines

This command enables event logging globally for all voice applications. To enable or disable event logging for a specific application, use one of the following commands:

param event-log (application parameter configuration mode)

paramspace appcommon event-log (service configuration mode)

Note To prevent event logging from adversely impacting system resources for production traffic, the gateway uses a throttling mechanism. When free processor memory drops below 20-percent, the gateway automatically disables all event logging. It resumes event logging when free memory rises above 30 percent. While throttling is occurring, the gateway does not capture any new event logs even if event logging is enabled. You should monitor free memory and enable event logging only when necessary for isolating faults.

Examples

The following example shows event logging enabled:

```
application
 monitor
  event-log
```

The following example shows OSPF for IPv6 event logging enabled. The router instance is 1, the event-log size is 10,000, and the mode is one-shot.

```
ipv6 router ospf 1
 event-log size 10000 one-shot
```

Related Commands

Command	Description
call application event-log	Enables event logging for all voice application instances.
event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
event-log error-only	Restricts event logging to error events only for application instances.
event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
param event-log	Enables or disables event logging for a package.
paramspace appcommon event-log	Enables or disables event logging for a service (application).

event-log (Privileged EXEC)

To configure different event logging functions, use the **event-log** command in privileged EXEC mode.

event-log {**calibrate** | {**circular** | **platform-ticks**} {**off** | **on**} | {**disable** | **enable**} [*event-group*] | **init** | **mark** | **save** {*hostname* | *IP-address*} *prefix* | **timelog**}

Syntax Description

calibrate	Caliberates the platform clock.
circular	Enables or disables the circular event log.
off	Disables the circular event log.
on	Enables the circular event log.
disable	Disables event logging.
event-group	(Optional) Event group to be enabled or disabled. The range is from 1 to FFFFFFF.
enable	Enables event logging.
init	Initializes the event logging data structures.
mark	Marks an event log.
platform-ticks	Enables or disables platform ticks for a clock.
save	Saves the event log to the TFTP host as elog.out.
hostname	Hostname of the TFTP server to receive elog.out.
IP-address	IP address of the TFTP server to receive elog.out.
prefix	Prefix for the saved files.
timelog	Specifies time logging of 1000 events.

Command Default

Event logging functions are not configured.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SRC	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SRC.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.

Examples

The following example shows how to enable the circular event log:

```
Router# event-log circular on
```

Related Commands

Command	Description
event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
event-log error-only	Restricts event logging to error events only for application instances.
event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.
param event-log	Enables or disables event logging for a package.
paramspace appcommon event-log	Enables or disables event logging for a service (application).

event-log dump ftp

To enable the gateway to write the contents of the application event log buffer to an external file, use the, use the **event-log dump ftp** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

event-log dump ftp *server[:port]/file username* **password** [*encryption-type*] *password*

no event-log dump ftp

Syntax Description

server	Name or IP address of FTP server where file is located.
port	(Optional) Specific port number on server.
file	Name and path of file.
username	Username required to access file.
encryption-type	(Optional) The Cisco proprietary algorithm used to encrypt the password. Values are 0 or 7. To disable encryption enter 0; to enable encryption enter 7. If you specify 7, you must enter an encrypted password (a password already encrypted by a Cisco router).
password	Password required to access file.

Command Default By default, this feature is not enabled on the gateway.

Command Modes Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application event-log dump ftp** command.

Usage Guidelines This command enables the gateway to automatically write the event log buffer to the named file either after an active application instance terminates or when the event log buffer becomes full. The default buffer size is 4 KB. To modify the size of the buffer, use the **event-log max-buffer-size** command in application configuration monitor mode.

Enabling the gateway to write event logs to FTP could adversely impact gateway memory resources in some scenarios, for example, when:

- The gateway is consuming high processor resources and FTP does not have enough processor resources to flush the logged buffers to the FTP server.
- The designated FTP server is not powerful enough to perform FTP transfers quickly
- Bandwidth on the link between the gateway and the FTP server is not large enough
- The gateway is receiving a high volume of short-duration calls or calls that are failing

You should enable FTP dumping only when necessary and not enable it in situations where it might adversely impact system performance.

Examples

The following example enables the gateway to write application event logs to an external file named app_elogs.log on a server named ftp-server:

```
application
monitor
 event-log dump ftp ftp-server/elogs/app-elogs.log username myname password 0 mypass
```

The following example specifies that application event logs are written to an external file named app_elogs.log on a server with the IP address of 10.10.10.101:

```
application
monitor
 event-log dump ftp 10.10.10.101/elogs/app-elogs.log username myname password 0 mypass
```

Related Commands

Command	Description
call application event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
event-log	Enables event logging for applications.
event-log error-only	Restricts event logging to error events only for application instances.
event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance.

event-log error-only

To restrict event logging to error events only for application instances, use the **event-log error-only** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

event-log error-only

no event-log error-only

Syntax Description This command has no arguments or keywords.

Command Default If logging is enabled, all application events are logged.

Command Modes Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application event-log error-only** command.

Usage Guidelines

- This command limits new event logging to error events only; it does not enable logging.

You must use this command with either the **event-log** command, which enables event logging for all voice applications, or enable event logging for a specific application using the **param event-log** command (package appcommon configuration mode) or the **paramspace appcommon event-log** command (service configuration mode).

- Any events logged before this command is issued are not affected.

Examples The following example enables event logging for error events only:

```
application
monitor
 event-log
 event-log error-only
```

Related Commands

Command	Description
call application event-log error-only	Restricts event logging to error events only for application instances.
event-log	Enables event logging for applications.

Command	Description
event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
event-log max-buffer-size	Sets the maximum size of the event log buffer for each application instance

event-log max-buffer-size

To set the maximum size of the event log buffer for each application instance, use the **event-log max-buffer-size** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

event-log max-buffer-size *kbytes*

no event-log max-buffer-size

Syntax Description

kbytes	Maximum buffer size, in kilobytes. Range is 1 to 50. Default is 4 KB.

Command Default

By default, the maximum size is set to 4 KB.

Command Modes

Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application event-log max-buffer-size** command.

Usage Guidelines

If the event log buffer reaches the limit set by this command, the gateway allocates a second buffer of equal size. The contents of both buffers is displayed when you use the **show call application session-level** command. When the first event log buffer becomes full, the gateway automatically appends its contents to an external FTP location if the **event-log dump ftp** command is used.

A maximum of two buffers are allocated for an event log. If both buffers are filled, the first buffer is deleted and another buffer is allocated for new events (buffer wraps around). If the **event-log dump ftp** command is configured and the second buffer becomes full before the first buffer is dumped, event messages are dropped and are not recorded in the buffer.

Note

- Do not set the maximum buffer size to more than you need for a typical application session. After an active session terminates, the amount of memory used by the buffer is allocated to the history table and is maintained for the length of time set by the **history session retain-timer** command. Also consider that most fatal errors are captured at the end of an event log.
- To conserve memory resources, write the event log buffer to FTP by using the **event-log dump ftp** command.

Examples

The following example sets the application event log buffer to 8 KB:

```
application
 monitor
 event-log max-buffer-size 8
```

Related Commands

Command	Description
event-log	Enables event logging for applications.
event-log dump ftp	Enables the gateway to write the contents of the application event log buffer to an external file.
call application event-log max-buffer-size	Maximums size of the event log buffer for each application instance.

expect-factor

To set the expect-factor value for voice quality, which affects the threshold calculated planning impairment factor (ICPIF) loss/delay busyout value, use the **expect-factor** command in dial peer configuration mode. To reset to the default, use the **no** form of this command.

expect-factor *value*

no expect-factor *value*

Syntax Description

value	Integers that represent quality of voice as described in ITU G.107. Range: 0 to 20, with 0 representing toll quality. Default: 10.

Command Default 10

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
12.2(8)T	The *value* default changed from 10 to 0.
12.3(3)T	The *value* default changed from 0 to 10.

Usage Guidelines The expect factor impacts the calculated value of ICPIF. This value is used in conjunction with Simple Network Management Protocol (SNMP) to generate a trap when voice quality falls below a configured value. It also impacts the value of ICPIF reported in call-account records as well as in call-history values on the gateway.

Use this and related commands together on a dial peer as follows:

- Use this command to set the expect-factor value.
- Use the **icpif** command to set a threshold ICPIF value (the ICPIF calculation uses the expect-factor value as well as values for loss and delay).
- Use the **snmp enable peer-trap poor-qov** command to generate notifications in the form of SNMP traps to the network manager for calls whose ICPIF value exceeds the threshold.

Note For more information on ICPIF, see *IP SLAs—Analyzing VoIP Service Levels Using the VoIP Jitter Operation* at http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cg/hsla_c/hsvoipj.htm

Examples The following example sets the expect factor for a dial peer:

```
dial-peer voice 10 voip
 expect-factor 0
```

Related Commands

Command	Description
icpif	Specifies the ICPIF threshold for calls sent by a dial peer.
snmp enable peer-trap poor-qov	Generates poor-quality-of-voice notifications for applicable calls associated with a VoIP dial peer.

extsig mgcp

To configure external signaling control by Media Gateway Control Protocol (MGCP) for a T1 or E1 trunk controller card, use the **extsig mgcp** command in controller configuration mode. To discontinue MGCP control for this controller, use the **no** form of this command.

extsig mgcp

no extsig mgcp

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Controller configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command is supported on the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.

Usage Guidelines

For T3 lines, each logical T1 trunk controller card must be configured using the **extsig mgcp** command.

Examples

The following example shows MGCP signaling control being configured for T1 controller 7/0:

```
controller T1 7/0
 framing esf
 extsig mgcp
 guard-timer 10 on-expiry reject
 linecode b8zs
 ds0-group 1 timeslots 1-24 type none service mgcp
```

Related Commands

Command	Description
dialer extsig	Configures an interface to initiate and terminate calls using an external signaling protocol.

Cisco IOS Voice Commands: F

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Guide*.

fax interface-type

To specify the interface to be used for a fax call, use the **fax interface-type** command in global configuration mode. To reset to the default fax protocol, use the **no** form of this command.

fax interface-type {**fax-mail** | **modem** | **vfc**}

no fax interface-type {**fax-mail** | **modem** | **vfc**}

Syntax Description

fax-mail	Specifies that voice digital signal processors (DSPs) process fax store-and-forward data. This keyword replaces the **vfc** keyword for DSPs.
modem	(Cisco AS5300 only) Specifies that modem cards process fax store-and-forward data. **Note** This keyword is not supported except for instances documented in the "Usage Guidelines" section.
vfc	(Cisco AS5300 only) Specifies that voice feature cards (VFCs) process fax store-and-forward data. This keyword has been superseded by the **fax-mail** keyword and is retained for backward compatibility only.

Command Default

Cisco AS5300: See the "Usage Guidelines" section
All other platforms: **fax-mail**

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.1(5)XM	The command was implemented on the Cisco AS5800.
12.1(5)XM2	The command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on Cisco 1750 and the **fax-mail** keyword was added.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

When using this command to change the interface type for store-and-forward fax, you must reload (reboot or reset) the router.

On the Cisco AS5300 access server, the keyword **vfc** maps internally to the **fax-mail** keyword. If you use the **vfc** keyword with the **fax interface-type** command, the output from the **show running-config** command displays **fax-mail** as the option that was set.

The Cisco AS5300 defaults for the **fax interface-type** command are as follows:

- If the Cisco AS5300 has voice cards only, the default is the **fax-mail** keyword. The **modem** keyword is unavailable.
- If the Cisco AS5300 has modem cards only, the default is the **modem** keyword.
- If the Cisco AS5300 has both modem and voice cards, the default is the **modem** keyword.

Examples

The following example specifies the use of voice DSPs to process fax store-and-forward data:

```
Router(config)# fax interface-type fax-mail
```

The following example specifies the use of modems to process fax store-and-forward data on a Cisco AS5300:

```
Router(config)# fax interface-type modem
```

fax protocol (dial peer)

To specify the fax protocol to be used for a specific VoIP dial peer, use the **fax protocol** command in dial peer configuration mode. To return to the global default fax protocol, use the **system** keyword or the **no** form of this command.

Cisco AS5350, Cisco AS5400, Cisco AS5850

fax protocol {**none** | **system** | **pass-through** {**g711ulaw** | **g711alaw**}}

no fax protocol

All Other Platforms

fax protocol {**cisco** | **none** | **system** | **pass-through** {**g711ulaw** | **g711alaw**}}

no fax protocol

Syntax Description

cisco	Cisco-proprietary fax protocol.
none	No fax pass-through is attempted. All special fax handling is disabled, except for modem pass-through if configured with the **modem pass-through** command.
system	Uses the global configuration that was set using the **fax protocol** command in voice-service configuration mode.
pass-through	The fax stream uses one of the following high-bandwidth codecs: • **g711ulaw**—Uses the G.711 u-law codec. • **g711alaw**—Uses the G.711 a-law codec.

Command Default

system

Command Modes

Dial peer configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.1(3)XI	This command was implemented on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.1(5)XM	This command was implemented on the Cisco AS5800. The **none** keyword was introduced.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.

Release	Modification
12.2(11)T	This command was implemented on the Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T. The **t.38** keyword and its options were moved to two new commands: **fax protocol t38** (dial peer) and **fax protocol t38** (voice-service).

Usage Guidelines

Use the **fax protocol** command in dial-peer configuration mode to configure the type of fax relay capability for a specific dial peer. Note the following command behavior:

- **fax protocol none**—Disables all fax handling.
- **no fax protocol**—Sets the fax protocol for the dial peer to the default, which is **system**.

If the **fax protocol** (voice-service) command is used to set fax relay options for all dial peers and the **fax protocol** (dial peer) command is used on a specific dial peer, the dial-peer configuration takes precedence over the global configuration for that dial peer.

Examples

The following example specifies that the fax stream use fax pass-through for VoIP dial peer 99:

```
dial-peer voice 99 voip
 fax protocol pass-through g711ulaw
```

Related Commands

Command	Description
fax protocol (voice-service)	Specifies the global default fax protocol to be used for all VoIP dial peers.
fax protocol t38 (dial peer)	Specifies the ITU-T T.38 standard fax protocol to be used for a specific VoIP dial peer.
fax protocol t38 (voice-service)	Specifies the global default ITU-T T.38 standard fax protocol to be used for all VoIP dial peers.

fax protocol (voice-service)

To specify the global default fax protocol to be used for all VoIP dial peers, use the **fax protocol** command in voice-service configuration mode. To return to the default fax protocol, use the **no** form of this command.

Cisco AS5350, Cisco AS5400, Cisco AS5850

fax protocol {**none** | **pass-through** {**g711ulaw** | **g711alaw**}}

no fax protocol

All Other Platforms

fax protocol {**cisco** | **none** | **pass-through** {**g711ulaw** | **g711alaw**}}

no fax protocol

Syntax Description

none	No fax pass-through is attempted. All special fax handling is disabled, except for modem pass-through (if configured with the **modem pass-through** command).
pass-through	The fax stream uses one of the following high-bandwidth codecs: • **g711alaw**—Uses the G.711 A-law codec. • **g711ulaw**—Uses the G.711 mu-law codec.
cisco	Cisco-proprietary fax protocol. The **cisco** keyword is the default for all platforms except the Cisco AS5350, Cisco AS5400, and Cisco AS5850. • This is the only valid option when you are using Cisco Unified CME 4.0(3) or a later version on Skinny Call Control Protocol (SCCP)-controlled FXS ports.

Command Default

If no fax protocol is specified, the **cisco** protocol is the default for all platforms except the Cisco AS5350, Cisco AS5400, and Cisco AS5850. For these three platforms, **none** is the default, so no fax pass-through is attempted.

Command Modes

Voice-service configuration (config-voi-serv)

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.1(3)XI	This command was implemented on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.1(5)XM	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.

Release	Modification
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco 1750.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T. The **t.38** keyword and its options were removed and added to two new commands: **fax protocol t38 (dial peer)** and **fax protocol t38 (voice-service)**.
12.4(11)T	Support for SCCP-controlled FXS ports was added.

Usage Guidelines

Use the **fax protocol** command with the **voice service voip** command to configure the fax relay capability for all VoIP dial peers.

Note the following command behavior:

- **fax protocol none**— Disables all fax handling.
- **no fax protocol**—Sets the fax protocol to the default.

If the **fax protocol** (voice-service) command is used to set fax relay options for all dial peers and the **fax protocol** (dial peer) command is used on a specific dial peer, the dial-peer configuration takes precedence over the global configuration for that dial peer. When the **system** keyword is used in the dial-peer configuration of the **fax protocol** command, it specifies that the global default fax protocol set with this command is used by that dial peer.

In Cisco Unified CME 4.0(3) and later, the **fax protocol cisco** (voice-service) command is the only supported fax protocol option for SCCP-controlled FXS ports. G.711 fax pass-through is not supported for Cisco VG 224 and FXS ports.

Note The **modem passthrough protocol** and **fax protocol** commands cannot be configured at the same time. If you enter either one of these commands when the other is already configured, the command-line interface returns an error message.

The error message serves as a confirmation notice because the **modem passthrough protocol** command is internally treated the same as the **fax protocol passthrough** command by the Cisco IOS software. For example, no other mode of fax protocol (for example, fax protocol T.38) can operate if the **modem passthrough protocol** command is configured.

Note Even though the **modem passthrough protocol** and **fax protocol passthrough** commands are treated the same internally, be aware that if you change the configuration from the **modem passthrough protocol** command to the **modem passthrough nse** command, the configured **fax protocol passthrough** command is not automatically reset to the default. If default settings are required for the **fax protocol** command, you have to specifically configure the **fax protocol** command.

Examples

The following example specifies that the fax stream for all VoIP dial peers use fax pass-through:

```
voice service voip
 fax protocol pass-through g711ulaw
```

Related Commands

Command	Description
fax protocol (dial peer)	Specifies the fax protocol for a specific VoIP dial peer.
fax protocol t38 (dial peer)	Specifies the ITU-T T.38 standard fax protocol to be used for a specific VoIP dial peer.
fax protocol t38 (voice-service)	Specifies the global default ITU-T T.38 standard fax protocol to be used for all VoIP dial peers.
modem passthrough	Enables fax or modem pass-through over VoIP globally for all dial peers.
voice service voip	Enters voice-service configuration mode.

fax protocol t38 (dial peer)

To specify the ITU-T T.38 standard fax protocol to be used for a specific VoIP dial peer, use the **fax protocol t38** command in dial-peer configuration mode. To return to the default fax protocol, use the **no** form of this command.

Cisco AS5350, Cisco AS5400, Cisco AS5850 Platforms

fax protocol t38 [**nse** [**force**]] [**ls-redundancy** *value* [**hs-redundancy** *value*]] [**fallback** {**none** | **pass-through** {**g711ulaw** | **g711alaw**}}]

no fax protocol t38

All Other Platforms

fax protocol t38 [**nse** [**force**]] [**version** {**0** | **3**}] [**ls-redundancy** *value* [**hs-redundancy** *value*]] [**fallback** {**cisco** | **none** | **pass-through** {**g711ulaw** | **g711alaw**}}]

no fax protocol t38

Syntax Description

nse	(Optional) Uses NSEs to switch to T.38 fax relay.
force	(Optional) Unconditionally, uses Cisco network services engines (NSE) to switch to T.38 fax relay. This option allows T.38 fax relay to be used between Cisco H.323 or Session Initiation Protocol (SIP) gateways and Media Gateway Control Protocol (MGCP) gateways.
version {**0** | **3**}	(Optional) Specifies a version for configuring fax speed: • **0**—Configures version 0, which uses T.38 version 0 (1998—G3 faxing) • **3**—Configures version 3, which uses T.38 version 3 (2004—V.34 or SG3 faxing)
ls-redundancy *value*	(Optional) (T.38 fax relay only) Specifies the number of redundant T.38 fax packets to be sent for the low-speed V.21-based T.30 fax machine protocol. Range varies by platform from 0 (no redundancy) to 5 or 7. For details, see to command-line interface (CLI) help. Default is 0.
hs-redundancy *value*	(Optional) (T.38 fax relay only) Specifies the number of redundant T.38 fax packets to be sent for high-speed V.17, V.27, and V.29 T.4 or T.6 fax machine image data. Range varies by platform from 0 (no redundancy) to 2 or 3. For details, see the command-line interface (CLI) help. Default is 0.
fallback	(Optional) A fallback mode is used to transfer a fax across a VoIP network if T.38 fax relay could not be successfully negotiated at the time of the fax transfer.
cisco	(Optional) Cisco-proprietary fax protocol.
none	(Optional) No fax pass-through or T.38 fax relay is attempted. All special fax handling is disabled, except for modem pass-through if configured with the **modem pass-through** command.
pass-through	(Optional) The fax stream uses one of the following high-bandwidth codecs: • **g711ulaw**—Uses the G.711 mu-law codec. • **g711alaw**—Uses the G.711 a-law codec.

Command Default **ls-redundancy 0 hs-redundancy 0 fallback none** for the Cisco AS5350, Cisco AS5400, and Cisco AS5850 platforms
ls-redundancy 0 hs-redundancy 0 fallback cisco for all other platforms

Command Modes Dial-peer configuration (config-dial-peer)

Command History

Release	Modification
12.2(13)T	This command was introduced.
15.1(1)T	This command was modified. The **version** keyword was added with the **0** and **3** keywords to specify fax speed as G3 or SG3.

Usage Guidelines Use this command in dial-peer configuration mode to configure the type of fax relay capability for a specific dial peer. If the **fax protocol t38 (voice-service)** command is used to set fax relay options for all dial peers and the **fax protocol t38 (dial peer)** command is used on a specific dial peer, the dial-peer configuration takes precedence over the global configuration for that dial peer.

If you specify **version 3** in the **fax protocol t38** command and negotiate T.38 version 3, the fax rate is automatically set to 33600.

The **ls-redundancy** and **hs-redundancy** keywords are used to send redundant T.38 fax packets. Setting the **hs-redundancy** keyword to a value greater than 0 causes a significant increase in the network bandwidth consumed by the fax call.

Use the **nse force** option when the H.323 or SIP gateway is interoperating with a Cisco MGCP gateway and the call agent does not support the interworking and negotiation of T.38 fax relay and NSE attributes at the time of call setup. When the corresponding option is configured on the MGCP gateway, the **nse force** option allows T.38 fax relay to be used between Cisco H.323 or SIP gateways and MGCP gateways.

Examples The following example show how to configure T.38 fax relay for VoIP:

```
dial-peer voice 99 voip
 fax protocol t38
```

The following example shows how to use NSEs to enter T.38 fax relay mode:

```
dial-peer voice 99 voip
 fax protocol t38 nse
```

The following example shows how to specify the T.38 fax protocol for this dial peer, set low-speed redundancy to a value of 1, and set high-speed redundancy to a value of 0:

```
dial-peer voice 99 voip
 fax protocol t38 ls-redundancy 1 hs-redundancy 0
```

Related Commands

Command	Description
fax protocol (dial peer)	Specifies the fax protocol for a specific VoIP dial peer.
fax protocol (voice-service)	Specifies the global default fax protocol to be used for all VoIP dial peers.
fax protocol t38 (voice-service)	Specifies the global default ITU-T T.38 standard fax protocol to be used for all VoIP dial peers.

fax protocol t38 (voice-service)

To specify the global default ITU-T T.38 standard fax protocol to be used for all VoIP dial peers, use the **fax protocol t38** command in voice-service configuration mode. To return to the default fax protocol, use the **no** form of this command.

Cisco AS5350, Cisco AS5400, Cisco AS5850 Platforms

fax protocol t38 [**nse** [**force**]] [**version** {**0** | **3**}] [**ls-redundancy** *value* [**hs-redundancy** *value*]] [**fallback** {**none** | **pass-through** {**g711ulaw** | **g711alaw**}}]

no fax protocol t38

All Other Platforms

fax protocol t38 [**nse** [**force**]] [**version** {**0** | **3**}] [**ls-redundancy** *value* [**hs-redundancy** *value*]] [**fallback** {**cisco** | **none** | **pass-through** {**g711ulaw** | **g711alaw**}}]

no fax protocol t38

Syntax Description

nse	(Optional) Uses network services engines (NSE) to switch to T.38 fax relay.
force	(Optional) Unconditionally, uses Cisco NSEs to switch to T.38 fax relay. This option allows T.38 fax relay to be used between Cisco H.323 or Session Initiation Protocol (SIP) gateways and Media Gateway Control Protocol (MGCP) gateways.
version {**0** | **3**}	(Optional) Specifies a version for configuring fax speed: • **0**—Configures version 0, which uses T.38 version 0 (1998—G3 faxing) • **3**—Configures version 3, which uses T.38 version 3 (2004—V.34 or SG3 faxing)
ls-redundancy *value*	(Optional) (T.38 fax relay only) Specifies the number of redundant T.38 fax packets to be sent for the low-speed V.21-based T.30 fax machine protocol. Range varies by platform from 0 (no redundancy) to 5 or 7. For details, refer to command-line interface (CLI) help. Default is 0.
hs-redundancy *value*	(Optional) (T.38 fax relay only) Specifies the number of redundant T.38 fax packets to be sent for high-speed V.17, V.27, and V.29 T.4 or T.6 fax machine image data. Range varies by platform from 0 (no redundancy) to 2 or 3. For details, refer to the command-line interface (CLI) help. Default is 0.
fallback	(Optional) A fallback mode is used to transfer a fax across a VoIP network if T.38 fax relay could not be successfully negotiated at the time of the fax transfer.
cisco	(Optional) Cisco-proprietary fax protocol.
none	(Optional) No fax pass-through or T.38 fax relay is attempted. All special fax handling is disabled, except for modem pass-through if configured with the **modem pass-through** command.
pass-through	(Optional) The fax stream uses one of the following high-bandwidth codecs: • **g711ulaw**—Uses the G.711 mu-law codec. • **g711alaw**—Uses the G.711 a-law codec.

Command Default

ls-redundancy 0 hs-redundancy 0 fallback none for the Cisco AS5350, Cisco AS5400, and Cisco AS5850 platforms
ls-redundancy 0 hs-redundancy 0 fallback cisco for all other platforms

Command Modes

Voice-service configuration (config-voi-srv)

Command History

Release	Modification
12.2(13)T	This command was introduced.
15.1(1)T	This command was Modified. The **version** keyword was added with the **0** and **3** keywords to specify fax speed.

Usage Guidelines

Use the **fax protocol t38** command and the **voice service voip** command to configure T.38 fax relay capability for all VoIP dial peers. If the **fax protocol t38** (voice-service) command is used to set fax relay options for all dial peers and the **fax protocol t38** (dial-peer) command is used on a specific dial peer, the dial-peer configuration takes precedence over the global configuration for that dial peer.

If you specify **version 3** in the **fax protocol t38** command and negotiate T.38 version 3, the fax rate is automatically set to 33600.

The **ls-redundancy** and **hs-redundancy** keywords are used to send redundant T.38 fax packets. Setting the **hs-redundancy** keyword to a value greater than 0 causes a significant increase in the network bandwidth consumed by the fax call.

Use the **nse force** option when the H.323 or SIP gateway is interoperating with a Cisco MGCP gateway and the call agent does not support the interworking and negotiation of T.38 fax relay and NSE attributes at the time of call setup. When the corresponding option is configured on the MGCP gateway, the **nse force** option allows T.38 fax relay to be used between Cisco H.323 or SIP gateways and MGCP gateways.

Note Do not use the **cisco** keyword for the fallback option if you specified **version 3** for SG3 fax transmission.

Examples

The following example shows how to configure the T.38 fax protocol for VoIP:

```
voice service voip
 fax protocol t38
```

The following example shows how to use NSEs to unconditionally enter T.38 fax relay mode:

```
voice service voip
 fax protocol t38 nse
```

The following example shows how to specify the T.38 fax protocol for all VoIP dial peers, set low-speed redundancy to a value of 1, and set high-speed redundancy to a value of 0:

```
voice service voip
 fax protocol t38 ls-redundancy 1 hs-redundancy 0
```

Related Commands

Command	Description
fax protocol (dial peer)	Specifies the fax protocol for a specific VoIP dial peer.
fax protocol (voice-service)	Specifies the global default fax protocol to be used for all VoIP dial peers.
fax protocol t38 (dial peer)	Specifies the ITU-T T.38 standard fax protocol to be used for a specific VoIP dial peer.
voice service voip	Enters voice-service configuration mode.

fax rate (dial peer)

To establish the rate at which a fax is sent to a specified dial peer, use the **fax rate** command in dial-peer configuration mode. To reset the dial peer for voice calls, use the **no** form of this command.

fax rate {**2400** | **4800** | **7200** | **9600** | **12000** | **14400**} {**disable** | **voice**} [**bytes** *milliseconds*]

no fax rate

Syntax Description

2400	2400 bits per second (bps) fax transmission speed.
4800	4800 bps fax transmission speed.
7200	7200 bps fax transmission speed.
9600	9600 bps fax transmission speed.
12000	12000 bps fax transmission speed.
14400	14400 bps fax transmission speed.
disable	Disables fax relay transmission capability.
voice	Highest possible transmission speed allowed by the voice rate.
bytes *milliseconds*	(Optional) Specifies fax packetization rate, in milliseconds. Range is 20 to 48. Default is 20. • For Cisco fax relay, this keyword-argument pair is valid only on Cisco 2600 series, Cisco 3600 series, Cisco AS5300, and Cisco 7200 series routers. • For T.38 fax relay, this keyword-argument pair is valid only on Cisco AS5350, Cisco AS5400, and Cisco AS5850 routers. For other routers, the packetization rate for T.38 fax relay is fixed at 40 ms and cannot be changed.

Command Default Voice rate

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced as the **fax-rate** command on the Cisco 3600.
12.0(2)XH	The **12000** keyword was added.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T and implemented on the Cisco MC3810.
12.1(3)T	The command name changed from **fax-rate** to **fax rate** (nonhyphenated).
12.1(3)XI	This command was implemented on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.1(5)XM	This command was implemented on the Cisco AS5800.
12.1(5)XM2	The command was implemented on the Cisco AS5350 and Cisco AS5400.

Release	Modification
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

Use this command to specify the fax transmission rate to the specified dial peer.

The values for this command apply only to the fax transmission speed and do not affect the quality of the fax itself. The higher transmission speed values (14,400 bps) provide a faster transmission speed but monopolize a significantly large portion of the available bandwidth. The lower transmission speed values (2400 bps) provide a slower transmission speed and use a relatively smaller portion of the available bandwidth.

Note The fax call is not compressed using the **ip rtp header-compression** command because User Datagram Protocol (UDP) is being used and not Real-Time Transport Protocol (RTP). For example, a 9600 bps fax call takes approximately 24 kbps.

If the fax rate transmission speed is set higher than the codec rate in the same dial peer, the data sent over the network for fax transmission is above the bandwidth reserved for Resource Reservation Protocol (RSVP).

Tip Because a large portion of the available network bandwidth is monopolized by the fax transmission, Cisco does not recommend setting the fax rate value higher than the value of the selected codec. If the fax rate value is set lower than the codec value, faxes take longer to send but use less bandwidth.

The **voice** keyword specifies the highest possible transmission speed allowed by the voice rate. For example, if the voice codec is G.711, the fax transmission may occur at a rate up to 14,400 bps because 14,400 bps is less than the 64k voice rate. If the voice codec is G.729 (8k), the fax transmission speed is 7200 bps.

Examples

The following example configures a fax rate transmission speed of 9600 bps for faxes sent using a dial peer:

```
dial-peer voice 100 voip
 fax rate 9600 voice
```

The following example sets a fax rate transmission speed at 12,000 bps and the packetization rate at 20 milliseconds:

fax rate 12000 bytes 20

Related Commands

Command	Description
codec (dial peer)	Specifies the voice coder rate of speech for a dial peer.
fax protocol (dial peer)	Specifies the fax protocol for a specific VoIP dial peer.

fax rate (pots)

To establish the rate at which a fax is sent to the specified plain old telephone service (POTS) dial peer, use the **fax rate** command in dial-peer configuration mode. To reset the dial peer to handle only voice calls, use the **no** form of this command.

fax rate {**disable** | **system** | **voice**}

no fax rate

Syntax Description

disable	Disables fax-relay transmission capability.
system	Uses rate choice specified in global fax rate CLI under the **voice service pots** command.
voice	Highest possible transmission speed allowed by the voice rate for this dial peer. For example, if the voice codec is G.711, fax transmission may occur at a rate of up to 14,400 bps.

Command Default System

Command Modes dial peer configuration

Command History

Release	Modification
12.2(8)T	This command was introduced on the following platforms: Cisco 1700 series, Cisco 3600 series, and Cisco ICS 7750.

Usage Guidelines This implementation of the **fax rate** command is only applicable to POTS dial peers.

Examples The following example shows a fax rate transmission set to **voice** on POTS dial peer 1:

```
dial-peer voice 1 pots
 fax rate voice
```

Related Commands

Command	Description
codec (dial peer)	Specifies the voice coder rate of speech for a dial peer.
fax rate (voip)	Establishes the rate at which a fax is sent to the specified VoIP dial peer.

fax rate (voice-service)

To establish the rate at which a fax is sent for POTS-to-POTS voice calls, use the **fax rate** command in voice-service configuration mode. To reset for voice only calls, use the **no** form of this command.

fax rate {**disable** | **voice**}

no fax rate

Syntax Description

disable	Disables fax relay transmission capability.
voice	Highest possible transmission speed allowed by the voice rate. For example, if the voice codec is G.711, fax transmission may occur at a rate of up to 14400 bps.

Command Default **fax rate voice** command behavior is enabled by default

Command Modes Voice-service configuration

Command History

Release	Modification
12.2(8)T	This command was introduced on the following platforms: Cisco 1700 series, Cisco 3600 series, and Cisco ICS 7750.
12.3(4)T	This command was modified so that the "fax rate voice" setting is the default setting for the **fax rate** command in voice-service configuration mode and, hence, will no longer be displayed in the running configuration.

Usage Guidelines This implementation of the **fax rate** command applies only when voice service is set to POTS. Although **fax rate voice** command behavior is the default setting, you must specify this functionality in voice-service configuration mode in order to establish the rate at which a fax is sent for POTS-to-POTS voice calls. If you do not configure **fax rate voice** functionality and you do not specify **fax rate disable** command behavior, fax calls are processed as a regular voice calls and their completion is subject to line quality just like any other form of voice communication.

Note Because the **fax rate voice** command has been reclassified as a default setting, it will no longer automatically generate an entry in your gateway router's running configuration in NVRAM. If your gateway configuration requires **fax rate voice** command functionality, you must reconfigure your gateway after loading a Cisco IOS image earlier than Cisco IOS Release 12.3(4)T.

Examples The following example shows voice service fax rate transmission set to **disable**:

```
voice service pots
 fax rate disable
```

Related Commands

Command	Description
fax protocol (voice-service)	Specifies the global default fax protocol for all VoIP dial peers.
voice service	Specifies the voice encapsulation type.

fax receive called-subscriber

To define the called subscriber identification (CSI), use the **fax receive called-subscriber** command in global configuration mode. To disable the configured CSI, use the **no** form of this command.

fax receive called-subscriber {**d** | *telephone-number*}

no fax receive called-subscriber {**d** | *telephone-number*}

Syntax Description

d	Wildcard that indicates that the information displayed is captured from the configured destination pattern.
telephone-number	Destination telephone number. Valid entries are the plus sign (+), numerals from 0 through 9, and the space character. This string can specify an E.164 telephone number; if you choose to configure an E.164 telephone number, you must use the plus sign as the first character.

Command Default

Enabled with a null string

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

Use this command to define the number displayed in the liquid crystal display (LCD) of the sending fax device when you are sending a fax to a recipient. Typically, with a standard Group 3 fax device, this is the telephone number associated with the receiving fax device. The command defines the CSI.

This command applies to on-ramp store-and-forward fax functions.

Examples

The following example configures the number 555-0134 as the called subscriber number:

```
fax receive called-subscriber 5550134
```

fax-relay (dial peer)

To allow for the suppression of tones from the fax machine side so that Super Group 3 (SG3) fax machines can negotiate down to G3 speeds using fax relay or to disable fax-relay Error Correction Mode (ECM) on a VoIP dial peer, use the **fax-relay** command in dial peer configuration mode. To disable these functions, use the **no** form of this command.

fax-relay {**ans-disable** | **ecm-disable** | **sg3-to-g3** [*system*]}

no fax-relay {**ans-disable** | **ecm-disable** | **sg3-to-g3** [*system*]}

Syntax Description

ans-disable	Suppresses ANS tones from originating SG3 fax machines so that these machines can operate at G3 speeds using fax relay.
ecm-disable	Disables fax-relay ECM on a VoIP dial peer.
sg3-to-g3	Allows SG3 machines to negotiate down to G3 speeds using fax relay.
system	(Optional) The protocol set to be used in the voice-service configuration mode.

Command Default

If this command is not enabled, modem upspeed can occur when ANS tones are detected, fax-relay ECM is enabled, and SG3-to-SG3 fax relay communication is not supported and probably will fail.

Command Modes

Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.1(3)T	This command was introduced as the **fax-relay ecm-disable** command.
12.1(5)XM	This command was implemented on the Cisco AS5800.
12.1(5)XM2	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.4(4)T	The **sg3-to-g3** keyword and *system* argument were added.
12.4(6)T	This command was implemented on the Cisco 1700 series and Cisco 2800 series.
12.4(20)T1	The **ans-disable** keyword was added.

Usage Guidelines

The **ans-disable** keyword was added to ensure that modem upspeed does not occur when an ANS tone is detected. When the **fax-relay ans-disable** command is entered, the modem-related sessions fail because the ANS tones are squelched at the digital signal processor (DSP) level by the TI C5510 DSP.

When the **fax-relay ecm-disable** command is entered, the DSP fax-relay firmware disables ECM by modifying the Digital Information Signal (DIS) T.30 message. This is performed on DIS signals in both directions so that ECM is disabled in both directions even if only one gateway is configured with ECM disabled. This setting is provisioned when the DSP channel starts fax relay and cannot be changed during the fax relay session.

When the **fax-relay sg3-to-g3** command is entered, the DSP fax-relay firmware suppresses the V.8 call menu (CM) tone and the fax machines negotiate down to G3 speeds for the fax stream. Modem communication is impacted if the session does not negotiate either modem passthrough or relay. Use this command for H.323 and Session Initiation Protocol (SIP) signaling types.

The **fax-relay** command is also available in voice-service configuration mode, but the **ecm-disable** keyword and *system* argument are not available.

Examples

The following dial-peer configuration disables ECM on the voice dial peer:

```
Router(config)# dial-peer voice 25 voip
Router(config-dial-peer)# fax-relay ecm-disable
```

The following dial-peer configuration shows SG3 V.8 fax CM message suppression being enabled on the voice dial peer for H.323 and SIP signaling types:

```
Router(config)# dial-peer voice 25 voip
Router(config-dial-peer)# fax-relay sg3-to-g3
```

The following dial-peer configuration shows how to enable ANS tone squelching at the DSP level for all VoIP dial peers:

```
Router(config)# dial-peer voice 25 voip
Router(config-dial-peer)# fax-relay ans-disable
```

Related Commands

Command	Description
fax protocol (dial peer)	Specifies the fax protocol to be used for a specific VoIP dial peer.
fax protocol t38 (dial peer)	Specifies the ITU-T T.38 standard fax protocol to be used for a specific VoIP dial peer.
fax-relay (voice-service)	Allows ANS tones to be disabled for SG3 machines to operate at G3 speeds using fax relay and to enable the fax stream between two SG3 fax machines to negotiate down to G3 speeds on a VoIP dial peer.
mgcp fax-relay	Allow ANS tones to be disabled for SG3 machines to operate at G3 speeds for MGCP fax relay or to enable the fax stream between two SG3 fax machines to negotiate down to G3 speeds for MGCP fax relay.

fax send center-header

To specify the data that appears in the center position of the fax header information, use the **fax send center-header** command in global configuration mode. To remove the selected options, use the **no** form of this command.

fax send center-header {**a** | **d** | **p** | **s** | **t** | *string*}

no fax send center-header {**a** | **d** | **p** | **s** | **t** | *string*}

Syntax Description

a	Wildcard that inserts the date in the selected position.
d	Wildcard that inserts the destination address in the selected position.
p	Wildcard that inserts the page count in the selected position.
s	Wildcard that inserts the sender's address in the selected position.
t	Wildcard that inserts the transmission time in the selected position.
string	Text string that provides personalized information. Valid characters are any text plus wildcards—for example, Time:t. There is no default.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines Mail messages that contain only text or contain text attachments (text of the MIME media type) can be converted by the off-ramp gateway into a format understood by a fax machine's text-to-fax converter. When this conversion is performed, this command indicates what header information is added to the center top position of those pages.

Mail messages with TIFF attachments (MIME media image type and TIFF subtype) are expected to include their own per-page headers.

Note Faxed header information cannot be converted from TIFF files to standard fax transmissions.

This command lets you configure several options by combining one or more wildcards with text string information to customize your fax header information.

Note If the information you have selected for the **fax send center-header** command exceeds the space allocated for the center fax header, the information is truncated.

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example selects the fax transmission time as the centered fax header:

```
fax send center-header $t$
```

The following example configures the company name “Widget” and its address as the centered fax header:

```
fax send center-header widget $s$
```

Related Commands

Command	Description
fax send left-header	Specifies the data that appears on the left in the fax header.
fax send right-header	Specifies the data that appears on the right in the fax header.

fax send coverpage comment

To define customized text for the title field of a fax cover sheet, use the **fax send coverpage comment** command in global configuration mode. To disable the defined comment, use the **no** form of this command.

fax send coverpage comment *string*

no fax send coverpage comment *string*

Syntax Description

string	Text string that adds customized text in the title field of the fax cover sheet. Valid characters are any ASCII characters.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

This command can be overridden by the **fax send coverpage e-mail-controllable** command.

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example configures an individualized title comment of "XYZ Fax Services" for generated fax cover sheets:

```
fax send coverpage enable
fax send coverpage comment XYZ Fax Services
```

Related Commands

Command	Description
fax send coverpage e-mail-controllable	Controls the cover page generation on a per-recipient basis, based on the information contained in the destination address of the e-mail message.
fax send coverpage enable	Generates fax cover sheets.
fax send coverpage show-detail	Prints all of the e-mail header information as part of the fax cover sheet.

fax send coverpage e-mail-controllable

To defer to the cover page setting in the e-mail header to generate a standard fax cover sheet, use the **fax send coverpage e-mail-controllable** command in global configuration mode. To disable standard fax sheet generation, use the **no** form of this command.

fax send coverpage e-mail-controllable

no fax send coverpage e-mail-controllable

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300 universal access server.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750 access router.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

You can also use the destination address of an e-mail message to control the cover page generation on a per-recipient basis. Use this command to configure the router to defer to the cover page setting in the e-mail header.

In essence, the off-ramp router defers to the setting configured in the e-mail address itself. For example, if the address has a parameter set to cover=no, this parameter overrides the setting for the **fax send coverpage enable** command, and the off-ramp gateway does not generate and send a fax cover page. If the address has a parameter set to cover=yes, the off-ramp gateway defers to this parameter setting to generate and send a fax cover page.

Table 24 shows examples of what the user would enter in the To: field of the e-mail message.

Table 24 Sample Entries for the To: Field

To: Field Entries	Description
`FAX=+1-312-555-3260@fax.com`	Fax sent to an E.164-compliant long distance telephone number in the United States. If the **fax coverpage enable** command is entered, store-and-forward fax generate a fax cover page.

Table 24 Sample Entries for the To: Field (continued)

To: Field Entries	Description
`FAX=+1-312-555-3260/cover=no@fax.com`	Fax sent to an E.164-compliant long distance telephone number in the United States. In this example, the **fax send coverpage enable** command is superseded by the cover=no statement. No cover page is generated.
`FAX=+1-312-555-3260/cover=yes@fax.com`	Fax sent to an E.164-compliant long distance telephone number in the United States. In this example, the **fax send coverpage enable** command is superseded by the cover=yes statement. Store-and-forward fax generates a fax cover page.

Note This command applies to off-ramp store-and-forward fax functions.

Examples

The following example enables standard generated fax cover sheets:

```
fax send coverpage enable
fax send coverpage e-mail-controllable
```

Related Commands

Command	Description
fax send coverpage comment	Defines customized text for the title field of a fax cover sheet.
fax send coverpage enable	Generates fax cover sheets.
fax send coverpage show-detail	Prints all the e-mail header information as part of the fax cover sheet.

fax send coverpage enable

To generate fax cover sheets for faxes that were converted into e-mail messages, use the **fax send coverpage enable** command in global configuration mode. To disable fax cover sheet generation, use the **no** form of this command.

fax send coverpage enable

no fax send coverpage enable

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines This command applies to off-ramp store-and-forward fax functions.

Note This command is applicable only to faxes that were converted to e-mail messages. The Cisco AS5300 universal access server does not alter fax TIFF attachments. Therefore you cannot use this command to enable the Cisco AS5300 to generate fax cover pages for faxes that are converted from TIFF files to standard fax transmissions.

Examples The following example enables the generation of fax cover sheets:

```
fax send coverpage enable
```

Related Commands

Command	Description
fax send coverpage comment	Defines customized text for the title field of a fax cover sheet.
fax send coverpage e-mail-controllable	Defers to the cover page setting in the e-mail header to generate a standard fax cover sheet
fax send coverpage show-detail	Prints all the e-mail header information as part of the fax cover sheet.

fax send coverpage show-detail

To display all e-mail header information as part of the fax cover sheet, use the **fax send coverpage show-detail** command in global configuration mode. To prevent the e-mail header information from being displayed, use the **no** form of this command.

fax send coverpage show-detail

no fax send coverpage show-detail

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guideliness This command applies to off-ramp store-and-forward fax functions.

Note This command is applicable only to faxes that are converted to e-mail messages. The Cisco AS5300 universal access server does not alter fax TIFF attachments. Therefore, you cannot use this command to enable the Cisco AS5300 to display additional fax cover page information for faxes that are converted from TIFF files to standard fax transmissions.

Examples The following example configures an individualized generated fax cover sheet that contains the e-mail header text:

```
fax send coverpage enable
no fax send coverpage e-mail-controllable
fax send coverpage show-detail
```

Related Commands

Command	Description
fax send coverpage comment	Defines customized text for the title field of a fax cover sheet.
fax send coverpage e-mail-controllable	Defers to the cover page setting in the e-mail header to generate a standard fax cover sheet.
fax send coverpage enable	Generates fax cover sheets.

fax send left-header

To specify the data that appears on the left in the fax header, use the **fax send left-header** command in global configuration mode. To disable the selected options, use the **no** form of this command.

fax send left-header {**a** | **d** | **p** | **s** | **t** | *string*}

no fax send left-header {**a** | **d** | **p** | **s** | **t** | *string*}

Syntax Description

a	Wildcard that inserts the date in the selected position.
d	Wildcard that inserts the destination address in the selected position.
p	Wildcard that inserts the page count in the selected position.
s	Wildcard that inserts the sender's address in the selected position.
t	Wildcard that inserts the transmission time in the selected position.
string	Text string that provides customized information. Valid characters are any combination of ASCII characters and the wildcards listed above.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

Mail messages that contain only text or text attachments (text of MIME media type) can be converted by the off-ramp device into a format understood by fax machines using a text-to-fax converter. When this conversion is performed, the **fax send left-header** command is used to indicate what header information should be added to the top left of those pages.

Mail messages with TIFF attachments (MIME media image type and TIFF subtype) are expected to include their own per-page headers, and the Cisco IOS software does not modify TIFF attachments.

This command lets you configure several options at once by combining one or more wildcards with text string information to customize your fax header information.

If the information you select for the **fax send left-header** command exceeds the space allocated for the left fax header, the information is truncated.

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example puts the fax transmission time on the left side of the fax header:

```
fax send left-header $t$
```

The following example puts the company name “widget” and its address on the left side of the fax header:

```
fax send left-header widget $s$
```

Related Commands

Command	Description
fax send center-header	Specifies the data that appears in the center of the fax header.
fax send right-header	Specifies the data that appears on the right in the fax header.

fax send max-speed

To specify the maximum speed at which an outbound fax is transmitted, use the **fax send max-speed** command in global configuration mode. To disable the selected speed, use the **no** form of this command.

fax send max-speed {**2400** | **4800** | **7200** | **9600** | **12000** | **14400**}

no fax send max-speed {**2400** | **4800** | **7200** | **9600** | **12000** | **14400**}

Syntax Description

2400	Transmission speed of 2400 bits per second (bps).
4800	Transmission speed of 4800 bps.
7200	Transmission speed of 7200 bps.
9600	Transmission speed of 9600 bps.
12000	Transmission speed of 12,000 bps.
14400	Transmission speed of 14,400 bps. This is the default.

Command Default

14,400 bps

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example sets the outbound fax transmission rate at 2400 bps:

```
fax send max-speed 2400
```

fax send right-header

To specify the data that appears on the right in the fax header information, use the **fax send right-header** command in global configuration mode. To disable the selected options, use the **no** form of this command.

fax send right-header {**a** | **d** | **p** | **s** | **t** | *string*}

no fax send right-header {**a** | **d** | **p** | **s** | **t** | *string*}

Syntax Description

a	Wildcard that inserts the date in the selected position.
d	Wildcard that inserts the destination address in the selected position.
p	Wildcard that inserts the page count in the selected position.
s	Wildcard that inserts the sender address in the selected position.
t	Wildcard that inserts the transmission time in the selected position.
string	Text string that provides customized information. Valid characters are any combination of ASCII characters and the wildcards listed above.

Command Default

No default behavior or values

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

Mail messages that contain only text or text attachments (text of MIME media type) can be converted by the off-ramp device into a format understood by fax machines using the text-to-fax converter. When this conversion is performed, this command is used to indicate what header information should be added to top right of those pages.

Mail messages with TIFF attachments (MIME media image type and TIFF subtype) are expected to include their own per-page headers, and the Cisco IOS software does not modify TIFF attachments.

This command lets you configure several options at once by combining one or more wildcards with text string information to customize your fax header information.

Note If the information you select for the **fax send right-header** command exceeds the space allocated for the right fax header, the information is truncated.

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example puts the fax date in the right-hand side of the fax header:

```
fax send right-header $a$
```

The following example puts the company name "XYZ" and its address in the right-hand side of the fax header:

```
fax send right-header XYZ $s$
```

Related Commands

Command	Description
fax send center-header	Specifies the data that appears in the center in the fax header.
fax send left-header	Specifies the data that appears on the left in the fax header.

fax send transmitting-subscriber

To define the transmitting subscriber information (TSI), use the **fax send transmitting-subscriber** command in global configuration mode. To disable the configured value, use the **no** form of this command.

fax send transmitting-subscriber {**s** | *string*}

no fax send transmitting-subscriber {**s** | *string*}

Syntax Description

s	Wildcard that inserts the sender name from the RFC 822 header (captured by the on-ramp device from the sending fax machine) in the selected position.
string	Originating telephone number. Valid entries are the plus sign (+), numerals from 0 through 9, and the space character. This string can specify an E.164 telephone number; if you choose to configure an E.164 telephone number, you must use the plus sign as the first character.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines The transmitting subscriber number is the number of the originating fax and is displayed in the LCD of the receiving fax device. Typically, with a standard Group 3 fax device, this number is the telephone number associated with the transmitting or sending fax device. This command defines the TSI.

This command applies to off-ramp store-and-forward fax functions.

Examples The following example configures the company number as captured by the on-ramp device from the sending fax machine:

```
fax send transmitting-subscriber +14085550134
```

file-acct flush

To manually flush call detail records (CDRs) from the buffer to the accounting file, use the **file-acct flush** command in privileged EXEC mode.

file-acct flush {**with-close** | **without-close**}

Syntax Description

with-close	Call records are appended to the accounting file and the file is closed.
without-close	Call records are appended to the accounting file and the file remains open.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Use this command if you need to manually flush the buffer, for example, if flash becomes full or you do not want to wait until the buffer is automatically flushed. This command immediately flushes the buffer and appends all CDRs in the buffer to the current accounting file. CDRs are automatically flushed from the buffer and written to the file whenever there is enough data based on the **maximum buffer-size** command or after the timer set with the **maximum cdrflush-timer** command expires.

Using the **with-close** keyword closes the current file and opens a new file after appending the records. Using the **without-close** keyword leaves the current file open after appending the records.

Examples

The following example appends the records to the accounting file and closes the file:

```
file-acct flush with-close
```

Related Commands

Command	Description
gw-accounting	Enables an accounting method for collecting CDRs.
maximum buffer-size	Sets the maximum size of the file accounting buffer.
maximum cdrflush-timer	Sets the maximum time to hold call records in the buffer before appending the records to the accounting file.
maximum fileclose-timer	Sets the maximum time for saving records to an accounting file before closing the file and creating a new one.
primary	Sets the primary location for storing the CDRs generated for file accounting.
secondary	Sets the backup location for storing CDRs if the primary location becomes unavailable.

file-acct reset

To manually switch back to the primary device for file accounting, use the **file-acct reset** command in privileged EXEC mode.

file-acct reset

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

This command allows you to switch back to the primary device when it becomes available if the backup device is currently being used because the primary device failed.

If the file transfer to the primary device fails, the file accounting process retries the primary device up to the number of times defined by the **maximum retry-count** command and then switches to the secondary device defined with the **secondary** command. This command flushes the buffer and writes the call detail records (CDRs) to the currently active file before resetting to the primary device and opening a new file.

If the secondary device also fails, the accounting process ends and the system logs an error. New CDRs are dropped until one device comes back online and you use this command. The system then immediately resets to the primary device, if available.

Examples

The following example shows how to switch back to the primary device:

```
Router# file-acct reset
```

Related Commands

Command	Description
gw-accounting	Enables an accounting method for collecting CDRs.
maximum retry-count	Sets the maximum number of times the router attempts to connect to the primary file device before switching to the secondary device
primary	Sets the primary location for storing the CDRs generated for file accounting.
secondary	Sets the backup location for storing CDRs if the primary location becomes unavailable.

filter voice

To specify that voice calls bypass authentication, authorization, and accounting (AAA) preauthentication, use the **filter voice** command in AAA preauthentication configuration mode. To disable AAA bypass, use the **no** form of this command.

filter voice

no filter voice

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes AAA preauthentication configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Examples The following example specifies that voice calls bypass AAA preauthentication:

```
Router(config)# aaa preauth
Router(config-preauth)# filter voice
```

Related Commands

Command	Description
aaa preauth	Enters AAA preauthentication configuration mode.

flush

To enable file mode accounting flush options, use the **flush** command in privileged EXEC mode.

flush {**with-close** | **without-close**}

Syntax Description

with-close	Enables file accounting flush pending accounting to the file, and closes the file when the process is complete.
without-close	Enables file accounting flush pending accounting to file.

Command Default File mode accounting flush options are not enabled.

Command Modes Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines The **flush** command flushes pending accounting records to the file.

Examples In the following example, the **flush with-close** command enables file accounting flush pending accounting to the file, and closes the file when the process is complete:

```
Router# flush with-close
```

Related Commands

Command	Description
maximum cdrflush-timer	Sets the maximum time to hold call records in the buffer before appending the records to the accounting file.

fmtp

To set a format-specific string for a codec, use the **fmtp** command in codec-profile configuration mode. To disable the format string, use the **no** form of this command.

fmtp *string*

no fmtp

Syntax Description

string	fmtp:payload type name1= val1; name2 = val2...

For Cisco Unified Customer Voice Portal (Cisco Unified CVP), the dynamic payload number is in the range of 96 to 127 for H.263+. For H263, it is always 34. For H.263+, this number must be entered but it is not used. Cisco Unified CVP uses either the default value for H.263+ (118) or the value defined for the VoIP dial peer using the command **rtp payload-type cisco-codec-video-h263+,** a number in the range 96 to 127.

Other parameters can be the following:

- SQCIF = 1 - 32
- QCIF = 1 - 32
- CIF = 1 - 32
- 4CIF = 1 - 32
- 16CIF = 1 - 32
- MAXBR (max bitrate) = Value in 100 bits per second (500 = 50000 bits per second). This value is another that is not used. Always set H.324 to 50K.
- D—1 (Enable H.263 Annex D)
- F—1 (Enable H.263 Annex F)
- I—1 (Enable H.263 Annex I)
- J—1 (Enable H.263 Annex J)
- K—1 to 4 (Enable H.263 Annex K) (Annex K is Slice Structured Mode)
  - 1—Slices In Order, Nonrectangular
  - 2—Slices In Order, Rectangular
  - 3—Slices Not Ordered, Nonrectangular
  - 4—Slices Not Ordered, Rectangular
- N=[1,4] (Enable H.263 Annex N) (Annex N is Reference Picture Selection Mode)
  - 1—NEITHER: No back-channel data is returned from the decoder to the encoder.
  - 2—ACK: The decoder returns only acknowledgment messages.
  - 3—NACK: The decoder returns only nonacknowledgment messages.
  - 4—ACK+NACK: The decoder returns both acknowledgment and nonacknowledgment messages.

- P=[x,y] (Enable H.263 Annex P) (Annex P is Reference Picture Resampling). Annex P can have either one or two parameters, depending on the values selected. There are four options, and six valid combinations.
  - 1—dynamicPictureResizingByFour
  - 2—dynamicPictureResizingBySixteenthPel
  - 3—dynamicWarpingHalfPel
  - 4—dynamicWarpingSixteenthPel.

  The valid combinations are:
  - 1
  - 1,3
  - 2
  - 2, 3
  - 2, 4
  - 3
- T=1 (Enable H.263 Annex T)
- CUSTOM = x, y, MPI — Defines a custom picture format, where X is the X-axis size in pixels, Y is the Y-axis size in pixels, and MPI is the frame rate (30/(1.001*MPI)). X and Y must be divisible by 4, and MPI has a value of 1to 32.

Command Default No string is configured.

Command Modes Codec-profile configuration (config-codec-profile)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines The profile is selected by entering the command:

video codec h263/h263+ profile 1000

The video codec h263/h263+ profile can be used in a voip dial peer or as a voice class codec entry.

Examples The following example shows an fmtp string for video codec profile 116:

```
codec profile 116 H263
    clockrate 90000
    fmtp "fmtp:120 SQCIF=1;QCIF=1;CIF=1;CIF4=2;MAXBR=3840;I=1"
```

Related Commands

Command	Description
clock-rate	Sets the clock rate for the codec.

forward-alarms

To turn on alarm forwarding so that alarms that arrive on one T1/E1 port are sent to the other port on dual-mode multiflex trunk interface cards, use the **forward-alarms** command in controller configuration mode on the one port. To reset to the default so that no alarms are forwarded, use the **no** form of this command.

forward-alarms

no forward-alarms

Syntax Description

This command has no arguments or keywords.

Command Default

Alarm forwarding is disabled

Command Modes

Controller configuration

Command History

Release	Modification
12.0(7)XR	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Usage Guidelines

When you enter this command, physical-layer alarms on the configured port are forwarded to the other port on dual-port cards, simulating a one-way repeater operations. The system forwards RAIs (remote alarm indications, or Yellow Alarms), alarm indication signals (AIS, or Blue Alarms), losses of frame (LOF alarms, or Red Alarms), and losses of signaling (LOS alarms, or Red Alarms).

Examples

The following example turns on alarm forwarding on controller E1 0/0:

```
controller e1 0/0
 forward-alarms
```

forward-digits

To specify which digits to forward for voice calls, use the **forward-digits** command in dial peer configuration mode. To specify that any digits not matching the destination-pattern are not to be forwarded, use the **no** form of this command. To reset to the default, use the **default** form of this command.

forward-digits {*num-digit* | **all** | **extra**}

no forward-digits

default forward-digits

Syntax Description

num-digit	The number of digits to be forwarded. If the number of digits is greater than the length of a destination phone number, the length of the destination number is used. Range is 0 to 32. Setting the value to 0 is equivalent to entering the **no forward-digits** command.
all	Forwards all digits. If **all** is entered, the full length of the destination pattern is used.
extra	If the length of the dialed digit string is greater than the length of the dial-peer destination pattern, the extra right-justified digits are forwarded. However, if the dial-peer destination pattern is variable length ending with the character "T" (for example: T, 123T, 123...T), extra digits are not forwarded.

Command Default Dialed digits not matching the destination pattern are forwarded

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0(2)T	This command was integrated into Cisco IOS Release 12.0(2)T. The **implicit** option was added.
12.0(4)T	This command was modified to support ISDNBF PRI QSIG signaling calls.
12.0(7)XK	This command was implemented on the Cisco 2600 series and Cisco 3600 series. The **implicit** keyword was removed and the **extra** keyword was added.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines This command applies only to POTS dial peers. Forwarded digits are always right justified so that extra leading digits are stripped. The destination pattern includes both explicit digits and wildcards if present. Use the **default** form of this command if a nondefault digit-forwarding scheme was entered previously and you wish to restore the default.

For QSIG ISDN connections, entering the **forward-digits all** command implies that all the digits of the called party number are sent to the ISDN connection. When the **forward-digits** *num-digit* command and a number from 1 to 32 are entered, the number of digits of the called party number specified (right justified) are sent to the ISDN connection.

Examples

The following example shows that all digits in the destination pattern of a POTS dial peer are forwarded:

```
dial-peer voice 1 pots
 destination-pattern 8...
 forward-digits all
```

The following example shows that four of the digits in the destination pattern of a POTS dial peer are forwarded:

```
dial-peer voice 1 pots
 destination-pattern 555....
 forward-digits 4
```

The following example shows that the extra right-justified digits that exceed the length of the destination pattern of a POTS dial peer are forwarded:

```
dial-peer voice 1 pots
 destination-pattern 555....
 forward-digits extra
```

Related Commands

Command	Description
destination-pattern	Defines the prefix or the full E.164 telephone number to be used for a dial peer.
show dial-peer voice	Displays configuration information for dial peers.

frame-relay voice bandwidth

To specify how much bandwidth should be reserved for voice traffic on a specific data-link connection identifier (DLCI), use the **frame-relay voice bandwidth** command in map-class configuration mode. To release the bandwidth previously reserved for voice traffic, use the **no** form of this command.

frame-relay voice bandwidth *bps-reserved*

no frame-relay voice bandwidth *bps-reserved*

Syntax Description

bps-reserved	Bandwidth, in bits per second (bps), reserved for voice traffic for the specified map class. Range is from 8000 to 45000000. Default is 0, which disables voice calls.

Command Default Disabled (zero)

Command Modes Map-class configuration

Command History

Release	Modification
12.0(3)XG	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco MC3810.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.0(5)T	The **queue** *depth* keyword and argument were added.
12.2(1)	The **queue** *depth* keyword and argument were removed.

Usage Guidelines To use this command, you must first associate a Frame Relay map class with a specific DLCI and then enter map-class configuration mode and set the amount of bandwidth to be reserved for voice traffic for that map class.

If a call is attempted and there is not enough remaining bandwidth reserved for voice to handle the additional call, the call is rejected. For example, if 64 kbps is reserved for voice traffic and a codec and payload size is being used that requires 10 kbps of bandwidth for each call, the first six calls attempted are accepted, but the seventh call is rejected.

Reserve queues are not required for Voice over Frame Relay (VoFR).

Note Cisco strongly recommends that you set voice bandwidth to a value less than the committed information rate (CIR) if Frame Relay traffic shaping is configured. Cisco also strongly recommends that you set the minimum CIR (using the **frame-relay mincir** command) to be at least equal to or greater than the voice bandwidth.

Calculating Required Bandwidth

The bandwidth required for a voice call depends on the bandwidth of the codec, the voice packetization overhead, and the voice frame payload size. The smaller the voice frame payload size, the higher the bandwidth required for the call. To make the calculation, use the following formula:

required_bandwidth = codec_bandwidth x (1 + overhead / payload_size)

As an example, the overhead for a VoFR voice packet is between 6 and 8 bytes: a 2-byte Frame Relay header, a 1- or 2-byte FRF.11 header (depending on the CID value), a 2-byte cyclic redundancy check (CRC), and a 1-byte trailing flag. If voice sequence numbers are enabled in the voice packets, there is an additional 1-byte sequence number. Table 25 shows the required voice bandwidth for the G.729 8000-bps speech coder for various payload sizes.

Table 25 Required Voice Bandwidth Calculations for G.729

Codec	Codec Bandwidth	Voice Frame Payload Size	Required Bandwidth per Call (6-Byte OH)	Required Bandwidth per Call (8-Byte OH)
G.729	8000 bps	120 bytes	8400 bps	8534 bps
G.729	8000 bps	80 bytes	8600 bps	8800 bps
G.729	8000 bps	40 bytes	9200 bps	9600 bps
G.729	8000 bps	30 bytes	9600 bps	10134 bps
G.729	8000 bps	20 bytes	10400 bps	11200 bps

To configure the payload size for the voice frames, use the **codec** command from dial peer configuration mode.

Examples

The following example shows how to reserve 64 kbps for voice traffic for the “vofr” Frame Relay map class:

```
interface serial 1/1
 frame-relay interface-dlci 100
  class vofr
  exit
map-class frame-relay vofr
 frame-relay voice bandwidth 64000
```

Related Commands

Command	Description
codec (dial peer)	Specifies the voice coder rate of speech for a VoFR dial peer.
frame-relay fair-queue	Enables weighted fair queueing for one or more Frame Relay PVCs.
frame-relay fragment	Enables fragmentation for a Frame Relay map class.
frame-relay interface-dlci	Assigns a DLCI to a specified Frame Relay subinterface on the router or access server.
frame-relay mincir	Assigns the minimum CIR for Frame Relay traffic shaping.
map-class frame-relay	Specifies a map class to define QoS values for an SVC.

freq-max-delay

To specify the maximum timing difference allowed between the two frequencies for detection of a tone, use the **freq-max-delay** command **in** voice-class configuration mode. To reset to the default allowed timing difference, use the **no** form of this command.

freq-max-delay *time*

no freq-max-delay

Syntax Description

time	Maximum number of 10-millisecond time intervals by which the two frequencies in a tone may differ from each other and be detected. Range is from 10 to 100 (100 milliseconds to 1 second). The Default is 10 (100 milliseconds).

Command Default

10 (100 milliseconds)

Command Modes

Voice-class configuration

Command History

Release	Modification
12.1(5)XM	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750.

Usage Guidelines

This command creates a detection limit for one parameter within a voice class that you can apply to any voice port.

You must specify a time value greater than the timing difference expected in the tone to be detected.

Examples

The following example configures a maximum timing difference of 200 milliseconds for voice class 100:

```
voice class dualtone 100
 freq-max-delay 20
```

The following example configures a maximum timing difference of 160 milliseconds for voice class 70:

```
voice class dualtone-detect-params 70
 freq-max-delay 1
```

Related Commands

Command	Description
dualtone	Defines the tone and cadence for a custom call-progress tone.
freq-pair	Specifies the frequency components of a tone to be detected.
supervisory answer dualtone	Enables answer supervision on a voice port.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

freq-max-deviation

To specify the maximum frequency deviation allowed in a tone, use the **freq-max-deviation command in** voice-class configuration mode. To reset to the default maximum frequency deviation, use the **no** form of this command.

freq-max-deviation *frequency*

no freq-max-deviation

Syntax Description

frequency	Maximum cycles per second (Hz) by which tone frequencies may deviate from the configured frequencies and be detected. The value applies to both frequencies of a dual tone. Range is from 10 to 125. The default is 10.

Command Default 10 Hz

Command Modes Voice-class configuration

Command History

Release	Modification
12.1(5)XM	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750.

Usage Guidelines This command creates a detection limit for one parameter within a voice class that you can apply to any voice port.

Be sure that the frequency deviation is less than the smallest frequency difference between any two call-progress tones to prevent overlapping of detectable frequencies. If detectable frequencies overlap, one of the call-progress tones is not detected.

You must specify a time value greater than the expected frequency deviation in the tone to be detected.

Examples The following example configures a maximum frequency deviation of 20 Hz for voice class 100:

```
voice class dualtone 100
 freq-max-deviation 20
```

The following example configures a maximum frequency deviation of 20 Hz for voice class 70:

```
voice class dualtone-detect-params 70
 freq-max-deviation 20
```

Related Commands

Command	Description
dualtone	Defines the tone and cadence for a custom call-progress tone.
freq-pair	Specifies the frequency components of a tone to be detected.
supervisory answer dualtone	Enables answer supervision on a voice port.
supervisory dualtone-detect-params	Assigns the boundary and detection tolerance parameters to a voice port.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

freq-max-power

To specify the upper limit of tone power allowed in a tone, use the **freq-max-power** command in voice-class configuration mode. To reset to the default maximum tone power, use the **no** form of this command.

freq-max-power *dBm0*

no freq-max-power

Syntax Description

dBm0	Upper limit of the tone power that is detected, in dBm0 (where dBm0 is decibels referred to one milliwatt and corrected to a 0-dBm effective power level). Range is from 0 to 20. The default is 10. **Note** The range is expressed in the negative of the desired level. A configured value of 20, equals -20 dBmO.

Command Default

10 dBm0

Command Modes

Voice-class configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750.

Usage Guidelines

This command creates a detection limit for one parameter within a voice class that you can apply to any voice port.

You must specify a power value greater than the expected maximum power of a tone to be detected.

Examples

The following example configures a maximum tone power of -20 dBm0 for voice class 100:

```
voice class dualtone 100
 freq-max-power 20
```

The following example configures a maximum tone power of -6 dBm0 for voice class 70:

```
voice class dualtone-detect-params 70
 freq-max-power 6
```

Related Commands

Command	Description
dualtone	Defines the tone and cadence for a custom call-progress tone.
freq-pair	Specifies the frequency components of a tone to be detected.
supervisory answer dualtone	Enables answer supervision on a voice port.
supervisory dualtone-detect-params	Assigns the boundary and detection tolerance parameters defined by the **voice class dualtone-detect-params** command to a voice port.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

freq-min-power

To specify the lower limit of tone power allowed in a tone, use the **freq-min-power** command in voice-class configuration mode. To reset to the default minimum tone power, use the **no** form of this command.

freq-min-power *dBm0*

no freq-min-power

Syntax Description

dBm0	Lower limit of tone power that is detected, in dBm0 (where dBm0 is decibels referred to one milliwatt and corrected to a 0-dBm effective power level). Range is from 10 to 35. The default is 30. **Note** The range is expressed in the negative of the desired level. A configured value of 20, equals -20 dBmO.

Command Default 30 dBm0

Command Modes Voice-class configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750.

Usage Guidelines This command creates a detection limit for one parameter within a voice class that you can apply to any voice port.

You must specify a power value less than the expected minimum power of a tone to be detected.

Examples The following example configures a tone-power lower limit of -15 dBm0 for voice class 100:

```
voice class dualtone 100
 freq-min-power 15
```

The following example configures a tone-power lower limit of -25 dBm0 for voice class 70:

```
voice class dualtone-detect-params 70
 freq-min-power 25
```

Related Commands

Command	Description
dualtone	Defines the tone and cadence for a custom call-progress tone.
freq-pair	Specifies the frequency components of a tone to be detected.
supervisory answer dualtone	Enables answer supervision on a voice port.
supervisory dualtone-detect-params	Assigns the boundary and detection tolerance parameters to a voice port.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

freq-pair

To specify the frequency components of a tone to be detected, use the **freq-pair command in** voice-class configuration mode. To cancel detection of a tone, use the **no** form of this command.

freq-pair *tone-id frequency-1 frequency-2*

no freq-pair *tone-id*

Syntax Description

tone-id	Tag identifier for a tone to be detected. Range is from 1 to 16. There is no default.
frequency-1	One frequency component of the tone to be detected, in Hz. Range is from 300 to 3600. There is no default.
frequency-2	A second frequency component of the tone to be detected, in Hz. Range is frm 300 to 3600, or you can specify 0. There is no default.

Command Default No tone is specified for detection

Command Modes Voice-class configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.

Usage Guidelines To detect a tone with two frequency components (a dualtone), configure frequencies for *frequency-1* and *frequency-2*.

To detect a tone with only one frequency component, configure a frequency for *frequency-1* and enter 0 for *frequency-2*.

You can configure a router to detect up to 16 tones.

Examples The following example configures tone number 1 (tone-id 1) with frequency components of 480 Hz and 2400 Hz:

```
voice class dualtone 100
 freq-pair 1 480 2400
 exit
```

The following example configures tone number 1 (tone-id 1) with frequency components of 480 Hz and 2400 Hz and tone number 2 (tone-id 2) with frequency components of 560 Hz and 880 Hz:

```
voice class dualtone 50
 freq-pair 1 480 2400
 freq-pair 2 560 880
 exit
```

Related Commands

Command	Description
frag-pre-queuing	Specifies the maximum timing difference allowed between the two frequencies for detection of a tone.
freq-max-deviation	Specifies the maximum frequency deviation allowed in a tone.
freq-max-power	Specifies the upper limit of the tone power allowed in a tone.
freq-min-power	Specifies the lower limit of the tone power allowed in a tone.
freq-power-twist	Specifies the power difference allowed between the two frequencies of a tone.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

freq-power-twist

To specify the power difference allowed between the two frequencies of a tone, use the **freq-power-twist command in** voice-class configuration mode. To reset to the default power difference allowed, use the **no** form of this command.

freq-power-twist *dBm0*

no freq-power-twist

Syntax Description

dBm0	Maximum power difference allowed between the two frequencies of a tone, in dBm0 (where dBm0 is decibels referred to one milliwatt and corrected to a 0-dBm effective power level). Range is from 0 to 15. The default is 6.

Command Default

6 dBm0

Command Modes

Voice-class configuration

Command History

Release	Modification
12.1(5)XM	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750.

Usage Guidelines

This command creates a detection limit for one parameter within a voice class that you can apply to any voice port.

You must specify a power value greater than the expected maximum power difference of the two frequencies in the tone to be detected.

Examples

The following example configures a maximum allowed power difference of 3 dBm0 between the two tone frequencies for voice class 100:

```
voice class dualtone 100
 freq-power-twist 3
```

The following example configures a maximum allowed power difference of 15 dBm0 between the two tone frequencies in voice class 70:

```
voice class dualtone-detect-params 70
 freq-power-twist 15
```

Related Commands

Command	Description
dualtone	Defines the tone and cadence for a custom call-progress tone.
freq-pair	Specifies the frequency components of a tone to be detected.
supervisory answer dualtone	Enables answer supervision on a voice port.
supervisory dualtone-detect-params	Assigns the boundary and detection tolerance parameters defined by the **voice class dualtone-detect-params** command to a voice port.
voice class dualtone	Creates a voice class for FXO tone detection parameters.

frequency (cp-dualtone)

To define the frequency components for a call-progress tone, use the **frequency** command in cp-dualtone configuration mode. To reset to the default frequency components, use the **no** form of this command.

frequency *frequency-1* [*frequency-2*]

no frequency

Syntax Description

frequency-1	One frequency component of the tone to be detected, in Hz. Range is from 300 to 3600. The default is 300.
frequency-2	(Optional) A second frequency component of the tone to be detected, in Hz. Range is from 300 to 3600 or you can specify 0. The default is that no second frequency component is detected.

Command Default 300-Hz single tone

Command Modes cp-dualtone configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 1750.

Usage Guidelines This command specifies the frequency component for a class of custom call-progress tones.

You need to define the frequency that you want a voice port to detect. Reenter the command for each additional frequency to be detected.

You need to associate the class of custom call-progress tones with a voice port for this command to affect tone detection.

Examples The following example defines the frequency components for the busy tone in custom-cptone voice class country-x.

```
voice class custom-cptone country-x
 dualtone busy frequency 480 620
```

Related Commands

Command	Description
supervisory custom-cptone	Associates a class of custom call-progress tones with a voice port.
voice class custom-cptone	Creates a voice class for defining custom call-progress tones.
voice class dualtone-detect-params	Modifies the boundaries and limits for custom call-progress tones defined by the **voice class custom-cptone** command.

Cisco IOS Voice Commands: G

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Guide*.

g729 annexb-all

To configure Cisco IOS Session Initiation Protocol (SIP) gateway to treat the G.729br8 codec as superset of G.729r8 and G.729br8 codecs to interoperate with the Cisco Unified Communications Manager, use the **g729 annexb-all** command in voice service SIP configuration mode. To return to the default global setting for the gateway, where G.729br8 codec represents only the G.729br8 codec, use the **no** form of this command.

g729 annexb-all

no g729 annexb-all

Syntax Description

annexb-all	Specifies that the G.729br8 codec is treated as a superset of G.729r8 and G.729br8 codecs to communicate with Cisco Unified Communications Manager.

Command Default

G.729br8 codec is not viewed as superset of G.729r8 and G.729br8 codecs.

Command Modes

Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(15)XZ	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

There are four variations of the G.729 coder-decoder (codec), which fall into two categories:

High Complexity

- G.729 (g729r8)—a high complexity algorithm codec on which all other G.729 codec variations are based.
- G.729 Annex-B (g729br8 or G.729B)—a variation of the G.729 codec that allows the DSP to detect and measure voice activity and convey suppressed noise levels for re-creation at the other end. Additionally, the Annex-B codec includes Internet Engineering Task Force (IETF) voice activity detection (VAD) and comfort noise generation (CNG) functionality.

Medium Complexity

- G.729 Annex-A (g729ar8 or G.729A)—a variation of the G.729 codec that sacrifices some voice quality to lessen the load on the DSP. All platforms that support G.729 also support G.729A.
- G.729A Annex-B (g729abr8 or G.729AB)—a variation of the G.729 Annex-B codec that, like G.729B, sacrifices voice quality to lessen the load on the DSP. Additionally, the G.729AB codec also includes IETF VAD and CNG functionality.

The VAD and CNG functionality is what causes the instability during communication attempts between two DSPs where one DSP is configured with Annex-B (G.729B or G.729AB) and the other without (G.729 or G.729A). All other combinations interoperate. To configure a Cisco IOS SIP gateway for

interoperation with Cisco Unified Communications Manager (formerly known as the Cisco CallManager, or CCM), use the **g729-annexb-all** command in voice service SIP configuration mode to allow connection of calls between two DSPs with incompatible G.729 codecs. Use the **voice-class sip g729 annexb-all** command in dial peer voice configuration mode to configure G.729 codec interoperation settings for a dial peer that override global settings for the Cisco IOS SIP gateway.

Examples

The following example configures a Cisco IOS SIP gateway (globally) to be able to connect calls between otherwise incompatible G.729 codecs:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# g729 annexb-all
```

Related Commands

Command	Description
voice-class sip g729 annexb-all	Configures an individual dial peer on a Cisco IOS SIP gateway to view a G.729br8 codec as superset of G.729r8 and G.729br8 codecs.

g732 ber

To enable G.732 processing and reporting for the E1 controller, use the **g732 ber** command in controller configuration mode. To disable processing and reporting, use the **no** form of this command.

g732 ber

no g732 ber

Syntax Description

This command has no arguments or keywords.

Command Default

G.732 is disabled.

Command Modes

Controller configuration

Command History

Release	Modification
12.2(2)T	This command was introduced on the Cisco 2611.
12.2(15)T	This command was implemented on the Cisco AS5350 and Cisco AS5400 network access server (NAS) platforms.

Usage Guidelines

By default, G.732 reporting is disabled to prevent a change in E1 behavior for sites that do not want G.732 reporting.

Once ITU-T G.732 is enabled, the E1 controller is placed in the DOWN state if the bit error rate (BER) on the line is greater than 10e-3. The controller is restored to the UP state if the BER drops below 10e-4 for longer than two seconds. When the G.732 alarm is declared, the transmitter sends a remote alarm indication (RAI) yellow alarm.

You can restore ITU-T G.732 functionality by performing a power cycle or a software reload.

Examples

The following example applies to a Cisco 2611 and shows enabled G.732 processing and reporting for E1 controller 0/0:

```
controller e1 0/0
 g732 ber
```

The following example applies to a Cisco AS5400 with an 8-PRI E1 dial feature card (DFC) in slot 4:

```
controller e1 4/0
 g732 ber
```

Related Commands

Command	Description
show controllers e1	Displays information about E1 links.

gatekeeper

To enter gatekeeper configuration mode, use the **gatekeeper** command in global configuration mode.

gatekeeper

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on the Cisco 2500 series and Cisco 3600 series.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T and implemented on the Cisco MC3810.

Usage Guidelines Press **Ctrl-Z** or use the **exit** command to exit gatekeeper configuration mode.

Examples The following example brings the gatekeeper online:

```
gatekeeper
 no shutdown
```

gateway

To enable the H.323 VoIP gateway, use the **gateway** command in global configuration mode. To disable the gateway, use the **no** form of this command.

gateway

no gateway

Syntax Description This command has no arguments or keywords.

Command Default The gateway is unregistered

Command Modes Global configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the following platforms: Cisco 3600 series, Cisco AS5300, and Cisco AS5800.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines Use this command to enable H.323 VoIP gateway functionality. After you enable the gateway, it attempts to discover a gatekeeper by using the H.323 RAS GRQ message. If you enter **no gateway voip**, the VoIP gateway unregisters with the gatekeeper via the H.323 RAS URQ message.

Examples The following example enables the gateway:

```
gateway
```

gcid

To enable Global Call ID (Gcid) for every call on an outbound leg of a VoIP dial peer for a SIP endpoint, use the **gcid** command in voice-service configuration mode. To return to the default, use the **no** form of this command.

gcid

no gcid

Syntax Description

This command has no arguments or keywords.

Command Default

Gcid is disabled.

Command Modes

Voice-service configuration (config-voi-serve)

Command History

Cisco IOS Release	Cisco Product	Modification
12.4(11)XW2	Cisco Unified CME 4.2	This command was introduced.
12.4(15)XY	Cisco Unified CME 4.2 (1)	This command was introduced.
12.4(15)XZ	Cisco Unified CME 4.3	This command was introduced.
12.4(20)T	—	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

This command in voice-service configuration mode enables Global Call ID (Gcid) in the SIP header for every call on an outbound leg of a VoIP dial peer for a SIP endpoint.

When a call moves around and between the SIP endpoint and the target on a VoIP network because of redirect, transfer, and conference, the SIP Call-ID continues to change. For call control purposes, a unique Gcid is issued for every outbound call leg. A single Gcid remains the same for the same call in the system, and is valid for redirect, transfer, and conference events, including 3-party conferencing when a call center phone acts as a conference host. A SIP header, Cisco_GCID, is added into SIP Invite and REFER requests and to certain other responses to pass the Gcid to the target.

Examples

The following partial output shows the configuration for the **gcid** command:

```
router# show running-configuration
!
!
!
voice service voip
 gcid
 callmonitor
 allow-connections h323 to h323
 allow-connections h323 to sip
 allow-connections sip to h323
 allow-connections sip to sip
 no supplementary-service sip moved-temporarily
 sip
 registrar server expires max 120 min 60
```

global (application configuration)

To enter application configuration global mode, use the **global** command in application configuration mode.

global

Syntax Description No arguments or keywords

Command Default No default behavior or values

Command Modes Application configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines Use this command to enter application configuration global mode. You can then configure applications for a dial peer to use for incoming calls when it does not have an explicit application configured.

If an application is defined on the dial peer, that application always takes precedence over the global application configured in application configuration global mode. The applications configured in this mode execute only when a dial peer has no application configured.

Examples The following example shows the clid_authen_collect application is configured as the default global application for all inbound dial peers that do not have a specific application configured:

```
application
    global
    service default clid_authen_collect
```

Related Commands

Command	Description
call application global	Configures an application to use for incoming calls whose incoming dial peer does not have an explicit application configured.

groundstart auto-tip

To configure a timing delay on an FXO groundstart voice port, use the **groundstart auto-tip** command in voice-port configuration mode. To disable the configured timeout, use the **no** form of this command.

groundstart auto-tip [**delay** *timer*]

no groundstart auto-tip [**delay** *timer*]

Syntax Description

delay	Indicates that a specific delay time will be configured.
timer	Specifies the wait time in milliseconds that the FXO groundstart voice port will wait for a tip ground acknowledgment.

Command Default

This command is disabled by default. If the command is used without the optional keyword, the default time of 200 ms is activated.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.3(11)T2	This command was introduced into Cisco IOS Release 12.3(11)T2. This command is not supported on the Cisco 1700 series platform.

Usage Guidelines

This command should only be used after you encounter call setup problems involving FXO groundstart analog voice ports. If these problems occur, first load the latest image for your Cisco IOS Release (for example, if you are running Release 12.3(11)T, you should replace this image with Release 12.3(11)T2. Upgrading the software image should eliminate the problem. If not, then use this command as a troubleshooting measure—it should be enabled in a configuration only if you encounter problems in connecting outgoing calls. After the **groundstart auto-tip** command is configured, the problem should not occur again.

Use the **groundstart auto-tip** command only for voice ports configured for FXO groundstart signaling.

The following example sets the delay wait time for tip ground acknowledgment to 250 ms:

```
Router# configure terminal
Router(config)# voice-port 2/0/0
Router(config-voiceport)# shutdown
Router(config-voiceport)# groundstart auto-tip delay 250
Router(config-voiceport)# no shutdown
Router(config-voiceport)# exit
```

Related Commands

Command	Description
voice-port	Specifies that a voice port will be used in the connection.

group

To configure the maximum number of segments that are received in a session group or to associate the group with a specified session set, use the **group** command in backhaul-session-manager configuration mode. To restore the default number, use the **no** form of this command.

group {*group-name* **cumulative ack** *count* | **out-of-sequence** *count* | **receive** *count* | **retransmit** *count* | **set** *set-name*}

no group {*group-name* **cumulative ack** | **out-of-sequence** | **receive** | **retransmit** | **set**}

Caution Do not change this command or the keywords unless instructed to do so by Cisco technical support. There are relationships between group parameters that can cause sessions to fail if not set correctly.

Syntax Description

group-name	Session-group name.
cumulative ack *count*	Maximum number of segments received before acknowledgment. Range is from 0 to 255. Default is 3 segments.
out-of-sequence *count*	Maximum number of out-of-sequence segments that can be received in a session group before an ACK is sent. Range is from 0 to 255. Default is 3 segments.
receive *count*	Maximum number of segments in the receive window of the media gateway. This is the maximum number of segments the media gateway is allowed to receive before it sends an ACK. Range is from 1 to 64. Default is 32 segments.
retransmit *count*	Maximum number of retransmits allowed in a session group. Range is from 0 to 255. Default is 2 retransmits.
set *set-name*	Session-set name.

Command Default

For the **cumulative ack** and **out-of-sequenc**e keywords, the default is 3 segments.
For the **receive** keyword, the default is 32 segments.
For the **retransmit** keyword, the default is 2 retransmits.
The **set** keyword has no default behavior or values.

Command Modes

Backhaul-session-manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Release	Modification
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T. This command was implemented on the Cisco IAD2420 series. This command does not support the access servers in this release.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples

The following example configures the session group named group5 to send an acknowledgment after four segments have been received:

```
group group5 cumulative-ack 4
```

The following example configures the session group named group5 to send an acknowledgment after four out-of-sequence segments have been received:

```
group group5 out-of-sequence 4
```

The following example configures the session group named group5 to receive a maximum of 10 segments:

```
group group5 receive 10
```

The following example configures the session group named group5 to allow as many as 3 retransmits:

```
group group5 retransmit 3
```

The following example associates the session group named group5 with the session set named set1:

```
group group5 set set1
```

Related Commands

Command	Description
group auto-reset	Specifies the maximum number of auto-resets for a session group.
group cumulative-ack	Specifies maximum cumulative acknowledgments.
group out-of-sequence	Specifies maximum out-of-sequence segments that are received before an EACK is sent.
group receive	Specifies maximum receive segments.
group retransmit	Specifies maximum retransmits.
group timer	Specifies timeouts.

group auto-reset

To specify the maximum number of auto-resets for a session group, use the **group auto-reset** command in backhaul session manager configuration mode. To restore the default number, use the **no** form of this command.

group *group-name* **auto-reset** *count*

no group *group-name* **auto-reset**

Caution Do not change the auto-reset number unless instructed to do so by Cisco technical support. There are relationships between group parameters that can cause sessions to fail if not set correctly.

Syntax Description

group-name	Name of session group.
count	Maximum number of auto-resets before the connection is considered failed. Range is from 0 to 255. The default is 5.

Command Default

5 auto-resets

Command Modes

Backhaul session manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810 series.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and was implemented on the Cisco IAD2420 series.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples

The following example specifies a maximum of six auto-resets for the session group named “group5”:

```
Router(config-bsm)# group group5 auto-reset 6
```

Related Commands

Command	Description
group cumulative-ack	Configures the maximum number of segments that are received in a session group before an acknowledgment is sent.
group out-of-sequence	Configures the maximum out-of-sequence segments that are received before an EACK is sent.
group receive	Configures the maximum number of segments in the receive window of a session group.
group retransmit	Configures the maximum number of retransmits.

group cumulative-ack

To configure the maximum number of segments that are received before an acknowledgment is sent, use the **group cumulative-ack** command in backhaul session manager configuration mode. To set the value to the default, use the **no** form of this command.

group *group-name* **cumulative-ack** *count*

no group *group-name* **cumulative-ack** *count*

Caution Do not change this parameter unless instructed to do so by Cisco technical support. Incorrectly set parameters can cause sessions to fail.

Syntax Description

group-name	Name of session group.
count	Maximum number of segments that are received before acknowledgment. Range is from 0 to 255. The default is 3.

Command Default

3 segments

Command Modes

Backhaul session manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200 series.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810 series.
12.2(8)T	This command was implemented on the Cisco IAD2420 series.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples

The following example sets the cumulative acknowledgment maximum to 4 for the group named "group1":

```
Router(config-bsm)# group group5 cumulative-ack 4
```

Related Commands

Command	Description
group auto-reset	Configures the maximum auto-reset value.
group out-of-sequence	Configures the maximum number of out-of-sequence segments that are received before an EACK is sent.

group receive	Configures the maximum number of receive segments.
group retransmit	Configures the maximum number of retransmits.

group out-of-sequence

To configure the maximum number of out-of-sequence segments that are received before an error acknowledgement (EACK) is sent, use the **group out-of-sequence** command in backhaul session manager configuration mode. To set the value to the default, use the **no** form of this command.

group *group-name* **out-of-sequence** *count*

no group *group-name* **out-of-sequence** *count*

Caution Do not change this parameter unless instructed to do so by Cisco technical support. Incorrectly set parameters can cause sessions to fail.

Syntax Description

group-name	Name of the session group.
count	Maximum number of out-of-sequence segments. Range is from 0 to 255. The default is 3.

Command Default

3 segments

Command Modes

Backhaul session manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200 series.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810 series.

12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples

The following example sets the out-of-sequence maximum to 4 for the group named “group5”:

```
Router(config-bsm)# group group5 out-of-sequence 4
```

Related Commands

Command	Description
group auto-reset	Configures the maximum auto-reset value.
group cumulative-ack	Configures the maximum number of cumulative acknowledgments.
group receive	Configures the maximum number of receive segments.
group retransmit	Configures the maximum number of retransmits.

group receive

To configure the maximum number of receive segments, use the **group receive** command in backhaul session manager configuration mode. To set the value to the default, use the **no** form of this command.

group *group-name* **receive** *count*

no group *group-name* **receive** *count*

Caution Do not change this parameter unless instructed to do so by Cisco technical support. Incorrectly set parameters can cause sessions to fail.

Syntax Description

group-name	Name of the session group.
count	Maximum number of segments in a receive window. The far end should send no more than this number of segments before receiving an acknowledgment for the oldest outstanding segment. Range is 1 to 64. The default is 32.

Command Default 32 segments

Command Modes Backhaul session manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200 series.

12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples The following example sets the receive maximum to 10 for the group named “group5”:

```
Router(config-bsm)# group group5 receive 10
```

Related Commands

Command	Description
group auto-reset	Configures the maximum auto-reset value.
group cumulative-ack	Configures the maximum number of cumulative acknowledgments.

group out-of-sequence	Configures the maximum number of out-of-sequence segments that are received before an EACK is sent.
group retransmit	Configures the maximum number of retransmits.

group retransmit

To configure the maximum number of retransmits, use the **group retransmit** command in backhaul session manager configuration mode. To set the value to the default, use the **no** form of this command.

group *group-name* **retransmit** *count*

no group *group-name* **retransmit** *count*

Caution Do not change this parameter unless instructed to do so by Cisco technical support. Incorrectly set parameters can cause sessions to fail.

Syntax Description

group-name	Name of the session group.
count	Maximum number of retransmits. Range is 0 to 255. The default is 2.

Command Default 2 retransmits

Command Modes Backhaul session manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200 series.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810 series.
12.2(8)T	This command was implemented on the Cisco IAD2420 series.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples The following example sets the retransmit maximum to 3 for the group named “group5”:

```
Router(config-bsm)# group group5 retrans 3
```

Related Commands

Command	Description
group auto-reset	Configures the maximum auto-reset value.
group cumulative-ack	Configures the maximum number of cumulative acknowledgments.
group out-of-sequence	Configures the maximum number of out-of-sequence segments that are received before an EACK is sent.
group receive	Configures the maximum number of receive segments.

group set

To create a session group and associate it with a specified session set, use the **group** command in backhaul session manager configuration mode. To delete the group, use the **no** form of this command.

group *grp-name* **set** *set-name*

no group *grp-name*

Syntax Description

grp-name	Name of the session group.
set-name	Name of the session set.

Command Default No default behavior or values

Command Modes Backhaul session manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810 series.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and was implemented on the Cisco IAD2420 series.

Examples The following example shows session group **group5** being associated with session set **set1**:

```
Router(config-bsm)# group group5 set set1
```

Related Commands

Command	Description
group auto-reset	Specifies the maximum number of auto-resets for a session group.
group cumulative-ack	Configures the maximum number of segments that are received in a session group before an acknowledgment is sent.
group out-of-sequence	Configures the maximum out-of-sequence segments that are received before an EACK is sent.
group receive	Configures the maximum number of segments in the receive window of a session group.
group retransmit	Configures the maximum number of retransmits.
group timer cumulative-ack	Configures cumulative acknowledgment timeout.
group timer keepalive	Configures keepalive (or null segment) timeout.
group timer retransmit	Configures retransmission timeout.

Command	Description
group timer transfer	Configures state transfer timeout.
group auto-reset	Specifies the maximum number of auto-resets for a session group.

group timer

To configure the maximum number of milliseconds for which the Reliable User Datagram Protocol (RUDP) delays before sending an acknowledgment for a received segment, sending a keepalive segment, retransmitting a segment, or transferring a segment, use the **group timer** command in backhaul-session-manager configuration mode. To restore the default values, use the **no** form of this command.

group *group-name* **timer** {**cumulative ack** *time* | **keepalive** *time* | **retransmit** *time* | **transfer** *time*}

no group *group-name* **timer** {**cumulative ack**}

Caution Do not change the group timer parameters unless instructed to do so by Cisco technical support. There are relationships between group parameters that can cause sessions to fail if not set correctly.

Syntax Description

group-name	Name of session group.
cumulative ack *time*	Number of milliseconds for which RUDP delays before sending an acknowledgment for a received segment. Range is 100 to 65535. The default is 100.
keepalive *time*	Number of milliseconds before RUDP sends a keepalive segment when no RUDP packets are received or sent. Range is 100 to 65535. The default is 1000.
retransmit *time*	Number of milliseconds for which RUDP waits before retransmitting the segment. Range is 100 to 65535. The default is 300.
transfer *time*	Number of milliseconds for which RUDP waits to receive a selection of a new session from the application during a transfer state. Range is 0 to 65535. The default is 2000.

Command Default

cumulative ack: 100 milliseconds
keepalive: 1000 milliseconds
retransmit: 300 milliseconds
transfer: 2000 milliseconds

Command Modes

Backhaul-session-manager configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Release	Modification
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and was implemented on the Cisco IAD2420 series.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Usage Guidelines

The retransmit timer must be greater than the cumulative-ack timer.

Cumulative acknowledgment timeout is the maximum number of milliseconds for which RUDP delays before sending an acknowledgment for a received segment.

Examples

The following example specifies 325 milliseconds as the maximum acknowledgment delay for the session group named “group5”:

```
group group5 timer cumulative-ack 325
```

The following example configures RUDP to send keepalive segments if no RUDP packets are received or sent for 2.5 seconds (2500 milliseconds) in the session group named “group5”.

```
group group5 timer keepalive 2500
```

The following example sets a retransmit time of 650 milliseconds for the session group named “group5”:

```
group group5 timer retransmit 650
```

Related Commands

Command	Description
group	Specifies the maximum number of segments that are received in a session group.

group-params

To define groups of parameters that can be used by applications, use the **group-params** command in application configuration mode.

group-params *groupname*

Syntax Description

groupname	Name of the parameter group you are creating.

Command Modes

Application configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command allows you to define groups of parameters so that a group of parameters can be used by multiple services or packages (applications). Parameter groups are defined globally and once a group is defined, it is available for another service or package to use. Groups can contain parameters under multiple parameterspaces. In cases where a parameter is defined individually and in a parameter group, the individual parameter definition is given precedence.

Examples

The following example shows a parameter group named “fax,” that contains two parameters:

```
application
group-params fax
  paramspace fax_detect2 pin-len 9
  paramspace fax_detect1 retry-count 9
```

gw-accounting

To enable an accounting method for collecting call detail records (CDRs), use the **gw-accounting** command in global configuration mode. To disable an accounting method, use the **no** form of this command.

gw-accounting {**aaa** | **file** | **syslog** [**stats**] }

no gw-accounting {**aaa** | **file** | **syslog** [**stats**] }

Cisco IOS Release 12.2(8)T and Earlier Releases

gw-accounting {**h323** [**vsa**] | **syslog** | **voip**}

no gw-accounting {**h323** [**vsa**] | **syslog** | **voip**}

Syntax Description

aaa	Enables accounting through the AAA system and sends call detail records to the RADIUS server in the form of vendor-specific attributes (VSAs).
file	Enables the file accounting method to store call detail records in .csv format.
syslog	Enables the system logging facility to output accounting information in the form of a system log message.
stats	(Optional) Enables voice quality statistics to be sent to the system log.
h323	Enables standard H.323 accounting using Internet Engineering Task Force (IETF) RADIUS attributes.
vsa	(Optional) Enables H.323 accounting using RADIUS VSAs.
voip	Enables generic gateway-specific accounting.

Command Default

No accounting method is enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.3(6)NA2	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T. The **vsa** keyword was added.
12.1(1)T	The **voip** keyword was added.
12.2(11)T	The **h323**, **vsa**, and **voip** keywords were replaced by the **aaa** keyword.
12.4(11)XW	The **stats** keyword was added.
12.4(15)XY	The **file** keyword was added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

This command enables you to output accounting data in one of the following ways:

Using RADIUS Vendor-Specific Attributes

The IETF draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not appropriate for general use. The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. The Cisco vendor ID is 9, and the supported option has vendor-type 1, which is named "cisco-avpair." The value is a string of the format:

```
protocol: attribute sep value *
```

"Protocol" is a value of the Cisco "protocol" attribute for a particular type of authorization. "Attribute" and "value" are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and "sep" is "=" for mandatory attributes and "*" for optional attributes. This allows the full set of features available for TACACS+ authorization to also be used for RADIUS. For a list of VSA fields and their ASCII values, see the *Cisco IOS Security Configuration Guide* for your Cisco IOS release.

Use the **gw-accounting aaa** command to enable the VSA method of accounting.

Note Releases earlier than Cisco IOS Release 12.2(11)T use the **gw-accounting h323 vsa** command.

Using File Format

This method stores CDRs in comma separated values (CSV) format. These CDR records can be stored in a file on external or internal flash or on a file on a FTP server.

Each CDR has a fixed number of fields whose names and position order are predefined. Ten generic fields capture feature-related information. The CDR has feature fields representing the basic feature and feature fields representing the supplementary services.

Use the **gw-accounting file** command to enable the .csv file method of accounting.

Using syslog Records

The syslog accounting option exports the information elements associated with each call leg through a system log message, which can be captured by a syslog daemon on the network. The syslog output consists of the following:

```
<server timestamp> <gateway id> <message number> : <message label> : <list of AV pairs>
```

Use the **gw-accounting syslog** command to enable the syslog method of gathering accounting data.

Table 26 describes the syslog message fields.

Table 26 syslog Message Output Fields

Field	Description
server timestamp	Time stamp created by the server when it receives the message to log.
gateway id	Name of the gateway that sends the message.
message number	Number assigned to the message by the gateway.
message label	String used to identify the message category.
list of AV pairs	String that consists of <attribute name> <attribute value> pairs separated by commas.

You can enable **aaa**, **file**, or **syslog** simultaneously; call detail records are generated using all methods that you enable.

Overloading the Acct-Session-ID field

Attributes that cannot be mapped to standard RADIUS are packed into the Acct-Session-ID field as ASCII strings separated by the character "/". The Acct-Session-ID attribute definition contains the RADIUS account session ID, which is a unique identifier that links accounting records associated with the same login session for a user. To support additional fields, the following string format is defined for this field:

```
<session id>/<call leg setup time>/<gateway id>/<connection id>/<call origin>/
<call type>/<connect time>/<disconnect time>/<disconnect cause>/<remote ip address>
```

Table 27 describes the field attributes that are used with the overloaded acct-session-ID method.

Table 27 Field Attributes in Overloaded Acct-Session-ID

Field Attribute	Description
Session-Id	Standard RADIUS account session ID.
Setup-Time	Q.931 setup time for this connection in Network Time Protocol (NTP) format: hour, minutes, seconds, milliseconds, time zone, day of week, month, day of month, and year.
Gateway-Id	Name of the underlying gateway in the form "gateway.domain_name."
Call-Origin	Origin of the call relative to the gateway. Possible values are **originate** and **answer**.
Call-Type	Call leg type. Possible values are **telephony** and **VoIP**.
Connection-Id	Unique global identifier used to correlate call legs that belong to the same end-to-end call. The field consists of 4 long words (128 bits). Each long word displays as a hexadecimal value separated by a space character.
Connect-Time	Q.931 connect time for this call leg, in NTP format.
Disconnect-Time	Q.931 disconnect time for this call leg, in NTP format.
Disconnect-Cause	Reason that a call was taken offline as defined in the Q.931 specification.
Remote-Ip-Address	Address of the remote gateway port where the call is connected.

Because of the limited size of the Acct-Session-ID string, it is impossible to include many information elements in it. Therefore, this feature supports only a limited set of accounting information elements.

Use the **attribute acct-session-id overloaded** command to configure the overloaded session ID method of applying H.323 gateway-specific accounting.

Note Releases earlier than Cisco IOS Release 12.2(11)T use the **gw-accounting h323** command.

Examples

The following example shows accounting enabled using RADIUS VSA attributes:

```
gw-accounting aaa
```

The following example shows accounting enabled using the syslog method:

```
gw-accounting syslog
```

The following example shows accounting enabled using the file method:

```
gw-accounting file
```

Related Commands

Command	Description
acct-template	Selects a group of voice accounting attributes to collect.
attribute acct-session-id overloaded	Overloads the acct-session-id attribute with call detail records.
radius-server vsa send	Enables the voice gateway to recognize and use VSAs.

gw-type-prefix

To configure a technology prefix in the gatekeeper, use the **gw-type-prefix** command in gatekeeper configuration mode. To remove the technology prefix, use the **no** form of this command.

gw-type-prefix *type-prefix* [[**hopoff** *gkid1*] [**hopoff** *gkid2*] [**hopoff** *gkidn*] [**seq | blast**]] [**default-technology**] [[**gw ipaddr** *ipaddr* [*port*]]]

no gw-type-prefix *type-prefix* [[**hopoff** *gkid1*] [**hopoff** *gkid2*] [**hopoff** *gkidn*] [**seq | blast**]] [**default-technology**] [[**gw ipaddr** *ipaddr* [*port*]]]

Syntax Description

type-prefix	A technology prefix is recognized and is stripped before checking for the zone prefix. It is strongly recommended that you select technology prefixes that do not lead to ambiguity with zone prefixes. Do this by using the # character to terminate technology prefixes, for example, 3#.
hopoff *gkid*	(Optional) Use this option to specify the gatekeeper where the call is to hop off, regardless of the zone prefix in the destination address. The *gkid* argument refers to a gatekeeper previously configured using the zone local or zone remote comment. You can enter this keyword and argument multiple times to configure redundant gatekeepers for a given technology prefix.
seq | blast	(Optional) If you list multiple hopoffs, this indicates that the LRQs should be sent sequentially or simultaneously (blast) to the gatekeepers according to the order in which they were listed. The default is to send them sequentially.
default-technology	(Optional) Gateways registering with this prefix option are used as the default for routing any addresses that are otherwise unresolved.
gw ipaddr *ipaddr* [*port*]	(Optional) Use this option to indicate that the gateway is incapable of registering technology prefixes. When it registers, it adds the gateway to the group for this type prefix, just as if it had sent the technology prefix in its registration. This parameter can be repeated to associate more than one gateway with a technology prefix.

Command Default

By default, no technology prefix is defined, and LRQs are sent sequentially to all the gatekeepers listed.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the following platforms: Cisco 2500 series, Cisco 3600 series, and Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T. This command was modified to allow the user to specify multiple hopoffs.
12.1(2)T	This command was modified to allow the user to specify whether LRQs should be sent simultaneously or sequentially to the gatekeepers.
12.2(11)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco MC3810, and Cisco 7200 series.

Usage Guidelines

More than one gateway can register with the same technology prefix. In such cases, a random selection is made of one of them.

You do not have to define a technology prefix to a gatekeeper if there are gateways configured to register with that prefix and if there are no special flags (**hopoff** *gkid* or **default-technology**) that you want to associate with that prefix.

You need to configure the gateway type prefix of all remote technology prefixes that are routed through this gatekeeper.

Examples

The following example defines two gatekeepers for technology zone 3:

```
gw-type-prefix 3#* hopoff c2600-1-gk hopoff c2514-1-gk
```

Related Commands

Command	Description
show gatekeeper gw-type-prefix	Displays the list of currently defined technology zones and the gatekeepers responsible for each.
zone prefix	Configures the gatekeeper with knowledge of its own prefix and the prefix of any remote zone.

Cisco IOS Voice Commands: H

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command referenefces. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Guide*.

h225 alt-ep hunt

To configure alternate endpoint hunts for failed calls in an IP-to-IP gateway (IPIPGW), use the **h225 alt-ep hunt** command in H.323 voice-service configuration mode. To control the alternate endpoint hunts based on call disconnect cause codes, use the **no** form of this command.

h225 alt-ep hunt

no h225 alt-ep hunt [**all** | *cause-code*]

Syntax Description

all	Perform alternate hunt for all disconnect cause codes.
cause-code	A code returned from the destination router to indicate why an attempted end-to-end call was unsuccessful. Table 28 in the "Usage Guidelines" section describes the possible values.

Command Default

Alternate endpoint hunt is enabled for all cause codes

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

The default behavior of the gateway is to retry all alternate endpoints received from the gatekeeper regardless of the ReasonComplete reason. Only the **no alt-ep hunt** command will be visible in the configuration. A code returned from the destination router to indicate why an attempted end-to-end call was unsuccessful. If the specified disconnect cause code is returned from the last destination endpoint, dial peer hunting is enabled or disabled. You can enter the keyword, decimal value, or hexadecimal value.

The disconnect cause codes are described in Table 28. The decimal and hexadecimal value of the disconnect cause code follows the description of each possible keyword.

Table 28 Standard Disconnect Cause Codes

Keyword	Description	Decimal	Hex
access-info-discard	Access information discarded.	43	0x2b
all	Continue dial-peer hunting for all disconnect cause codes received from a destination router.		
b-cap-not-implemented	Bearer capability not implemented.	65	0x41
b-cap-restrict	Restricted digital information bearer capability only.	70	0x46
b-cap-unauthorized	Bearer capability not authorized.	57	0x39

Table 28 Standard Disconnect Cause Codes (continued)

Keyword	Description	Decimal	Hex
b-cap-unavail	Bearer capability not available.	58	0x3a
call-awarded	Call awarded.	7	0x7
call-cid-in-use	Call exists, call ID in use.	83	0x53
call-clear	Call cleared.	86	0x56
call-reject	Call rejected.	21	0x15
cell-rate-unavail	Cell rate not available.	37	0x25
channel-unacceptable	Channel unacceptable.	6	0x6
chantype-not-implement	Channel type not implemented.	66	0x42
cid-in-use	Call ID in use.	84	0x54
codec-incompatible	Codec incompatible.	171	0xab
cug-incalls-bar	Closed user group (CUG) incoming calls barred.	55	0x37
cug-outcalls-bar	CUG outgoing calls barred.	53	0x35
dest-incompatible	Destination incompatible.	88	0x58
dest-out-of-order	Destination out of order.	27	0x1b
dest-unroutable	No route to destination.	3	0x3
dsp-error	Digital signal processor (DSP) error.	172	0xac
dtl-trans-not-node-id	Designated transit list (DTL) transit not my node ID.	160	0xa0
facility-not-implemented	Facility not implemented.	69	0x45
facility-not-subscribed	Facility not subscribed.	50	0x32
facility-reject	Facility rejected.	29	0x1d
glare	Glare.	15	0xf
glaring-switch-pri	Glaring switch primary rate ISDN (PRI).	180	0xb4
htspm-oos	Holst Telephony Service Provider Module (HTSPM) out of service.	129	0x81
ie-missing	Mandatory information element missing.	96	0x60

serv/opt-unavail-unspecified	Service or option not available, unspecified.	63	0x3f
stat-enquiry-resp	Response to status inquiry.	30	0x1e
subscriber-absent	Subscriber absent.	20	0x14
switch-congestion	Switch congestion.	42	0x2a

Table 28 Standard Disconnect Cause Codes (continued)

Keyword	Description	Decimal	Hex
temp-fail	Temporary failure.	41	0x29
transit-net-unroutable	No route to transit network.	2	0x2
unassigned-number	Unassigned number.	1	0x1
unknown-param-msg-discard	Unrecognized parameter message discarded.	110	0x6e
unsupported-aal-parms	ATM adaptation layer (AAL) parameters not supported.	93	0x5d
user-busy	User busy.	17	0x11
vpci-vci-assign-fail	Virtual path connection identifier virtual channel identifier (VPCI VCI) assignment failure.	36	0x24
vpci-vci-unavail	No VPCI VCI available.	45	0x2d

Examples

The following example shows the alternate endpoint hunts with the user-busy disconnect cause code disabled:

```
Router(conf-serv-h323)# no h225 alt-ep hunt user-busy
```

Related Commands

Command	Description
gatekeeper	Enters gatekeeper configuration mode.

h225 connect-passthru

To immediately pass H.225 connect messages from the trunking gateway to the outgoing gateway via a Cisco Unified Border Element, use the **h225 connect-passthru** command in voice class or H.323 voice-service configuration mode. To return to the default behavior, use the **no** form of this command.

h225 connect-passthru

no h225 connect-passthru

Syntax Description

This command has no arguments or keywords.

Command Default

The H.225 messages are not sent to the outgoing gateway until TCS/MSD/OLC negotiation takes place.

Command Modes

H.323 voice-service configuration (conf-serv-h323)
Voice class configuration (config-class)

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

Calls placed through a Cisco Unified Border Element may fail to connect when the originating or terminating H.323 device is a non-Cisco IOS VoIP device such as Cisco Unified Communications Manager.

The default behavior of H.323-to-H.323 calls through a Cisco Unified Border Element is to delay sending a H.225 Connect message to the originating H323 device until the H245 TCS/MSD/OLC negotiation takes place. During this process, an H.225 Connect message with an H.245 address present from the terminating H.323 device is changed to an H.225 Progress message, followed by an H.225 Facility message with the embedded H.245 address. This can cause connection failures if the originating H.323 device is waiting for the H.225 Connect message to begin the H245 TCS/MSD/OLC negotiation.

The **h225 connect-passthru** command is used to immediately pass H.225 connect messages from the trunking gateway to the outgoing gateway via a Cisco Unified Border Element.

Configuring the **h225 connect-passthru** command in H.323 voice-service configuration is recommended for all calls passed through the Cisco Unified Border Element. This command option will be present only when the **allow-connections** command is configured.

This command is often configured with the **h245 passthru tcsnonstd-passthru** command and **emptycapability** command when interworking is configured between non-Cisco IOS H.323 devices.

Examples

The following example shows the **h225 connect-passthru** command being configured under H.323 voice-service configuration mode:

```
Router(conf-serv-h323)# h225 connect-passthru
```

The following example shows the **h225 connect-passthru** command being configured under voice class configuration mode:

```
Router(config-class)# h225 connect-passthru
```

Related Commands

Command	Description
allow-connections	Allows connections between specific types of endpoints in a VoIP network.
emptycapability	Eliminates the need for identical codec capabilities for all dial peers in the rotary group
h245 passthru tcsnonstd-passthru	Passes TCS parameter (CCM data only).

h225 display-ie

To allow the Cisco Unified Communication Manager to ignore the H.225 Facility message and process the H.225 Notify message used to display the calling name on the IP Phone, use the **h225 display-ie ccm-compatible** command in voice service or voice class configuration mode. To return to the default configuration, use the **no** version of the command.

h225 display-ie ccm-compatible system

no h225 display-ie ccm-compatible system

Syntax Description

ccm-compatible	Q931 Facility with calling name is received the gateway sends both H225 Notify and H225 Facility messages with the calling name in the Display IE.
system	Interprets the H.323 Notify Display IE so that the IP Phone can display the calling name on the IP Phone

Command Default

Disabled. The Cisco Unified Communication Manager ignores the IE and does not display the calling name on the Cisco IP Phone.

Command Modes

H.323 voice-service configuration (conf-serv-h323)
Voice class configuration (config-class)

Command History

Release	Modification
12.4(11)XW	This command was introduced.
12. 4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

When the gateway is interoperating with Cisco Unified Communication Manager, you must enable the **h225 display-ie ccm-compatible** command to display the IE received in Q931 Facility message is sent out in the H.225 Notify message.

When the **h225 display-ie ccm-compatible** command is configured, the gateway sends the H.225 Facility message and the H.225 Notify message to the Cisco Unified Communication Manager, which ignores the H.225 Facility message, and processes the H.225 Notify message.

Note While interoperating only with Cisco Unified Connections Manager you must configure the **h225 display-ie ccm-compatible** command.

Behavior and configuration will vary based on the configuration mode the command is configured:

- When the **h225 display-ie ccm-compatible** command is configured under voice class, the CLI under voice class takes precedence. Even if the **h225 display-ie ccm-compatible** command is not configured under global voice service voip, the command configured under voice class takes effect. This means that when a Q931 Facility with calling name is received the gateway sends both H225 Notify and H225 Facility messages with the calling name in the Display IE.

The configured command is visible in the **show running-configuration** output under voice class.

- When the **h225 display-ie ccm-compatible system** command is configured under voice class, the command configured under global voice service VoIP takes precedence. If the **h225 display-ie ccm-compatible system** command is configured under voice service voip, the gateway sends a H225 Notify message. If the **h225 display-ie ccm-compatible system** command is not configured under voice service voip, the gateway will not send the H225 Notify message.

  When the **system** keyword is configured, the command is not visible in the **show running-configuration** output.

- Configuring **no h225 display-ie ccm-compatible system** in voice class configuration mode, the command that is configured under voice class takes precedence. Even when **no h225 display-ie ccm-compatible system** command is configured under voice service voip, the gateway will not send the H225 Notify message received, and the calling name does not display on the IP Phone.

  Use the **no** version to disable sending H225 Notify message on a particular VoIP dial-peer. The **no** form of the command is shown under voice class in the **show running-configuration**.

Examples

The following example shows a gateway being configured to send H.225 Notify message that displays the calling name on an IP Phone.

```
voice class h323 1
h225 display-ie ccm-compatible system
```

Related Commands

Command	Description
show running-configuration	Displays the contents of the currently running configuration file.

h225 h245-address

To control sending an H.245 address to a remote site use the **h225 h245-address** command in H.323 voice service configuration mode or to a H.323 voice class in global configuration mode. To disable the delay in sending H.245 address in H.225 messages, use the **no** form of this command.

h225 h245-address {**facility** | **listen-on-setup** | **on-alert** | **on-progress**}

no h225 h245-address

Syntax Description

facility	Provides IP-to-IP H.245 address reporting via the H.225 Facility msg.
listen-on-setup	IP-to-IP invokes H.245 listener if the H.245 address received in setup.
on-alert	Specifies the H.225 address on alerting control.
on-progress	Specifies the H.225 address progress control.

Defaults

The H.245 address is sent in H.225 Callproceeding message.

Command Modes

Voice service H.323 configuration (conf-serv-h323)
H.323 voice class (config-class)

Command History

Release	Modification
12.4(15)T7	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

The **h225 h245-address on-alert** command controls sending the local H.245 address to the remote side. Configuring the **h225 h245-address on-alert** command forces the Cisco IOS gateway to send the H.245 address in the H.225 alerting message instead of in the H.225 callproceeding message.

To configure the **h225 h245-address on-alert** command for a voice class. First create an H.323 voice class that is independent of a dial peer with the **voice class h323** command in global configuration mode and configure the **allow-connections** command.

Note The **voice-class h323** command in dial peer configuration mode includes a hyphen and in global configuration mode does not include a hyphen.

Examples

The following example globally delays the sending the H.245 transport address until call alerting happens:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 h245-address on-alert
```

The following example shows listen-on-setup capability configured mode after creating a voice class in global configuration mode and configuring the required **allow-connections** command:

```
Router> enable
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# voice service voip
Router(conf-voi-serv)# allow-connections H323 to h323
Router(conf-voi-serv)# exit

Router(config)# voice class h323 5
Router(config-class)# h225 h245-address listen-on-setup
```

Related Commands

Command	Description
allow-connections	Allows connections between specific types of endpoints in a VoIP network.
h225 h245-address on-connect (H.323 voice-class)	Enables for an individual dial peer a delay in the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made.
h323	Enters Voice service H.323 configuration mode.
voice class h323	Creates an H.323 voice class that is independent of a dial peer and can be used on multiple dial peers.
voice-class h323	Assigns an H.323 voice class to a VoIP dial peer.
voice service	Enters voice-service configuration mode.

h225 h245-address on-connect (H.323 voice-class)

To enable for an individual dial peer a delay in the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made, use the **h225 h245-address on-connect** command in H.323 voice-class configuration mode. To disable the delay of H.225 messages, use the **no** form of this command.

h225 h245-address on-connect

no h225 h245-address on-connect

Syntax Description

This command has no arguments or keywords.

Command Default

H.225 messages that contain H.245 addresses are delayed until calls are connected.

Command Modes

H.323 voice-class configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

The functionality specified by this command allows Cisco CallManager Express 3.1 (Cisco CME 3.1) or later systems to interwork with Cisco CallManager in the same network. This command should always be enabled.

When simple A-to-B calls are made from a Cisco CallManager phone to a Cisco CME IP phone, the Cisco CallManager must play in-band ringback tone locally to the originating phone. The Cisco CallManager stops the tone generation if it receives the call's H.245 address before the call is answered. The **h225 h245-address on-connect** command ensures that the H.245 address is not sent before the call is answered (connected). This command is enabled by default unless the **no** form of this command has been used. In addition, the **telephony-service ccm-compatible** command must also be enabled to detect calls from Cisco CallManager, which is the default.

This command can also be used in an H.323 voice-service definition to globally enable or disable this behavior.

Examples

The following example creates a voice class with the tag of 4, which delays the exchange of H.225 messages for H.245 transport address relay until a call connection is made. Voice class 4 is then applied to dial peer 36.

```
Router(config)# voice class h323 4
Router(config-voice-class)# h225 h245-address on-connect

Router(config)# dial-peer voice 36 voip
Router(config-dial-peer)# destination-pattern 555....
Router(config-dial-peer)# session target ipv4:10.5.6.7
Router(config-dial-peer)# voice-class h323 4
```

Related Commands

Command	Description
h225 h245-address on-connect (H.323 voice-service)	Globally delays the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made.
telephony-service ccm-compatible (H.323 voice-class)	For an individual dial peer, enables the detection of a Cisco CallManager system in the network.
telephony-service ccm-compatible (H.323 voice-service)	Globally enables the detection of a Cisco CallManager system in the network.
voice class	Enters voice-class configuration mode.

h225 h245-address on-connect (H.323 voice-service)

To globally delay the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made, use the **h225 h245-address on-connect** command in H.323 voice-service configuration mode. To globally disable the delay, use the **no** form of this command.

h225 h245-address on-connect

no h225 h245-address on-connect

Syntax Description

This command has no arguments or keywords.

Command Default

H.225 messages that contain H.245 addresses are delayed until calls are connected.

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

The functionality specified by this command allows Cisco CallManager Express 3.1 (Cisco CME 3.1) or later systems to interwork with Cisco CallManager in the same network. This command should always be enabled.

When simple A-to-B calls are made from a Cisco CallManager phone to a Cisco CME IP phone, the Cisco CallManager must play in-band ringback tone locally to the originating phone. The Cisco CallManager stops the tone generation if it receives the call's H.245 address before the call is answered. The **h225 h245-address on-connect** command ensures that the H.245 address is not sent before the call is answered (connected). This behavior is the default when a Cisco CME system detects an incoming call from a Cisco CallManager unless the **no** form of this command has been used. In addition, the **telephony-service ccm-compatible** command must also be enabled to detect calls from Cisco CallManager, which is the default.

This command can also be used in an H.323 voice-class definition to enable or disable this behavior for individual dial peers.

Examples

The following example globally delays the exchange of H.225 messages for H.245 transport address relay until a call connection is made.

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 h245-address on-connect
```

Related Commands

Command	Description
h225 h245-address on-connect (H.323 voice-class)	Enables for an individual dial peer a delay in the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made.
h323	Enters H.323 voice-service configuration mode.
telephony-service ccm-compatible (H.323 voice-service)	Globally enables detection of Cisco CallManager in a network for all dial peers.
telephony-service ccm-compatible (voice-class)	Enables Cisco CallManager detection in a network by individual dial peers.
voice service	Enters voice-service configuration mode.

h225 h245-address setup

To allow a gateway to connect to an H.245 address received simultaneously with the H.225 setup message use the **h225 h245-address setup** command in voice service configuration mode or a H.323 voice class in global configuration mode. To return to the default behavior, use the **no** form of this command.

h225 h245-address setup

no h225 h245-address setup

Syntax Description

setup	Connects the gateway to the H.245 address simultaneously with an incoming H.225 setup message.

Defaults

This command is disabled by default. The gateway does not connect to the H.245 address received along with the H.225 setup message.

Command Modes

H.323 voice-service configuration (conf-serv-h323)
H.323 Voice class (config-class)

Command History

Release	Modification
12.4(15)T3	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Configuring the **h225 h245-address setup** command allows the gateways to receive both the H.225 setup message simultaneously with the H.245 address message.

To configure the **h225 h245-address setup** command for a voice class. First create an H.323 voice class that is independent of a dial peer with the **voice class h323** command in global configuration mode and configure the **allow-connections** command.

Note The **voice-class h323** command in dial peer configuration mode includes a hyphen and in global configuration mode does not include a hyphen.

Examples

The following example shows the gateway globally configured to connect to the H.245 address received along with the H.225 setup message:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 h245-address setup
```

The following example shows the gateway configured in a voice-class to connect to the H.245 address received along with H.225 setup message:

```
Router(config)# voice class h323 12
Router(config-class)# h225 h245-address setup
```

Related Commands

Command	Description
allow-connections	Allows connections between specific types of endpoints in a VoIP network.
h225 h245-address on-connect (H.323 voice-class)	Enables for an individual dial peer a delay in the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made.
h323	Enters Voice service H.323 configuration mode.
voice class h323	Creates an H.323 voice class that is independent of a dial peer and can be used on multiple dial peers.
voice-class h323	Assigns an H.323 voice class to a VoIP dial peer.
voice service	Enters voice-service configuration mode.

h225 id-passthru

To enable video call connections to pass through between endpoints regardless of software version, use the **h225 id-passthru** command in H.323 voice-service configuration mode. To return to the default, use the **no** form of this command.

h225 id-passthru

no h225 id-passthru

Syntax Description

This command has no arguments or keywords.

Command Default

Video calls are completed on endpoints using the same software version.

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Video calls complete when the endpoints are operating the same version of software. Use this command to allow connections between video endpoints that are using different software versions.

Examples

The following example allows video calls to connect when the polycom endpoints are using different software versions:

```
Router(config-serv-h323)# h225 id-passthru
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.

h225 plus-digit passthru

To prefix and pass the plus digit (+) into a phone number on an H.323 trunk, use the **h225 plus-digit passthru** command in H.323 voice service configuration mode. To stop passing of the plus digit into a phone number, use the **no** form of this command.

For releases prior to 15.1(3)T

h225 plus-digit-passthru-calling

no h225 plus-digit-passthru-calling

h225 plus-digit-passthru-called

no h225 plus-digit-passthru-called

For 15.1(3)T and later releases

h225 plus-digit passthru {**destination** | **source**}

no h225 plus-digit passthru {**destination** | **source**}

Syntax Description

destination	Prefixes and passes the plus digit (+) into a destination (called) number on an H.323 trunk.
source	Prefixes and passes the plus digit (+) into a source (calling) number on an H.323 trunk.

Command Default

The plus digit is not prefixed and passed into a called or a calling number on an H.323 trunk.

Command Modes

H.323 voice service configuration (conf-serv-h323)

Command History

Release	Modification
15.0(1)M	This command was introduced.
15.1(3)T	This command was modified. The **destination** and **source** keywords replaced **plus-digit-passthru-calling** and **plus-digit-passthru-called** for Cisco IOS Releaase 15.1(3)T and later releases.

Usage Guidelines

When a “+” is prefixed before the dialed digits, the carrier recognizes the call as an International call without the country specific international operator dial string. The leading "+" digit in a dial-peer match pattern is used to match a phone number with a leading "+" E.164 digit. It is not used as a regular expression symbol but is a valid E.164 digit that should be preserved across the VoIP network.

Examples

The following example shows how to add the plus digit for the calling number using the **h225 plus-digit passthru source** command:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 plus-digit passthru source
```

The following example shows how to add the plus digit for the called number using the **h225 plus-digit passthru destination** command:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 plus-digit passthru destination
```

h225 signal overlap

To activate overlap signaling to the destination gateway, use the **h225 signal overlap** command in H.225 voice-service configuration mode. To stop sending overlap signaling messages, use the **no** form of this command.

h225 signal overlap

no h225 signal overlap

Syntax Description

This command has no arguments or keywords.

Command Default

H.225 signaling overlap is disabled.

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.2(15)T11	This command was introduced.
12.3	This command was integrated into Cisco IOS Release 12.3.

Usage Guidelines

The terminating gateway is responsible for collecting all the called number digits. This is implemented by the dial peers matching destination patterns. When H.225 signal overlap is configured on the originating gateway, it sends the SETUP to the terminating gateway once a dial-peer match is found. The originating gateway sends all further digits received from user to the terminating gateway using INFO messages until it receives a sending complete from the user. The terminating gateway receives the digits in SETUP and subsequent INFO messages and does a dial-peer match. If a match is found, it sends a SETUP with the collected digits to the PSTN. All subsequent digits are sent to the PSTN using INFO messages at which time the call is complete.

Examples

The following example enables overlap signalling on the H.225 gateway:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 signal overlap
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.
voice service	Enters voice-service configuration mode and specifies the voice encapsulation type.

h225 start-h245

To hold the H.245 connection procedures until after the H.225 connections are made, use the **h225 start-h245** command in H.323 voice-class configuration mode. To disable the connection sequence, use the **no** form of this command.

h225 start-h245 on-connect

no h225 start-h245 on-connect

Syntax Description

on-connect	Starts the H.245 procedure upon call connection.

Command Default

By default, h225 start-h245 on-connect is disabled. In case of IP-to-IP gateway (IPIPGW), the outbound gateway echoes the same h245 address and port number sent by the remote endpoint.

Command Modes

H.323 voice-class configuration (config-voice-class)
H.323 voice-service (conf-serv-h323)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

The **h225 start-245 on-connect** command ensures that the H.245 address is not sent before the call is answered (connected).

Configure this command in H.323 voice-service configuration mode to globally enable or disable the connection behavior.

Examples

The following example shows a voice class with the tag of 4 being created, which delays the exchange of H.225 messages for H.245 transport address relay until a call connection is made.

```
Router(conf-serv-h323)#h225 start-h245 on-connect
```

Related Commands

Command	Description
h225 h245-address on-connect (H.323 voice-service)	Globally delays the exchange of H.225 messages for the relay of H.245 transport addresses until call connections are made.
telephony-service ccm-compatible (H.323 voice-class)	Detects a Cisco CallManager system in the network for an individual dial peer.
telephony-service ccm-compatible (H.323 voice-service)	Detects a Cisco CallManager system in the network globally.
voice class	Enters voice-class configuration mode.

h225 timeout call-proceeding

To set the H.225 call-proceeding (T310) disconnect timer, use the **h225 timeout call-proceeding** command in either voice-service or dial peer configuration mode. To revert to the default, use the **no** form of this command.

h225 timeout call-proceeding *duration*

no h225 timeout call-proceeding

Syntax Description

duration	Call-proceeding timeout, in seconds. Range: 1 to 300. Default: 60.

Command Default

60 seconds

Command Modes

For all dial peers: Voice-service configuration
For a single dial peer: Dial peer configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Use this command to set a maximum duration for the time between call setup and call connect.

You can use this command in either of two configuration modes:

- For all peers: Use voice-service configuration mode by entering the **voice service voip** command
- For just a single dial peer: Use dial peer configuration mode for the desired dial peer by entering the **voice class h323** command.

Examples

The following example sets the disconnect timer for all dial peers:

```
Router(config)# voice service voip
Router(config-voi-serv)# h225 timeout call-processing 5
```

The following example sets the disconnect timer for a single dial peer:

```
Router(config)# voice class h323 1
Router(config-class)# h225 timeout call-processing 5
```

Related Commands

Command	Description
h225 timeout setup	Sets a timer for the response of the outgoing SETUP message.
h225 timeout tcp call-idle	Sets a timer for an idle call connection.

Command	Description
h225 timeout tcp establish	Sets an H.225 TCP timer for VoIP dial peers.
scenario-cause	Configures new Q.850 call-disconnect cause codes for use if an H.323 call fails.

h225 timeout keepalive

To disconnect H.323 calls when a TCP keepalive timeout occurs, use the **h225 timeout keepalive** command in H.323 voice-service configuration mode. To enable H.323 calls to remain active and ignore the TCP keepalive timeout, use the no form of this command.

h225 timeout keepalive

no h225 timeout keepalive

Syntax Description

This command has no arguments or keywords.

Command Default

TCP keepalives are enabled.

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.2(15)T12	This command was introduced.
12.3	This command was integrated into Cisco IOS Release 12.3.
12.3(4)T5	This command was integrated into Cisco IOS Release 12.3(4)T5.

Usage Guidelines

When using the default configuration of the **h225 timeout keepalive** command, if a TCP timeout occurs on the H.225 channel, all active calls are disconnected and corresponding H.225 TCP sockets are closed.

When the **no h225 timeout keepalive** command is configured and a timeout occurs, the H.225 TCP socket is closed for all calls; Active TDM-IP calls will be preserved, but IP to IP calls are disconnected. In both cases the H.225 TCP socket is closed.

Note This command is visible in the running configuration only when the user configures the **no** form of the command.

Examples

The following example enables TCP keepalives on H.225 VoIP call control sessions:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 timeout keepalive
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.
voice service	Enters voice-service configuration mode and specifies the voice encapsulation type.

h225 timeout setup

To configure the timeout value for the response of the outgoing SETUP message, use the **h225 timeout setup** command in voice class configuration mode. To remove the timeout value, use the **no** form of this command.

h225 timeout setup *seconds*

no h225 timeout setup

Syntax Description

seconds	Timeout value for the response of the outgoing SETUP message, in seconds. Default is 15.

Command Default 15 seconds

Command Modes Voice class configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples The following example configures a timeout setup value of 10 seconds:

```
Router(config-class)# h225 timeout setup 10
```

Related Commands

Command	Description
h225 timeout tcp call-idle	Sets a timer for an idle call connection.
h225 timeout tcp establish	Configures the H.225 TCP timeout.

h225 timeout t302

To set the t302 timer when using overlap signaling, use the **h225 timeout t302** command in H.225 voice-service configuration mode. To return to the default overlap signaling setting, use the **no** form of this command

h225 timeout t302 *seconds*

no h225 timeout t302 *seconds*

Syntax Description

seconds	Number of seconds for timeouts. Range: 1 to 30

Command Default

The t302 timer is disabled.

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

Use this command to establish the maximum amount of time allowed to complete the dial-peer match when H.225 signal overlap is configured on the originating gateway.

Examples

The following example allows 15 seconds for the t302 timer to complete the dial-peer match before timing out:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 timeout t302 15
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.
voice service	Enters voice-service configuration mode and specifies the voice encapsulation type.
h225 signal overlap	Activates overlap signaling to the destination gateway.

h225 timeout t304

To set the t304 timer when using overlap signaling, use the **h225 timeout t304** command in H.323 voice-service configuration mode. To return to the default overlap signaling setting, use the **no** form of this command.

h225 timeout t304 *seconds*

no h225 timeout t304 *seconds*

Syntax Description

seconds	Length of timeout, in seconds. The range is from 1 to 30. The default is 10.

Command Default

The timer is enabled and set to 10 seconds.

Command Modes

H.323 voice-service configuration (conf-serv-h323)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Use the **h225 timeout t304** command to configure the maximum interdigit delay on the originating gateway when H.225 overlap signaling is configured. Configure this command for the H.323 call leg on the originating gateway. If this timer expires, the call is disconnected with a cause code 28 (invalid number).

Examples

The following example allows 12 seconds for the t304 timer to complete the dial-peer match before timing out:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 timeout t304 12
```

Related Commands

Command	Description
h225 timeout t302	Sets the t302 timer when using overlap signaling.
h225 signal overlap	Activates overlap signaling to the destination gateway.
h323	Enables H.323 voice-service configuration commands.
voice service	Enters voice-service configuration mode and specifies the voice encapsulation type.

h225 timeout tcp call-idle (H.323 voice-service)

To set a timer for an idle call connection, use the **h225 timeout tcp call-idle** command in voice service h323 configuration mode. To reset to the default, use the **no** form of this command.

h225 timeout tcp call-idle {**value** *value* | **never**}

no h225 timeout tcp call-idle

Syntax Description

value *value*	Timeout value, in minutes. Range is 0 to 1440. The default is 10. If you specify 0, the timer is disabled and the TCP connection is closed immediately after all the calls are cleared.
never	The connection is maintained permanently or until the other endpoint closes it.

Command Default 10 minutes

Command Modes H.323 voice-service configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines This command specifies the time to maintain an established H.225 TCP connection when there are no calls on that connection. If the timer expires, the connection is closed. If the timer is running and any new call is made on that connection, the timer stops. When all the calls are cleared on that connection, the timer starts again.

Examples The following example sets the timer for an idle call connection to 10 minutes:

```
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h225 timeout tcp call-idle value 10
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.

h225 timeout tcp establish

To set the H.225 TCP timeout value for Voice over IP (VoIP) dial peers, use the **h225 timeout tcp establish** command in voice class configuration mode. To reset to the default, use the **no** form of this command.

h225 timeout tcp establish *seconds*

no h225 timeout tcp establish

Syntax Description

seconds	Number of seconds for the timeout. Range is 0 to 30. The default is 15. If you specify 0, the H.225 TCP timer is disabled.

Command Default

15 seconds

Command Modes

Voice class configuration

Command History

Release	Modification
12.1(2)T	This command was introduced on the following platforms: Cisco 1700, Cisco 2500 series, Cisco 2600 series, Cisco 3600 series, Cisco 7200, Cisco AS5300, Cisco uBR900, and Cisco uBR924.

Examples

The following example sets a timeout of 10 seconds, which is associated with the H.323 voice class labeled 1:

```
voice class h323 1
 h225 timeout tcp establish 10
```

Related Commands

Command	Description
voice class h323	Establishes an H.323 voice class.

h225 timeut ntf

To enable Cisco Unified Communications Manager to interpret the calling name coming in the Display IE of H.225 facility message, use the **h225 timeout ntf** command in voice service or voice class configuration mode. To return to the default configuration, use the **no** form of this command.

h225 timeout ntf *milliseconds*

no h225 timeout ntf *milliseconds*

Syntax Description

milliseconds	Amount of time in milliseconds. Valid range is 50 to 5000.

Command Default

Disabled. The Cisco Unified Communications Manager ignores the IE and does not display the calling name on the IP phone.

Command Modes

H.323 voice-service configuration (conf-serv-h323)
Voice class configuration (config-class)

Command History

Release	Modification
12.4(11)XW	This command was introduced.
12. 4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

Configure this command on the gateway to control the Q931 setup message. This command is configured in voice service or voice class configuration mode.

When Cisco Unified Communications Manager (Cisco Unified CM) is interworking with Cisco Gateways, The Cisco Unified CM can interpret the calling name coming in Display IE of H.225 Setup and H.225 Notify messages, and display the calling name on the Cisco IP Phone. Calling names sent in Display IE of the H.225 Facility message are not interpreted by default.

When the **h225 timeout ntf** command is configured on the Cisco gateway, if a Q931 Setup message with name-to-follow comes, the gateway will not send the H.225 Setup message and buffers it until the ntf timer expires, or a Q931 Facility message is received from ISDN side.

Note In the event the facility is received before the timer expires, the gateway will stop the buffer timer, extract the relevent information and send it to terming endpoint.

When a Cisco gateway is connected to ISDN switches that send name-to-follow in Q931 Setup and the calling name in subsequent Q931 Facility message, configuring the **h225 timeout ntf** command is recommended.

Examples

The following example shows how to set the ntf buffering time to 60 milliseconds in the voice servides configuration mode:

```
voice service voip
 h323
  h225 timeout ntf 60
```

The following example sshows hotto se the ntf buffering time to 1000 milliseconds in the voice class configuration mode:

```
voice class h323 1
 h225 timeout ntf 1000
```

h245 address-check

To close the TCP connection of the endpoint with the numerically smaller H.245 address when two endpoints simultaneously initiate separate H.245 connections, use the **h245 address-check** command in H.323 voice-service configuration mode. To return to the default behavior, use the **no** form of this command.

h245 address-check

no h245 address-check

Syntax Description

This command has no arguments or keywords.

Command Default

The gateway automatically closes its TCP connection when the remote side TCP connection attempts to overwrite the data on the existing gateway TCP connection.

Command Modes

H.323 voice-service configuration (conf-serv-h323)

Command History

Release	Modification
15.0(**1**)M2	This command was introduced.

Usage Guidelines

The **h245 address-check** command causes the gateway to use IP addresses to determine which endpoint to close when TCP connections are opened simultaneously. The gateway TCP connection is closed only if the IP address is smaller.

Examples

The following example shows how to close the TCP connection of the endpoint with the numerically smaller H.245 address when two endpoints simultaneously initiate separate H.245 connections

```
Router(conf-serv-h323)# h245 address-check
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.

h245 passthru

To allow H.245 calls to pass through to the Cisco Unified CallManager when the IP-to-IP gateway sends an incorrect intercluster trunk (ICT) version, use the **h245 passthru** command in voice service configuration mode. To disable this command use, the **no** form of this command.

h245 passthru {**all** | **tcsnonstd-passthru**}

no h245 passthru {**all** | **tcsnonstd-passthru**}

Syntax Description

all	Passes non-standard codec through the IP-to-IP gateway.
tcsnonstd-passthru	Passes terminal capabilities set (TCS) non-standard parameter pass through (CCM data only).

Command Default This command is disabled.

Command Modes Voice service configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines When resuming a call that was placed on hold fails on a Cisco Unified CallManager, generally the call fails on the second Cisco Unified CallManager because the IP-to-IP gateway (IPIPGW) sends an incorrect intercluster trunk (ICT) version for the first Cisco Unified CallManager to the second Cisco Unified CallManager, and because the IPIPGW drops the non-standard fields in the callproc, alert, and connect messages from the second Cisco Unified CallManager to the first Cisco Unified CallManager. To resolve this behavior configure the **h245 passthru** command

Note For IP-to-IP gateway functionality the **allow-connections h323 to h323** command must be configured.

Examples The following example show how you configure h.245 to pass through to the Cisco Unified CallManager, regardless of the intercluster trunk (ICT) version:

```
Router(conf-serv-h323)#h245 passthru tcsnonstd-passthru
```

Related Commands

Command	Description
allow-connections	Allows connections between specific types of endpoints in a VoIP network.

h245 timeout olc

To set the timeout value for the OpenLogicalChannel (OLC) message, use the **h245 timeout olc** command in H.323 voice-service configuration mode. To disable the timeout value for the OLC message, use the **no** form of this command.

h245 timeout olc *timeout value*

no h245 timeout olc *timeout value*

Syntax Description

timeout value	Length of timeout value, in seconds. Range: 1 to 30. Default: 4.

Command Default

Timeout value for the OLC message is enabled and set to 4 seconds.

Command Modes

H.323 voice-service configuration

Command History

Release	Modification
12.4	This command was introduced.

Usage Guidelines

After the originating gateway sends an OLC message during the H.245 procedure, it waits for 4 seconds for the terminating gateway to respond with an OLC acknowledgment. This behavior is enabled by default, and the timeout value of the OLC message is set to 4 seconds.

However, sometimes when a slow link, such as a satellite link, is involved in sending messages, a delay can occur. In that case, 4 seconds are not enough to receive OLC messages, and the call fails even when the terminating gateway had responded with OLC acknowledgment. To avoid the random dropping of VoIP calls, use the **h245 timeout olc** command to change the length of time that the originating gateway waits for OLC acknowledgment from the terminating gateway.

Examples

The following example sets the timeout value for the OLC message to 20 seconds. It also shows that you can change the setting to 15 seconds:

```
h245 timeout olc 20
h245 timeout olc 15
```

The following example sets the timeout value back to the default setting of 4 seconds:

```
no h245 timeout olc 15
```

The output of the **show run** command does not show the default setting; however, it does include the command if the timeout value is modified:

```
voice service voip
 h323
  h245 timeout olc 20
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.

h323

To enable the H.323 voice service configuration commands, use the **h323** command in voice service configuration mode.

h323

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Voice service configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples

The following example enters H.323 voice service configuration mode:

```
Router(conf-voi-serv)# h323
```

Related Commands

Command	Description
call start	Forces the H.323 Version 2 gateway to use Fast Connect or Slow Connect procedures for all H.323 calls.
h225 timeout setup	Configures the timeout value for the response of the outgoing SETUP message.
h225 timeout tcp call-idle	Sets a timer for an idle call connection.
session transport	Configures the underlying transport layer protocol for H.323 messages to be used across all VoIP dial peers.

h323 asr

To enable application-specific routing (ASR) and specify the maximum bandwidth for a proxy, use the **h323 asr** command in interface configuration mode. To remove a bandwidth setting but keep ASR enabled, use **no** form of this command.

h323 asr [**bandwidth** *max-bandwidth*]

no h323 asr [**bandwidth** *max-bandwidth*]

Syntax Description

bandwidth *max-bandwidth*	(Optional) Maximum bandwidth, in mbps on the interface. Range is from 1 to 10000000. The default is the interface bandwidth. If you specify a value greater than the interface bandwidth, the bandwidth defaults to the interface bandwidth.

Command Default

ASR is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on the Cisco 2500 series and Cisco 3600 series.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines

This command is independent of the **h323 interface** command.

Note Specifying the **no h323 asr bandwidth** *max-bandwidth command* removes the bandwidth setting but leaves ASR enabled. You must enter the **no h323 asr** command to disable ASR.

Examples

The following example enables ASR and specifies a maximum bandwidth of 10,000 kbps:

```
h323 asr bandwidth 10000
```

h323 call start

To force the H.323 Version 2 gateway to use Fast Connect or Slow Connect procedures for all H.323 calls, use the **h323 call start** command in voice-service configuration mode. To reset to the default, use the **no** form of this command.

h323 call start {**fast** | **slow**}

no h323 call start

Syntax Description

fast	Gateway uses H.323 Version 2 (Fast Connect) procedures.
slow	Gateway uses H.323 Version 1 (Slow Connect) procedures.

Command Default

fast

Command Modes

Voice-service configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, Cisco AS5300, Cisco AS5800, and Cisco MC3810.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

In Cisco IOS Release 12.1(3)XI and later releases, H.323 Voice over IP (VoIP) gateways by default use H.323 Version 2 (Fast Connect) for all calls including those initiating RSVP. Previously, gateways used only Slow Connect procedures for RSVP calls. To enable Cisco IOS Release 12.1(3)XI gateways to be backward compatible with earlier releases of Cisco IOS Release 12.1 T, the **h323 call start** command forces the originating gateway to initiate calls using Slow Connect.

This **h323 call start** command is configured as part of the global voice-service configuration for VoIP services. It does not take effect unless the **call start system** voice-class configuration command is configured in the VoIP dial peer.

Examples

The following example selects Slow Connect procedures for the gateway:

```
voice service voip
 h323 call start slow
```

Related Commands

Command	Description
call rsvp-sync	Enables synchronization between RSVP and the H.323 voice signaling protocol.
call rsvp-sync resv-timer	Sets the timer for RSVP reservation setup.
call start	Selects whether the H.323 gateway uses Fast Connect or Slow Connect procedures for the specific VoIP dial peer.
debug call rsvp-sync events	Displays the events that occur during RSVP synchronization.
show call rsvp-sync conf	Displays the RSVP synchronization configuration.
show call rsvp-sync stats	Displays statistics for calls that attempted RSVP reservation.
voice service	Enters voice-service configuration mode and specifies the voice encapsulation type.

h323 gatekeeper

To specify the gatekeeper associated with a proxy and to control how the gatekeeper is discovered, use the **h323 gatekeeper** command in interface configuration mode. To disassociate the gatekeeper, use the **no** form of this command.

h323 gatekeeper [**id** *gatekeeper-id]* {**ipaddr** *ipaddr* [*port*] | **multicast**}

no h323 gatekeeper [**id** *gatekeeper-id]* {**ipaddr** *ipaddr* [*port*] | **multicast**}

Syntax Description

id *gatekeeper-id*	(Optional) Gatekeeper name. Typically, this is a Domain Name Server (DNS) name, but it can also be a raw IP address in dotted form. If this parameter is specified, gatekeepers that have either the default or explicit flags set for the subnet of the proxy respond. If this parameter is not specified, only those gatekeepers with the default subnet flag respond.
ipaddr *ipaddr* [*port*]	The gatekeeper discovery message is unicast to this address and, optionally, the port specified.
multicast	The gatekeeper discovery message is multicast to the well-known RAS multicast address and port.

Command Default

No gatekeeper is configured for the proxy

Command Modes

Interface configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on Cisco 2500 series and Cisco 3600 series.

Usage Guidelines

You must enter the **h323 interface** and **h323 h323-id** commands before using this command. The **h323 gatekeeper** command must be specified on your Cisco IOS platform or the proxy does not go online. The proxy uses the interface address as its RAS signaling address.

Examples

The following example sets up a unicast discovery to a gatekeeper whose name is unknown:

```
h323 gatekeeper ipaddr 192.168.5.2
```

The following example sets up a multicast discovery for a gatekeeper of a particular name:

```
h323 gatekeeper id gk.zone5.com multicast
```

Related Commands

Command	Description
h323 h323-id	Registers an H.323 proxy alias with a gatekeeper.
h323 interface	Specifies the interface from which the proxy takes its IP address.

h323 h323-id

To register an H.323 proxy alias with a gatekeeper, use the **h323 h323-id** command in interface configuration mode. To remove an H.323 proxy alias, use the **no** form of this command.

h323 h323-id *h323-id*

no h323 h323-id *h323-id*

Syntax Description

h323-id	Name of the proxy. It is recommended that this name be a fully qualified e-mail ID, with the domain name being the same as that of its gatekeeper.

Command Default No H.323 proxy alias is registered

Command Modes Interface configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on Cisco 2500 and Cisco 3600 series routers.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines Each entry registers a specified H.323 ID proxy alias to a gatekeeper. Typically, these aliases are either simple text strings or legitimate e-mail IDs.

Note You must enter the **h323 interface** command before using this command. The **h323 h323-id** command must be entered on the same interface as the **h323 gatekeeper** command. The proxy does not go online without the **h323 interface** command.

Examples The following example registers an H.323 proxy alias called proxy1@zone5.com with a gatekeeper:

```
h323 h323-id proxy1@zone5.com
```

Related Commands

Command	Description
h323 gatekeeper	Specifies the gatekeeper associated with a proxy and controls how the gatekeeper is discovered.
h323 interface	Specifies the interface from which the proxy takes its IP address.

h323 interface

To select an interface whose IP address is used by the proxy to register with the gatekeeper, use the **h323 interface** command in interface configuration mode. To reset to the default port, use the **no** version of the command and then the **h323 interface** command.

h323 interface [*port-number*]

no h323 interface [*port-number*]

Syntax Description

port-number	(Optional) Port number that the proxy listens on for incoming call-setup requests. Range is from 1 to 65356. The default port number for the proxy is 11,720 in -isx- or -jsx- Cisco IOS images. The default port number for the proxy is 1720 in -ix- Cisco IOS images, which do not contain the VoIP gateway.

Command Default

Default port number is image dependent as described in the Syntax Description.

Command Modes

Interface configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on Cisco 2500 and Cisco 3600 series routers.
12.1(5)T	The ability to specify the proxy port number was added on the Cisco 2600 series, Cisco 3600 series, Cisco 7200 series and on the Cisco MC3810.

Usage Guidelines

At proxy startup, Cisco IOS software checks for the presence of the VoIP gateway subsystem. If the subsystem is found to be present, the proxy code opens and listens for call setup requests on the new port. The proxy then registers this port with the gatekeeper.

Examples

The following example configures Ethernet interface 0 for incoming call-setup requests:

```
interface ethernet0
 h323 interface
```

Related Commands

Command	Description
bandwidth	Specifies the maximum aggregate bandwidth for H.323 traffic from a zone to another zone, within a zone, or for a session in a zone.
bandwidth remote	Specifies the total bandwidth for H.323 traffic between this gatekeeper and any other gatekeeper.

Command	Description
h323 qos	Enables QoS on the proxy.
h323 t120	Enables the T.120 capabilities on your router and specifies bypass or proxy mode.

h323 qos

To enable quality of service (QoS) on the proxy, use the **h323 qos** command in interface configuration mode. To disable QoS, use the **no** form of this command.

h323 qos {**ip-precedence** *value* | **rsvp** {**controlled-load** | **guaranteed-qos**}}

no h323 qos {**ip-precedence** *value* | **rsvp** {**controlled-load** | **guaranteed-qos**}}

Syntax Description

ip-precedence *value*	RTP streams set their IP precedence bits to the specified *value*.
rsvp controlled-load	Controlled load class of service.
rsvp guaranteed-qos	Guaranteed QoS class of service.

Command Default

No QoS is configured

Command Modes

Interface configuration

Command History

Release	Modification
11.3(2)NA	This command was introduced on Cisco 2500 and Cisco 3600 series routers.

Usage Guidelines

You must execute the **h323 interface** command before using this command.

Both IP precedence and RSVP QoS can be configured by invoking this command twice with the two different QoS forms.

Examples

The following example enables QoS on the proxy:

```
interface Ethernet0
 ip address 172.21.127.38 255.255.255.192
 no ip redirects
 ip rsvp bandwidth 7000 7000
 ip route-cache same-interface
 fair-queue 64 256 1000
 h323 interface
 h323 qos rsvp controlled-load
 h323 h323-id px1@zone1.com
 h323 gatekeeper ipaddr 172.21.127.39
```

Related Commands

Command	Description
h323 interface	Specifies the interface from which the proxy takes its IP address.

h323 t120

To enable the T.120 capabilities on your router and to specify bypass or proxy mode, use the **h323 t120** command in interface configuration mode.

h323 t120 {bypass | proxy}

Syntax Description

bypass	Bypass mode. In this mode, the H.245 Open Logical Channel messages for T.120 data channels are passed unmodified through the proxy, and TCP connections for T.120 are established directly between the two endpoints of the H.323 call.
proxy	Proxy mode. In this mode, T.120 features function properly.

Command Default

Bypass mode

Command Modes

Interface configuration

Command History

Release	Modification
12.1(5)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200, and Cisco MC3810.

Usage Guidelines

The **no** form of this command has no function—the only possible commands are **h323 t120 bypass** and **h323 t120 proxy**.

Examples

The following example enables T.120 capabilities:

```
proxy h323
interface ethernet0
 h323 t120 proxy
```

Related Commands

Command	Description
bandwidth	Specifies the maximum aggregate bandwidth for H.323 traffic from a zone to another zone, within a zone, or for a session in a zone.
bandwidth remote	Specifies the total bandwidth for H.323 traffic between this gatekeeper and any other gatekeeper.
h323 interface	Defines which port the proxy listens on.

h323-annexg

To enable the border element (BE) on the gatekeeper and to enter BE configuration mode, use the **h323-annexg** command in gatekeeper configuration mode. To disable the BE, use the **no** form of this command.

h323-annexg *border-element-id* **cost** *cost* **priority** *priority*

no h323-annexg

Syntax Description

border-element-id	Identifier of the Annex G border element that you are provisioning. Possible values are any International Alphabet 5 (IA5) string, without spaces and up to 20 characters in length. The *border-element-id* argument associates the gatekeeper with the BE identifier that is configured on the BE.
cost *cost*	Cost associated with this Annex G border element. When a gatekeeper sends requests to remote zones and to the BE in its attempt to resolve an address, the remote zone or BE that resolves the address and has the lowest cost and highest priority is given preference. Range is from 1 to 99. Default is 50.
priority *priority*	Priority associated with this Annex G border element. When a gatekeeper sends requests to remote zones and to the BE in its attempt to resolve an address, the remote zone or BE that resolves the address and has the lowest cost and highest priority is given preference. Range is 1 to 99. The default is 50.

Command Default

Cost: 50
Priority: 50

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. Support for the Cisco AS5300, Cisco AS5350, and Cisco AS5400 is not included in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

The Annex G border element must be configured using the **call-router** command before the gatekeeper can be associated with the Annex G border element. The **h323-annexg** command associates the gatekeeper with a previously configured Annex G border element and indicates that the gatekeeper should interact with the BE in address resolution.

Examples

The following example enables Annex G configuration for a BE named “be20”:

```
Router(config-gk)# h323-annexg be20 cost 10 priority 40
Router(config-gk-annexg)#
```

Related Commands

Command	Description
call-router	Enables the Annex G border element configuration commands.
prefix	Restricts the prefixes for which the gatekeeper should query the Annex G BE.

h323-gateway voip bind srcaddr

To designate a source IP address for the voice gateway, use the **h323-gateway voip bind srcaddr** command in interface configuration mode. To remove the source IP address, use the **no** form of the command.

h323-gateway voip bind srcaddr *ip-address*

no h323-gateway voip bind srcaddr

Syntax Description

ip-address	Source IP address, in dotted-decimal notation.

Command Default

No default behaviors or values

Command Modes

Interface configuration

Command History

Release	Modification
12.1(2)T	This command was introduced on the following platforms: Cisco 1700, Cisco 2500, Cisco 2600 series, Cisco 3600 series, Cisco 7200, Cisco S5300, and Cisco uBR924.

Usage Guidelines

You do not have to issue this command on the interface that you defined as the voice gateway interface (although it may be more convenient to do so). Use this command the interface that contains the IP address to which you want to bind.

Examples

The following example assigns a source IP address of 10.1.1.1:

```
h323-gateway voip bind srcaddr 10.1.1.1
```

h323-gateway voip h323-id

To configure the H.323 name of the gateway that identifies this gateway to its associated gatekeeper, use the **h323-gateway voip h323-id** command in interface configuration mode. To disable this defined gateway name, use the **no** form of this command.

h323-gateway voip h323-id *interface-id*

no h323-gateway voip h323-id *interface-id*

Syntax Description

interface-id	H.323 name (ID) used by this gateway when this gateway communicates with its associated gatekeeper. Usually, this ID is the name of the gateway with the gatekeeper domain name appended to the end and in name@domain-name.

Command Default No gateway identification is defined

Command Modes Interface configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the Cisco 2500 series, Cisco 3600 series, and Cisco AS5300.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples The following example configures Ethernet interface 0.0 as the gateway interface. In this example, the gateway ID is GW13@cisco.com.

```
interface Ethernet0/0
 ip address 172.16.53.13 255.255.255.0
 h323-gateway voip interface
 h323-gateway voip id GK15.cisco.com ipaddr 172.16.53.15 1719
 h323-gateway voip h323-id GW13@cisco.com
 h323-gateway voip tech-prefix 13#
```

Related Commands

Command	Description
h323-gateway voip id	Defines the name and location of the gatekeeper for this gateway.
h323-gateway voip interface	Configures an interface as an H.323 interface.
h323-gateway voip tech-prefix	Defines the technology prefix that the gateway registers with the gatekeeper.

h323-gateway voip id

To define the name and location of the gatekeeper for a specific gateway, use the **h323-gateway voip id** command in interface configuration mode. To disable this gatekeeper identification, use the **no** form of this command.

h323-gateway voip id *gatekeeper-id* {**ipaddr** *ip-address* [*port-number*] | **multicast**} [**priority** *number*]

no h323-gateway voip id *gatekeeper-id* {**ipaddr** *ip-address* [*port-number*] | **multicast**} [**priority** *number*]

Syntax Description

gatekeeper-id	H.323 identification of the gatekeeper. This value must exactly match the gatekeeper ID in the gatekeeper configuration. The recommended format is *name.doman-name*.
ipaddr	The gateway uses an IP address to locate the gatekeeper.
ip-address	IP address used to identify the gatekeeper.
port-number	(Optional) Port number used.
multicast	Indicates that the gateway uses multicast to locate the gatekeeper.
priority *number*	(Optional) Priority of this gatekeeper. Range is 1 to 127, 1 has the highest priority. The default is 127.

Command Default

No gatekeeper identification is defined.

Command Modes

Interface configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the following platforms: Cisco 2500 series, Cisco 3600 series, and Cisco AS5300.
12.0(7)T	The **priority** *number* keyword and argument were added.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

This command tells the H.323 gateway associated with this interface which H.323 gatekeeper to talk to and where to locate it. The gatekeeper ID configured here must exactly match the gatekeeper ID in the gatekeeper configuration.

You can configure one or two alternate gatekeepers.

The IP address of the gatekeeper does not have to be explicit; you can also use the multicast option. Multicasting saves bandwidth by forcing the network to replicate packets only when necessary. The multicast option, shown below, notifies every gatekeeper in the LAN using a universal address, 224.0.1.41.

```
h323-gateway voip id GK1 multicast
h323-gateway voip id GK2 ipaddr 172.18.193.65 1719
```

Examples

The following example configures Ethernet interface 0.0 as the gateway interface and defines a specific gatekeeper for it. In this example, the gatekeeper ID is GK15.cisco.com, and its IP address is 172.16.53.15 (using port 1719).

```
interface Ethernet0/0
 ip address 172.16.53.13 255.255.255.0
 h323-gateway voip interface
 h323-gateway voip id GK15.cisco.com ipaddr 172.16.53.15 1719
 h323-gateway voip h323-id GW13@cisco.com
 h323-gateway voip tech-prefix 13#
```

Related Commands

Command	Description
h323-gateway voip h323-id	Configures the H.323 name of the gateway that identifies this gateway to its associated gatekeeper.
h323-gateway voip interface	Configures an interface as an H.323 interface.
h323-gateway voip tech-prefix	Defines the technology prefix that the gateway registers with the gatekeeper.

h323-gateway voip interface

To configure an interface as an H.323 gateway interface, use the **h323-gateway voip interface** command in interface configuration mode. To disable H.323 gateway functionality for an interface, use the **no** form of this command.

h323-gateway voip interface

no h323-gateway voip interface

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the following platforms: Cisco 2500, Cisco 3600 series, and Cisco AS5300.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples

The following example configures Ethernet interface 0.0 as the gateway interface. In this example, the **h323-gateway voip interface** command configures this interface as an H.323 interface.

```
interface Ethernet0/0
 ip address 172.16.53.13 255.255.255.0
 h323-gateway voip interface
 h323-gateway voip id GK15.cisco.com ipaddr 172.16.53.15 1719
 h323-gateway voip h323-id GW13@cisco.com
 h323-gateway voip tech-prefix 13#
```

Related Commands

Command	Description
h323-gateway voip h323-id	Configures the H.323 name of the gateway that identifies this gateway to its associated gatekeeper.
h323-gateway voip id	Defines the name and location of the gatekeeper for this gateway.
h323-gateway voip tech-prefix	Defines the technology prefix that the gateway registers with the gatekeeper.

h323-gateway voip tech-prefix

To define the technology prefix that the gateway registers with the gatekeeper, use the **h323-gateway voip tech-prefix** command in interface configuration mode. To disable this defined technology prefix, use the **no** form of this command.

h323-gateway voip tech-prefix *prefix*

no h323-gateway voip tech-prefix *prefix*

Syntax Description

prefix	Numbers used as the technology prefixes. Each technology prefix can contain up to 11 characters. Although not strictly necessary, a pound sign (#) is frequently used as the last digit in a technology prefix. Valid characters are 0 to 9, the pound sign (#), and the asterisk (*).

Command Default Disabled

Command Modes Interface configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the following platforms: Cisco 2500, Cisco 3600 series, and Cisco AS5300.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines This command defines a technology prefix that the gateway then registers with the gatekeeper. Technology prefixes can be used as a discriminator so that the gateway can tell the gatekeeper that a certain technology is associated with a particular call (for example, 15# could mean a fax transmission), or it can be used like an area code for more generic routing. No standard currently defines what the numbers in a technology prefix mean. By convention, technology prefixes are designated by a pound sign (#) as the last character.

Note Cisco gatekeepers use the asterisk (*) as a reserved character. If you are using Cisco gatekeepers, do not use the asterisk as part of the technology prefix.

Examples

The following example configures Ethernet interface 0.0 as the gateway interface. In this example, the technology prefix is defined as 13#.

```
interface Ethernet0/0
 ip address 172.16.53.13 255.255.255.0
 h323-gateway voip interface
 h323-gateway voip id GK15.cisco.com ipaddr 172.16.53.15 1719
 h323-gateway voip h323-id GW13@cisco.com
 h323-gateway voip tech-prefix 13#
```

Related Commands

Command	Description
h323-gateway voip h323-id	Configures the H.323 name of the gateway that identifies this gateway to its associated gatekeeper.
h323-gateway voip id	Defines the name and location of the gatekeeper for this gateway.
h323-gateway voip interface	Configures an interface as an H.323 interface.

h323zone-id (voice source group)

To specify the zone identification for an incoming H.323 call, use the **h323zone-id** command in voice source-group configuration mode. To delete the zone ID, use the **no** form of this command.

h323zone-id *name*

no h323zone-id *name*

Syntax Description

name	Zone ID name. Maximum size is 127 alphanumeric characters.

Command Default No default behavior or values

Command Modes Voice source-group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines Use this command to specify the zone to use for incoming H.323 calls in the voice source-group definition. The zone ID name matches the source zone ID of an incoming H.323 call.

Note The SIP protocol does not support zone ID functionality.

Examples The following example associates zone ID "5400-gw1" with incoming calls for source IP group "northcal":

```
Router(config)# voice source-group northcal
Router(cfg-source-grp)# h323zone-id 5400-gw1
```

Related Commands

Command	Description
voice source-group	Defines a source group for voice calls.

h450 h450-3 timeout

To specify timeout values for call forwarding using the ITU-T H.450.3 standard, use the **h450 h450-3 timeout** command in H.323 voice service configuration mode. To return to the default, use the **no** form of this command.

h450 h450-3 timeout T1 *milliseconds*

no h450 h450-3 timeout T1

Syntax Description

T1	Timeout value to wait for a rerouting response.
milliseconds	Number of milliseconds. Range is from 500 to 60000. Default is 5000.

Command Default

T1 timer is 5000 milliseconds.

Command Modes

H323 voice service configuration

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines

Use this command with Cisco IOS Telephony Service (ITS) V2.1 or a later version.

This command is primarily used when the default setting for this timer does not match your network delay parameters. Refer to the ITU-T H.450.3 specification for more information on these timers.

Examples

The following example defines a T1 timeout of 3000 milliseconds:

```
Router(config)# voice service voip
Router(conf-voi-serv)# h323
Router(conf-serv-h323)# h450 h450-3 timeout T1 3000
```

Related Commands

Command	Description
h323	Enables H.323 voice service configuration commands.
voice service	Enters voice-service configuration mode.

handle-replaces

To configure a Cisco IOS device to handle Session Initiation Protocol (SIP) INVITE with Replaces header messages at the SIP protocol level, use the **handle-replaces** command in SIP UA configuration mode. To return to the default handling of SIP INVITE with Replaces header messages where messages are handled at the application layer, use the **no** form of this command.

handle-replaces

no handle-replaces

Syntax Description

This command has no arguments or keywords.

Command Default

Handling of SIP INVITE with Replaces header messages takes place at the application layer.

Command Modes

SIP UA configuration (config-sip-ua)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

On Cisco IOS devices running software earlier than Cisco IOS Release 12.4(22)T, SIP INVITE with Replaces header messages (such as those associated with Call Replacement during a Consult Call transfer scenario) are handled at the SIP protocol level. Beginning with Cisco IOS Release 12.4(22)T, the default behavior is for Cisco IOS devices to handle SIP INVITE with Replaces header messages at the application layer. To configure your Cisco IOS device to handle SIP INVITE with Replaces header messages at the SIP protocol level, use the **handle-replaces** command in SIP UA configuration mode.

Examples

The following example shows how to configure fallback to legacy handling of SIP INVITE messages:

```
Router(config)# sip-ua
Router(config-sip-ua)# handle-replaces
```

Related Commands

Command	Description
supplementary-service sip	Enables SIP supplementary service capabilities for call forwarding and call transfers across a SIP network.

hangup-last-active-call

To define a Feature Access Code (FAC) to access the Hangup Last Active Call feature in feature mode on analog phones connected to FXS ports, use the **hangup-last-active-call** command in STC application feature-mode call-control configuration mode. To return the code to its default, use the **no** form of this command.

hangup-last-active-call *keypad-character*

no hangup-last-active-call

Syntax Description

keypad-character	Character string of one to four characters that can be dialed on a telephone keypad (0—9, *, #). Default is #1.

Command Default

The default value is #1.

Command Modes

STC application feature-mode call-control configuration (config-stcapp-fmcode)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command changes the value of the FAC for the Hangup Last Active Call feature from the default (#1) to the specified value.

If you attempt to configure this command with a value that is already configured for another FAC in feature mode, you receive a message. This message will not prevent you from configuring the feature code. If you configure a duplicate FAC, the system implements the first feature it matches in the order of precedence as determined by the value for each FAC (#1 to #5).

If you attempt to configure this command with a value that precludes or is precluded by another FAC in feature mode, you receive a message. If you configure a FAC to a value that precludes or is precluded by another FAC in feature mode, the system always executes the call feature with the shortest code and ignores the longer code. For example, 1 will always preclude 12 and 123. These messages will not prevent you from configuring the feature code. You must configure a new value for the precluded code in order to enable phone user access to that feature.

Note For analog phones connected to FXS ports in Cisco Unified Communications Manager Express (CME), the **keep-conference drop-last** command must be enabled on the Cisco router.

Examples

The following example shows how to change the value of the feature code for the Hangup Last Active Call feature from the default (#1). With this configuration, a phone user must press hook flash during a three-party conference to get the feature tone and then dial 11 to drop the last active call party. The conference becomes a basic call.

```
Router(config)# stcapp call-control mode feature
Router(config-stcapp-fmcode)# hangup-last-active-call 11
Router(config-stcapp-fmcode)# exit
```

Related Commands

Command	Description
conference	Defines FAC in Feature Mode to initiate a three-party conference.
drop-last-conferee	Defines FAC in feature mode to use to drop last active call during a three-party conference.
toggle-between-two-calls	Defines FAC in feature mode to toggle between two active calls.
transfer	Defines FAC in feature mode to connect a call to a third party that the phone user dials.

header-passing

To enable the passing of headers to and from Session Initiation Protocol (SIP) INVITE, SUBSCRIBE, and NOTIFY messages, use the **header-passing** command in voice service voip sip configuration mode. To disable header passing, use the **no** form of this command.

header-passing

no header-passing

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

voice service voip sip configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

- This command applies to all SIP VoIP dial peers configured on a gateway. It enables header passing for SIP INVITE, SUBSCRIBE and NOTIFY messages; disabling header passing affects only incoming INVITE messages.
- There is no command to enable header passing on a per-call or per-application basis.
- Enabling header passing results in a slight increase in memory and CPU utilization.

Examples

The following example shows header-passing enabled:

```
Router(conf-serv-sip)# header-passing
```

Related Commands

Command	Description
debug voip ccapi protoheaders	Displays messages related to protocol headers.
retry subscribe	Configures the number of retries for SUBSCRIBE messages.
show subscription sip	Displays active SIP subscriptions.
subscription maximum originate	Specifies the maximum number of outstanding subscriptions that are originated by the gateway.

history-info

To enable Session Initiation Protocol (SIP) history-info header support on Cisco IOS gateway at a global level, use the **history-info** command in voice service voip sip configuration mode. To disable SIP history-info header support, use the **no** form of this command.

history-info

no history-info

Syntax Description

This command has no keywords or arguments.

Command Default

History-info header support is disabled.

Command Modes

Voice service voip sip configuration (conf-serv-sip)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

Use this command to enable history-info header support at a global level. The history-info header (as defined in RFC 4244) records the call or dialog history. The receiving application uses the history-info header information to determine how and why the call has reached it.

Note The Cisco IOS SIP gateway cannot use the information in the history-info header to make routing decisions.

Examples

The following example enables SIP history-info header support:

```
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# history-info
```

Related Commands

Command	Description
voice-class sip history-info	Enables SIP history-info header support at the dial-peer level.

history session event-log save-exception-only

To save in history only the event logs for application sessions that have at least one error, use the **history session event-log save-exception-only** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

history session event-log save-exception-only

no history session event-log save-exception-only

Syntax Description

This command has no arguments or keywords.

Command Default

All event logs for sessions are saved to history.

Command Modes

Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application history session event-log save-exception-only** command.

Usage Guidelines

Application event logs move from active to history after an instance terminates. If you use this command, the voice gateway saves event logs only for instances that had one or more errors. Event logs for normal instances that do not contain any errors are not saved to history.

Note This command does not affect records saved to an FTP server by using the **dump event-log** command.

Examples

The following example saves an event log in history only if the instance had an error:

```
application
 monitor
 history session event-log save-exception-only
```

Related Commands

Command	Description
call application history session event-log save-exception-only	Saves in history only the event logs for application sessions that have at least one error.
history session max-records	Sets the maximum number of application instance records saved in history.
history session retain-timer	Sets the maximum number of minutes for which application instance records are saved in history.

history session max-records

To set the maximum number of application instance records saved in history, use the **history session max-records** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

history session max-records *number*

no history session max-records

Syntax Description

number	Maximum number of records to save in history. Range is 0 to 2000. Default is 360.

Command Default

360

Command Modes

Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application history session max-records** command.

Usage Guidelines

This command affects the number of records that display when you use the **show call application history session-level** command.

Examples

The following example sets the maximum record limit to 500:

```
application
 monitor
 history session max-records 500
```

Related Commands

Command	Description
call application history session max-records	Sets the maximum number of application instance records saved in history.
history session event-log save-exception-only	Saves in history only the event logs for application sessions that have at least one error.
history session retain-timer	Sets the maximum number of minutes for which application instance records are saved in history.

history session retain-timer

To set the maximum number of minutes for which application instance records are saved in history, use the **history session retain-timer** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

history session retain-timer *minutes*

no history session retain-timer

Syntax Description

minutes	Maximum time, in minutes, for which history records are saved. Range is 0 to 4294,967,295. Default is 15.

Command Default 15

Command Modes Application configuration mode

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application history session retain-timer** command.

Usage Guidelines This command affects the number of records that display when you use the **show call application history session-level** command.

To enable event logging for voice applications, use the **event-log** command.

Examples The following example sets the maximum time to save history records to 1 hour:

```
application
 monitor
 history session retain-timer 60
```

Related Commands

Command	Description
call application history session retain-timer	Sets the maximum number of minutes for which application instance records are saved in history.
event-log	Enables event logging for voice application instances.
history session event-log save-exception-only	Saves in history only the event logs for application instances that have at least one error.

Command	Description
history session max-records	Sets the maximum number of application instance records saved in history.
show call application session-level	Displays event logs and statistics for voice application instances.

hold-resume

To enable the Hold/Resume STC application supplementary-service feature on an FXS port, use the **hold-resume** command in supplementary-service voice-port configuration mode. To disable, use the **no** form of this command.

hold-resume

no hold-resume

Syntax Description

This command has no arguments or keywords.

Command Default

Feature is disabled.

Command Modes

Supplementary-service voice-port configuration (config-stcapp-suppl-serv-port)

Command History

Release	Modification
12.4(20)YA	This command was introduced.
12.4(22)T	This command was integrated into Cisco IOS Release 12.4(22)T.

Usage Guidelines

This command enables the Hold/Resume STC application supplementary-service feature on analog endpoints that are connected to FXS ports on a Cisco IOS voice gateway, such as a Cisco integrated services router (ISR) or Cisco VG224 Analog Phone Gateway.

Examples

The following example shows how to enable Hold/Resume on port 2/0 on a Cisco VG 224.

```
Router(config)# stcapp supplementary-services
Router(config-stcapp-suppl-serv)# port 2/0
Router(config-stcapp-suppl-serv-port)# hold-resume
Router(config-stcapp-suppl-serv-port)# end
```

Related Commands

Command	Description
stcapp supplementary-services	Enters supplementary-service configuration mode for configuring STC application supplementary-service features on an FXS port.

hopcount

To specify the maximum number of border element (BE) hops through which an address resolution request can be forwarded, use the **hopcount** command in Annex G configuration mode. To restore the default, use the **no** form of this command.

hopcount *hopcount-value*

no hopcount

Syntax Description

hopcount-value	Maximum number of BE hops through which an address resolution request can be forwarded. Range is from 1 to 255. The default is 7.

Command Default 7 hops

Command Modes Annex G configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples The following example sets address-resolution forwarding to a maximum of 10 hops:

```
Router(config)# call-router h323-annexg be20
Router(config-annexg)# hopcount 10
```

Related Commands

Command	Description
call-router	Enables the Annex G border element configuration commands.
show call-router status	Displays the Annex G BE status.

host (SIP URI)

To match a call based on the host field, a valid domain name, IPv4 address, IPv6 address, or the complete domain name in a Session Initiation Protocol (SIP) uniform resource identifier (URI), use the **host** command in voice URI class configuration mode. To remove the host match, use the **no** form of this command.

host {**ipv4:***ipv4-address* | **ipv6:***ipv6-address* | **dns:***dns-name* | *hostname-pattern*}

no host

Syntax Description

ipv4:*ipv4-address*	Specifies a valid IPv4 address.
ipv6:*ipv6-address*	Specifies a valid IPv6 address.
dns:*dns-name*	Specifies a valid domain name. The maximum length of a valid domain name is 64 characters.
hostname-pattern	Cisco IOS regular expression pattern to match the host field in a SIP URI. The maximum length of a hostname pattern is 32 characters.

Command Default

The calls are not matched on the host field, IPv4 address, IPv6 address, valid domain name, or complete domain name in the SIP URI.

Command Modes

Voice URI class configuration (config-voice-uri-class)

Command History

Release	Modification
12.3(4)T	This command was introduced.
15.1(2)T	This command was modified. The **ipv4:***ipv4-address*, **ipv6:***ipv6-address*, and **dns:***dns-name* arguments were included.

Usage Guidelines

You can use this command only in a voice class for SIP URIs.

You cannot use this command if you use the **pattern** command in the voice class. The **pattern** command matches on the entire URI, whereas this command matches only a specific field.

You can configure ten instances of the **host** command by specifying IPv4 addresses, IPv6 addresses, or domain name service (DNS) names for each instance. You can configure the **host** command specifying the *hostname-pattern* argument only once.

Examples

The following example defines a voice class that matches on the host field in a SIP URI:

```
voice class uri r100 sip
  user-id abc123
  host server1
  host ipv4:10.0.0.0
  host ipv6:[2001:0DB8:0:1:FFFF:1234::5]
  host dns:example.sip.com
  phone context 408
```

Related Commands

Command	Description
pattern	Matches a call based on the entire SIP or TEL URI.
phone context	Filters out URIs that do not contain a phone-context field that matches the configured pattern.
user-id	Matches a call based on the user-id field in the SIP URI.
voice class uri	Creates or modifies a voice class for matching dial peers to calls containing a SIP or TEL URI.
voice class uri sip preference	Sets a preference for selecting voice classes for a SIP URI.

host-registrar

To populate the sip-ua registrar domain name or IP address value in the host portion of the diversion header and to redirect the contact header of the 302 response, use the **host-registrar** command in SIP user-agent configuration mode. To remove the sip-ua registrar domain name or IP address from the host portion of the diversion and redirect contact headers, use the **no** form of this command.

host-registrar

no host-registrar

Syntax Description

This command has no arguments or keywords.

Command Default

This command's functionality is disabled. In the default condition, diversion headers are populated with the domain name or IP address of the gateway, and redirect contact headers are populated with the dial peer session target IP address or hostname.

Command Modes

SIP user-agent configuration (config-sip-ua)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

You must first configure the **sip-ua** command to place the router in SIP user-agent configuration mode before you can use the **host-registrar** command.

By default, the Session Initiation Protocol (SIP) gateway and Cisco Unified Communications Manager Express (Cisco Unified CME) populate the host portion of the diversion header with the domain name or IP address of the gateway that generates the request or response. The SIP gateway and Cisco Unified CME also populate the host portion of the redirect contact header with the session target IP address or hostname of the matching dial peer.

When the **host-registrar** command and the **registrar** command are both configured in SIP user-agent configuration mode, the SIP gateway or Cisco Unified CME populate the host portion of both the diversion and redirect contact headers with the domain name or IP address configured by the **registrar** command.

The **host-registrar** command should be configured along with the **registrar** command in SIP user-agent configuration mode. If the **host-registrar** command is configured without the **registrar** command, the host portion of the diversion header is populated with the domain name or IP address of the gateway and the host portion of the redirect contact header is populated with the session target IP address or hostname of the matching dial peer.

Examples

The following example shows how to configure the **host-registrar** and **registrar** commands in SIP user-agent configuration mode to specify a URL scheme with SIP security:

```
sup-ua
 retry invite 3
 retry register 3
 timers register 150
 registrar dns:example.com scheme sips
 host-registrar
```

Related Commands

Command	Description
registrar	Enables SIP gateways to register E.164-numbers on behalf of analog telephone voice ports (FXS), IP phone virtual voice ports (EFXS), and SCCP phones with an external SIP proxy or SIP registrar.
sip-ua	Enables SIP user-agent configuration commands and configures the user agent.

http client cache memory

To set the memory file and pool limits for the HTTP client cache, use the **http client cache memory** command in global configuration mode. To reset to the default, use the **no** form of this command.

http client cache memory {**file** *file-size* | **pool** *pool-size*}

no http client cache memory {**file** | **pool**}

Syntax Description

file *file-size*	Maximum file size, in kilobytes, allowed for caching. Any file that is larger is not cached. Range is 1 to 10000. The default is 50.
pool *pool-size*	Maximum pool size, in kilobytes, allowed for caching. Range is 0 to 100000. The default is 10000. Setting the memory pool size to 0 disables HTTP caching.

Command Default

Memory file size: 50 KB
Memory pool size: 10 MB

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.3(5)	The default for the *file-size* argument was increased from 2 to 50 KB and the default of the *pool-size* argument was increased from 100 to 10000 KB.
12.3(7)T	The default changes in Cisco IOS Release 12.3(5) were integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

A larger cache size may permit caching of frequently used files, decreasing the fetching time between the client and server and increasing performance. Allocation of memory to increase file size or pool size does not reduce the amount of memory available. Cache memory is used only when needed, and afterward returns to being memory shared with other resources.

The amount of memory required for an expected level of performance depends on a number of factors, including the type of voice gateway (for example, Cisco 2600 series or Cisco AS5400).

The recommended maximum file size is 10 MB; the recommended maximum pool size is 100 MB.

The gateway might accept invalid characters such as "#" or "!" when you input the value for this command. The gateway ignores any invalid characters.

Note For more information on HTTP caching, see the specification on which it is based: RFC 2616, *Hypertext Transfer Protocol HTTP/1.1,* June 1999, IETF.

Examples

The following example sets the HTTP client cache memory pool to 50,000 KB:

```
http client cache memory pool 50000
```

The following example sets the HTTP client cache memory file to 8000 KB:

```
http client cache memory file 8000
```

Related Commands

Command	Description
http client cache refresh	Configures the refresh time for the HTTP client cache.
http client connection idle timeout	Configures the HTTP client connection.
http client response timeout	Configures the HTTP client server response.
show http client cache	Displays current HTTP client cache information.

http client cache query

To enable caching of query data returned from the HTTP server, use the **http client cache query** command in global configuration mode. To disable caching of query data, use the **no** form of this command.

http client cache query

no http client cache query

Syntax Description This command has no arguments or keywords.

Command Default Query data is not cached.

Command Modes Global configuration (config)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines Use the **show http client cache** command to display cached query data. To protect caller privacy, values of the URL attributes are masked out with asterisks (*) in the **show http client cache** command output. If you use this command to enable caching of query data, use the **http client cache memory** command to increase the size of the HTTP client cache memory pool to accommodate the cached query data.

Examples The following example enables caching of query data returned from the HTTP server:

```
Router# http client cache query
```

Related Commands

Command	Description
http client cache memory	Sets the memory file and pool limits for the HTTP client cache.
show http client cache	Displays information about the entries contained in the HTTP client cache.

http client cache refresh

To set the time limit for how long a cached entry is considered current by the HTTP client, use the **http client cache refresh** command in global configuration mode. To reset to the default, use the **no** form of this command.

http client *cache* refresh *seconds*

no http client cache refresh

Syntax Description

seconds	Lifetime of a cached HTTP entry, in seconds. Range is from 1 to 864000. The default is 86400 (24 hours).

Command Default 86,400 seconds (24 hours)

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines This command must be used to set the refresh time only if the HTTP server does not provide the necessary information in the HTTP header to calculate this value.

The gateway might accept invalid characters such as "#" or "!" when you input the value for this command. The gateway ignores any invalid characters.

When a request is made to an expired cached entry (that is, an entry that is the same age as or older than the refresh time), the HTTP client sends the server a conditional request for an update.

An expired entry is not automatically updated unless a request from the user hits the same cached entry. Expired entries are not cleaned up until 70 percent or more of the cache pool memory is consumed; then all expired entries that lack a user reference are deleted from the cache table.

Note For more information on HTTP caching, see the specification on which it is based: RFC 2616, *Hypertext Transfer Protocol HTTP/1.1,* June 1999, IETF.

Examples The following example shows the HTTP client cache refresh to be 10 seconds:

```
http client cache refresh 10
```

Related Commands

Command	Description
http client cache memory	Configures the memory limits for the HTTP client cache.
http client connection idle timeout	Configures the HTTP client connection.
http client response timeout	Configures the HTTP client server response.
show http client cache	Displays current HTTP client cache information.

http client connection idle timeout

To set the number of seconds for which the HTTP client waits before terminating an idle connection, use the **http client connection idle timeout** command in global configuration mode. To reset to the default, use the **no** form of this command.

http client connection idle timeout *seconds*

no http client connection idle timeout

Syntax Description

seconds	How long, in seconds, the HTTP client waits before terminating an idle connection. Range is from 1 to 60. The default is 2.

Command Default 2 seconds

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines The setting of this command determines when the HTTP client is disconnected from the HTTP server, which is necessary when the server does not disconnect the client after a desirable length of time.

The default value is recommended and should normally not be changed.

In the **show http client connection** command output, this parameter is displayed as *connection idle timeout.*

The gateway might accept invalid characters such as “#” or “!” when you input the value for this command. The gateway ignores any invalid characters.

Examples The following example sets the timeout to 40 seconds:

```
http client connection idle timeout 40
```

Related Commands

Command	Description
http client cache memory	Configures the HTTP client cache.
http client response timeout	Configures the HTTP client server response.
show http client connection	Displays current HTTP client connection information.

http client connection persistent

To enable HTTP persistent connections so that multiple files can be loaded using the same connection, use the **http client connection persistent** command in global configuration mode. To disable HTTP persistent connections, use the **no** form of this command.

http client connection persistent

no http client connection persistent

Syntax Description

This command has no arguments or keywords.

Command Default

Persistent connections are enabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines

The setting of this command determines whether the HTTP client requests a keepalive or closed connection from the server. The HTTP server is responsible for granting or denying the keepalive connection request from the client.

Enabling persistent connections is recommended.

In the **show http client connection** command output, activation of this command is displayed as *persistent connection.*

Examples

The following example shows the HTTP client connection persistent parameter to be enabled:

```
http client connection persistent
```

Related Commands

Command	Description
http client cache memory	Configures the HTTP client cache.
http client response timeout	Configures the HTTP client server response.
show http client connection	Displays current HTTP client connection information.

http client connection timeout

To set the number of seconds for which the HTTP client waits for a server to establish a connection before abandoning its connection attempt, use the **http client connection timeout** command in global configuration mode. To reset to the default, use the **no** form of this command.

http client connection timeout *seconds*

no http client connection timeout

Syntax Description

seconds	How long, in seconds, the HTTP client waits for a server to establish a connection before abandoning its connection attempt. Range is from 1 to 60. The default is 5.

Command Default 5 seconds

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines The setting of this command determines when the HTTP client abandons its attempt to connect to the server, which is necessary when a connection to the server cannot be established after a desirable length of time.

The default value is recommended and should normally not be changed.

In the **show http client connection** command output, activation of this command is displayed as *initial socket connection timeout.*

The gateway might accept invalid characters such as “#” or “!” when you input the value for this command. The gateway ignores any invalid characters.

Examples The following example shows the HTTP client connection timeout parameter to be 20 seconds:

```
http client connection timeout 20
```

Related Commands

Command	Description
http client cache memory	Configures the HTTP client cache.
http client response timeout	Configures the HTTP client server response.
show http client connection	Displays current HTTP client connection information.

http client cookie

To enable the HTTP client to send and receive cookies, use the **http client cookie** command in global configuration mode. To disable cookie support, use the **no** form of this command.

http client cookie

no http client cookie

Syntax Description This command has no arguments or keywords.

Command Default Enabled

Command Modes Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines This command enables RFC 2109-compliant support with the following exceptions:

- Cookies cannot be cached.
- Maximum number of cookies that are stored for a call is 10. If this limit is reached, any subsequent cookies are discarded when they are received.
- Cookies are only maintained for the duration of the call; when a call terminates, all associated cookies are discarded.
- Secure method is not supported.

Examples The following example enables HTTP cookie support if it was previously disabled using the **no http client cookie** command:

```
Router(config)# http client cookie
```

Related Commands

Command	Description
debug http client cookie	Displays debugging traces related to HTTP cookies.
http client cache memory	Configures the memory limits for the HTTP client cache.
http client cache refresh	Configures the refresh time for the HTTP client cache.
show http client cookie	Displays cookies that are being stored by the HTTP client.

http client post-multipart

To configure the HTTP client to generate a filename string that is not enclosed in quotation marks, use the **http client post-multipart content-disposition filename no-quote** command in global configuration mode. To return to the default, use the **no** form of this command.

http client post-multipart content-disposition filename no-quote

no http client post-multipart content-disposition filename no-quote

Syntax Description

content-disposition filename no-quote	HTTP client generates a filename string that is not enclosed in quotation marks.

Command Default

Filename string is enclosed in quotation marks.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

In a multipart HTTP POST request, the HTTP client on the router generates the filename string enclosed in quotation marks (“”). Although the Multipurpose Internet Mail Extension (MIME) standard recommends that quotation marks be used, some HTTP servers conform to RFC 2068, which does not include quotation marks. Some older Hypertext Preprocessor (PHP) files require that the filename string be embedded in quotation marks. Use the **http client post-multipart** command to remove the quotation marks from the filename if you do not need them.

Examples

The following example configures the HTTP client to generate filenames that are not enclosed in quotation marks in a multipart POST request:

```
Router# http client post-multipart content-disposition filename no-quote
```

http client response timeout

To configure the number of seconds for which the HTTP client waits for a server response, use the **http client response timeout** command in global configuration mode. To reset to the default, use the **no** form of this command.

http client response timeout *seconds*

no http client response timeout

Syntax Description

seconds	How long, in seconds, the HTTP client waits for a response from the server after making a request. Range is from 1 to 300. The default is 10.

Command Default

10 seconds

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.2(11)T	This command was implemented on the Cisco 3640 and Cisco 3660.

Usage Guidelines

This command is used to adjust the time allowed for the HTTP client to wait for the server to respond to a request before declaring a timeout error. Under normal conditions, the default of 10 seconds is sufficient. If more or less server response time is desired, use this command. For example, if your server responds slowly to the HTTP client requests, you may want to set this timer to wait longer.

In the **show running-config** command output, the value is displayed only if it is set to other than the default.

The gateway might accept invalid characters such as “#” or “!” when you input the value for this command. The gateway ignores any invalid characters.

Examples

The following example shows the HTTP client response timeout to be 5 seconds:

```
http client response timeout 5
```

Related Commands

Command	Description
show http client cache	Displays the HTTP client cache.
show http client connection	Displays the HTTP client connection.

http client secure-ciphersuite

To set the secure encryption cipher suite for the HTTP client, use the **http client secure-ciphersuite** command in global configuration mode. To reset to the default, use the **no** form of this command.

http client secure-ciphersuite {[**3des_cbc_sha**] [**des_cbc_sha**] [**null_md5**] [**rc4_128_md5**] [**rc4_128_sha**]}

no http client secure-ciphersuite

Syntax Description

3des_cbc_sha	Triple DES (Data Encryption Standard) encryption and the SHA (Secure Hash Algorithm) integrity method. The first portion of the keyword indicates the encryption; the last portion indicates the hash or integrity method.
des_cbc_sha	DES encryption and the SHA integrity method.
null_md5	NULL encryption and the MD5 (Message-Digest algorithm 5) integrity method.
rc4_128_md5	RC4 (or ARCFOUR) encryption and the MD5 integrity method.
rc4_128_sha	RC4 encryption and the SHA integrity method.

Command Default

All cipher suites.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Use this command to configure one or more cipher suites, or sets of encryption and hash algorithms, on the HTTP client. You must include at least one of the keywords and can include more than one. Use the **show http client secure status** command to display the cipher suites configured.

Examples

The following example sets the HTTP client to use the 3des_cbc_sha and null_md5 cipher suites:

```
Router(config)# http client secure-ciphersuite 3des_cbc_sha null_md5
```

Related Commands

Command	Description
http client secure-trustpoint	Declares the trustpoint that the HTTP client should use for HTTPS sessions.
show http client secure status	Displays the trustpoint and cipher suites that are configured in the HTTP client.

http client secure-trustpoint

To declare the trustpoint that the HTTP client will use for HTTPS (HTTP over Secure Socket Layer (SSL)) sessions, use the **http client secure-trustpoint** command in global configuration mode. To delete all identity information and certificates associated with the trustpoint, use the **no** form of this command.

http client secure-trustpoint *name*

no http client secure-trustpoint *name*

Syntax Description

name	Creates a name for the secure certification authority (CA) trustpoint.

Command Default

The Public Key Infrastructure (PKI) trustpoint configured on the router, or the primary trustpoint if more than one trustpoint is configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T	This command was introduced.

Usage Guidelines

Use the **show http client secure status** command to display the trustpoints and cipher suites configured for the client.

Examples

The following example sets the HTTP client's secure CA trustpoint to myca:

```
Router(config)# http client secure-trustpoint myca
```

Related Commands

Command	Description
http client secure-ciphersuite	Sets the secure encryption cipher suite for the HTTP client.
show http client secure status	Displays the trustpoint and cipher suites that are configured in the HTTP client.

hunt-scheme least-idle

To enable the least-idle search method for finding an available channel in a trunk group for outgoing calls, use the **hunt-scheme least-idle** command in trunk group configuration mode. To delete the hunt scheme from the trunk group profile, use the **no** form of the command.

hunt-scheme least-idle [**both** | **even** | **odd**]

no hunt-scheme

Syntax Description

both	(Optional) Searches both even- and odd-numbered channels.
even	Searches for an idle even-numbered channel with the shortest idle time. If no idle even-numbered channel is available, an odd-numbered channel with the longest idle time is sought.
odd	Searches for an idle odd-numbered channel with the shortest idle time. If no idle odd-numbered channel is available, an even-numbered channel with the longest idle time is sought.

Command Default

Hunt scheme: least-used
Channel number: **both**

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

Use the least-idle hunt scheme in situations where you want to reuse the most recently selected channel.

The least-idle hunt scheme looks for the channel that has just become available. The software looks at all the channels in the trunk group, regardless of member precedence, and selects the channel that has most recently come into the available queue.

If no channels are available at the time of the call request, the software returns a cause code determined by the application configured on the inbound dial peer.

If the **even** quantifier is set, the even-numbered channel with the shortest idle time is selected. If the **odd** quantifier is set, the odd-numbered channel with the shortest idle time is selected. If **both** is set, the most recently available channel, regardless of channel number, is selected.

Examples

The following example searches for an even-numbered idle channel having the shortest idle time within a trunk group:

```
Router(config)# trunk group northwestsales
Router(config-trunk-group)# hunt-scheme least-idle even
```

Related Commands

Command	Description
hunt-scheme longest-idle	Enables the longest-idle hunt scheme.
trunk group	Initiates a trunk group profile.

hunt-scheme least-used

To enable the least used search method for finding an available channel in a trunk group for outgoing calls, use the **hunt-scheme least-used** command in trunk group configuration mode. To delete the hunt scheme from the trunk group profile, use the **no** form of the command.

hunt-scheme least-used [**both** | **even** | **odd** [**up** | **down**]]

no hunt-scheme

Syntax Description

both	Searches both even- and odd-numbered channels.
even	Searches for an idle even-numbered channel. If no idle even-numbered channels are available, an odd-numbered channel is sought.
odd	Searches for an idle odd-numbered channel. If no idle odd-numbered channels are available, an even-numbered channel is sought.
up	Searches channels in ascending order based within a trunk group member. Used with **even**, **odd**, **both**.
down	Searches channels in descending order within a trunk group member. Used with **even**, **odd**, **both**.

Command Default

Hunt scheme: least-used
Channel number: both
Direction: up

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The least-used search method selects an idle channel from a trunk group member that has the highest number of available channels at the time that the hunt request is initiated. The high number of unused channels indicates that the trunk group member has not been very active in comparison with other trunk group members.

After selecting the trunk group member, the software searches the channels by direction and then by channel number:

- If **even up** is set, the software searches the trunk group members in ascending order of preference to determine which member has the highest number of available even-numbered channels. If no available even-numbered channel is found, the software searches the members again in ascending order for the member that has the highest number of available odd-numbered channels.

- If **odd up** is set, the software searches the trunk group members in ascending order of preference to determine which member has the highest number of available odd-numbered channels. If no available odd-numbered channel is found, the software searches the members again in ascending order for the member that has the highest number of available even-numbered channels.
- If **even down** is set, the software searches in descending order of preference to determine which member has the highest number of available even-numbered channels. If no available even-numbered channel is found, the software searches the members again in descending order for the member that has the highest number of available odd-numbered channels.
- If **odd down** is set, the software searches in descending order of preference to determine which member has the highest number of available odd-numbered channels. If no available odd-numbered channel is found, the software searches the members again in descending order for the member that has the highest number of available even-numbered channels.

If no channel is available in any of the trunk group members, the software returns the standard "no service" message.

Examples

The following example searches in ascending order for an even-numbered idle channel in a trunk group member having the highest number of available channels:

```
Router(config)# trunk group northwestsales
Router(config-trunk-group)# hunt-scheme least-used even up
```

Related Commands

Command	Description
trunk group	Initiates a trunk group profile.

hunt-scheme longest-idle

To enable the longest-idle search method for finding an available channel in a trunk group for outgoing calls, use the **hunt-scheme longest-idle** command in trunk group configuration mode. To delete the hunt scheme from the trunk group profile, use the **no** form of this command.

hunt-scheme longest-idle [**both** | **even** | **odd**]

no hunt-scheme

Syntax Description

both	Searches both even- and odd-numbered channels.
even	Searches for an idle even-numbered channel with the longest idle time. If no idle even-numbered channel is available, an odd-numbered channel with the shortest idle time is sought.
odd	Searches for an idle odd-numbered channel with the longest idle time. If no idle odd-numbered channel is available, an even-numbered channel with the shortest idle time is sought.

Command Default

Hunt scheme: least-used
Channel number: both

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The longest-idle hunt schemes attempts to route a call using a channel from the trunk group member that has been idle for the longest time.

If the **even** qualifier is set, the search looks for an even-numbered idle channel from the trunk group member that has been idle the longest. If no even-numbered idle channel is found, the search looks for an odd-numbered idle channel from the trunk group member that has the shortest idle time.

If the **odd** qualifier is set, the search begins looking for an odd-numbered channel from the trunk group member that has been idle the longest. If no odd-numbered idle channel is found, the search looks for an even-numbered idle channel from the trunk group member that has the shortest idle time.

If the **both** qualifier is set, the search looks for any (odd or even) idle channel in the trunk group member that has been idle the longest.

If no channel is available in any of the trunk group members, the software returns the standard “no service” message.

Examples

The following example searches in ascending order for an even-numbered idle channel in the trunk group member having the largest idle time:

```
Router(config)# trunk group northwestsales
Router(config-trunk-group)# hunt-scheme longest-idle even
```

Related Commands

Command	Description
hunt-scheme least-idle	Enables the least-idle hunt scheme.
trunk group	Initiates a trunk group profile.

hunt-scheme random

To enable the random search method for finding an available channel in a trunk group for outgoing calls, use the **hunt-scheme random** command in trunk group configuration mode. To delete the hunt scheme from the trunk group profile, use the **no** form of this command.

hunt-scheme random

no hunt-scheme

Syntax Description

This command has no arguments or keywords.

Command Default

Hunt scheme: least-used

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The random search method selects trunk group member at random for an idle channel. After the trunk group member is selected, a channel is chosen at random. If that channel is not available, another trunk group member is chosen at random, and one of its channels is randomly chosen.

If no channel is available, the software returns the standard “no service” message.

Examples

The following example searches trunk group members in random order for an idle channel:

```
Router(config)# trunk group northwestsales
Router(config-trunk-group)# hunt-scheme random
```

Related Commands

Command	Description
trunk group	Initiates a trunk group profile.

hunt-scheme round-robin

To enable the round robin search method for finding an available channel in a trunk group for outgoing calls, use the **hunt-scheme** command in trunk group configuration mode. To delete the hunt scheme from the trunk group profile, use the **no** form of this command.

hunt-scheme round-robin [**both | even | odd** [**up | down**]]

no hunt-scheme

Syntax Description

both	Searches for an idle channel among both even- and odd-numbered channels at the same precedence.
even	Searches for an idle even-numbered channel. If no idle even-numbered channel is available, an odd-numbered channel is used.
odd	Searches for an idle odd-numbered channel. If no idle odd-numbered channel is available, an even-numbered channel is used.
up	Searches channels in ascending order based within a trunk group member. Used with **even**, **odd**, **both**.
down	Searches channels in descending order within a trunk group member. Used with **even**, **odd**, **both**.

Command Default

Hunt scheme: least-used
Channel number: both

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The round-robin hunt scheme searches trunk group members one after the other for an idle channel. The history of the most recently used trunk group member is saved to identify the next trunk group member to use for a new idle channel request. This method tries to balance the load of channel use across trunk group members.

For example, suppose a trunk group has three trunk group members: A, B, and C. Trunk group member A has the highest preference, B has the next highest, and C has the lowest. The software starts the search with A:

- If A has an idle channel, that channel is used, and the next request for an idle channel starts with B.
- If A does not have an idle channel, the search moves to B:
- If B has an idle channel, that channel is used, and the next request for an idle channel starts with C.
- If B does not have an idle channel, the search moves to C:

- If C has an idle channel, that channel is used, and the next request for an idle channel starts with A.
- If C does not have an idle channel, the search returns to A.

If none of the trunk group members has an idle channel available for the current channel request, the software returns the standard "no service" message.

Compare this hunt scheme with **hunt-scheme sequential**, in which the next request for an idle channel always starts with the first trunk group member of the trunk group, regardless of where the last idle channel was found.

If the **even** qualifier is set, the search looks for an even-numbered idle channel starting with the trunk group member having the highest preference. If no even-numbered idle channel is found, the search looks for an even-numbered idle channel in the next trunk group member. If no even-numbered idle channel is found in any trunk group member, the search repeats the process for an odd-numbered channel.

If the **odd** qualifier is set, the search begins looking for an odd-numbered channel, and if none is found in any of the trunk group members, the search repeats the process for an even-numbered channel.

If the **both** qualifier is set, the search looks for any idle channel in the trunk group member.

Examples

The following example searches for an even-numbered idle channel starting with the trunk group member next in order after the previously used member:

```
Router(config)# trunk group northwestregion
Router(config-trunk-group)# hunt-scheme round-robin even
```

Related Commands

Command	Description
hunt-scheme sequential	Enables a "sequential idle channel" hunt scheme.
trunk group	Initiates a trunk group profile definition.

hunt-scheme sequential

To specify the sequential search method for finding an available channel in a trunk group for outgoing calls, use the **hunt-scheme sequential** command in trunk group configuration mode. To delete the hunt scheme from the trunk group profile, use the **no** form of this command.

hunt-scheme sequential [**both** | **even** | **odd** [**up** | **down**]]

no hunt-scheme

Syntax Description

both	Searches both even- and odd-numbered channels.
even	Searches for an idle even-numbered channel. If no idle even-numbered channel is available, an odd-numbered channel is sought.
odd	Searches for an idle odd-numbered channel. If no idle odd-numbered channel is available, an even-numbered channel is sought.
up	Searches channels in ascending order based within a trunk group member. Used with **even**, **odd**, **both**.
down	Searches channels in descending order within a trunk group member. Used with **even**, **odd**, **both**.

Command Default

Hunt scheme: least-used
Channel number: both
Direction: up

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The sequential hunt scheme selects an idle channel, starting with the trunk group member that has the highest preference within the trunk group. Regardless of where the last idle channel was found, an idle channel request starts searching with this highest-preference trunk group member.

For example, suppose a trunk group has three trunk group members: A, B, and C. Trunk group member A has the highest preference, B has the next highest, and C has the lowest. The software starts the search with trunk group A:

- If A has an idle channel, that channel is used, and the next request for an idle channel starts with A.
- If A does not have an idle channel, the search moves to B:
- If B has an idle channel, that channel is used, and the next request for an idle channel starts with A.
- If B does not have an idle channel, the search moves to C:
- If C has an idle channel, that channel is used, and the next request for an idle channel starts with A.
- If C does not have an idle channel, the software returns the standard “no service” message.

Compare this hunt scheme with **hunt-scheme round-robin**, where the next request for an idle channel starts with the next unused trunk group member of the trunk group.

If the **even** qualifier is set, the search looks for an even-numbered idle channel starting with the trunk group member having the highest preference. If no even-numbered idle channel is found, the search looks for an even-numbered idle channel in the next trunk group member. If no even-numbered idle channel is found, the search repeats the process for an odd-numbered idle channel.

If the **odd** qualifier is set, the search begins looking for an odd-numbered channel, starting with the trunk group member having the highest preference. If none is found in any of the trunk group members, the search repeats the process for an even-numbered channel.

If the **both** qualifier is set, the search looks for any idle channel in the trunk group member.

Use the sequential hunt scheme in situations that benefit from a predictable channel allocation. In addition, if one end of the routing path is defined with **sequential even up** and the other end with **sequential odd up**, glare conditions are avoided.

Examples

The following example searches in ascending order for an even-numbered idle channel starting with the trunk group member of highest precedence:

```
Router(config)# trunk group northwestsales
Router(config-trunk-group)# hunt-scheme sequential even up
```

Related Commands

Command	Description
hunt-scheme round-robin	Enables a round-robin hunt scheme.
trunk group	Initiates a trunk group profile definition.

huntstop

To disable all dial-peer hunting if a call fails when using hunt groups, use the **huntstop** command in dial peer configuration mode. To reenable dial-peer hunting, use the **no** form of this command.

huntstop

no huntstop

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Dial peer configuration

Command History

Release	Modification
12.0(5)T	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on Cisco 2600 series and Cisco 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines Once you enter this command, no further hunting is allowed if a call fails on the specified dial peer.

Note This command can be used with all types of dial peers.

Examples The following example shows how to disable dial-peer hunting on a specific dial peer:

```
dial peer voice 100 vofr
 huntstop
```

The following example shows how to reenable dial-peer hunting on a specific dial peer:

```
dial peer voice 100 vofr
 no huntstop
```

Related Commands

Command	Description
dial-peer voice	Enters dial peer configuration mode and specifies the method of voice-related encapsulation.

Cisco IOS Voice Commands: I

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the master index of commands or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Library.*

icpif

To specify the Calculated Planning Impairment Factor (ICPIF) for calls sent by a dial peer, use the **icpif** command in dial peer configuration mode. To reset to the default, use the **no** form of this command.

icpif *number*

no icpif

Syntax Description

number	Integer, expressed in equipment impairment factor units, that specifies the ICPIF value. Range is 0 to 55. The default is 20.

Command Default

20

Command Modes

Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
12.0(7)XK	This command was implemented on the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.2(8)T	The *number* default value for this command was changed from 30 to 20.

Usage Guidelines

This command is applicable only to VoIP dial peers.

Use this command to specify the maximum acceptable impairment factor for the voice calls sent by the selected dial peer.

Examples

The following example disables the **icpif** command:

```
dial-peer voice 10 voip
 icpif 0
```

id

To configure the local identification (ID) for a neighboring border element (BE), use the **id** command in Annex G neighbor border element (BE) configuration mode. To remove the local ID, use the **no** form of this command.

id *neighbor-id*

no id *neighbor-id*

Syntax Description

neighbor-id	ID for a neighboring BE. The identification ID must be an International Alphabet 5 (IA5) string and cannot include spaces. This identifier is local and is not related to the border element ID.

Defaults

No default behavior or values

Command Modes

Annex G neighbor BE configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. This command is not supported on the Cisco AS5300, Cisco AS5350, and Cisco AS5400 in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples

The following example configures the local ID for a neighboring BE. The identifier is 2333.

```
Router(config-annexg-neigh)# id 2333
```

The following example shows the the error response when an undefined neighbor ID is entered:

```
Router(config-annexg-neigh)#no id def
% Entry not valid, id not configured.

To deconfigure id under different neighbor you have to expilicitly go into that neighbor
and deconfigure the id.
```

Related Commands

Command	Description
advertise (annex G)	Controls the type of descriptors that the BE advertises to its neighbors.
port	Configures the port number of the neighbor that is used for exchanging Annex G messages.
query-interval	Configures the interval at which the local BE queries the neighboring BE.

idle-voltage

To specify the idle voltage on an Foreign Exchange Station (FXS) voice port, use the **idle-voltage** command in voice-port configuration mode. To reset to the default, use the **no** form of this command.

idle-voltage {**high** | **low**}

no idle-voltage

Syntax Description

high	The talk-battery (tip-to-ring) voltage is high (–48V) when the FXS port is idle.
low	The talk-battery (tip-to-ring) voltage is low (–24V) when the FXS port is idle.

Command Default

The idle voltage is –24V

Command Modes

Voice-port configuration

Command History

Release	Modification
12.0(4)T	This command was introduced on the Cisco MC3810.

Usage Guidelines

Some fax equipment and answering machines require a –48V idle voltage to be able to detect an off-hook condition in a parallel phone.

If the idle voltage setting is **high**, the talk battery reverts to –24V whenever the voice port is active (off hook).

Examples

The following example sets the idle voltage to –48V on voice port 1/1:

```
voice-port 1/1
 idle-voltage high
```

The following example restores the default idle voltage (–24V) on voice port 1/1:

```
voice-port 1/1
 no idle-voltage
```

Related Commands

Command	Description
show voice port	Displays voice port configuration information.

ignore

To configure the North American E&M or E&M MELCAS voice port to ignore specific receive bits, use the **ignore** command in voice-port configuration mode. To reset to the default, use the **no** form of this command.

ignore {**rx-a-bit** | **rx-b-bit** | **rx-c-bit** | **rx-d-bit**}

no ignore {**rx-a-bit** | **rx-b-bit** | **rx-c-bit** | **rx-d-bit**}

Syntax Description

rx-a-bit	Ignores the receive A bit.
rx-b-bit	Ignores the receive B bit.
rx-c-bit	Ignores the receive C bit.
rx-d-bit	Ignores the receive D bit.

Command Default

The default is mode-dependent:

- North American E&M:
  - The receive B, C, and D bits are ignored
  - The receive A bit is not ignored
- E&M MELCAS:
  - The receive A bit is ignored
  - The receive B, C, and D bits are not ignored

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0(7)XK	This command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

The **ignore** command applies to E&M digital voice ports associated with T1/E1 controllers. Repeat the command for each receive bit to be configured. Use this command with the **define** command.

Examples

To configure voice port 1/1 to ignore receive bits A, B, and C and to monitor receive bit D, enter the following commands:

```
voice-port 1/1
 ignore rx-a-bit
 ignore rx-b-bit
 ignore rx-c-bit
 no ignore rx-d-bit
```

To configure voice port 1/0/0 to ignore receive bits A, C, and D and to monitor receive bit B, enter the following commands:

```
voice-port 1/0/0
 ignore rx-a-bit
 ignore rx-c-bit
 ignore rx-d-bit
 no ignore rx-b-bit
```

Related Commands

Command	Description
condition	Manipulates the signaling bit pattern for all voice signaling types.
define	Defines the transmit and receive bits for North American E&M and E&M MELCAS voice signaling.
show voice port	Displays configuration information for voice ports.

ignore (interface)

To configure the serial interface to ignore the specified serial signals as the line up/down indicator, use the **ignore** command in interface configuration mode. To restore the default, use the **no** form of this command.

DCE Asynchronous Mode

ignore [dtr | rts]

no ignore [dtr | rts]

DCE Synchronous Mode

ignore [dtr | local-loopback | rts]

no ignore [dtr | local-loopback | rts]

DTE Asynchronous Mode

ignore [cts | dsr]

no ignore [cts | dsr]

DTE Synchronous Mode

ignore [cts | dcd | dsr]

no ignore [cts | dcd | dsr]

Syntax Description

dtr	Specifies that the DCE ignores the Data Terminal Ready (DTR) signal.
rts	Specifies that the DCE ignores the Request To Send (RTS) signal.
local-loopback	Specifies that the DCE ignores the local loopback signal.
cts	Specifies that the DTE ignores the Clear To Send (CTS) signal.
dsr	Specifies that the DTE ignores the Data Set Ready (DSR) signal.
dcd	Specifies that the DTE ignores the Data Carrier Detect (DCD) signal.

Command Default

The **no** form of this command is the default. The serial interface monitors the serial signal as the line up/down indicator.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(15)ZJ	This command was introduced on the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 routers.
12.3(2)T	This command was integrated into Cisco IOS Release 12.3(2)T.

Usage Guidelines

Serial Interfaces in DTE Mode

When the serial interface is operating in DTE mode, it monitors the DCD signal as the line up/down indicator. By default, the attached DCE device sends the DCD signal. When the DTE interface detects the DCD signal, it changes the state of the interface to up.

SDLC Multidrop Environments

In some configurations, such as a Synchronous Data Link Control (SDLC) multidrop environment, the DCE device sends the DSR signal instead of the DCD signal, which prevents the interface from coming up. Use this command to tell the interface to monitor the DSR signal instead of the DCD signal as the line up/down indicator.

Examples

The following example shows how to configure serial interface 0 to ignore the DCD signal as the line up/down indicator:

```
Router(config)# interface serial 0
Router(config-if)# ignore dcd
```

Related Commands

Command	Description
debug serial lead-transition	Activates the leads status transition debug capability for all capable ports.
show interfaces serial	Displays information about a serial interface.

image encoding

To specify an encoding method for fax images associated with a Multimedia Mail over IP (MMoIP) dial peer, use the **image encoding** command in dial peer configuration mode. To reset to the default, use the **no** form of this command.

image encoding {**mh** | **mr** | **mmr** | **passthrough**}

no image encoding {**mh** | **mr** | **mmr** | **passthrough**}

Syntax Description

mh	Modified Huffman image encoding. This is the IETF standard.
mr	Modified Read image encoding.
mmr	Modified Modified Read image encoding.
passthrough	The image is not modified by an encoding method.

Command Default Passthrough encoding

Command Modes Dial peer configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines Use this command to specify an encoding method for e-mail fax TIFF images for a specific MMoIP dial peer. This command applies primarily to the on-ramp MMoIP dial peer. Although you can optionally create an off-ramp dial peer and configure a particular image encoding value for that off-ramp call leg, store-and-forward fax ignores the off-ramp MMoIP setting and sends the file using Modified Huffman encoding.

There are four available encoding methods:

- Modified Huffman (MH)—One-dimensional data compression scheme that compresses data in only one direction (horizontal). Modified Huffman compression does not allow the transmission of redundant data. This encoding method produces the largest image file size.
- Modified Read (MR)—Two-dimensional data compression scheme (used by fax devices) that handles the data compression of the vertical line and that concentrates on the space between lines and within given characters.

- Modified Modified Read (MMR)—Data compression scheme used by newer Group 3 fax devices. This encoding method produces the smallest possible image file size and is slightly more efficient than Modified Read.
- Passthrough—No encoding method is applied to the image—meaning that the image is encoded by whatever encoding method is used by the fax device.

The IETF standard for sending fax TIFF images is Modified Huffman encoding with fine or standard resolution. RFC 2301 requires that compliant receivers support TIFF images with MH encoding and fine or standard resolution. If a receiver supports features beyond this minimal requirement, you might want to configure the Cisco AS5300 universal access server to send enhanced-quality documents to that receiver.

The primary reason to use a different encoding scheme from MH is to save network bandwidth. MH ensures interoperability with all Internet fax devices, but it is the least efficient of the encoding schemes for sending fax TIFF images. For most images, MR is more efficient than MH, and MMR is more efficient than MR. If you know that the recipient is capable of receiving more efficient encodings than just MH, store-and-forward fax allows you to send the most efficient encoding that the recipient can process. For end-to-end closed networks, you can choose any encoding scheme because the off-ramp gateway can process MH, MR, and MMR.

Another factor to consider is the viewing software. Many viewing applications (for example, those that come with Windows 95 or Windows NT) are able to display MH, MR, and MMR. Therefore you should decide, on the basis of the viewing application and the available bandwidth, which encoding scheme is right for your network.

This command applies to both on-ramp and off-ramp store-and-forward fax functions.

Examples

The following example selects Modified Modified Read as the encoding method for fax TIFF images sent by MMoIP dial peer 10:

```
dial-peer voice 10 mmoip
 image encoding mmr
```

Related Commands

Command	Description
image resolution	Specifies a particular fax image resolution for a specific MMoIP dial peer.

image resolution

To specify a particular fax image resolution for a specific multimedia mail over IP (MMoIP) dial peer, use the **image resolution** command in dial peer configuration mode. To reset to the default, use the **no** form of this command.

image resolution {**fine | standard | superfine | passthrough**}

no image resolution {**fine | standard | superfine | passthrough**}

Syntax Description

fine	Configures the fax TIFF image resolution to be 204-by-196 pixels per inch.
standard	Configures the fax TIFF image resolution to be 204-by-98 pixels per inch.
superfine	Configures the fax TIFF image resolution to be 204-by-391 pixels per inch.
passthrough	Indicates that the resolution of the fax TIFF image is not altered.

Command Default

passthrough

Command Modes

Dial peer configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750 access router.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600, Cisco 3600, Cisco 3725, and Cisco 3745.

Usage Guidelines

Use this command to specify a resolution (in pixels per inch) for e-mail fax TIFF images sent by the specified MMoIP dial peer. This command applies primarily to the on-ramp MMoIP dial peer. Although you can optionally create an off-ramp dial peer and configure a particular image resolution value for that off-ramp call leg, store-and-forward fax ignores the off-ramp MMoIP setting and sends the file using fine resolution.

This command enables you to increase or decrease the resolution of a fax TIFF image, thereby changing not only the resolution but also the size of the fax TIFF file. The IETF standard for sending fax TIFF images is Modified Huffman encoding with fine or standard resolution. The primary reason to configure a different resolution is to save network bandwidth.

This command applies to both on-ramp and off-ramp store-and-forward fax functions.

Examples

The following example selects fine resolution (204-by-196 pixels per inch) for e-mail fax TIFF images associated with MMoIP dial peer 10:

```
dial-peer voice 10 mmoip
 image encoding mh
 image resolution fine
```

Related Commands

Command	Description
image encoding	Specifies an encoding method for fax images associated with an MMoIP dial peer.

impedance

To specify the terminating impedance of a voice-port interface, use the **impedance** command in voice-port configuration mode. To reset to the default, use the **no** form of this command.

impedance {**600c** | **600r** | **900c** | **900r** | **complex1** | **complex2** | **complex3** | **complex4** | **complex5** | **complex6**}

no impedance {**600c** | **600r** | **900c** | **900r** | **complex1** | **complex2** | **complex3** | **complex4** | **complex5** | **complex6**}

Syntax Description

600c	600 ohms + 2.15uF[1].
600r	Resistive 600-ohm termination.
900c	900 ohms + 2.15uF[1].
900r	Resistive 900-ohm termination.
complex1	220 ohms + (820 ohms || 115 nF)[1].
complex2	270 ohms + (750 ohms || 150 nF)[1].
complex3	370 ohms + (620 ohms || 310 nF)[1].
complex4	600r, line = 270 ohms + (750 ohms || 150 nF)[1].
complex5	320 + (1050 ohms || 230 nF), line = 12 Kft[1].
complex6	600r, line = 350 + (1000 ohms || 210 nF)[1].

1. The plus symbol (+) indicates serial. The double pipe (||) indicates parallel.

Note This table represents the full set of impedances. Not all modules support the full set of impedance values shown here. To determine which impedance values are available on your modules, enter impedance ? in the command-line interface to see a list of the values you can configure.

Command Default 600r

Command Modes Voice-port configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on Cisco 3600 series.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T and support was added for the **complex3**, **complex4**, **complex5**, and **complex6** keywords on the Cisco 2600XM series, Cisco 2691, Cisco 2800 series, Cisco 3662 (telco models), Cisco 3700 series, and Cisco 3800 series.

Usage Guidelines

Use this command to specify the terminating impedance of analog telephony interfaces. The impedance value must match the specifications from the telephony system to which it is connected. Different countries often have different standards for impedance. CO switches in the United States are predominantly 600r. PBXs in the United States are 600r or 900c.

If the impedance is set incorrectly (if there is an impedance mismatch), a significant amount of echo is generated (which could be masked if the **echo-cancel** command has been enabled). In addition, gains might not work correctly if there is an impedance mismatch.

Configuring the impedance on a voice port changes the impedance on both voice ports of a VPM card. This voice port must be shut down and then opened for the new value to take effect.

Examples

The following example configures an FXO voice port on the Cisco 3600 series router for an impedance of 600 ohms (real):

```
voice-port 1/0/0
impedance 600r
shutdown/no shutdown
```

The following example configures an E&M voice port on a Cisco 2800 for an impedance of complex3:

```
voice-port 1/1
impedance complex3
shutdown/no shutdown
```

Related Commands

Command	Description
voice-port	Enters voice-port configuration mode.
echo-cancel enable	Enables the cancellation of voice that is sent out the interface and received back on the same interface.

inband-alerting

To enable inband alerting, use the **inband-alerting** command in the SIP user agent configuration mode. To disable inband alerting, use the **no** form of this command.

inband-alerting

no inband-alerting

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

SIP user agent configuration

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.1(3)T	This command was limited to enabling and disabling inband alerting.
12.2(2)XA	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was introduced on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

If inband alerting is enabled, the originating gateway can open an early media path (upon receiving a 180 or 183 message with a SDP body). Inband alerting allows the terminating gateway or switch to feed tones or announcements before a call is connected. If inband alerting is disabled, local alerting is generated on the originating gateway.

To reset this command to the default value, use the **default** command.

Examples

The following example disables inband alerting:

```
Router(config)# sip-ua
Router(config-sip-ua)# no inband-alerting
```

Related Commands

Command	Description
default	Sets a command to its default.
exit	Exits the SIP user agent configuration mode.
max-forwards	Specifies the maximum number of hops for a request.
no	Negates a command or set its defaults.
retry	Configures the SIP signaling timers for retry attempts.

Command	Description
timers	Configures the SIP signaling timers.
transport	Enables SIP UA transport for TCP/UDP.

inbound ttl

To set the inbound time-to-live value, use the **inbound ttl** command in Annex G neighbor service configuration mode. To reset to the default, use the **no** form of this command.

inbound ttl *ttl-value*

no inbound ttl

Syntax Description

ttl-value	Inbound time-to-live (TTL) value, in seconds. Range is 0 to 2147483. When set to 0, the service relationship does not expire. The default is 120.

Defaults

120 seconds

Command Modes

Annex G neighbor service configuration (config-nxg-neigh-svc)

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

Service relationships are defined to be unidirectional. Establishing a service relationship between border element A and border element B entitles A to send requests to B and expect responses. For B to send requests to A and expect responses, a second service relationship must be established. From A's perspective, the service relationship that B establishes with A is designated the "inbound" service relationship. Use this command to indicate the duration of the relationship between border elements that participate in a service relationship.

Examples

The following example sets the inbound time-to-live value to 420 seconds (7 minutes):

```
Router(config-nxg-neigh-svc)# inbound ttl 420
```

Related Commands

Command	Description
access-policy	Requires that a neighbor be explicitly configured.
outbound retry-interval	Defines the retry period for attempting to establish the outbound relationship between border elements.
retry interval	Defines the time between delivery attempts.
retry window	Defines the total time that a border element attempts delivery.
service-relationship	Establishes a service relationship between two border elements.
shutdown	Enables or disables the border element.

incoming alerting

To instruct an FXO ground-start voice port to modify its means of detecting an incoming call, use the **incoming alerting** command in voice-port configuration mode. To return to the default call detection method, use the **no** form of this command.

incoming alerting {**ring-only**}

no incoming alerting

Syntax Description

ring-only	Count incoming rings to detect incoming calls to the voice port that should be answered by the router.

Command Default

The FXO ground-start voice port detects an incoming call either by detecting the ring voltage applied to the line by the PSTN central office (CO) or by detecting that tip-ground is present for greater than about 7 seconds.

Command Modes

Voice-port configuration

Command History

Cisco IOS Release	Modification
12.4(4)XC	This command was introduced.

Usage Guidelines

This command is valid only on FXO ports that have been configured with the **signal ground-start** command.

This command is necessary when two Cisco Unified CallManager Express (Cisco Unified CME) routers are used to provide redundant failover for incoming PSTN FXO ground-start lines. The voice ports for these trunk lines are wired in parallel between the two routers. The primary router is set to answer incoming calls after the first ring by default. The secondary router is set to answer incoming calls after 2 or 3 rings using the **ring number** command in voice-port configuration mode. As long as the primary router is operating, then the secondary router will not see enough rings to trigger it to answer the call. When the primary router is not operating, the secondary router has to be able to detect incoming ring signals so that it can answer calls. The default method of incoming call detection is not appropriate for voice ports on a secondary Cisco Unified CME router. The **incoming alerting ring-only** command must be used to modify the incoming call detection logic so that the voice port counts the number of incoming call rings instead of using the default call detection method.

Examples

The following example sets ring-only as the detection method for incoming calls on voice port 3/0/0, which is an FXO ground-start voice port.

```
Router(config)# voice-port 3/0/0
Router(config-voiceport)# signal ground-start
Router(config-voiceport)# incoming alerting ring-only
```

Related Commands

Command	Description
ring number	Specifies the maximum number of rings to be detected before an incoming call is answered by the router.
signal	Specifies the type of signaling for a voice port.

incoming called-number (call filter match list)

To configure debug filtering for incoming called numbers, use the **incoming called-number** command in call filter match list configuration mode. To disable, use the **no** form of this command.

incoming called-number [**+**]*string*[**T**]

no incoming called-number [**+**]*string*[**T**]

Syntax Description

+	(Optional) Character that indicates an E.164 standard number.
string	Series of digits that specify a pattern for the E.164 or private dialing plan telephone number. Valid entries are the digits 0 through 9, the letters A through D, and the following special characters: • The asterisk (*) and pound sign (#) that appear on standard touch-tone dial pads. • Comma (,), which inserts a pause between digits. • Period (.), which matches any entered digit (this character is used as a wildcard). • Percent sign (%), which indicates that the preceding digit occurred zero or more times; similar to the wildcard usage. • Plus sign (+), which indicates that the preceding digit occurred one or more times. **Note** The plus sign used as part of a digit string is different from the plus sign that can be used in front of a digit string to indicate that the string is an E.164 standard number. • Circumflex (^), which indicates a match to the beginning of the string. • Dollar sign ($), which matches the null string at the end of the input string. • Backslash symbol (\), which is followed by a single character, and matches that character. Can be used with a single character with no other significance (matching that character). • Question mark (?), which indicates that the preceding digit occurred zero or one time. • Brackets ([ ]), which indicate a range. A range is a sequence of characters enclosed in the brackets; only numeric characters from 0 to 9 are allowed in the range. • Parentheses (( )), which indicate a pattern and are the same as the regular expression rule.
T	(Optional) Control character that indicates that the **destination-pattern** value is a variable-length dial string. Using this control character enables the router to wait until all digits are received before routing the call.

Command Default No default behavior or values

Command Modes Call filter match list configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples The following example shows the voice call debug filter set to match incoming called number 5550123:

```
call filter match-list 1 voice
 incoming called-number 5550123
```

Related Commands

Command	Description
call filter match-list voice	Create a call filter match list for debugging voice calls.
debug condition match-list	Run a filtered debug on a voice call.
incoming calling-number	Configure debug filtering for incoming calling numbers.
incoming dialpeer	Configure debug filtering for the incoming dial peer.
incoming secondary-called-number	Configure debug filtering for incoming called numbers from the second stage of a two-stage scenario.
outgoing called-number	Configure debug filtering for outgoing called numbers.
outgoing calling-number	Configure debug filtering for outgoing calling numbers.
outgoing dialpeer	Configure debug filtering for the outgoing dial peer.
show call filter match-list	Display call filter match lists.

incoming called-number (dial peer)

To specify a digit string that can be matched by an incoming call to associate the call with a dial peer, use the **incoming called-number** command in dial-peer configuration mode. To reset to the default, use the **no** form of this command.

incoming called-number [**+**]*string*[**T**]

no incoming called-number [**+**]*string*[**T**]

Syntax Description

+	(Optional) Character that indicates an E.164 standard number.
string	Series of digits that specify a pattern for the E.164 or private dialing plan telephone number. Valid entries are the digits 0 through 9, the letters A through D, and the following special characters: • The asterisk (*) and pound sign (#) that appear on standard touch-tone dial pads. • Comma (,), which inserts a pause between digits. • Period (.), which matches any entered digit (this character is used as a wildcard). • Percent sign (%), which indicates that the preceding digit occurred zero or more times; similar to the wildcard usage. • Plus sign (+), which indicates that the preceding digit occurred one or more times. **Note** The plus sign used as part of a digit string is different from the plus sign that can be used in front of a digit string to indicate that the string is an E.164 standard number. • Circumflex (^), which indicates a match to the beginning of the string. • Dollar sign ($), which matches the null string at the end of the input string. • Backslash symbol (\), which is followed by a single character, and matches that character. Can be used with a single character with no other significance (matching that character). • Question mark (?), which indicates that the preceding digit occurred zero or one time. • Brackets ([ ]), which indicate a range. A range is a sequence of characters enclosed in the brackets; only numeric characters from 0 to 9 are allowed in the range. • Parentheses (( )), which indicate a pattern and are the same as the regular expression rule.
T	(Optional) Control character that indicates that the destination-pattern value is a variable-length dial string. Using this control character enables the router to wait until all digits are received before routing the call.

Command Default No incoming called number is defined

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
11.3NA	This command was implemented on the Cisco AS5800.
12.0(4)XJ	This command was modified for store-and-forward fax.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.0(7)XK	This command was implemented on the Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines When a Cisco device is handling both modem and voice calls, it needs to be able to identify the service type of the call—meaning whether the incoming call to the server is a modem or a voice call. When the access server handles only modem calls, the service type identification is handled through modem pools. Modem pools associate calls with modem resources based on the dialed number identification service (DNIS). In a mixed environment, in which the server receives both modem and voice calls, you need to identify the service type of a call by using this command.

If you do not use this command, the server attempts to resolve whether an incoming call is a modem or voice call on the basis of the interface over which the call arrives. If the call comes in over an interface associated with a modem pool, the call is assumed to be a modem call; if a call comes in over a voice port associated with a dial peer, the call is assumed to be a voice call.

By default, there is no called number associated with the dial peer, which means that incoming calls are associated with dial peers by matching calling number with answer address, call number with destination pattern, or calling interface with configured interface.

Use this command to define the destination telephone number for a particular dial peer. For the on-ramp POTS dial peer, this telephone number is the DNIS number of the incoming fax call. For the off-ramp MMoIP dial peer, this telephone number is the telephone number of the destination fax machine.

This command applies to both VoIP and POTS dial peers and to on-ramp and off-ramp store-and-forward fax functions.

This command is also used to provide a matching VoIP dial peer on the basis of called number when fax or modem pass-through with named signaling events (NSEs) is defined globally on a terminating gateway.

You can ensure that all calls will match at least one dial peer by using the following commands:

```
Router(config)# dial-peer voice tag voip
Router(config-dial-peer)# incoming called-number.
```

Examples

The following example configures calls that come into the router with a called number of 555-0163 as being voice calls:

```
dial peer voice 10 pots
 incoming called-number 5550163
```

The following example sets the number (310) 555-0142 as the incoming called number for MMoIP dial peer 10:

```
dial-peer voice 10 mmoip
 incoming called-number 3105550142
```

incoming calling-number (call filter match list)

To configure debug filtering for incoming calling numbers, use the **incoming calling-number** command in call filter match list configuration mode. To disable, use the **no** form of this command.

incoming calling-number [**+**]*string*[**T**]

no incoming calling-number [**+**]*string*[**T**]

Syntax Description

+	(Optional) Character that indicates an E.164 standard number.
string	Series of digits that specify a pattern for the E.164 or private dialing plan telephone number. Valid entries are the digits 0 through 9, the letters A through D, and the following special characters: • The asterisk (*) and pound sign (#) that appear on standard touch-tone dial pads. • Comma (,), which inserts a pause between digits. • Period (.), which matches any entered digit (this character is used as a wildcard). • Percent sign (%), which indicates that the preceding digit occurred zero or more times; similar to the wildcard usage. • Plus sign (+), which indicates that the preceding digit occurred one or more times. **Note** The plus sign used as part of a digit string is different from the plus sign that can be used in front of a digit string to indicate that the string is an E.164 standard number. • Circumflex (^), which indicates a match to the beginning of the string. • Dollar sign ($), which matches the null string at the end of the input string. • Backslash symbol (\), which is followed by a single character, and matches that character. Can be used with a single character with no other significance (matching that character). • Question mark (?), which indicates that the preceding digit occurred zero or one time. • Brackets ([ ]), which indicate a range. A range is a sequence of characters enclosed in the brackets; only numeric characters from 0 to 9 are allowed in the range. • Parentheses (( )), which indicate a pattern and are the same as the regular expression rule.
T	(Optional) Control character that indicates that the **destination-pattern** value is a variable-length dial string. Using this control character enables the router to wait until all digits are received before routing the call.

Cisco MC3810

incoming port *slot*/*port*

no incoming port *slot*/*port*

Syntax Description

Cisco 2600, Cisco 3600 Series and Cisco 3700 Series

slot-number	Number of the slot in the router in which the VIC is installed. Valid entries are 0 to 3, depending on the slot in which it has been installed.
subunit-number	Subunit on the VIC in which the voice port is located. Valid entries are 0 or 1.
port	Voice port number. Valid entries are 0 and 1.
slot	The router location in which the voice port adapter is installed. Valid entries are 0 to 3.

port:	Indicates the voice interface card location. Valid entries are 0 and 3.
ds0-group-no	Indicates the defined DS0 group number. Each defined DS0 group number is represented on a separate voice port. This allows you to define individual DS0s on the digital T1/E1 card.

Cisco AS5300

controller-number	T1 or E1 controller.
:D	D channel associated with ISDN PRI.

Cisco AS5400

card	Specifies the T1 or E1 card. Valid entries for the *card* argument are 1 to 7.
port	Specifies the voice port number. Valid entries are 0 to 7.
:D	Indicates the D channel associated with ISDN PRI.

Cisco AS5800

shelf	Specifies the T1 or E1 controller on the T1 card, or the T1 controller on the T3 card. Valid entries for the *shelf* argument are 0 to 9999.
slot	Specifies the T1 or E1 controller on the T1 card, or the T1 controller on the T3 card. Valid entries for the *slot* argument are 0 to 11.
port	Specifies the voice port number. • T1 or E1 controller on the T1 card —Valid entries are 0 to 11. • T1 controller on the T3 card—Valid entries are 1 to 28.
:*port*	Specifies the value for the *parent* argument. The valid entry is 0.
:D	Indicates the D channel associated with ISDN PRI.

Cisco MC3810

slot	The *slot* argument specifies the number slot in the router in which the VIC is installed. The only valid entry is 1.
port	The *port* variable specifies the voice port number. Valid interface ranges are as follows: • T1—ANSI T1.403 (1989), Telcordia TR-54016. • E1— ITU G.703. • Analog Voice—Up to six ports (FXS, FXO, E & M). • Digital Voice— Single T1/E1 with cross-connect drop and insert, CAS and CCS signaling, PRI QSIG. • Ethernet—Single 10BASE-T. • Serial—Two five-in-one synchronous serial (ANSI EIA/TA-530, EIA/TA-232, EIA/TA-449; ITU V.35, X.21, Bisync, Polled async).

incoming secondary-called-number

To configure debug filtering for incoming called numbers from the second stage of a two-stage scenario, use the **incoming secondary-called-number** command in call filter match list configuration mode. To disable, use the **no** form of this command.

incoming secondary-called-number *string*

no incoming secondary-called-number *string*

Syntax Description

string	Series of digits that specify a pattern for the E.164 or private dialing plan telephone number. Valid entries are the digits 0 to 9, the letters A to D, and the following special characters: • The asterisk (*) and pound sign (#) that appear on standard touchtone dial pads. On the Cisco 3600 series routers only, these characters cannot be used as leading characters in a string (for example, *650). • Comma (,), which inserts a pause between digits. • Period (.), which matches any entered digit (this character is used as a wildcard). On the Cisco 3600 series routers, the period cannot be used as a leading character in a string (for example, .650). • Percent sign (%), which indicates that the preceding digit occurred zero or more times; similar to the wildcard usage. • Plus sign (+), which indicates that the preceding digit occurred one or more times. **Note** The plus sign used as part of a digit string is different from the plus sign that can be used in front of a digit string to indicate that the string is an E.164 standard number. • Circumflex (^), which indicates a match to the beginning of the string. • Dollar sign ($), which matches the null string at the end of the input string. • Backslash symbol (\), which is followed by a single character; matches that character. Can be used with a single character with no other significance (matching that character). • Question mark (?), which indicates that the preceding digit occurred zero or one time. • Brackets ([ ]), which indicate a range. A range is a sequence of characters enclosed in the brackets; only numeric characters 0 to 9 are allowed in the range. • Parentheses ( ), which indicate a pattern and are the same as the regular expression rule.

Command Default No default behavior or values

Command Modes Call filter match list configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines Two-stage dialing occurs when the voice gateway presents a dial-tone before accepting digits. When a voice call comes into the Cisco IOS voice gateway, the voice port on the router is seized inbound by a PBX or CO switch. The voice gateway then presents a dial tone to the caller and collects digits until it can identify an outbound dial-peer. Dial-peer matching is done digit-by-digit whether the digits are dialed with irregular intervals by humans or in a regular fashion by telephony equipment sending the precollected digits. The voice gateway attempts to match a dial-peer after each digit is received.

Examples The following example shows the voice call debug filter set to match incoming secondary called number 8288807:

```
call filter match-list 1 voice
 incoming secondary-called-number 8288807
```

Related Commands

Command	Description
call filter match-list voice	Create a call filter match list for debugging voice calls.
debug condition match-list	Run a filtered debug on a voice call.
incoming called-number (call filter match list)	Configure debug filtering for incoming called numbers.
incoming calling-number	Configure debug filtering for incoming calling numbers.
incoming dialpeer	Configure debug filtering for the incoming dial peer.
outgoing called-number	Configure debug filtering for outgoing called numbers.
outgoing calling-number	Configure debug filtering for outgoing calling numbers.
outgoing dialpeer	Configure debug filtering for the outgoing dial peer.
show call filter match-list	Display call filter match lists.

incoming signaling local ipv4

To configure debug filtering for the incoming signaling local IPv4 addresses for the gatekeeper managing the signaling, use the **incoming signaling local ipv4** command in call filter match list configuration mode. To disable, use the **no** form of this command.

incoming signaling local ipv4 *ip_address*

no incoming signaling local ipv4 *ip_address*

Syntax Description

ip_address	IP address of the local voice gateway

Command Default No default behavior or values

Command Modes Call filter match list configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples The following example shows the voice call debug filter set to match incoming signaling on the local voice gateway, which has IP address 192.168.10.255:

```
call filter match-list 1 voice
 incoming signaling local ipv4 192.168.10.255
```

Related Commands

Command	Description
call filter match-list voice	Create a call filter match list for debugging voice calls.
debug condition match-list	Run a filtered debug on a voice call.
incoming port	Configure debug filtering for the incoming port.
incoming signaling remote ipv4	Configure debug filtering for the incoming signaling IPv4 addresses for calls to the IP side from the remote IP device.
outgoing port	Configure debug filtering for the outgoing port.
outgoing signaling local ipv4	Configure debug filtering for the outgoing signaling IPv4 addresses for calls to the IP side from the local voice gateway.
outgoing signaling remote ipv4	Configure debug filtering for the outgoing signaling IPv4 addresses for calls to the IP side from the remote IP device.
show call filter match-list	Display call filter match lists.

incoming signaling remote ipv4

To configure debug filtering for the incoming signaling remote IPv4 addresses for the gatekeeper managing the signaling, use the **incoming signaling remote ipv4** command in call filter match list configuration mode. To disable, use the **no** form of this command.

incoming signaling remote ipv4 *ip_address*

no incoming signaling remote ipv4 *ip_address*

Syntax Description

ip_address	IP address of the remote IP device

Command Default No default behavior or values

Command Modes Call filter match list configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Examples The following example shows the voice call debug filter set to match incoming signaling on the remote IP device, which has IP address 192.168.10.255:

```
call filter match-list 1 voice
 incoming signaling remote ipv4 192.168.10.255
```

Related Commands

Command	Description
call filter match-list voice	Create a call filter match list for debugging voice calls.
debug condition match-list	Run a filtered debug on a voice call.
incoming port	Configure debug filtering for the incoming port.
incoming signaling local ipv4	Configure debug filtering for the incoming signaling IPv4 addresses for calls to the IP side from the local voice gateway.
outgoing port	Configure debug filtering for the outgoing port.
outgoing signaling local ipv4	Configure debug filtering for the outgoing signaling IPv4 addresses for calls to the IP side from the local voice gateway.
outgoing signaling remote ipv4	Configure debug filtering for the outgoing signaling IPv4 addresses for calls to the IP side from the remote IP device.
show call filter match-list	Display call filter match lists.

incoming uri

To specify the voice class used to match a VoIP dial peer to the uniform resource identifier (URI) of an incoming call, use the **incoming uri** command in dial peer voice configuration mode. To remove the URI voice class from the dial peer, use the **no** form of this command.

H.323 Session Protocol

incoming uri {**called** | **calling**} *tag*

no incoming uri {**called** | **calling**}

Session Initiation Protocol (SIP) Session Protocol

incoming uri {**from** | **request** | **to** | **via**} *tag*

no incoming uri {**from** | **request** | **to** | **via**}

Syntax Description

called	Destination URI in the H.225 message of an H.323 call.
calling	Source URI in the H.225 message of an H.323 call.
tag	Alphanumeric label that uniquely identifies the voice class. This *tag* argument must be configured with the **voice class uri** command.
from	From header in an incoming SIP Invite message.
request	Request-URI in an incoming SIP Invite message.
to	To header in an incoming SIP Invite message.
via	Via header in an incoming SIP Invite message.

Command Default

No voice class is specified.

Command Modes

Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.3(4)T	This command was introduced.
15.1(2)T	This command was modified. The **via** keyword was included.

Usage Guidelines

- Before you use this command, configure the voice class by using the **voice class uri** command.
- The keywords depend on whether the dial peer is configured for SIP with the **session protocol sipv2** command. The **from**, **request**, **to**, and **via** keywords are available only for SIP dial peers. The **called** and **calling** keywords are available only for dial peers using H.323.

- This command applies rules for dial peer matching. Table 29 and Table 30 show the rules and the order in which they are applied when the **incoming uri** command is used. The gateway compares the dial-peer command to the call parameter in its search to match an inbound call to a dial peer. All dial peers are searched based on the first match criterion. Only if no match is found does the gateway move on to the next criterion.

Table 29 Dial-Peer Matching Rules for Inbound URI in SIP Calls

Match Order	Cisco IOS Command	Incoming Call Parameter
1	**incoming uri via**	Via URI
2	**incoming uri request**	Request-URI
3	**incoming uri to**	To URI
4	**incoming uri from**	From URI
5	**incoming called-number**	Called number
6	**answer-address**	Calling number
7	**destination-pattern**	Calling number
8	**carrier-id source**	Carrier-ID associated with the call

Table 30 Dial-Peer Matching Rules for Inbound URI in H.323 Calls

Match Order	Cisco IOS Command	Incoming Call Parameter
1	**incoming uri called**	Destination URI in H.225 message
2	**incoming uri calling**	Source URI in H.225 message
3	**incoming called-number**	Called number
4	**answer-address**	Calling number
5	**destination-pattern**	Calling number
6	**carrier-id source**	Source carrier-ID associated with the call

Note Calls using an E.164 number, rather than a URI, use the dial-peer matching rules that existed prior to Cisco IOS Release 15.1(2)T. For information, see the*Dial Peer Configuration on Voice Gateway Routers* document, Cisco IOS Voice Configuration Library.

- You can use this command multiple times in the same dial peer with different keywords. For example, you can use **incoming uri called** and **incoming uri calling** in the same dial peer. The gateway then selects the dial peer based on the matching rules described in Table 29 and Table 30.

Examples

The following example matches on the destination telephone URI in incoming H.323 calls by using the ab100 voice class:

```
dial-peer voice 100 voip
 incoming uri called ab100
```

The following example matches on the incoming via URI for SIP calls by using the ab100 voice class:

```
dial-peer voice 100 voip
 session protocol sipv2
 incoming uri via ab100
```

Related Commands

Command	Description
answer-address	Specifies the calling number to match for a dial peer.
debug voice uri	Displays debugging messages related to URI voice classes.
destination-pattern	Specifies the telephone number to match for a dial peer.
dial-peer voice	Enters dial peer voice configuration mode to create or modify a dial peer.
incoming called-number	Specifies the incoming called number matched to a dial peer.
session protocol	Specifies the session protocol in the dial peer for calls between the local and remote router.
show dialplan incall uri	Displays which dial peer is matched for a specific URI in an incoming voice call.
voice class uri	Creates or modifies a voice class for matching dial peers to calls containing a SIP or TEL URI.

index (voice class)

To define one or more numbers for a voice class called number, or a range of numbers for a voice class called number pool, use the **index** command in voice class configuration mode. To remove the number or range of numbers, use the **no** form of this command.

index *number called-number*

no index *number called-number*

Syntax Description

number	Digits that identify this index. Range is 1 to 2147483647.
called-number	Specifies a called number, or a range of called numbers, in E.164 format.

Command Default No index is configured.

Command Modes Voice class configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines Use this command to define one or more numbers for a voice class called number, or a range of numbers for a voice class called number pool. You can define multiple indexes for any inbound or outbound voice class called number or voice class called number pool.

When defining a range of numbers for a called number pool:

- The range of numbers must be in E.164 format.
- The beginning number and ending number must be the same length.
- The last digit of each number must be 0 to 9.
- Leading '+' (if used) must be defined from in the range of called numbers.

Examples The following example shows the configuration for indexes in voice class called number pool 100:

```
voice class called number pool 100
 index 1 4085550100 - 4085550111 (Range of called numbers are 4085550100 up to 4085550111)
 index 2 +3227045000
```

The following example shows configuration for indexes in voice class called number outbound 222:

```
voice class called number outbound 222
 index 1 4085550101
 index 2 4085550102
 index 2 4085550103
```

Related Commands

Command	Description
voice class called number	One or more called numbers configured for a voice class.

info-digits

To automatically prepend two information digits to the beginning of a dialed number associated with the given POTS dial peer, use the **info-digits** command in dial-peer configuration mode. To prepend the info-digits with "00" use the **default info-digits** form of this command. To keep the router from automatically prepending the two-digit information numbers to the beginning of the POTS dial peer, use the **no** form of this command.

info-digits *xx*

default info-digits

no info-digits

Syntax Description

xx	Specifies the two-digit prefix that the router will automatically prepend to the dialed number for the given POTS dial peer to identify the origin of the call. This value cannot contain any more or less than two digits. Valid values include: • 00—Regular line • 01—4- and 8-party • 06—Hotel or Motel • 07—Coinless • 10—Test call • 27—Coin • 95—Test call **Note** Values 12 through 19 cannot be assigned because of conflicts with international 20 Automatic Identification of Outward listed directory number sent.

Defaults

The dialed number is prepended with "00", indicating that the dialed number is a regular line.

Command Modes

Dial-peer configuration

Command History

Release	Modification
12.2(1)T	This command was introduced.
12.3(7)T	This command was modified. The default behavior was changed to prepend the dialed number the with "00".

Usage Guidelines

This command is designed to prepend a pair of information digits to the beginning of the dialed number string for the POTS dial peer that will enable you to dynamically redirect the outgoing call. The **info-digits** command is only available for POTS dial peers tied to a voice-port that corresponds to Feature Group-D (FGD) Exchange Access North American (EANA) signaling that provides specific call services such as emergency 911 calls in the United States. Configuring the info-digit command for other voice-port types is not advised and may yield undesirable results.

Examples

The following example prepends the information number string 91 to the beginning of the dialed number for POTS dial peer 10:

```
dial-peer voice 10 pots
 info-digits 91
```

information-type

To select a specific information type for a Voice over IP (VoIP) or plain old telephone service (POTS) dial peer, use the **information-type** command in dial peer configuration mode. To remove the current information type setting, use the **no** form of this command. To return to the default configuration, use the **no** form of this command.

information-type {**fax** | **voice** | **video**}

no information-type

Syntax Description

fax	The information type is set to store-and-forward fax.
voice	The information type is set to voice. This is the default.
video	The information type is set to video.

Command Default Voice

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.
12.0(4)XJ	This command was modified for store-and-forward fax.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.
12.4(11)T	The **video** keyword was added.

Usage Guidelines The **fax** keyword applies to both on-ramp and off-ramp store-and-forward fax functions.

Examples The following example shows the configuration for information type fax for VoIP dial peer 10:

```
dial-peer voice 10 voip
 information-type fax
```

The following example shows the configuration for information type video for POTS dial peer 22:

```
dial-peer voice 22 pots
 information-type video
```

Related Commands

Command	Description
isdn integrate calltype all	Enables integrated mode (for data, voice, and video) on ISDN BRI or PRI interfaces.

inject guard-tone

To play out a guard tone with the voice packet, use the **inject guard-tone** command in voice-class configuration mode. To remove the guard tone, use the **no** form of this command.

inject guard-tone *frequency amplitude* [**idle**]

no inject guard-tone *frequency amplitude* [**idle**]

Syntax Description

frequency	Frequency, in Hz, of the tone to be injected. Range is integers from 1 to 4000.
amplitude	Amplitude, in dBm, of the tone to be injected. Range is integers from –50 to –3.
idle	(Optional) Play out the inverse of the guard tone when there are no voice packets. Idle tone and guard tone are mutually exclusive.

Command Default

No guard tone is injected.

Command Modes

Voice-class configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

The **inject guard-tone** command has an effect on an ear and mouth (E&M) analog or digital voice port only if the signal type for that port is Land Mobile Radio (LMR). The guard tone is played out with the voice packet to keep the radio channel up. Guard tones of 1950 Hz and 2175 Hz can be filtered out before the voice packet is sent from the digital signal processor (DSP) to the network using the **digital-filter** command.

Examples

The following example configures a guard tone of 1950 Hz and –10 dBm to be played out with voice packets:

```
voice class tone-signal tone1
 inject guard-tone 2175 -30
```

Related Commands

Command	Description
digital-filter	Specifies the digital filter to be used before the voice packet is sent from the DSP to the network.

inject pause

To specify a pause between injected tones, use the **inject pause** command in voice-class configuration mode. To remove the pause, use the **no** form of this command.

inject pause *index milliseconds*

no inject pause *index milliseconds*

Syntax Description

index	Order of pauses and tones. Range is integers from 1 to 10.
milliseconds	Duration, in milliseconds, of the pause between injected tones. Range is integers from 10 to 500.

Command Default

milliseconds: 0 milliseconds

Command Modes

Voice-class configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

The **inject pause** command has an effect on an ear and mouth (E&M) voice port only if the signal type for that port is Land Mobile Radio (LMR). Use this command to specify the pause between injected tones specified with the **inject tone** command. Use the *index* argument of this command in conjunction with the *index* argument of the inject tone command to specify the order of the pauses and tones.

Examples

The following example configures a pause of 100 milliseconds after the injected tone:

```
voice class tone-signal 100
 inject tone 1 2000 0 200
 inject pause 2 100
```

Related Commands

Command	Description
inject tone	Specifies a wakeup or frequency selection tone to be played out before the voice packet.

inject tone

To specify a wakeup or frequency selection tone to be played out before the voice packet, use the **inject tone** command in voice-class configuration mode. To remove the tone, use the **no** form of this command.

inject tone *index frequency amplitude duration*

no inject tone *index frequency amplitude duration*

Syntax Description

index	Order of pauses and tones. Range is integers from 1 to 10.
frequency	Frequency, in Hz, of the tone to be injected. Range is integers from 1 to 4000.
amplitude	Amplitude, in dBm, of the tone to be injected. Range is integers from –30 to 3.
duration	Duration, in milliseconds, of the tone to be injected. Range is integers from 10 to 500.

Command Default No tone is injected.

Command Modes Voice-class configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines The **inject tone** command has an effect on an ear and mouth (E&M) voice port only if the signal type for that port is Land Mobile Radio (LMR). Use this command with the **inject pause** command to configure wakeup and frequency selection tones. Use the *index* argument of this command in conjunction with the *index* argument of the **inject pause** command to specify the order of the pauses and tones.

If you configure injected tones with this command, be sure to use the **timing delay-voice tdm** command to configure a delay before the voice packet is played out. The delay must be equal to the sum of the durations of the injected tones and pauses in the tone-signal voice class.

Examples The following example configures a frequency selection tone to be played out before the voice packet:

```
voice class tone-signal 100
 inject tone 1 1950 3 150
 inject tone 2 2000 0 60
 inject pause 3 60
 inject tone 4 2175 3 150
 inject tone 5 1000 0 50
```

Related Commands

Command	Description
inject pause	Specifies a pause between injected tones.
timing delay-voice tdm	Specifies the delay before a voice packet is played out.

input gain

To configure a specific input gain value or enable automatic gain control, use the **input gain** command in voice-port configuration mode. To disable the selected amount of inserted gain, use the **no** form of this command.

input gain {*decibels* | **auto-control** [*auto-dbm*]}

no input gain {*decibels* | **auto-control** [*auto-dbm*]}

Syntax Description

decibels	Gain, in decibels (dB), to be inserted at the receiver side of the interface. Range is integers from –27 to 16. The default is 0.
auto-control	Enable automatic gain control.
auto-dbm	(Optional) Target speech level, in decibels per milliwatt (dBm), to be achieved at the receiver side of the interface. Range is integers from –30 to 3. The default is –9.

Command Default

decibels: 0 decibels
auto-dbm: –9 dBm

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)T	This command was introduced.
11.3(1)MA	This command was implemented on the Cisco MC3810.
12.3(4)XD	The range of values for the *decibels* argument was increased.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(14)T	This command was implemented on the Cisco 2800 series and Cisco 3800 series.
12.4(2)T	The **auto-control** keyword and *auto-dbm* argument were added.

Usage Guidelines

A system-wide loss plan must be implemented using both the **input gain** and **output attenuation** commands. You must consider other equipment (including PBXs) in the system when creating a loss plan. The default value for this command assumes that a standard transmission loss plan is in effect, meaning that there is typically a minimum attenuation of –6 dB between phones, especially if echo cancellers are present. Connections are implemented to provide 0 dB of attenuation when the **input gain** and **output attenuation** commands are configured with the default value of 0 dB.

You cannot increase the gain of a signal to the public switched telephone network (PSTN), but you can decrease it. If the voice level is too high, you can decrease the volume by either decreasing the input gain or increasing the output attenuation.

You can increase the gain of a signal coming into the router. If the voice level is too low, you can increase the input gain by using the **input gain** command.

Typical Land Mobile Radio (LMR) signaling systems send 0 dB out and expect –10 dB in. Setting output attenuation to 10 dB is typical. Output attenuation should be adjusted to provide the voice level required by the radio to produce correct transmitter modulation.

The **auto-control** keyword and *auto-dbm* argument are available on an ear and mouth (E&M) voice port only if the signal type for that port is LMR. The **auto-control** keyword enables automatic gain control, which is performed by the digital signal processor (DSP). Automatic gain control adjusts speech to a comfortable volume when it becomes too loud or too soft. Because of radio network loss and other environmental factors, the speech level arriving at a router from an LMR system could be very low. You can use automatic gain control to ensure that the speech is played back at a more comfortable level. Because the gain is inserted digitally, the background noise can also be amplified. Automatic gain control is implemented as follows:

- Output level: –9 dB
- Gain range: –12 dB to 20 dB
- Attack time (low to high): 30 milliseconds
- Attack time (high to low): 8 seconds

Examples

The following example inserts a 3-dB gain at the receiver side of the interface in the Cisco 3600 series router:

```
port 1/0/0
 input gain 3
```

Related Commands

Command	Description
output attenuation	Configures a specific output attenuation value or enables automatic gain control for a voice port.

interface (RLM server)

To define the IP addresses of the Redundant Link Manager (RLM) server, use the **interface** command in interface configuration mode. To disable this function, use the **no** form of this command.

interface *name-tag*

no interface *name-tag*

Syntax Description

name-tag	Name to identify the server configuration so that multiple entries of server configuration can be entered.

Command Default Disabled

Command Modes Interface configuration

Command History

Release	Modification
11.3(7)	This command was introduced.

Usage Guidelines Each server can have multiple entries of IP addresses or aliases.

Examples The following example configures the access-server interfaces for RLM servers “Loopback1” and “Loopback2”:

```
interface Loopback1
 ip address 10.1.1.1 255.255.255.255
 interface Loopback2
 ip address 10.1.1.2 255.255.255.255
rlm group 1
 server r1-server
 link address 10.1.4.1 source Loopback1 weight 4
 link address 10.1.4.2 source Loopback2 weight 3
```

Related Commands

Command	Description
clear interface	Resets the hardware logic on an interface.
clear rlm group	Clears all RLM group time stamps to zero.
link (RLM)	Specifies the link preference.
protocol rlm port	Reconfigures the port number for the basic RLM connection for the whole rlm-group.
retry keepalive	Allows consecutive keepalive failures a certain amount of time before the link is declared down.

Command	Description
server (RLM)	Defines the IP addresses of the server.
show rlm group statistics	Displays the network latency of the RLM group.
show rlm group status	Displays the status of the RLM group.
show rlm group timer	Displays the current RLM group timer values.
shutdown (RLM)	Shuts down all of the links under the RLM group.
timer	Overwrites the default setting of timeout values.

interface Dchannel

To specify an ISDN D-channel interface and enter interface configuration mode, use the **interface Dchannel** command in global configuration mode.

interface Dchannel *interface-number*

Syntax Description

interface-number	Specifies the ISDN interface number.

Note The *interface-number* argument depends on which controller the **rlm-group** subkeyword in the **pri-group timeslots** controller configuration command uses. For example, if the Redundant Link Manager (RLM) group is configured using the **controller e1 2/3** command, the D-channel interface command will be **interface Dchannel 2/3**.

Command Default No D-channel interface is specified.

Command Modes Global configuration

Command History

Release	Modification
12.2(8)B	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines This command is used specifically in Voice over IP (VoIP) applications that require release of the ISDN PRI signaling time slot for RLM configurations.

Examples The following example configures a D-channel interface for a Signaling System 7 (SS7)-enabled shared T1 link:

```
controller T1 1
 pri-group timeslots 1-3 nfas_d primary nfas_int 0 nfas_group 0 rlm-group 0
 channel group 23 timeslot 24
 end

! D-channel interface is created for configuration of ISDN parameters:
interface Dchannel1
 isdn T309 4000
 end
```

Related Commands

Command	Description
pri-group timeslots	Specifies an ISDN PRI group on a channelized T1 or E1 controller, and releases the ISDN PRI signaling time slot for environments that require that SS7-enabled VoIP applications share all slots in a PRI group.

interface event-log dump ftp

To enable the gateway to write the contents of the interface event log buffer to an external file, use the **interface event-log dump ftp** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

interface event-log dump ftp *server*[**:***port]/file* **username** *username* **password** [*encryption-type*] *password*

no interface event-log dump ftp *server*[**:***port]/file* **username** *username* **password** [*encryption-type*] *password*

Syntax Description

server	Name or IP address of FTP server where the file is located.
port	(Optional) Specific port number on server.
file	Name and path of file.
username	Username required to access file.
encryption-type	(Optional) The Cisco proprietary algorithm used to encrypt the password. Values are 0 or 7. To disable encryption enter 0; to enable encryption enter 7. If you specify 7, you must enter an encrypted password (a password already encrypted by a Cisco router).
password	Password required to access file.

Command Default

Interface event log buffer is not written to an external file.

Command Modes

Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application interface event-log dump ftp** command.

Usage Guidelines

This command enables the gateway to automatically write the interface event log buffer to the named file when the buffer becomes full. The default buffer size is 4 KB. To modify the size of the buffer, use the **interface event-log max-buffer-size** command. To manually flush the event log buffer, use the **interface dump event-log** command in privileged EXEC mode.

Note

- Enabling the gateway to write event logs to FTP could adversely impact gateway memory resources in some scenarios, for example, when:
- The gateway is consuming high processor resources and FTP does not have enough processor resources to flush the logged buffers to the FTP server.
- The designated FTP server is not powerful enough to perform FTP transfers quickly
- Bandwidth on the link between the gateway and the FTP server is not large enough
- The gateway is receiving a high volume of short-duration calls or calls that are failing

You should enable FTP dumping only when necessary and not enable it in situations where it might adversely impact system performance.

Examples

The following example specifies that interface event log are written to an external file named int_elogs.log on a server named ftp-server:

```
application
    monitor
    interface event-log dump ftp ftp-server/elogs/int_elogs.log username myname password 0
    mypass
```

The following example specifies that application event logs are written to an external file named int_elogs.log on a server with the IP address of 10.10.10.101:

```
application
    monitor
    interface event-log dump ftp 10.10.10.101/elogs/int_elogs.log username myname password
    0 mypass
```

Related Commands

Command	Description
call application interface event-log dump ftp	Enable the gateway to write the contents of the interface event log buffer to an external file.
interface dump event-log	Flushes the event log buffer for application interfaces to an external file.
interface event-log	Enables event logging for external interfaces used by voice applications.
interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
interface max-server-records	Sets the maximum number of application interface records that are saved.
show call application interface	Displays event logs and statistics for application interfaces.

interface event-log error only

To restrict event logging to error events only for application interfaces, use the **interface event-log error-only** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

interface event-log error-only

no interface event-log error-only

Syntax Description

This command has no arguments or keywords.

Command Default

All events are logged.

Command Modes

Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application interface event-log error only** command.

Usage Guidelines

This command limits the severity level of the events that are logged; it does not enable logging. You must use this command with the **interface event-log** command, which enables event logging for all application interfaces.

Examples

The following example enables event logging for error events only:

```
application
    monitor
    interface event-log error-only
```

Related Commands

Command	Description
call application interface event-log error-only	Restricts event logging to error events only for application interfaces.
interface event-log	Enables event logging for external interfaces used by voice applications.
interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
interface max-server-records	Sets the maximum number of application interface records that are saved.
show call application interface	Displays event logs and statistics for application interfaces.

interface event-log max-buffer-size

To set the maximum size of the event log buffer for each application interface, use the **interface event-log max-buffer-size** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

interface event-log max-buffer-size *kbytes*

no interface event-log max-buffer-size

Syntax Description

kbytes	Maximum buffer size, in kilobytes. Range is 1 to 10. Default is 4.

Command Default

4 KB

Command Modes

Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application interface event-log max-buffer-size** command.

Usage Guidelines

If the event log buffer reaches the limit set by this command, the gateway allocates a second buffer of equal size. The contents of both buffers is displayed when you use the **show call application interface** command. When the first event log buffer becomes full, the gateway automatically appends its contents to an external FTP location if the **interface event-log dump ftp** command is used.

A maximum of two buffers are allocated for an event log. If both buffers are filled, the first buffer is deleted and another buffer is allocated for new events (buffer wraps around). If the **interface event-log dump ftp** command is configured and the second buffer becomes full before the first buffer is dumped, event messages are dropped and are not recorded in the buffer.

Examples

The following example sets the maximum buffer size to 8 KB:

```
application
    monitor
    interface event-log max-buffer-size 8
```

Related Commands

Command	Description
call application interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
interface dump event-log	Flushes the event log buffer for application interfaces to an external file.
interface event-log dump ftp	Enables the gateway to write the contents of the interface event log buffer to an external file.

Command	Description
interface max-server-records	Sets the maximum number of application interface records that are saved.
show call application interface	Displays event logs and statistics for application interfaces.

interface max-server-records

To set the maximum number of application interface records that are saved, use the **interface max-server-records** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

interface max-server-records *number*

no interface max-server-records

Syntax Description		
	number	Maximum number of records to save. Range is 1 to 100. Default is 10.

Command Default 10

Command Modes Application configuration monitor

Command History	Release	Modification
	12.3(14)T	This command was introduced to replace the **call application interface max-server-records** command.

Usage Guidelines Only the specified number of records from the most recently accessed servers are kept.

Examples The following example sets the maximum saved records to 50:

```
application
    monitor
    interface max-server-records 50
```

Related Commands	Command	Description
	call application interface max-server-records	Sets the maximum number of application interface records that are saved.
	interface event-log	Enables event logging for external interfaces used by voice applications.
	interface event-log max-buffer-size	Sets the maximum size of the event log buffer for each application interface.
	show call application interface	Displays event logs and statistics for application interfaces.

interface stats

To enable statistics collection for application interfaces, use the **interface stats** command in application configuration monitor mode. To reset to the default, use the **no** form of this command.

interface stats

no interface stats

Syntax Description This command has no arguments or keywords.

Command Default Statistics collection is disabled.

Command Modes Application configuration monitor

Command History

Release	Modification
12.3(14)T	This command was introduced to replace the **call application interface stats** command.

Usage Guidelines To display the interface statistics enabled by this command, use the **show call application interface** command. To reset the interface counters to zero, use the **clear call application interface** command.

Examples The following example enables statistics collection for application interfaces:

```
application
    monitor
    interface stats
```

Related Commands

Command	Description
call application interface stats	Enables statistics collection for application interfaces.
clear call application interface	Clears application interface statistics or event logs.
interface event-log	Enables event logging for external interfaces used by voice applications.
show call application interface	Displays event logs and statistics for application interfaces.
stats	Enables statistics collection for voice applications.

ip circuit

To create carrier IDs on an IP virtual trunk group, and create a maximum capacity for the IP group, use the **ip circuit** command. To remove a trunk group or maximum capacity, use the **no** form of the command.

ip circuit {**carrier-id** *carrier-name* [**reserved-calls** *reserved*] | **max-calls** *maximum-calls* | **default** {**only** | **name** *carrier-name*}}

no ip circuit {**carrier-id** *carrier-name* | **default** {**only** | **name** *carrier-name*}}

Syntax Description

carrier-id	Sets the IP circuit associated with a specific carrier.
carrier-name	Defines an IP circuit using the specified name as the circuit ID.
reserved-calls *reserved*	(Optional) Specifies the maximum number of calls for the circuit ID. Default value is 200.
max-calls *maximum-calls*	Sets the number of maximum aggregate H.323 IP circuit carrier call legs. Default value is 1000.
default only	Creates a single carrier using the default carrier name.
default name	Changes the default circuit name.
carrier-name	Default carrier name.

Command Default

If this command is not specified, no IP carriers and no maximum call leg values are defined.

Command Modes

H.323 configuration.

Command History

Release	Modification
12.2(13)T3	This command was introduced.

Usage Guidelines

You can use the **ip circuit** command only when no calls are active. You can define multiple carrier IDs, and the ordering does not matter. IP circuit default only is mutually exclusive with defining carriers with circuit carrier id.

If **ip circuit default only** is specified, the maximum calls value is set to 1000.

Examples

The following example specifies a default circuit and maximum number of calls:

```
voice service voip
 no allow-connections any to pots
 no allow-connections pots to any
 allow-connections h323 to h323
 h323
  ip circuit max-calls 1000
  ip circuit default only
```

The following example specifies a default carrier and incoming source carrier:

```
voice service voip
 no allow-connections any to pots
 no allow-connections pots to any
 allow-connections h323 to h323
  h323
   ip circuit carrier-id AA reserved-calls 200

   ip circuit max-calls 1000
```

Related Commands

Command	Description
show crm	Displays some of the values set by this command.
voice-source group	Assigns a name to a set of source IP group characteristics, which are used to identify and translate an incoming VoIP call.

ip dhcp-client forcerenew

To enable forcerenew-message handling on the DHCP client when authentication is enabled, use the **ip dhcp-client forcerenew** command in global configuration mode. To disable the forced authentication, use the **no** form of this command.

ip dhcp-client forcerenew

no ip dhcp-client forcerenew

Syntax Description This command has no arguments or keywords.

Command Default Forcerenew messages are dropped.

Command Modes Global configuration (config)

Command History

Release	Modification
12.4(22)YB	This command was introduced.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines DHCP forcerenew handling is not enabled until the CLI is configured.

Examples The following example shows how to enable DHCP forcerenew-message handling on the DHCP client:

```
Router(config)# ip dhcp-client forcerenew
```

Related Commands

Command	Description
ip dhcp client authentication key-chain	Specifies the key chain to be used in DHCP authentication requests.
ip dhcp client authentication mode	Specifies the type of authentication to be used in DHCP messages on the interface.
key chain	Identifies a group of authentication keys for routing protocols.

ip precedence (dial peer)

To set IP precedence (priority) for packets sent by the dial peer, use the **ip precedence** command in dial peer configuration mode. To reset to the default, use the **no** form of this command.

ip precedence *number*

no ip precedence *number*

Syntax Description

number	Integer specifying the IP precedence value. Range is 0 to 7. A value of 0 means that no precedence (priority) has been set. The default is 0.

Command Default The default value for this command is zero (0)

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)NA	This command was introduced on the following platforms: Cisco 2500 series, Cisco 3600 series, and Cisco AS5300.

Usage Guidelines Use this command to configure the value set in the IP precedence field when voice data packets are sent over the IP network. This command should be used if the IP link utilization is high and the quality of service for voice packets needs to have a higher priority than other IP packets. This command should also be used if RSVP is not enabled and the user would like to give voice packets a higher priority than other IP data traffic.

This command applies to VoIP peers.

Examples The following example sets the IP precedence to 5:

```
dial-peer voice 10 voip
 ip precedence 5
```

ip qos defending-priority

To configure the Resource Reservation Protocol (RSVP) defending priority value for determining quality of service (QoS), use the **ip qos defending-priority** command in dial peer configuration mode. To disable RSVP defending priority as a QoS factor, use the **no** form of this command.

ip qos defending-priority *defending-pri-value*

no ip qos defending-priority

Syntax Description

defending-pri-value	The RSVP defending priority value for determining QoS priorities. Valid entries are from 0 to 65535.

Command Default

The RSVP defending priority value is disabled and is not a factor in determining QoS.

Command Modes

Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

To configure the RSVP defending priority value, use the **ip qos defending-priority** command in dial peer configuration mode. The defending priority value is passed to the QoS module during reservation initiation. In a situation where there is not enough bandwidth available to support all calls, this setting enables an existing call to avoid being preempted by a new call unless the preemption priority of the new call is higher than the defending priority of the existing call.

Examples

The following example shows how to specify the RSVP defending priority value:

```
dial-peer voice 100 voip
 ip qos defending-priority 1111
```

Related Commands

Command	Description
acc-qos	Defines the acceptable QoS for inbound and outbound calls on a VoIP dial peer.
ip qos dscp	Configures the DSCP value for QoS.
ip qos policy-locator	Configures the application ID of RSVP.
ip qos preemption-priority	Configures the RSVP preemption priority.
ip rsvp policy preempt	Enables RSVP to take bandwidth from lower-priority reservations and give it to new, higher-priority reservations.
req-qos	Requests a particular QoS using RSVP to be used in reaching a specified dial peer in VoIP.
show-sip-ua calls	Displays the active UAC and UAS information for SIP calls on a Cisco IOS device.
voice-class sip rsvp-fail-policy	Configures RSVP failure policies.

ip qos dscp

To configure the differentiated services code point (DSCP) value for quality of service (QoS), use the **ip qos dscp** command in dial peer configuration mode. To disable DSCP as a QoS factor, set the DSCP value to **default** (which sets the value to the 000000 bit pattern). To set DSCP values to their default settings, use the **no** form of this command.

ip qos dscp {*dscp-value* | *set-af* | *set-cs* | **default** | **ef**} {**signaling** | **media** [**rsvp-pass** | **rsvp-fail**] | **video** [**rsvp-none** | **rsvp-pass** | **rsvp-fail**]}

no ip qos dscp {*dscp-value* | *set-af* | *set-cs* | **default** | **ef**} {**signaling** | **media** [**rsvp-pass** | **rsvp-fail**] | **video** [**rsvp-none** | **rsvp-pass** | **rsvp-fail**]}

Syntax Description

dscp-value	DSCP value. Valid entries are from 0 to 63.
set-af	An assured forwarding bit pattern as the DSCP value: • **af11**—bit pattern 001010 • **af12**—bit pattern 001100 • **af13**—bit pattern 001110 • **af21**—bit pattern 010010 • **af22**—bit pattern 010100 • **af23**—bit pattern 010110 • **af31**—bit pattern 011010 • **af32**—bit pattern 011100 • **af33**—bit pattern 011110 • **af41**—bit pattern 100010 • **af42**—bit pattern 100100 • **af43**—bit pattern 100110
set-cs	Class-selector code point as the DSCP value: • **cs1**—code point 1 (precedence 1) • **cs2**—code point 2 (precedence 2) • **cs3**—code point 3 (precedence 3) • **cs4**—code point 4 (precedence 4) • **cs5**—code point 5 (precedence 5) • **cs6**—code point 6 (precedence 6) • **cs7**—code point 7 (precedence 7)
default	Specifies the default bit pattern 000000 as the DSCP value.
ef	Specifies the expedited forwarding bit pattern 101110 as the DSCP value.
signaling	Specifies that the DSCP value applies to signaling packets.
media	Specifies that the DSCP value applies to media packets (voice and fax).
rsvp-pass	(Optional) Specifies that the DSCP value applies to packets with successful Resource Reservation Protocol (RSVP) reservations.
rsvp-fail	(Optional) Specifies that the DSCP value applies to packets (media or video) with failed RSVP reservations.
video	Specifies that the DSCP value applies to video packets. This option is valid only for Cisco Unified Communications Manager Express (Cisco Unified CME) on a Cisco Unified Border Element.
rsvp-none	(Optional) Specifies that the DSCP value applies to video packets with no RSVP reservations (valid only for video packets.)

Command Default

The DSCP default values are as follows**:**

- The default DSCP value for all signaling packets is **af31**.
- The default DSCP value for all media (voice and fax) packets is **ef**.
- The default DSCP value for all video packets is **af41**.

Command Modes Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.2(2)T	This command was introduced. It replaced the **ip precedence** (dial peer) command
12.3(4)T	Keywords were added to support DSCP configuration for video streams.
12.4(22)T	Keywords were added to apply a DSCP value to media (voice and fax) packets with a specified (successful or failed) RSVP connection.

Usage Guidelines To configure voice, signaling, and video traffic priorities, use the **ip qos dscp** command in dial peer configuration mode. The recommended value for media (voice and fax) packets is **ef;** for signaling packets, the recommended value is **af31**; and for video packets, it is **af41** (all defaults).

Additionally, before you can specify RSVP QoS, you must first use the **ip rsvp bandwidth** command to enable RSVP on the IP interface.

Examples The following example shows how to set the DSCP value to a class-selector code point value of 1 and apply that DSCP setting to media (voice and fax) payload packets with no RSVP configured:

```
dial-peer voice 1 voip
 ip qos dscp cs1 media
```

The following example shows how to set the DSCP value to the expedited forwarding bit pattern and apply that DSCP setting to media (voice and fax) payload packets with a successful RSVP connection:

```
dial-peer voice 1 voip
ip qos dscp ef media rsvp-pass
```

The following example shows how to set the DSCP value to an assured forwarding code point value of 22 and apply that DSCP setting to all signaling packets:

```
dial-peer voice 1 voip
ip qos dscp af22 signaling
```

The following example shows how to set the DSCP value to an assured forwarding code point value of 43 and apply that DSCP setting to video packets with a successful RSVP connection:

```
dial-peer voice 100 voip
 ip qos dscp af43 video rsvp-pass
```

Related Commands

Command	Description
call rsvp-sync	Enables synchronization between RSVP signaling and the voice signaling protocol.
ip qos defending-priority	Configures the RSVP defending priority value.
ip qos policy-locator	Configures the application ID of RSVP.
ip qos preemption-priority	Configures the RSVP preemption priority value.

Command	Description
ip rsvp bandwidth	Enables RSVP for IP on an interface.
ip rsvp signalling dscp	Configures the DSCP settings to be used on RSVP messages on an interface.

ip qos policy-locator

To configure a quality of service (QoS) policy-locator (application ID) used to deploy Resource Reservation Protocol (RSVP) policies for specifying bandwidth reservations on Cisco IOS Session Initiation Protocol (SIP) devices, use the **ip qos policy-locator** command in dial peer configuration mode. To delete an application policy, use the **no** form of this command.

ip qos policy-locator {**video** | **voice**} [**app** *app-string*] [**guid** *guid-string*] [**sapp** *subapp-string*] [**ver** *version-string*]

no ip qos policy-locator {**video** | **voice**} [**app** *app-string*] [**guid** *guid-string*] [**sapp** *subapp-string*] [**ver** *version-string*]

Syntax Description

video	Specifies that the application ID applies to RSVP for video streams.
voice	Specifies that the application ID applies to RSVP for voice streams.
app	(Optional) Specifies an application.
app-string	Application ID. Consists of 1 to 31 alphanumeric characters.
guid	(Optional) Specifies a globally unique identifier (GUID).
guid-string	GUID. Consists of 1 to 31 alphanumeric characters.
sapp	(Optional) Specifies a subapplication.
sapp-string	Subapplication ID. Consists of 1 to 31 alphanumeric characters.
ver	(Optional) Specifies a version.
ver-string	Version ID. Consists of 1 to 15 alphanumeric characters.

Command Default

No policy is specified.

Command Modes

Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

In Cisco IOS software, the RSVP can process and accept requests by referring to multiple bandwidth pools. To enhance the granularity of local policy match criteria on Cisco IOS SIP devices, bandwidth pools can include policies based on application IDs. You can use these application-specific IDs to reserve bandwidth for each until specified bandwidth limits are reached.

To prevent one application type from consuming all bandwidth, RFC 2872, *Application and Sub Application Identity Policy Element for Use with RSVP*, allows for the creation of separate bandwidth reservation pools. For example, an RSVP reservation pool can be created for voice traffic and another for video traffic so that reservations tagged with these application IDs can then be matched to the interface bandwidth pools using RSVP local policies. To limit bandwidth per application, though, you must configure a bandwidth limit for each application and configure each with a reservation flag that associates the application with the appropriate bandwidth limit.

Before you can configure bandwidth limits for any application-specific policy, however, you must create application IDs. To create application IDs (application-specific reservation profiles), use the **ip qos policy-locator** command in dial peer configuration mode. After creating the necessary application IDs, you can then use the appropriate commands listed in the "Related Commands" section to configure bandwidth reservation. However, this feature is available only on supported devices that are running Cisco IOS Release 12.4(22)T or a later release.

For more information about configuring SIP RSVP features, see the "Configuring SIP RSVP Features" chapter in the *Cisco IOS SIP Configuration Guide*. For more general information about the application-specific policy feature, see the "Configuring RSVP" chapter in the RSVP section of the "Signaling" part in the *Cisco IOS Quality of Service Solutions Configuration Guide*.

Examples

The following example shows how to configure a policy for the application ID:

```
dial-peer voice 100 voip
 ip qos policy-locator voice app MyApp1 sapp MySubApp4
```

Related Commands

Command	Description
acc-qos	Defines the acceptable QoS for inbound and outbound calls on a VoIP dial peer.
handle-replaces	Configures fallback to legacy handling of SIP INVITE.
ip qos defending-priority	Configures the RSVP defending priority value.
ip qos dscp	Sets the DSCP value for QoS.
ip qos preemption-priority	Configures the RSVP preemption priority value.
ip rsvp bandwidth	Enables RSVP for IP on an interface.
ip rsvp policy default-reject	Configures blocking or passing of all messages that do not match any existing RSVP policies.
ip rsvp policy identity	Defines RSVP application IDs used to deploy RSVP policies.
ip rsvp policy preempt	Enables RSVP to take bandwidth from lower-priority reservations and give it to new, higher-priority reservations.
maximum (local policy)	Configures a local policy that limits RSVP resources.
preempt-priority	Configures RSVP QoS priorities to be inserted into PATH and RESV messages when they are not signaled from an upstream or downstream neighbor or local client application.
req-qos	Requests a particular QoS using RSVP to be used in reaching a specified dial peer in VoIP.
show sip-ua calls	Displays the active UAC and UAS information on SIP calls.
voice-class sip rsvp-fail-policy	Specifies the action that takes place when RSVP negotiation fails.

ip qos preemption-priority

To configure the Resource Reservation Protocol (RSVP) preemption priority value for determining quality of service (QoS), use the **ip qos preemption-priority** command in dial peer configuration mode. To disable RSVP preemption priority as a QoS factor, use the **no** form of this command.

ip qos preemption-priority *preemption-pri-value*

no ip qos preemption-priority

Syntax Description

preemption-pri-value	The RSVP preemption priority value for determining QoS priorities. Valid entries are from 0 to 65535.

Command Default

The RSVP preemption priority value is disabled and is not a factor in determining QoS.

Command Modes

Dial peer configuration (config-dial-peer)

Command History

Release	Modification
12.4(22)T	This command was introduced.

Usage Guidelines

To configure an RSVP preemption priority value, use the **ip qos preemption-priority** command in dial peer configuration mode. The preemption priority value is passed to the QoS module during reservation initiation. In a situation where there is not enough bandwidth available to support all calls, this setting enables a new call to preempt an existing call unless the defending priority of the existing call is higher than the preemption priority of the new call.

Examples

The following example shows how to specify the RSVP preemption priority value:

```
dial-peer voice 100 voip
 ip qos preemption-priority 1111
```

Related Commands

Command	Description
acc-qos	Defines the acceptable QoS for inbound and outbound calls on a VoIP dial peer.
ip qos dscp	Configures the DSCP value for QoS.
ip qos policy-locator	Configures the application ID of RSVP.
ip qos defending-priority	Configures the defending priority value of RSVP.
ip rsvp policy preempt	Enables RSVP to take bandwidth from lower-priority reservations and give it to new, higher-priority reservations.
req-qos	Requests a particular QoS using RSVP to be used in reaching a specified dial peer in VoIP.
show-sip-ua calls	Displays the active UAC and UAS information for SIP calls on a Cisco IOS device.
voice-class sip rsvp-fail-policy	Configures RSVP failure policies.

ip rtcp report interval

To configure the average reporting interval between subsequent Real-Time Control Protocol (RTCP) report transmissions, use the **ip rtcp report interval** command in global configuration mode. To reset to the default, use the **no** form of this command.

ip rtcp report interval *value*

no ip rtcp report interval

Syntax Description

value	Average interval for RTCP report transmissions, in ms. Range is 1 to 65535. Default is 5000.

Command Default

5000 ms

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800.

Usage Guidelines

This command configures the average interval between successive RTCP report transmissions for a given voice session. For example, if the *value* argument is set to 25,000 milliseconds, an RTCP report is sent every 25 seconds, on average.

For more information about RTCP, see RFC 1889, *RTP: A Transport Protocol for Real-Time Applications.*

Examples

The following example sets the reporting interval to 5000 ms:

```
Router(config)# ip rtcp report interval 5000
```

Related Commands

Command	Description
debug ccsip events	Displays all SIP SPI event tracing and traces the events posted to SIP SPI from all interfaces.
timer receive-rtcp	Enables the RTCP timer and configures a multiplication factor for the RTCP timer interval.

ip rtcp sub-rtcp

To specify sub-Real-Time Control Protocol (RTCP) message types, use the **ip rtcp sub-rtcp** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ip rtcp sub-rtcp *message-type number*

no ip rtcp sub-rtcp *message-type*

Syntax Description

message-type	Message type. For more information, use the question mark (?) online help function.
number	Message number. The range is from 209 to 255. The default is 209. For more information about the numbering syntax for your networking device, use the question mark (?) online help function.

Command Default

RTP payload type is set to the default value 209.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows how to specify sub-RTCP message typess:

```
Router# configure terminal
Router(config)# ip rtcp sub-rtcp message-type 210
```

Related Commands

Command	Description
ip rtcp report interval	Configures the average reporting interval between subsequent RTCP report transmissions.

ip udp checksum

To calculate the UDP checksum for voice packets sent by the dial peer, use the **ip udp checksum** command in dial peer configuration mode. To disable this feature, use the **no** form of this command.

ip udp checksum

no ip udp checksum

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced on the Cisco 3600 series.

Usage Guidelines Use this command to enable UDP checksum calculation for each of the outbound voice packets. This command is disabled by default to speed up the transmission of the voice packets. If you suspect that the connection has a high error rate, you should enable this command to prevent corrupted voice packets forwarded to the digital signal processor (DSP).

This command applies to VoIP peers.

Note To maintain performance and scalability of the Cisco 5850 when using images before 12.3(4)T, enable no more than 10% of active calls with UDP checksum.

Examples The following example calculates the UDP checksum for voice packets sent by dial peer 10:

```
dial-peer voice 10 voip
 ip udp checksum
```

Related Commands

Command	Description
loop-detect	Enables loop detection for T1 for Voice over ATM, Voice over Frame Relay, and Voice over HDLC.

irq global-request

To configure the gatekeeper to send information-request (IRQ) messages with the call-reference value (CRV) set to zero, use the **irq global-request** command in gatekeeper configuration mode. To disable the gatekeeper from sending IRQ messages, use the **no** form of this command.

irq global-request

no irq global-request

Syntax Description This command has no arguments or keywords.

Command Default The gatekeeper sends IRQ messages with the CRV set to zero.

Command Modes Gatekeeper configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco 3600 series.

Usage Guidelines Use this command to disable the gatekeeper from sending an IRQ message with the CRV set to zero when the gatekeeper requests the status of all calls after its initialization. Disabling IRQ messages can eliminate unnecessary information request response (IRR) messages if the reconstruction of call structures can be postponed until the next IRR or if the call information is no longer required because calls are terminated before the periodic IRR message is sent. Disabling IRQ messages is advantageous if direct bandwidth control is not used in the gatekeeper.

Examples The following example shows that IRQ messages are not sent from the gatekeeper:

```
.
.
.
 lrq reject-resource-low
 no irq global-request
 timer lrq seq delay 10
 timer lrq window 6
 timer irr period 6
 no shutdown
.
.
.
```

Related Commands

Command	Description
timer irr period	Configures the IRR timer.

isdn bind-l3

To configure an ISDN D-channel serial interface for signaling backhaul and associate it with a session set, use the **isdn bind-l3** command in interface configuration mode. To disable signaling backhaul on an ISDN D-channel serial interface, use the **no** form of this command.

isdn bind-l3 *set-name*

no isdn bind-l3

Syntax Description

set-name	Session set with which you are associating a D-channel interface.

Command Default

The ISDN D channel is not configured for signaling backhaul and is not associated with a session set

Command Modes

Interface configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.2(4)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was implemented on the Cisco IAD2420 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Examples

The following example configures T1 signaling channel serial 0:23 for signaling backhaul and associate the D channel with the session set named “Set1”:

```
Router(config)# interface s0:23
Router(config-if)# isdn bind-L3 set1
Router(config-if)# exit
```

The following example configures E1 signaling channel serial 0:15 for signaling backhaul and associates the D channel with the session set named “Set3”:

```
Router(config)# interface s0:15
Router(config-if)# isdn bind-L3 set3
Router(config-if)# exit
```

isdn bind-l3 (Interface BRI)

To cause a Basic Rate Interface (BRI) port to bind ISDN Layer 3 protocol to either a regular gateway (GW) q931 stack or a Cisco CallManager Transmission Control Protocol (TCP) backhaul application and, if the latter, to operate in Media Gateway Control Protocol (MGCP) mode for backhaul, use the **isdn bind-l3** command in interface-BRI configuration mode. To disable binding and reset the BRI to Session Application mode for backhaul, use the **no** form of this command.

isdn bind-l3 {**q931** | **ccm-manager service mgcp**}

no isdn bind-l3 {**q931** | **ccm-manager service mgcp**}

Syntax Description

q931	Regular GW q931 stack. This is the default.
ccm-manager service mgcp	Cisco CallManager TCP backhaul application. You must also select MGCP service mode for backhaul.

Command Default

If the command is not used, the BRI port uses Session Application mode and binding is disabled. If the command is used with no keywords, q931 is assumed.

Command Modes

Interface-BRI configuration

Command History

Release	Modification
12.2(15)ZJ	This command was integrated into Cisco IOS Release 12.2(15)ZJ on the Cisco 26xxXM, Cisco 2691, Cisco 3640, Cisco 3640A, Cisco 3660, and Cisco 37xx.
12.3(2)T	This command was integrated into Cisco IOS Release 12.3(2)T.

Usage Guidelines

This command reinitializes the BRI interface, including the two B-channel voice ports within the BRI, to support MGCP-backhaul call control. It also binds ISDN Q931 Layer 3 to the Cisco CallManager.

This command is visible when the BRI voice interface card (VIC) is present. The BRI VIC provides narrowband digital-voice connectivity in the voice network module on the Cisco 2600 series and Cisco 3600 series.

Before you use this command to enable binding, disable any active calls on the BRI interface by using the **shutdown** (voice-port) command. You need not shut down the interface if no active calls are present or to configure L3 binding.

The combined **ccm-manager service mgcp** keywords are available only for supported BRI interfaces.

Examples

The following example sets binding for BRI interface slot 1, port 0:

```
Router (config-if)# isdn bind-l3 q931
```

Related Commands

Command	Description
ccm-manager config	Supplies the local MGCP voice gateway with the IP address or logical name of the TFTP server from which to download XML configuration files and enable the download of the configuration.
debug ccm-manager	Displays debugging information about the Cisco CallManager.
show ccm-manager	Displays a list of Cisco CallManager servers, their current status, and their availability.
show ccm-manager fallback-mgcp	Displays the status of the MGCP gateway fallback feature.
show mgcp	Displays values for MGCP parameters.
shutdown (voice-port)	Takes voice ports for a specific VIC offline.

isdn bind-l3 ccm-manager

To bind Layer 3 of the ISDN PRI interface of the Media Gateway Control Protocol (MGCP) voice gateway to the Cisco CallManager for PRI Q.931 signaling backhaul support, use the **isdn bind-l3 ccm-manager** command in interface configuration mode. To disable this binding, use the **no** form of this command.

isdn bind-l3 ccm-manager

no isdn bind-l3 ccm-manager

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Interface configuration

Command History

Release	Modification
12.2(2)XN	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco Voice Gateway 200 (Cisco VG200).
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2, and implemented on the Cisco IAD2420.

Usage Guidelines This command enables ISDN PRI backhaul on an MGCP-enabled voice gateway.

Examples The following example binds PRI Layer 3 to the Cisco CallManager:

```
isdn bind-l3 ccm-manager
```

isdn bind-l3 iua-backhaul

To specify ISDN backhaul using Stream Control Transmission Protocol (SCTP) for an interface and to bind Layer 3 to DUA for DPNSS backhaul, use the **isdn bind-l3 iua-backhaul** command in interface configuration mode. To disable the backhaul capability, use the **no** form of this command.

isdn bind-l3 iua-backhaul [*application-server-name*]

no isdn bind-l3 iua-backhaul

Syntax Description

application-server-name	(Optional) Name of the application server (AS) to use for backhauling the interface.

Command Default No default behavior or values

Command Modes Interface configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.2(4)T	This command was introduced.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco IAD2420 series. The Cisco AS5850 is not included in this release.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.
12.2(15)ZJ	The capability to bind Layer 3 to DUA for DPNSS backhaul was added.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Usage Guidelines DPNSS is not configured for backhaul and is not associated with a session set.

Examples The following example configures DUA for DPNSS backhaul using an AS called “as1:”

```
Router(config-if)# isdn bind-l3 iua-backhaul as1
```

The following example configures T1 signaling channel serial 0:23 for signaling backhaul and associates the D channel with the session set named “set1”:

```
Router(config)# interface s0:23
Router(config-if)# isdn bind-l3 set1
```

The following example configures E1 signaling channel serial 0:15 for signaling backhaul and associates the D channel with the session set named “set3”:

```
Router(config)# interface s0:15
Router(config-if)# isdn bind-l3 set3
```

The following example shows IUA backhaul on the application server “as1”:

```
interface Serial1/0:23
 no ip address
 ip mroute-cache
 no logging event link-status
 isdn switch-type primary-5ess
 isdn incoming-voice voice
 isdn bind-L3 iua-backhaul as1
```

Related Commands

Command	Description
as	Defines an AS for backhaul.
asp	Defines an ASP for backhaul.

isdn contiguous-bchan

To configure contiguous bearer channel handling on an E1 PRI interface, use the **isdn contiguous-bchan** command in interface configuration mode. To disable the contiguous B-channel handling, use the **no** form of this command.

isdn contiguous-bchan

no isdn contiguous-bchan

Syntax Description This command has no arguments or keywords.

Command Default Contiguous B channel handling is disabled

Command Modes Interface configuration (config-if)

Command History

Release	Modification
12.0(7)XK	This command was introduced on the following platforms: Cisco 2500 series, Cisco 3600 series, Cisco 7200 series, and Cisco MC3810.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines Use this command to specify contiguous bearer channel handling so that B channels 1 to 30, skipping 16, map to time slots 1 to 31. This is available for E1 PRI interfaces only, when the **primary-qsig** or **primary-dms100** switch type option is configured by using the **isdn switch-type** command.

Examples The following example shows the configuration on the E1 interface of a Cisco 3660 router E1 interface:

```
interface Serial5/0:15
 no ip address
 ip mroute-cache
 no logging event link-status
 isdn switch-type primary-qsig
 isdn overlap-receiving
 isdn incoming-voice voice
 isdn continuous-bchan
```

Related Commands

Command	Description
isdn switch-type	Configures the **primary-qsig** or **primary-dms100** switch type for PRI support.

isdn dpnss

To indicate whether ISDN DPNSS is to act as PBX A or PBX B, or revert to Layer 2, use the **isdn dpnss** command in interface configuration mode. To reset to the default, use the **no** form of this command.

isdn dpnss [**pbxA | layer 2** [**retry max-count** *range*] [**timers** [**Tretry** *timer-value*] [**Ttest** *timer-value*]] [**test frame**]]

no isdn dpnss [**pbxA | layer 2** [**retry max-count** *range*] [**timers** [**Tretry** *timer-value*] [**Ttest** *timer-value*]] [**test frame**]]

Syntax Description

pbxA	(Optional) Enables DPNSS to act as PBX A.
layer 2	(Optional) Reverts to Layer 2.
retry max-count *range*	(Optional) Selects the number of times a frame will be retried if unacknowledged. The max-count value can be any number from 0 to 64. Default is 4
timers	(Optional) Selects DPNSS timers, which can be **Tretry** or **Ttest**.
Tretry *timer-value*	(Optional) Sets the Tretry timer in ms and seconds. Valid retry time values range from 5 ms to 10 seconds. Default is 500 ms.
Ttest *timer-value*	(Optional) Sets the Ttest timer in minutes. When the Ttest timer expires, frames are sent on all the DLCs. Valid test time values range from 1 to 60. Default is 5.
test frame	(Optional) Allows test frames to be sent periodically.

Command Default

PBX B

Command Modes

Interface configuration

Command History

Release	Modification
12.2(15)ZJ	This command was introduced.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.

Examples

The following example sets ISDN DPNSS to act as PBX A:

```
Router(config-if)# isdn dpnss pbxA
```

The following example sets the Tretry and Ttest timers:

```
Router(config-if)# isdn dpnss layer2 timers Tretry 500 Ttest 5
```

The following example selects the number of times a frame will be retried if unacknowledged:

```
Router(config-if)# isdn dpnss layer2 retry max-count 4
```

The following example allows test frames to be sent periodically:

```
Router(config-if)# isdn dpnss layer2 test frame
```

Related Commands

Command	Description
isdn bind-l3 iua-backhaul	Binds Layer 3 for DPNSS to DUA.
isdn switch-type (PRI)	Specifies the central office switch type on the ISDN interface.

isdn gateway-max-interworking

To prevent an H.323 gateway from checking for ISDN protocol compatibility and dropping information elements (IEs) in call messages, use the **isdn gateway-max-interworking** command global configuration mode. To reset to the default, use the **no** form of this command.

isdn gateway-max-interworking

no isdn gateway-max-interworking

Syntax Description

This command has no arguments or keywords.

Command Default

The gateway checks for protocol compatibility.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(2)XA	This command was implemented on the Cisco AS5400 and Cisco AS5350.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

If this command is enabled on an originating H.323 gateway, the information elements (IEs) in call messages to the terminating gateway are not checked for end-to-end protocol compatibility. If this command is enabled on a terminating gateway, IEs are not checked in the reverse direction. If this command is not enabled, and the ISDN protocols are not compatible on the originating and terminating gateways, the gateway drops all IEs, including the progress indicator. The gateway then inserts a progress indicator of 1 into all Progress messages.

Examples

The following example enables maximum interworking:

```
isdn gateway-max-interworking
```

isdn global-disconnect

To allow passage of RELEASE and RELEASE COMPLETE messages over a voice network, use the **isdn global-disconnect** command in interface configuration mode. To disallow passage of RELEASE and RELEASE COMPLETE messages, use the **no** form of this command.

isdn global-disconnect

no isdn global-disconnect

Syntax Description

This command has no arguments or keywords.

Command Default

RELEASE and RELEASE COMPLETE messages terminate locally; they are not passed over the voice network.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.1(2)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco MC3810.
12.4(15)XY	Support was added for SIP voice networks.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

The **isdn global-disconnect** command works with ISDN interfaces configured for Q-signaling (QSIG) tunneling using the bri-qsig or pri-qsig ISDN switch type (in either master or slave mode). This command must be enabled on both IP to time-division multiplexing (IP-TDM) gateways in a toll-bypass scenario where RELEASE and RELEASE COMPLETE messages need to be transparently passed end-to-end and in both directions.

Enabling the **isdn global-disconnect** command allows passage of the RELEASE and RELEASE COMPLETE messages (including information element (IE) content) end-to-end across a voice network between PBXs. Use the **no** form of this command to prevent RELEASE and RELEASE COMPLETE messages from being passed across the network.

Examples

The following example shows the configuration on the T1 PRI interface of a Cisco 3660 router:

```
interface Serial5/0:23
 no ip address
 ip mroute-cache
 no logging event link-status
 isdn switch-type primary-qsig
 isdn global-disconnect
 isdn overlap-receiving
 isdn incoming-voice voice
```

Related Commands

Command	Description
isdn protocol-emulate	Configures the interface to serve as either the QSIG slave or the QSIG master (must be the opposite setting as that set on the PBX.)
isdn switch-type (BRI)	Specifies the central office switch type on an ISDN BRI.
isdn switch-type (PRI)	Specifies the central office switch type or enables support of QSIG or Q.931 signaling on an ISDN PRI.
signaling forward	Specifies tunneling for QSIG, Q.931, H.225, and ISUP messages globally for a SIP or H.323 gateway.
signaling forward (dial-peer)	Specifies tunneling for QSIG, Q.931, H.225, and ISUP messages for a specific dial peer on a SIP or H.323 gateway.

isdn gtd

To enable generic transparency descriptor (GTD) mapping for information elements (IEs) sent in ISDN Setup messages, use the **isdn gtd** command in interface configuration mode. To disable GTD mapping, use the **no** form of this command.

isdn gtd

no isdn gtd

Syntax Description This command has no arguments or keywords.

Command Default GTD mapping is enabled.

Command Modes Interface configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines Use the **isdn gtd** command to enable parameter mapping for the following ISDN IEs to corresponding GTD parameters:

- Originating Line Information—OLI
- Bearer Capability—USI and TMR
- Called Party Number—CPN
- Calling Party Number—CGN
- Redirecting Number—RGN, OCN and RNI

The following GTD parameters, which have no corresponding ISDN IEs, are also supported:

- Calling Party Category—CPC
- Forward Call Indicators—FCI
- Protocol Name—PRN

Examples The following example enables GTD parameter mapping:

```
isdn gtd
```

isdn ie oli

To configure the value of the Originating Line Information (OLI) information element (IE) identifier when the gateway receives ISDN signaling from an MCI switch, use the **isdn ie oli** command in interface configuration mode. To disable the OLI IE identifier, use the **no** form of this command.

isdn ie oli *value*

no isdn ie oli *value*

Syntax Description

value	Hexadecimal number specifying the value that indicates OLI information from the MCI switch. Range is 00-7F.

Command Default

This command is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

Use the **isdn ie oli** command to configure gateway support for the MCI ISDN variant by specifying the IE value that indicates OLI information.

Examples

The following example configures the OLI IE value to a hex value of 7A:

```
isdn ie oli 7A
```

Related Commands

Command	Description
isdn gtd	Enables GTD parameter mapping for ISDN IEs.

isdn integrate calltype all

To enable integrated mode on an ISDN PRI interface, use the **isdn integrate calltype all** command in interface configuration mode. To disable integrated mode, use the **no** form of this command.

isdn integrate calltype all

no isdn integrate calltype all

Syntax Description This command has no arguments or keywords.

Command Default Integrated mode is disabled on the interface.

Command Modes Interface configuration

Command History

Release	Modification
12.4(4)XC	This command was introduced.
12.4(9)T	This command was integrated into Cisco IOS Release 12.4(9)T.

Usage Guidelines Configure this command from a PRI interface only. This command is not supported from a BRI interface.

Any incoming calls from an interface that has been configured for integrate calltype all is rejected with cause-code **invalid number 0x1C** if inbound dial-peer is not selected.

Examples In the following example, the interface is shut down.

```
Router(config)# interface Serial4/1:15
Router(config-if)# shutdown
```

In the following example, integrated mode is enabled.

```
Router(config)# interface Serial4/1:15
Router(config-if)# isdn integrate calltype all
% This command line will enable the Serial Interface to "integrated service" mode.
% The "isdn incoming-voice voice" setting will be removed from the interface.
% Continue? [confirm]
```

When you confirm, the default incoming-voice configuration is removed from the interface, and the interface is now in integrated service mode. The interface does not reset back to voice mode if an incoming call is originated from the interface.

In the following example, the interface is set to active.

```
Router(config)# interface Serial4/1:15
Router(config-if)# no shutdown
```

Related Commands

Command	Description
dial-peer data	Creates a data dial peer and enters dial peer configuration mode.
dial-peer search	Optimizes voice or data dial-peer searches.
isdn incoming-voice	Routes all incoming voice calls to the modem and determine how they will be treated.

isdn network-failure-cause

To specify the cause code to pass to the PBX when a call cannot be placed or completed because of internal network failures, use the **isdn network-failure-cause** command in interface configuration mode. To disable use of this cause code, use the **no** form of this command.

isdn network-failure-cause *value*

no isdn network-failure-cause *value*

Syntax Description

value	Number, from 1 to 127. See Table 31 for a list of failure cause code values.

Command Default

No default behavior or values

Command Modes

Interface configuration

Command History

Release	Modification
12.1(2)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco MC3810.

Usage Guidelines

The PBX can reroute calls based on the cause code returned by the router.

This command allows the original cause code to be changed to the value specified if the original cause code is not one of the following:

- NORMAL_CLEARING (16)
- USER_BUSY (17)
- NO_USER_RESPONDING (18)
- NO_USER_ANSWER (19)
- NUMBER_CHANGED (22)
- INVALID_NUMBER_FORMAT (28)
- UNSPECIFIED_CAUSE (31)
- UNASSIGNED_NUMBER (1)

Table 31 describes the cause codes.

Table 31 ISDN Failure Cause Codes

Failure Cause Code	Meaning
1	Unallocated or unassigned number.
2	No route to specified transit network.
3	No route to destination.

Table 31 ISDN Failure Cause Codes (continued)

Failure Cause Code	Meaning
6	Channel unacceptable.
7	Call awarded and being delivered in an established channel.
16	Normal call clearing.
17	User busy.
18	No user responding.
19	No answer from user (user alerted).
21	Call rejected.
22	Number changed.
26	Nonselected user clearing.
27	Destination out of order.
28	Invalid number format.
29	Facility rejected.
30	Response to status enquiry.
31	Normal, unspecified.
34	No circuit/channel available.
38	Network out of order.
41	Temporary failure.
42	Switch congestion.
43	Access information discarded.
44	Requested channel not available.
45	Preempted.
47	Resources unavailable, unspecified.
49	Quality of service unavailable.
50	Requested facility not subscribed.
52	Outgoing calls barred.
54	Incoming calls barred.
57	Bearer capability not authorized.
58	Bearer capability not available now.
63	Service or option not available, unspecified.
65	Bearer capability not implemented.
66	Channel type not implemented.
69	Requested facility not implemented.
70	Only restricted digital information bearer capability is available.
79	Service or option not implemented, unspecified.
81	Invalid call reference value.
82	Identified channel does not exist.

Table 31 ISDN Failure Cause Codes (continued)

Failure Cause Code	Meaning
83	Suspended call exists, but this call ID does not.
84	Call ID in use.
85	No call suspended.
86	Call with requested call ID is cleared.
88	Incompatible destination.
91	Invalid transit network selection.
95	Invalid message, unspecified.
96	Mandatory information element missing.
97	Message type nonexistent or not implemented.
98	Message not compatible with call state or message type nonexistent or not implemented.
99	Information element nonexistent or not implemented.
100	Invalid information element contents.
101	Message not compatible with call state.
102	Recovery on timer expiry.
111	Protocol error, unspecified.
127	Interworking, unspecified.

Examples

The following example specifies a cause code to pass to a PBX when a call cannot be placed or completed of internal network failures:

```
isdn network-failure-cause 28
```

isdn outgoing display-ie

To enable the display information element to be sent in the outgoing ISDN message if provided by the upper layers, such as voice or modem. To disable the displaying of the information element in the outgoing ISDN message, use the no form of this command.

isdn outgoing display-ie

no isdn outgoing display-ie

Syntax Description There are no arguments or keywords.

Command Default No default behavior or values

Command Modes Interface configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Usage Guidelines The **isdn outoing display-ie** command is direction dependent, such as network-to-user or user-to-network. Not all ISDN switch types support the **isdn outgoing display-ie** command. The following shows the direction dependency by switch type, and this command can be used to override the dependency:

- ETSI (NTT, NET3,and NET5)—Only network-to-user
- DMS—Both ways
- TS014—Only network-to-user
- TS013—Only network-to-user
- 1TR6—Only network-to-user

Note The 4ESS, 5ESS, NI1, and NI2 switch types are not supported in any direction.

Note When the **isdn protocol-emulate** command is switched between network and user, this command reverts to its default value. The **isdn outoing display-ie** command must be enabled again.

Examples

The following is a running configuration, showing how the the **isdn outgoing display-ie** command is used on a specified serial interface:

```
Router# show running-config interface serial0:23
interface Serial0:23
 no ip address
 dialer idle-timeout 999999
 isdn switch-type primary-ni
 isdn protocol-emulate network
 isdn T310 30000
 isdn outgoing display-ie
```

Related Commands

Command	Description
isdn protocol-emulate	Configures an ISDN data or voice port to emulate network or user functionality.

isdn protocol-emulate

To emulate the network side of an ISDN configuration for a PRI Net5 or PRI NTT switch type, use the **isdn protocol-emulate** command in interface configuration mode. To disable ISDN emulation, use the **no** form of this command.

isdn protocol-emulate {**network** | **user**}

no isdn protocol-emulate {**network** | **user**}

Syntax Description

network	Network side of an ISDN configuration.
user	User side of an ISDN configuration.

Command Default No default behavior or values

Command Modes Interface configuration mode

Command History

Release	Modification
12.0(3)XG	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco MC3810 concentrator.
12.1(1)T	This command was introduced in the T train.
12.2(2)XB	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was implemented on the Cisco IAD2420 series. This command is not supported on the access servers in this release.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.
12.3	This command was enhanced to support network emulation capability on the Lucent 4ESS, 5ESS, and Nortel DMS-100 ISDN switch types. These switch types can be configured as a network, but no additional changes were made and not all network side features are supported.
12.3(8)T	Added support for the PRI NTT switch type.

Usage Guidelines

- The current ISDN signaling stack can emulate the ISDN network side, but it does not conform to the specifications of the various switch types in emulating the network side.
- This command enables the Cisco IOS software to replicate the public switched network interface to a Private Branch Exchange (PBX).
- To emulate NT (network) or TE (user) functionality, use this command to configure the layer 2 and layer 3 port protocol of a BRI voice port or a PRI interface.

- Use this command to configure the Cisco AS5300 PRI interface to serve as either the primary QSIG slave or the primary QSIG master. To disable QSIG signaling, use the **no** form of this command; the layer 2 and layer 3 protocol emulation defaults to **user**.
- This feature is supported for the PRI Net5 and PRI NTT switch types.

Examples

The following example configures the interface (configured for Net5) to emulate the network-side ISDN:

```
Router(config)# int s0:15
Router(config-if)# isdn protocol-emulate network
```

The following example configures the layer 2 and layer 3 function of T1 PRI interface 23 to act as the QSIG master (NT):

```
interface serial 1:23
 isdn protocol-emulate network
```

The following example configures the layer 2 and layer 3 function of a BRI voice port to operate as QSIG slave (TE):

```
interface bri 1
 isdn protocol-emulate user
```

The following example configures the layer 2 and layer 3 function of an E1 PRI interface to operate as QSIG slave (TE):

```
interface serial 4:23
 isdn protocol-emulate user
```

Related Commands

Command	Description
isdn bchan-number-order	Configures an ISDN PRI interface to make outgoing call selection in ascending, descending, or round-robin order.
isdn logging	Enables logging of ISDN syslog messages.
isdn switch-type (PRI)	Specifies the central office switch type on the ISDN PRI interface.
network-clock-priority	Specifies the clock-recovery priority for the BRI voice ports in a BVM.
pri-group nec-fusion	Configures the NEC PBX to support FCCS.
show cdapi	Displays the CDAPI.
show rawmsg	Displays the raw messages owned by the required component.

isdn rlm-group

To specify a Redundant Link Manager (RLM) group number for ISDN to use, enter the **isdn rlm-group** command in controller configuration mode. To disable this function, use the **no** form of this command.

isdn rlm-group *number*

no isdn rlm-group *number*

Syntax Description

number	Number of the RLM group. Valid range is from 0 to 5.

Command Default

No RLM group is specified and the ISDN D channel is reserved for signaling information.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.0(2)T	This command was introduced.
12.4(16)	This command was removed from the Cisco IOS software code on the Cisco 2800 series and Cisco 3800 series platforms.
12.4(15)T	This command was removed from the Cisco IOS software code on the Cisco 2800 series and Cisco 3800 series platforms.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

RLM delivers ISDN Q.921 frames over an IP network. RLM affects D-channel signaling only; it does not affect the B channels. The time slot assigned originally to the D channel is freed and used as a B channel because D signaling occurs over the IP network.

The **isdn rlm-group** command allows RLM to be used to transport the D-channel information (signaling) over Ethernet.

The **isdn rlm-group** is supported only on the Cisco AS5300, AS5350, AS5400, and AS5850 series access servers. This command is not supported on Cisco 1800 series, 2800 series, 3700 series, and 3800 series platforms.

Prior to Cisco IOS Releases 12.4(16) and 12.4(15)T, the **isdn rlm-group** command could be entered on Cisco 2800 series and 3800 series platforms even though it was not supported. In some conditions, this could cause the router to reload. Effective with Cisco IOS Releases 12.4(16) and 12.4(15)T, the **isdn rlm-group** command is no longer available on the Cisco 2800 series and 3800 series platforms.

Examples

The following example defines RLM group 1:

```
interface Serial0:23
 ip address 10.0.0.1 255.0.0.0
 encapsulation ppp
 dialer map ip 10.0.0.2 name map1 1111111
```

```
dialer load-threshold 1 either
dialer-group 1
isdn switch-type primary-ni
isdn incoming-voice modem
isdn rlm-group 1
ppp authentication chap
ppp multilink
hold-queue 75 in
```

Related Commands

Command	Description
clear interface virtual-access	Resets the hardware logic on an interface.
clear rlm group	Clears all RLM group time stamps to zero.
interface	Defines the IP addresses of the server, configures an interface type, and enters interface configuration mode.
link (RLM)	Specifies the link preference.
protocol rlm port	Reconfigures the port number for the basic RLM connection for the whole RLM group.
retry keepalive	Allows consecutive keepalive failures a specified amount of time before the link is declared down.
server (RLM)	Defines the IP addresses of the server.
show rlm group statistics	Displays the network latency of the RLM group.
show rlm group status	Displays the status of the RLM group.
show rlm group timer	Displays the current RLM group timer values.
shutdown (RLM)	Shuts down all of the links under the RLM group.
timer	Overwrites the default setting of timeout values.

isdn skipsend-idverify

To stop the user side of a BRI interface from sending ID verify information, use the **isdn skipsend-idverify** command in interface configuration mode. To restore the user-side notification, use the **no** form of this command.

isdn skipsend-idverify

no isdn skipsend-idverify

Syntax Description

This command has no arguments or keywords.

Command Default

By default, the user side sends the ID verify information. The **no** form of this command is in effect by default.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(3)XI	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.

Usage Guidelines

For user-side BRI interfaces, you can send ID verify messages to confirm the status of a particular terminal endpoint identifier (TEI) when there is doubt about whether the TEI is in use (for example, after a Layer 1/Layer 2 flap). ID is the TEI value.

For network-side BRI interfaces, the command should always be set. In some cases, the command will automatically be configured after the BRI network-side protocol emulation is set. If not, you can manually configure the command on the network-side BRI interface. After the command has been configured either automatically or manually, it cannot be further changed. A network-side BRI interface should always be set so that it does not send ID verify information.

Examples

The following example shows user-side output, with the default in effect, so the ID verify is sent:

```
Router# show isdn status br0/0

Global ISDN Switchtype = basic-net3
ISDN BRI0/0 interface
        dsl 0, interface ISDN Switchtype = basic-net3
    Layer 1 Status:
        ACTIVE
    Layer 2 Status:
        TEI = 95, Ces = 1, SAPI = 0, State = MULTIPLE_FRAME_ESTABLISHED
    Layer 3 Status:
        0 Active Layer 3 Call(s)
    Active dsl 0 CCBs = 0
    The Free Channel Mask:  0x80000003
    Total Allocated ISDN CCBs = 0
```

The following sample output shows network-side output, with the default in effect:

```
ISDN BRI1/1 interface
        ******* Network side configuration *******
        dsl 9, interface ISDN Switchtype = basic-qsig
         **** Master side configuration ****
    Layer 1 Status:
        ACTIVE
    Layer 2 Status:
        TEI = 64, Ces = 1, SAPI = 0, State = MULTIPLE_FRAME_ESTABLISHED
    Layer 3 Status:
        0 Active Layer 3 Call(s)
    Active dsl 9 CCBs = 0
    The Free Channel Mask:  0x80000003
    Total Allocated ISDN CCBs = 0
```

The following sample output shows the BRI interface with the **isdn skipsend-idverify** command in effect (so the ID verify will *not* be sent):

```
Router# show run interface br0/0

Building configuration...

Current configuration : 185 bytes
!
interface BRI0/0
 no ip address
 encapsulation ppp
 no ip mroute-cache
 isdn switch-type basic-net3
 isdn point-to-point-setup
 isdn incoming-voice voice
 isdn skipsend-idverify
end
```

The following example shows the return to default so that the ID verify will be sent:

```
Router# configure

Configuring from terminal, memory, or network [terminal]?
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)#interface br0/0
Router(config-if)#no isdn skipsend-idverify
Router(config-if)#
```

The following output shows that the skip send has been removed (so the ID verify information *will* be sent):

```
Router# show run interface br0/0

Building configuration...

Current configuration : 161 bytes
!
interface BRI0/0
 no ip address
 encapsulation ppp
 no ip mroute-cache
 isdn switch-type basic-net3
 isdn point-to-point-setup
 isdn incoming-voice voice
end
```

This configuration example shows the warning message that appears when the command is applied or when the **no** form of the command is entered on a network-side BRI interface:

```
Router# configure

Configuring from terminal, memory, or network [terminal]?
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)#int br1/1
Router(config-if)#isdn skipsend-idverify
% Network side should never send ID VERIFY <---- warning message
Router(config-if)#
```

Related Commands

Command	Description
interface bri	Specifies the interface and enters interface configuration mode.

isdn spoofing

To enable ISDN spoofing so that loss of Layer 1 or Layer 2 connectivity of the ISDN BRI interface is not detected by the Trunk Group Resource Manager (TGRM) or similar application, use the **isdn spoofing** command in interface configuration mode. To disable ISDN spoofing so the TGRM or similar application can detect when the BRI interface is not operational (when the Layer 1 or Layer 2 connection is down), use the **no** form of this command.

isdn spoofing

no isdn spoofing

Syntax Description

This command has no arguments or keywords.

Command Default

The ISDN BRI interface is spoofing, which means that applications always see the BRI interface connection as operational (unless the interface has been manually shut down [ADMINDOWN state]).

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The ISDN BRI interface is spoofing by default. Spoofing makes the ISDN BRI interface available (up) for operation (for dialing in ISDN), even if the interface is down. For an ISDN BRI interface to be set to a down condition, the interface must be manually shut down (IDBS_ADMINDOWN state). Spoofing enables upper layers to dial out even when the interface is down.

Some upper layer modules, such as TGRM and similar applications, allow dial-out only if the channel is available. If the record for TGRM or similar application is notified of the actual status of BRI, then the TGRM or similar application can dial out accordingly. In this case, the **no isdn spoofing** command is appropriate.

Note ISDN spoofing can be applied only to BRI interfaces—it does not apply to PRI interfaces.

Examples

The following example shows how to configure an ISDN BRI interface to disable ISDN spoofing:

```
Router# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# interface bri0/0
Router(config-if)# no isdn spoofing
Router(config-if)#
```

Related Commands

Command	Description
interface bri	Configures a BRI interface and enters interface configuration mode.
show isdn status	Displays the status of all ISDN interfaces or a specific ISDN interface.

isdn supp-service calldiversion

To ensure that all calls on an ISDN serial interface can be traced if diverted, use the **isdn supp-service calldiversion** command in interface configuration mode. To disable tracing of diverted ISDN calls, use the **no** form of this command.

isdn supp-service calldiversion

no isdn supp-service calldiversion

Syntax Description

This command has no arguments or keywords.

Command Default

VoIP calls, when diverted, are not traceable and are translated into a Redirection Information Element (RedirectionIE).

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.4(2)T	This command was introduced.

Usage Guidelines

You must explicitly specify an ISDN serial interface. The D channel is always the :23 channel for T1 and the :15 channel for E1.

To enable traceability, the call diversion service requires that a VoIP call (when diverted) translates into a divertingLegInformation2 IE instead of a RedirectionIE. When the **isdn supp-service calldiversion** command is configured, the redirecting information coming from the application is packed in the Facility Information Element (FAC IE) as DiversionLeg2 information and sent in the outgoing SETUP message.

The **isdn supp-service calldiversion** command works only for NET5 switches.

Examples

The following example shows how to configure the primary NET5 switch so that the call diversion tracing service is enabled:

```
interface serial3:23
 no ip address
 isdn switch-type primary-net5
 isdn supp-service calldiversion
```

Related Commands

Command	Description
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller for ISDN PRI, CAS, or robbed-bit signaling.

isdn supp-service mcid

To enable an ISDN serial interface for Malicious Caller Identification (MCID), use the **isdn supp-service mcid** command in interface configuration mode. To disable MCID functionality, use the **no** form of this command.

isdn supp-service mcid

no isdn supp-service mcid

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

The ISDN interface must use the NET5 switch type, which is set using the **isdn switch-type primary-net5** command. Protocol emulation must be set to user, which is the default for the **isdn protocol-emulate** command. This command is valid only at the ISDN interface level.

Examples

The following configuration example shows MCID enabled for the PRI:

```
interface serial0:23
 isdn switch-type primary-net5
 ip address 10.10.10.0. 255.255.255.0
 isdn supp-service mcid
 isdn T-Activate 5000
```

Related Commands

Command	Description
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller for ISDN PRI, channel-associated signaling, or robbed-bit signaling.
isdn protocol-emulate	Configures the PRI interface to serve as either the primary slave (user) or the primary master (network).
isdn switch-type	Specifies the central office switch type on the ISDN interface.
isdn t-activate	Specifies how long the ISDN serial interface must wait for the malicious caller to be identified.

isdn supp-service name calling

To set the calling name display parameters sent out on an ISDN serial interface, use the **isdn supp-service name calling** command in interface configuration mode. To disable calling name delivery, use the **no** form of this command.

isdn supp-service name calling [**ie** | **operation-value-tag** | **profile** {**Network Extension operation-value-tag** {**ecma** | **iso** | **local**} | **ROSE**}]

no isdn supp-service name calling

Syntax Description

ie	(Optional) Specifies that the value of the calling name information element (ie) is to be sent.
operation-value-tag	(Optional) Specifies that the operation value tag for the calling name is to be sent.
profile	(Optional) Specifies that a particular protocol profile is to be sent.
Network-Extension	Specifies the networking extension (0x9F).
ecma	Specifies that the European Computer Manufacturers' Association (ECMA) object identifier (OID) global value (protocol profile 0x06 04 2B 0C 09 00) is to be sent.
iso	Specifies that the International Standards Organization (ISO) OID global value (protocol profile 0x06 05 28 EC 2C 00 00) is to be sent.
local	Specifies that the local OID global value (protocol profile 0x02 01 00) is to be sent.
ROSE	(Optional) Specifies that the Remote Operations Service Element (ROSE) value (protocol profile 0x91) is to be sent.

Command Default

Calling name delivery is disabled, so no calling-name display parameters are set.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.3(4)T	This command was introduced.
12.4(15)T1	The **ie**, **operation-value-tag**, **profile**, **Network Extension**, **ecma**, **iso**, **local**, and **ROSE** keywordswere added.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

You must explicitly specify an ISDN serial interface. The D channel is always the :23 channel for T1 and the :15 channel for E1.

Under the serial interface (interface serial command), the **isdn supp-service name calling** command must be configured so that when the calling name comes in the Facility Information Element (IE) of the ISDN setup message, the gateway sends the calling name to the Cisco Unified Communications Manager

as a Display IE. If the **isdn supp-service name calling** command is not configured under the ISDN serial interface, the calling name in the FacilityIE is sent as user-to-user data to the Cisco Unified Communications Manager without the display data.

Beginning with Cisco IOS Release 12.4(15)T1, the **ie**, **operation-value-tag**, **profile**, **Network Extension**, **ecma**, **iso**, **local**, and **ROSE** keywords were added to provide more specific information in defining calling name information that is to be sent.

Examples

The following example shows the H.323 Display feature without buffering for ISDN trunks being configured at the voice service level:

```
voice service voip
 h323
 h225 display-ie ccm-compatible
```

The following example shows the H.323 Display feature without buffering for ISDN trunks being configured at the voice class level:

```
voice class h323 1
 h225 display-ie ccm-compatible [system]
```

The following example shows the H.323 name display information on ISDN trunks:

```
interface Serial0/3/0:23
 no ip address
 encapsulation hdlc
 isdn switch-type primary-ni
 isdn incoming-voice voice
 isdn map address *. plan isdn type unknown
 isdn supp-service name calling
 isdn bind-l3 ccm-manager
 no cdp enable
```

Related Commands

Command	Description
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller for ISDN PRI, channel-associated signaling, or robbed-bit signaling.

isdn supp-service tbct

To enable ISDN Two B-Channel Transfer (TBCT) on PRI trunks, use the **isdn supp-service tbct** command in interface or trunk group configuration mode. To reset to the default, use the **no** form of this command.

isdn supp-service tbct [**notify-on-clear** | **tbct-with-crflg**]

no isdn supp-service tbct

Syntax Description

notify-on-clear	(Optional) ISDN switch notifies the gateway whenever a transferred call is cleared.
tbct-with-crflg	(Optional) Includes the call reference flag while sending a TBCT request.

Command Default

TBCT is disabled.

Command Modes

Interface configuration
Trunk-group configuration

Command History

Release	Modification
12.3(1)	This command was introduced.

Usage Guidelines

This command enables TBCT for a specific PRI when used in interface configuration mode. This command configures TBCT for all PRIs in a trunk group when used in trunk-group configuration mode.

The **notify-on-clear** keyword is necessary for the gateway to track billing. This keyword is supported only for user-side ISDN interfaces. You must configure the ISDN switch to send a notify message when a call is cleared.

On some PBX switches, the call reference flag (including the call reference value of the other call) is mandatory. To include the call reference flag in a TBCT request, use the **tbct-with-crflg** keyword. The call reference flag can be 00 or 80. So, for example, if the call reference value is 02, the call reference flag is 0002 or 8002.

Examples

The following example shows how to enable TBCT for interface 0:23:

```
interface Serial0:23
 isdn supp-service tbct
```

The following example shows how to enable TBCT for trunk group 1:

```
trunk group 1
 isdn supp-service tbct
```

The following example shows how to include the call reference flag in TBCT requests for trunk group 1:

```
trunk group 1
 isdn supp-service tbct tbct-with-crflg
```

Related Commands

Command	Description
call application voice transfer mode	Specifies the call-transfer behavior of a TCL or VoiceXML application.
show call active voice redirect	Displays information about active calls that are being redirected using RTPvt or TBCT.
tbct clear call	Terminates billing statistics for one or more active TBCT calls.
tbct max call-duration	Sets the maximum duration allowed for a call that is redirected using TBCT.
tbct max calls	Sets the maximum number of active calls that can use TBCT.
trunk group	Enters trunk-group configuration mode to define or modify a trunk group.

isdn t-activate

To specify how long the gateway waits for a response from the PSTN after sending a MCID request, use the **isdn t-activate** command in interface configuration mode. To disable the timer, use the **no** form of this command.

isdn t-activate *ms*

no isdn t-activate *ms*

Syntax Description

ms	Number of milliseconds (ms). Range is 1000 to 15000. Default is 4000; 5000 is recommended.

Command Default 4000 ms

Command Modes Interface configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines This command starts a timer when the voice gateway sends a Facility message to the PSTN. If a response is not received within the specified time, the TCL IVR script for MCID is notified. Depending on how the script is written, it could reinvoke MCID or perform some other action, such as playing a message if the MCID attempt fails. This command is valid only at the ISDN interface level. The ISDN interface must use the NET5 switch type, which is set using the **isdn switch-type primary-net5** command. Protocol emulation must be set to user, which is the default for the **isdn protocol-emulate** command.

Examples The following example shows the configuration of the timer on serial interface 0:23:

```
interface serial0:23
 isdn switch-type primary-net5
 ip address 10.10.10.0 255.255.255.0
 isdn suppserv mcid
 isdn T-Activate 5000
```

Related Commands

Command	Description
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller for ISDN PRI, channel-associated signaling, or robbed-bit signaling.
isdn protocol-emulate	Configures the PRI interface to serve as either the primary slave (user) or the primary master (network).

Command	Description
isdn switch-type	Specifies the central office switch type on the ISDN interface.
isdn suppserv mcid	Configures an ISDN serial interface for MCID.

isdn tei-negotiation (interface)

To configure when Layer 2 becomes active and ISDN terminal endpoint identifier (TEI) negotiation occurs, use the **isdn tei-negotiation** command in interface configuration mode. To remove TEI negotiation from an interface, use the **no** form of this command.

isdn tei-negotiation {**first-call** | **powerup**} {**preserve** | **remove**}

no isdn tei-negotiation {**first-call** | **powerup**} {**preserve** | **remove**}

Syntax Description

first-call	ISDN TEI negotiation should occur when the first ISDN call is placed or received.
powerup	ISDN TEI negotiation should occur when the router is powered on.
preserve	Preserves dynamic TEI negotiation when ISDN Layer 1 flaps, and when the **clear interface** or the **shut** and **no shut** EXEC commands are executed.
remove	Removes dynamic TEI negotiation when ISDN Layer 1 flaps, and when the **clear interface** or the **shut** and **no shut** EXEC commands are executed.

Command Default

The **powerup** state is the default condition. Depending upon the ISDN switch type configured, the default will be to preserve or remove the TEI negotiation options. See the "Usage Guidelines" and "Examples" sections for further explanation.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.3 T	This command was introduced as an interface command.
12.2	The **preserve** and **remove** keywords were added.

Usage Guidelines

This command is for BRI configuration only.

The **first-call** and **powerup**, and **preserve** and **remove** command pairs are mutually exclusive, that is, you must choose only one command from either the **first-call** and **powerup** or **preserve** and **remove** command pairs, per command line.

The **no isdn tei-negotiation** command returns the configuration to default to the **powerup** state.

The **preserve** keyword depends on the ISDN switch type configured, that is, the TEI negotiation configured will be preserved during ISN Layer 1 flaps, and when the **clear interface** or the **shut** and **no shut** EXEC commands are executed, on the switch types listed in Table 32.

Table 32 Switch Types with Preserved TEI Negotiation

Switch Type	Cisco IOS Keyword
French ISDN switch types	**vn2, vn3**
Lucent (AT&T) basic rate 5ESS switch	**basic-5ess**

Table 32 Switch Types with Preserved TEI Negotiation (continued)

Switch Type	Cisco IOS Keyword
Northern Telecom DMS-100 basic rate switch	**basic-dms100**
National ISDN basic rate switch	**basic-ni**
PINX (PBX) switches with QSIG signaling per Q.931	**basic-qsig**

For all other ISDN switch types, the TEI negotiation will be removed during ISDN Layer 1 flaps, and when the **clear interface** or the **shut** and **no shut** EXEC commands are executed. Use the **remove** keyword to specifically set one of the switches listed in Table 32 to the remove state.

Examples

The following example shows the ISDN TEI negotiation configuration with default settings. (Defaults settings do not appear in the router configuration.)

```
interface BRI0/0
 no ip address
 isdn switch-type basic-ni
 cdapi buffers regular 0
 cdapi buffers raw 0
 cdapi buffers large 0
```

The following example shows how to set TEI negotiation timing to the first call:

```
Router(config-if)# isdn tei-negotiation first-call
Router(config-if)# exit
Router(config)# exit
Router# show startup-config
.
.
.
interface BRI0/0
 no ip address
 isdn switch-type basic-ni
 isdn tei-negotiation first-call
 cdapi buffers regular 0
 cdapi buffers raw 0
 cdapi buffers large 0interface BRI0/0
```

The following example shows how to change TEI negotiation timing back to the default power-up state:

```
Router(config-if)# no isdn tei-negotiation first-call
Router(config-if)# exit
Router(config)# exit
Router# show startup-config
.
.
.
interface BRI0/0
 no ip address
 isdn switch-type basic-ni
 cdapi buffers regular 0
 cdapi buffers raw 0
 cdapi buffers large 0
```

The following example shows how to remove TEI negotiation when ISDN Layer 1 flaps (the preserve state is the default for the National ISDN basic rate switch):

```
Router(config-if)# isdn tei-negotiation remove
Router(config-if)# exit
Router(config)# exit
Router# show startup-config
.
.
.
interface BRI0/0
 no ip address
 isdn switch-type basic-ni
 isdn tei-negotiation first-call
 isdn tei-negotiation remove
 cdapi buffers regular 0
 cdapi buffers raw 0
 cdapi buffers large 0
```

The following example shows how to return the National ISDN basic rate switch to its default preserve state:

```
Router(config-if)# no isdn tei-negotiation remove
Router(config-if)# exit
Router(config)# exit
Router# show startup-config
.
.
.
interface BRI0/0
 no ip address
 isdn switch-type basic-ni
 isdn tei-negotiation first-call
 cdapi buffers regular 0
 cdapi buffers raw 0
 cdapi buffers large 0
```

iua

To specify backhaul using Stream Control Transmission Protocol (SCTP) and to enter IDSN User Adaptation Layer (IUA) configuration mode, use the **iua** command in terminal configuration mode.

iua

Syntax Description This command has no arguments or keywords.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(4)T	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and support was added for the Cisco AS5300 and Cisco AS5850.
12.2(15)T	This command was implemented on the Cisco 2420, Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series; and Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 network access server (NAS) platforms.

Usage Guidelines You must first enter IUA configuration mode to access SCTP configuration mode. First enter IUA configuration mode by using the example below and then enter **sctp** at the Router(config-iua)#prompt to bring up SCTP configuration mode. See the **sctp** command.

Examples The following example shows how to enter iua configuration mode:

```
Router# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# iua
Router(config-iua)#
```

The following example shows how to configure the failover-timer by setting the failover time (in milliseconds) to 1 second for a particular AS:

```
Router(config-iua)# as as5400-3 fail-over-timer 1000
```

The following example configure the number of SCTP streams for this AS to 57, which is the maximum value allowed:

```
Router(config-iua)# as as5400-3 sctp-streams 57
```

Related Commands

Command	Description
isdn bind-L3 iua-backhaul	Specifies ISDN backhaul using SCTP for an interface.
show iua as	Shows information about the current condition of an AS.
show iua asp	Shows information about the current condition of an ASP.

ivr asr-server

To specify the location of an external media server that provides automatic speech recognition (ASR) functionality to voice applications, use the **ivr asr-server** command in global configuration mode. To remove the server location, use the **no** form of this command.

ivr asr-server *url*

no ivr asr-server

Syntax Description

url	Location of the ASR resource on the media server, in uniform resource locator (URL) format.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.4(15)T	The *url* argument was modified to accept a Media Resource Control Protocol version 2 (MRCP v2) server URL.

Usage Guidelines

This command sets the server location globally for all voice applications on the gateway.

For Nuance media servers that use the default installation, specify the URL as follows:

ivr asr-server rtsp://*host***:**[*port*]**/recognizer**

(*host* is the host name of the media server; **:***port* is optional.)

For media servers using MRCP v2, specify the URL as follows:

ivr asr-server sip:*server-name@host-name* | *ip-address*

You can specify the location of the media server within a VoiceXML document, overriding the Cisco gateway configuration. For more information, see the *Cisco VoiceXML Programmer's Guide*.

Examples

The following example specifies that voice applications use the ASR server named "asr_serv":

```
Router(config)# ivr asr-server rtsp://asr_serv/recognizer
```

The following example specifies that voice applications use the MRCP v2 ASR server named "asr_mrcpv2serv":

```
Router(config)# ivr asr-server sip:asr_mrcpv2serv@mediaserver.com
```

Related Commands

Command	Description
ivr tts-server	Specifies the location of a media server that provides TTS functionality to voice applications.
ivr tts-voice-profile	Specifies the location of the voice profile that is used by the TTS server.

ivr autoload mode

To load files from TFTP to memory using either verbose or silent mode, use the **ivr autoload mode** command in global configuration mode. To disable this function, use the **no** form of this command.

ivr autoload mode {**verbose** [**url** *location*| **retry** *number*]} | {**silent** [**url** *location* | **retry** *number*]}

no ivr autoload mode

Syntax Description

verbose	Displays the file transfer activity to the console. This mode is recommended while debugging.
url *location*	URL that is used to locate the index file that contains a list of all available audio files.
retry *number*	(Optional) Number of times that the system tries to transfer a file when there are errors. This parameter applies to each file transfer. Range is from 1 to 5. Default is 3.
silent	Performs the file transfer in silent mode, meaning that no file transfer activity is displayed to the console.

Command Default Silent

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines The index file contains a list of audio files (URL) that can be downloaded from the TFTP server. Use this command to download audio files from TFTP to memory. The command only starts up a background process. The background process (loader) does the actual downloading of the files.

The background process first reads the index file from either Flash or TFTP. It parses the files line by line looking for the URL. It ignores lines that start with # as comment lines. Once it has a correct URL, it tries to read that.au file into memory and creates a media object. If there are any errors during the reading of the file, it retries the configured number of times. If the mode is set to **verbose**, the loader logs the transaction to console. Once parsing has reached the end of the index file, the background process exits memory.

Perform the following checks before initiating the background process. If one of the checks fails, it indicates the background process is not started, and instead you see an error response to the command.

- Check if any prompt is being actively used (IVR is actively playing some prompts). If there are active prompts, the command fails, displaying the following error message (.au files are also referred to as prompts):

  ```
  command is not allowed when prompts are active
  ```

- Check if there is already a background process in progress. If there is a process, the command fails, displaying the following error:

  ```
  previous autoload command is still in progress
  ```

- Check if an earlier **ivr autoload url** command has already been configured. If an **ivr autoload url** command has already been configured, the user sees the following response when the command is issued:

  ```
  previous command is being replaced
  ```

- When the **no ivr autoload url** command is issued, if there was already an **ivr autoload url** command in progress, the original command is aborted.

The audio files (prompts) loaded using the **ivr autoload url** command are not dynamically swapped out of memory. They are considered to be autoloaded prompts, as opposed to dynamic prompts. (See the **ivr prompt memory** command for details on dynamic prompts.)

Examples

The following example configures verbose mode:

```
ivr autoload mode verbose url tftp://blue/orange/tclware/index4 retry 3
```

The following example shows the resulting index file:

```
more index4
tftp://blue/orange/tclware/au/en/en_one.au
tftp://blue/orange/tclware/au/ch/ch_one.au
tftp://blue/orange/tclware/au/ch/ch_one.au
```

The following example shows an index file on Flash memory:

```
flash:index
```

Related Commands

Command	Description
ivr prompt memory	Configures the maximum amount of memory that the dynamic audio files occupy in memory.

ivr prompt memory

To configure the maximum amount of memory that the dynamic audio files (prompts) occupy in memory, use the **ivr prompt memory** command in global configuration mode. To disable the maximum memory size, use the **no** form of this command.

ivr prompt memory *size* **files** *number*

no ivr prompt memory

Syntax Description

size	Maximum memory to be used by the free dynamic prompts, in kilobytes. Range is 128 to 16384. The default is 128.
files *number*	Number of files that can stay in memory. Range is 50 to 1000. The default is 200.

Command Default

Memory size: 128 KB
Number of files: 200

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(7)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

When both the *number* and *size* parameters are specified, the minimum memory out of the two is used for memory calculations.

All the prompts that are not autoloaded or fixed are considered dynamic. Dynamic prompts are loaded in to memory from TFTP or Flash, as and when they are needed. When they are actively used for playing prompts, they are considered to be in “active” state. However, once the prompt playing is complete, these prompts are no longer active and are considered to be in a free state.

The free prompts either stay in memory or are removed from memory depending on the availability of space in memory for these free prompts. This command essentially specifies a maximum memory to be used for these free prompts.

The free prompts are saved in memory and are queued in a wait queue. When the wait queueis full (either because the totally memory occupied by the free prompts exceeds the maximum configured value or the number of files in the wait queue exceeds maximum configured), oldest free prompts are removed from memory.

Examples

The following example sets memory size to 2048 KB and number of files to 500:

```
ivr prompt memory 2048 files 500
```

Related Commands

Command	Description
ivr autoload	Loads files from a particular TFTP server.
show call prompt-mem-usage	Displays the memory site use by prompts.
ivr prompt streamed	Streams audio prompts from particular media types during playback.

ivr autoload url

To load files from a particular TFTP server (as indicated by a defined URL), use the **ivr autoload** command in global configuration mode. To disable this function, use the **no** form of this command.

ivr autoload url *location*

no ivr autoload url *location*

Syntax Description

url *location*	URL that is to be used to locate the index file that contains a list of all available audio files.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.0(7)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines The index file contains a list of audio files URLs that can be downloaded from the TFTP server. Use this command to download audio files from TFTP to memory. The command starts up a background process. The background process (loader) does the actual downloading of the files.

The background process first reads the index file from either Flash memory or TFTP. It parses the files line by line, looking for the URL. It ignores lines that start with # as comment lines. Once it has a correct URL, it tries to read that .au file into memory and creates a media object. If there are any errors during the reading of the file, it retries the configured number of times. If the *mode* is set to "verbose," in the ivr autoload mode command the loader logs the transaction to console. Once parsing has reached the end of the index file, the background process exits memory.

Perform the following checks before initiating the background process. If one of the checks fails, it indicates that the background process is not started, and instead you see an error response to the command.

- Check to see if any prompt is being actively used (IVR is actively playing some prompts). If there are active prompts, the command fails, displaying the following error message (.au files are also referred to as prompts):

  ```
  command is not allowed when prompts are active
  ```

- Check to see if there is already a background process in progress. If there is a process, the command fails, displaying the following error:

  ```
  previous autoload command is still in progress
  ```

- Check to see if an earlier **ivr autoload url** command has already been configured. If an **ivr autoload** command has already been configured, the user sees the following response when the command is issued:

  ```
  previous command is being replaced
  ```

- When the **no ivr autoload url** command is issued, If there is already an **ivr autoload url** command in progress, it is aborted.

The audio files (prompts) loaded using the **ivr autoload** command are not dynamically swapped out of memory. They are considered as autoloaded prompts as opposed to "dynamic" prompts. (See the **ivr prompt memory** command for details on dynamic prompts.)

Examples

The following example loads audio files from the TFTP server (located at //jurai/mgindi/tclware/index4):

```
ivr autoload url tftp://jurai/mgindi/tclware/index4
```

The following example shows the resulting index file:

```
more index4
tftp://jurai/mgindi/tclware/au/en/en_one.au
tftp://jurai/mgindi/tclware/au/ch/ch_one.au
tftp://jurai/mgindi/tclware/au/ch/ch_one.au
```

The following example shows an index file on Flash:

```
flash:index
```

Related Commands

Command	Description
ivr prompt memory	Configures the maximum amount of memory that the dynamic audio files (prompts) occupy in memory.

ivr contact-center

To enable a specific set of debug commands on a Cisco router that is being used in a contact center, use the **ivr command-cente**r command in global configuration mode. To stop automatically enabling these debug commands after the router is reloaded, use the **no** form of this command.

ivr command-center

no ivr command-center

Syntax Description

This command has no arguments or keywords.

Command Default

Specific individual debug commands must be manually enabled each time the router is reloaded.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T2	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.
12.4(15)T4	The ccapi, cch323, and ccsip error debugs were included in the output display.
12.4(20)YA	This command was integrated into Cisco IOS Release 12.4(20)YA.

Usage Guidelines

To troubleshoot a Cisco router that is being used in a contact center, it is often necessary to enable specific debug commands to display error messages. Typically, you must manually enable the individual debug commands each time the router is reloaded. Use the **ivr contact-center** command to enable the following debug commands and to automatically re-enable these commands each time the router is reloaded:

- **debug ccsip error**
- **debug cch323 error**
- **debug http client error**
- **debug mrcp error**
- **debug rtsp error**
- **debug voip application error**
- **debug voip application vxml error**
- **debug voice ccapi error**

While this command is configured, the listed debug commands cannot be disabled. Attempts to disable any of these debug commands while the **ivr contact-center** command is configured will display a warning message and the debug command will not be disabled.

Configuring the **no ivr contact-center** command does not disable the listed debug commands. To disable these debug commands after configuring the **no ivr contact-center** command, you must either manually disable each individual debug command or reload the router, after which these debug commands are not re-enabled.

You can verify that the listed debug commands are enabled after you configure the **ivr contact-center** command by using the **show debug** command.

Examples

The following partial output from the **show running-config** command shows that the **ivr contact-center** command is enabled:

```
Router# show running-confi
Building configuration...

Current configuration : 20256 bytes
!
version 12.4
no service pad
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
service internal
!
hostname c5400-02
!
! ***** snipped *****
!
ivr contact-center
ivr prompt memory 16384 files 1000
ivr asr-server rtsp://CVPASR/media/speechrecognizer
ivr tts-server rtsp://CVPTTS/media/speechsynthesizer
!
! ***** snipped *****
```

The following output from the **show debug** command displays current debugging information that includes the error debug messages automatically enabled by the **ivr contact-center**command:

To display current debugging information that includes the error debug messages automatically enabled by "ivr contact-center", use the show debug command in privileged EXEC mode.

```
c3825-01(config)#ivr contact-center
c3825-01(config)#end
Router# show debug

CCH323 SPI: Error debug is enabled
CCAPI:
  debug voip ccapi error call is ON (filter is OFF)
  debug voip ccapi error software is ON
CCSIP SPI: SIP error debug tracing is enabled   (filter is OFF)

  debug voip application vxml error software is ON
  debug voip application vxml error call is ON (filter is OFF)
c3825-01#
```

Related Commands

Command	Description
debug http client error	Displays error messages for the HTTP client.
debug mrcp error	Displays error messages for Media Resource Control Protocol (MRCP) operations.
debug rtsp error	Displays debug information about the Real-Time Streaming Protocol (RTSP) client.
debug voip application error	Displays error messages for all voice applications.
debug voip application vxml error	Displays error messages for a VoiceXML application.
debug voice ccapi error	Displays error messages for the call control application programming interface (CCAPI) contents.
debug ccsip error	Displays Session Initiation Protocol (SIP)-related error messages.
debug cch323 error	Displays error messages for components within the H.323 subsystem.
show debug	Displays current debugging information automatically enabled by **ivr contact-center** command.

ivr language link

To link configured language packages, use the **ivr language link** command in global configuration mode. To delink the configured language packages, use the **no** form of this command.

ivr language link {**all** | **on-demand**}

no ivr language link

Syntax Description

all	Links all the configured language packages.
on-demand	Links the language packages when asked for.

Command Modes

Global configuration (config)

Command Default

The language packages are not linked.

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows how to link all the configured language packages:

```
Router# configure terminal
Router(config)# ivr language link all
```

Related Commands

Command	Description
ivr asr-server	Specifies the location of an external media server that provides ASR functionality to voice applications.

ivr prompt cutoff-threshold

To configure the maximum delay time for audio prompts, use the **ivr prompt cut-off threshold** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ivr prompt cutoff-threshold *time*

no ivr prompt cutoff-threshold

Syntax Description

time	Maximum delay time, in milliseconds (ms). The range is from 120 to 1000.

Command Default The maximum delay time is not configured.

Command Modes Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples The following example shows how to configure the maximum delay time for audio prompts:

```
Router# configure terminal
Router(config)# ivr prompt cutoff-threshold 129
```

Related Commands

Command	Description
ivr prompt streamed	Streams audio prompts from particular media types during playback.

ivr prompt streamed

To stream audio prompts from particular media types during playback, use the **ivr prompt streamed** command in global configuration mode. To reset to the default, use the **no** form of this command.

Cisco IOS Release 12.4(20)T and Later Releases

ivr prompt streamed {**all** | **flash** | **http** | **none**}

no ivr prompt streamed {**all** | **flash** | **http** | **none**}

Cisco IOS Release 12.4(15)XZ and Earlier Releases

ivr prompt streamed {**all** | **flash** | **http** | **none** | **tftp**}

no ivr prompt streamed {**all** | **flash** | **http** | **none** | **tftp**}

Syntax Description

all	All audio prompts, from all URL types (Flash memory, HTTP).
flash	Audio prompts from Flash memory.
http	Audio prompts from an HTTP URL. This is the default value.
none	No audio prompts from any media type.
tftp	Audio prompts from a TFTP URL. **Note** Only available in Cisco IOS Release 12.4(15)XZ and earlier releases.

Command Default

Audio prompts from HTTP URLs and other media types are not streamed during playback.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.4(15)T	The command default was changed from streaming for audio prompts during playback to no streaming.
12.4(20)T	The **tftp** keyword was removed.

Usage Guidelines

To enable streaming for multiple media types, either enter this command for each URL type or enter the ivr prompt streamed all command. If you do not enter this command, audio prompts from HTTP servers and Flash servers are not streamed during playback.

Note Prompts from a Real Time Streaming Protocol (RTSP) server are not controlled by this command and are always streamed during playback.

Examples

The following example indicates that audio prompts from Flash memory are streamed when they are played back:

```
ivr prompt streamed flash
```

Related Commands

Command	Description
ivr prompt memory	Sets the maximum amount of memory that dynamic audio prompts can occupy in memory.

ivr record cpu flash

To configure the maximum percentage allowed for the flash write process in CPU, use the **ivr record cpu flash** command in global configuration mode. To disable this configuration, use the **no** form of this command.

ivr record cpu flash *number*

no ivr record cpu flash

Syntax Description

number	Numeric label that specifies the maximum percentage allowed for the flash write process in the CPU. The range is from 1 to 99. The default is 99.

Command Default

The maximum percentage is configured to 99.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows that the flash recording allowed is set to 50 percent:

```
Router# configure terminal
Router(config)# ivr record cpu flash 50
```

Related Commands

ivr prompt streamed	Streams audio prompts from particular media types during playback.

ivr record memory session

To set the maximum amount of memory that can be used to record voice messages during a single call session, use the **ivr record memory session** command in global configuration mode. To reset to the default, use the **no** form of this command.

ivr record memory session *kilobytes*

no ivr record memory session

Syntax Description

kilobytes	Memory size, in kilobytes. Range is 0 to 256000. The default is 256.

Command Default

256 KB

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300.
12.2(11)T	This command was implemented on the following platforms: Cisco 3640, Cisco 3660, Cisco AS5350, and Cisco AS5400.

Usage Guidelines

Use this command to limit the maximum memory allowed for audio recordings during a single call session on a VoiceXML-enabled gateway.

Note This command configures memory limits only for voice messages recorded to local memory on the gateway. Memory limits are not configurable on the gateway for HTTP, Real Time Streaming Protocol (RTSP), or Simple Mail Transfer Protocol (SMTP) recordings.

Examples

The following example sets the maximum memory limit to 512 KB for a single call session:

```
ivr record memory session 512
```

Related Commands

Command	Description
ivr record memory system	Sets the maximum amount of memory that can be used to store all voice recordings on the VoiceXML-enabled gateway.

ivr record memory system

To set the maximum amount of memory that can be used to store all voice recordings on the gateway, use the **ivr record memory system** command in global configuration mode. To reset to the default, use the **no** form of this command.

ivr record memory system *kilobytes*

no ivr record memory system

Syntax Description

kilobytes	Memory limit, in kilobytes. Range is 0 to 256000. If 0 is configured, the RAM recording function is disabled on the gateway. The default for Cisco 3640 and Cisco AS5300 is 10000. The default for Cisco 3660, Cisco AS5350, and Cisco AS5400 is 20000.

Command Default

Cisco 3640 and Cisco AS5300: 10,000 KB
Cisco 3660, Cisco AS5350, and Cisco AS5400: 20,000 KB

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced on the Cisco AS5300.
12.2(11)T	This command was implemented on the following platforms: Cisco 3640, Cisco 3660, Cisco AS5350, and Cisco AS5400.

Usage Guidelines

Use this command to limit the maximum amount of gateway memory that is used for storing all voice recordings.

Note This command configures memory limits only for voice messages recorded to local memory on the gateway. Memory limits are not configurable on the gateway for HTTP, Real Time Streaming Protocol (RTSP), or Simple Mail Transfer Protocol (SMTP) recordings.

Examples

The following example sets the total memory limit for all recordings to 8000 KB:

```
ivr record memory system 8000
```

Related Commands

Command	Description
ivr record memory session	Sets the maximum amount of memory that can be used to record voice messages during a single call session.

ivr tts-server

To specify the location of an external media server that provides text-to-speech (TTS) functionality to voice applications, use the **ivr tts-server** command in global configuration mode. To remove the server location, use the **no** form of this command.

ivr tts-server *url*

no ivr tts-server

Syntax Description

url	Location of the TTS resource on the media server, in uniform resource locator (URL) format.

Command Default

No default behavior or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.4(15)T	The *url* argument was modified to accept a Media Resource Control Protocol version 2 (MRCP v2) server URL.

Usage Guidelines

This command sets the server location globally for all voice applications on the gateway.

For Nuance media servers that use the default installation, specify the URL as follows:

ivr tts-server rtsp://*host***:***port***/synthesizer**

(*host* is the host name of the media server; **:***port* is optional.)

For media servers using MRCP v2, specify the URL as follows:

ivr tts-server sip:*server-name@host-name* | *ip-address*

You can specify the location of the media server within a VoiceXML document, overriding the Cisco gateway configuration. For more information, see the *Cisco VoiceXML Programmer's Guide*.

To specify the voice profile that the TTS server uses for voice synthesis operations, use the **ivr tts-voice-profile** command.

Examples

The following example specifies that voice applications use the TTS server named "tts_serv":

```
Router(config)# ivr tts-server rtsp://tts_serv/synthesizer
```

The following example specifies that voice applications use the MRCP v2 TTS server named "tts_mrcpv2serv":

```
Router(config)# ivr tts-server sip:tts_mrcpv2serv@mediaserver.com
```

Related Commands

Command	Description
ivr asr-server	Specifies the location of a media server that provides ASR functionality to IVR applications.
ivr tts-voice-profile	Specifies the location of the voice profile that is used by the TTS server.

ivr tts-voice-profile

To specify the location of the voice profile that is used by text-to-speech (TTS) servers, use the **ivr tts-voice-profile** command in global configuration mode. To remove the voice profile, use the **no** form of this command.

ivr tts-voice-profile *url*

no ivr tts-voice-profile

Syntax Description

url	Location of the TTS voice profile file, in URL format.

Command Default No default behavior or values

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3640, Cisco 3660, Cisco AS5300, Cisco AS5350, and Cisco AS5400.

Usage Guidelines This command specifies the voice profile that a TTS server uses for voice synthesis operations. The voice profile is a W3C Simple Markup Language (SML) file that specifies voice parameters like gender, speed, and so forth. The TTS server uses this voice profile unless the markup file that it is translating has overriding values.

The TTS voice profile can be stored on an HTTP server or on RTSP, TFTP, or FTP servers if the media sever supports these locations.

The TTS voice profile location can also be specified in the VoiceXML document by using the Cisco proprietary property com.cisco.tts-voice-profile. The VoiceXML property in the document overrides the value that is configured by using this command.

To specify the location of the external media server that is providing TTS functionality, use the **ivr tts-server** command.

Examples The following example tells the TTS server to use the voice profile file named “vprofil2”, which is located on an HTTP server:

```
ivr tts-voice-profile http://ttserver/vprofil2.sml
```

Related Commands

Command	Description
ivr asr-server	Specifies the location of a media server that provides ASR functionality to IVR applications.
ivr tts-server	Specifies the media server that provides TTS functionality to IVR applications.

ixi application cme

To enter XML application configuration mode for the Cisco Unified CallManager Express (Cisco Unified CME) application, use the **ixi application cme** command in global configuration mode.

ixi application cme

Syntax Description This command has no arguments or keywords.

Command Default XML parameters are not set for the Cisco Unified CME application.

Command Modes Global configuration (config)

Command History

Cisco IOS Release	Modification
12.4(4)XC	This command was introduced.
15.0(1)M	This command was integrated into a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines In Cisco Unified CME 4.0 and later versions, an XML interface is provided through the Cisco IOS XML Infrastructure (IXI), in which the parser and transport layers are separated from the application itself.

When you are using the Cisco IOS XML Infrastructure, the same HTTP transport layer can be used by multiple applications. The **ixi application cme** command enters XML application configuration mode to allow you to set Cisco IOS XML Infrastructure parameters for the Cisco Unified CME application. In this configuration mode, you can set the response timeout parameter using the **response timeout** command and enable communication with the application using the **no shutdown** command.

The **ixi transport** command allows you to set parameters for the Cisco IOS XML Infrastructure transport layer.

Note The **no** form of the **ixi application cme** command is not supported.

Examples The following example shows how to configure the Cisco Unified CME application to overwrite the Cisco IOS XML Infrastructure transport-level timeout with a 30-second response timeout and enable XML communication with the application.

```
Router(config)# ixi application cme
Router(conf-xml-app)# response timeout 30
Router(conf-xml-app)# no shutdown
```

Related Commands

Command	Description
ixi transport	Enters XML transport configuration mode.
no shutdown	Enables XML communication with the application.
response (XML application)	Sets a timeout for responding to the XML application and overwrites the IXI transport-level timeout.

ixi application mib

To enter XML application configuration mode, use the **ixi application mib** command in global configuration mode.

ixi application mib

Syntax Description

mib	XML application for which parameters will be configured. Valid value: **mib**.

Command Default No XML applications are configured.

Command Modes Global configuration mode

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines The Cisco IOS XML Infrastructure (IXI) simplifies the implementation and deployment of XML-based applicatiosn in Cisco IOS software. IXI applications can be clients and or servers where the parser and transport layers are separated from the application itself. This modularity provides scalability and enables future XML supports to be developed.

An eXtensible Markup Language (XML) application programming interface (API) supports Cisco IOS commands allowing you to specify certain parameters associated with the XML API.

Once you are in XML application configuration mode, you can use the following commands:

- **default**—XML application configuration parameters defaults.
- **exit**—Apply changes and exit from XML application configuration mode.
- **help**—Display of the interactive help system.
- **no**—Negate a command or set its defaults.
- **response**—Response parameters.
- **shutdown**—Stop the application.

Examples The following example shows how to enter XML application configuration mode, set the XML application timeout period to 30 seconds, format the response parameters to in human readable XML, and exit XML application configuration mode:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ixi application mib
Router(conf-xml-app)# response timeout 30
Router(conf-xml-app)# response formatted
Router(conf-xml-app)# exit
```

Related Commands

Command	Description
ixi transport http	Sets XML transport parameters.
response (XML application)	Sets XML application mode response parameters.

ixi transport http

To enter XML transport configuration mode, use the **ixi transport** command in global configuration mode.

ixi transport http

Syntax Description

http	Specifies the http transport protocol.

Command Default No XML transport is configured.

Command Modes Global configuration mode

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines The Cisco IOS XML Infrastructure (IXI) simplifies the implementation and deployment of XML-based applications in Cisco IOS software. IXI applications can be clients and or servers where the parser and transport layers are separated from the application itself. This modularity provides scalability and enables future XML supports to be developed. IXI allows applications to be written in a transport independent manner. The **ixi transport** command enters XML transport configuration mode where you can set transport configuration parameters.

Once you are in XML transport configuration mode, you can access the following commands:

- **default** *option*—XML transport configuration command defaults.
- **exit**—Apply changes and exit from XML application configuration mode.
- **help**—Display the interactive help system.
- **no**—Negate a command or set its defaults.
- **request**—Request handling parameters.
- **response size**—Response transport fragment size.
- **shutdown**—Stop the transport.

Examples The following example shows how to enter XML transport configuration mode, set the XML transport fragment size to 32 Kbytes, and exit XML transport configuration mode:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ixi transport http
Router(conf-xml-trans)# response size 32
Router(conf-xml-trans)# exit
```

Related Commands

Command	Description
ixi application mib	Sets XML application parameters.
request (XML transport)	Sets XML transport request handling parameters.
response size (XML transport)	Set the XML transport fragment size.

Cisco IOS Voice Commands: K

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Guide*.

keepalive retries

To set the number of keepalive retries from Skinny Client Control Protocol (SCCP) to Cisco Unified CallManager, use the **keepalive retries** command in SCCP Cisco CallManager configuration mode. To reset this number to the default value, use the **no** form of this command.

keepalive retries *number*

no keepalive retries

Syntax Description

number	Number of keepalive attempts. Range is 1 to 32. Default is 3.

Command Default

3 keepalive attempts

Command Modes

SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Use this command to control the number of keepalive retries before SCCP confirms that the Cisco Unified CallManager link is down. When SCCP confirms that the Cisco Unified CallManager link is down (if the number of keepalive messages sent without receiving an Ack reaches the keepalive retries value), Cisco Unified CallManager switchover is initiated.

Note The optimum setting for this command depends on the platform and your individual network characteristics. Adjust the keepalive retries to meet your needs.

Examples

The following example sets the number of times that a Cisco Unified CallManager retries before confirming that the link is down to seven:

```
Router(conf-sccp-ccm)# keepalive retries 7
```

Related Commands

Command	Description
keepalive timeout	Sets the length of time between keepalive messages from SCCP to Cisco Unified CallManager.
sccp ccm group	Creates a Cisco CallManger group and enters the SCCP Cisco CallManager configuration mode.

keepalive target

To identify Session Initiation Protocol (SIP) servers that will receive keepalive packets from the SIP gateway, use the **keepalive target** command in SIP user-agent configuration mode. To disable the **keepalive target** command behavior, use the **no** form of this command.

keepalive target {{**ipv4:***address* | **ipv6:***address*}[**:***port*] | **dns:***hostname*} | [**tcp** [**tls**]] | [**udp**] | [**secondary**]

no keepalive target [**secondary**]

Syntax Description

ipv4:*address*	IP address (in IP version 4 format) of the primary or secondary SIP server to monitor.
ipv6:*address*	IPv6 address of the primary or secondary SIP server to monitor.
:*port*	(Optional) SIP port number. Default SIP port number is 5060.
dns:*hostname*	DNS hostname of the primary or secondary SIP server to monitor.
tcp	(Optional) Sends keepalive packets over TCP.
tls	(Optional) Sends keepalive packets over Transport Layer Security (TLS).
udp	(Optional) Sends keepalive packets over User Datagram Protocol (UDP).
secondary	(Optional) Associates the IP version 4 address or the domain name system (DNS) hostname to a secondary SIP server to monitor.

Command Default

No keepalives are sent by default from SIP gateway to SIP gateway. The SIP port number is 5060 by default.

Command Modes

SIP user-agent configuration (config-sip-ua)

Command History

Release	Modification
12.4(6)T	This command was introduced.
12.4(22)T	Support for IPv6 was added.

Usage Guidelines

The primary or secondary SIP server addresses are in the following forms: dns:example.sip.com or ipv4:172.16.0.10.

Examples

The following example sets the primary SIP server address and defaults to the UDP transport:

```
sip-ua
 keepalive target ipv4:172.16.0.10
```

The following example sets the primary SIP server address and the transport to UDP:

```
sip-ua
 keepalive target ipv4:172.16.0.10 udp
```

The following example sets both the primary and secondary SIP server address and the transport to UDP:

```
sip-ua
 keepalive target ipv4:172.16.0.10 udp
 keepalive target ipv4:172.16.0.20 udp secondary
```

The following example sets both the primary and secondary SIP server addresses and defaults to the UDP transport:

```
sip-ua
 keepalive target ipv4:172.16.0.10
 keepalive target ipv4:172.16.0.20 secondary
```

The following example sets the primary SIP server address and the transport to TCP:

```
sip-ua
 keepalive target ipv4:172.16.0.10 tcp
```

The following example sets both the primary and secondary SIP server addresses and the transport to TCP:

```
sip-ua
 keepalive target ipv4:172.16.0.10 tcp
 keepalive target ipv4:172.16.0.20 tcp secondary
```

The following example sets the primary SIP server address and the transport to TCP and sets security to TLS mode:

```
sip-ua
 keepalive target ipv4:172.16.0.10 tcp tls
```

The following example sets both the primary and secondary SIP server addresses and the transport to TCP and sets security to the TLS mode:

```
sip-ua
 keepalive target ipv4:172.16.0.10 tcp tls
 keepalive target ipv4:172.16.0.20 tcp tls secondary
```

Related Commands

Command	Description
busyout monitor keepalive	Selects a voice port or ports to be busied out in cases of a keepalive failure.
keepalive trigger	Sets the trigger count to the number of Options message requests that must consecutively receive responses from the SIP servers in order to unbusy the voice ports when in the down state.
retry keepalive	Sets the retry keepalive count for retransmission.
timers keepalive	Sets the timers keepalive interval between sending Options message requests when the SIP server is active or down.

keepalive timeout

To set the length of time between keepalive messages from Skinny Client Control Protocol (SCCP) to Cisco Unified CallManager, use the **keepalive timeout** command in SCCP Cisco CallManager configuration mode. To reset the length of time to the default value, use the **no** form of this command.

keepalive timeout *seconds*

no keepalive timeout

Syntax Description

seconds	Time between keepalive messages. Range is 1 to 180. Default is 30.

Command Default

30 seconds

Command Modes

SCCP Cisco CallManager configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Whenever SCCP sends the keepalive message to the Cisco Unified CallManager, it initiates this timer. Once the timeout occurs, it sends the next keepalive message unless the number of keepalive (messages without an Ack) reaches the number set by the **keepalive retries** command. As of now, the SCCP protocol uses the value provided by the Cisco Unified CallManager.

Note The optimum setting for this command depends on the platform and your individual network characteristics. Adjust the keepalive timeout value to meet your needs.

Examples

The following example sets the length of time between Cisco Unified CallManager keepalive messages to 120 seconds (2 minutes):

```
Router(config-sccp-ccm)# keepalive timeout 120
```

Related Commands

Command	Description
keepalive retries	Sets the number of keepalive retries from SCCP to Cisco Unified CallManager.
sccp ccm group	Creates a Cisco CallManger group and enters SCCP Cisco CallManager configuration mode.

keepalive trigger

The trigger interval (in seconds) represent the number of Options message requests that must consecutively receive responses from the SIP servers when in the down state in order to unbusy the voice ports, use the **keepalive trigger** command in SIP UA configuration mode. To restore to the default value of 3 seconds, use the **no** form of this command.

keepalive trigger *seconds*

no keepalive trigger *seconds*

Syntax Description

seconds	Keepalive trigger value in the range from 1 to 10 seconds. The default value is 3 seconds.

Command Default

The default value for the keepalive trigger is 3 seconds.

Command Modes

SIP UA configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

Sets the time interval (in seconds) to represent the number of Options message requests that must be consecutively receive responses from the SIP servers in order to unbusy the voice ports when in the down state. The keepalive trigger interval is measured in seconds. The default is 3 seconds.

Examples

The following example sets a time interval (in seconds) after the number of Options message requests that must consecutively receive responses from the SIP servers in order to unbusy the voice ports when in the down state. The trigger interval is set to 8 seconds in the following example:

```
sip-ua
 keepalive trigger 8
```

Related Commands

Command	Description
busyout monitor keepalive	Selects a voice port or ports to be busied out in cases of a keepalive failure.
keepalive target	Identifies a SIP server that will receive keepalive packets from the SIP gateway.
retry keepalive	Sets the retry keepalive interval for retransmission.
timers keepalive	Sets the time interval between sending Options message requests when the SIP server is active or down.

Cisco IOS Voice Commands: L

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the command reference master index or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Guide*.

link (RLM)

To enable a Redundant Link Manager (RLM) link, use the **link** command in RLM configuration mode. To disable this function, use the **no** form of this command.

link {**hostname** *name* | **address** *ip-address*} **source** *loopback-source* **weight** *factor*

no link {**hostname** *name* | **address** *ip-address*} **source** *loopback-source* **weight** *factor*

Syntax Description

hostname ***name***	RLM host name. If host name is used, RLM looks up the DNS server periodically for the host name configured until lookup is successful or the configuration is removed.
address *ip-address*	IP address of the link.
source *loopback-source*	Loopback interface source. We recommend that you use the loopback interface as the source, so that it is independent of the hardware condition. Also, the source interface should be different in every link to avoid falling back to the same routing path. If you intend to use the same routing path for the failover, a single link is sufficient to implement it.
weight *factor*	An arbitrary number that sets link preference. The higher the weighting factor number assigned, the higher priority it gets to become the active link. If all entries have the same weighting factor assigned, all links are treated equally. There is no preference among servers according to the assumption that only one server accepts the connection requests at any given time. Otherwise, preferences are extended across all servers.

Command Default

Disabled

Command Modes

RLM configuration

Command History

Release	Modification
11.3(7)	This command was introduced.

Usage Guidelines

This command is a preference-weighted multiple entries command. Within the same server, the link preference is specified in weighting.

Examples

The following example specifies the RLM group (network access server), device name, and link addresses and their weighting preferences:

```
rlm group 1
 server r1-server
  link address 10.1.4.1 source Loopback1 weight 4
  link address 10.1.4.2 source Loopback2 weight 3
```

listen-port (SIP)

To manually change the defined Session Initiation Protocol (SIP) listen port for UDP/TCP/TLS calls, use the **listen-port** command in SIP configuration mode. To reset the UDP/TCP/TLS port to the default value, use the **no** form of this command.

listen-port {**secure** | **non-secure**} *port-number*

no listen-port non-secure

Syntax Description

secure	Specifies the TLS port value.
non-secure	Specified the TCP/UDP port value.
port-number	Port number. Range: 1 to 65535. The default for UDP/TCP is 5060; the default for TLS is 5061.

Command Default

The port number is set to the default value based on the transport layer protocol used.

Command Modes

SIP configuration mode (config-serv-sip)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

The **listen-port** command is configurable on both incoming and outgoing SIP calls, and is applicable for both TDM-IP gateway and Cisco Unified Border Element (Cisco Unified BE) (previously known as IPIPGW). The Cisco UBE gateway port number defined in global configuration will be used for both In leg and Out leg. Before configuring the SIP listen port for TCP/UDP/TLS, SIP service should be shut down using the **shutdown** in SIP configuration mode. If SIP service is not shut down, the **listen-port** command flashes an error message saying “shutdown SIP service before changing SIP listen port”. This ensures that there are no active calls when the SIP listen port is changed. The **non-secure** keyword is supported on non-Crypto images, and both the **secure** and **non-secure** keywords are supported on Crypto images.

The following restrictions apply:

- Configuring the SIP listen port on a dial-peer basis is not supported.
- Configuring same listening port for both UDP/TCP and TLS is not allowed.
- Configuring the SIP listen port to a port that is already in use is not supported and results in an error message.
- Changing SIP listen port when Transport services (TCP/UDP/TLS) are shut down, will not close or reopen the port. The result is that only the new port number is updated. The new port will be bound when Transport services (TCP/UDP/TLS) is enabled.

Examples

The following example shows the port number on a Crypto image being changed to port 2000:

```
Router(config-serv-sip)# listen-port secure 2000
```

The following example shows the port number being reset to the TLS default port:

```
Router(config-serv-sip)# no listen-port
```

Related Commands

Command	Description
shutdown	Disables the port.

lmr duplex half

To have the voice path for a voice port operate in half duplex mode, use the **lmr duplex half** command in voice-port configuration mode. To return to the default, use the **no** form of this command.

lmr duplex half

no lmr duplex half

Syntax Description This command has no arguments or keywords.

Command Default Full duplex mode

Command Modes Voice-port configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines When a radio system is receiving voice traffic from the radio, operating the voice path in half duplex mode prevents the speaker from being interrupted and prevents the voice stream from being fed back to itself.

Examples In the following example, the voice path for voice port 1/0/0 on a Cisco 3700 series router is set to operate in half duplex mode:

```
voice-port 1/0/0
 lmr duplex half
```

lmr e-lead

To define the use of the E-lead in signaling between the ear and mouth (E&M) voice port on the router and the attached Land Mobile Radio (LMR) device, use the **lmr e-lead** command in voice-port configuration mode. To return to the default use of the E-lead, use the **no** form of this command.

lmr e-lead {**inactive** | **seize** | **voice**}

no lmr e-lead {**inactive** | **seize** | **voice**}

Syntax Description

inactive	Specifies that the router never sends a seize signal on the E-lead to the LMR device. The router sends voice packets to LMR devices.
seize	Specifies that for PLAR and multicast connections, the router sends a seize signal on the E-lead when the LMR port is connected and removes the seize signal from the E-lead when the LMR port is not involved in a VoIP connection. This is the default. Specifies that for connection trunk connections, the router does not send a seize signal when the LMR port is connected. Instead, if the trunk connection is up, the M-lead signal from the far-end router is passed through as the E-lead on the near-end router. When the M-lead is dropped on the far-end router and the trunk connection is still up, the E-lead is dropped on the near-end router.
voice	Specifies that the router sends a seize signal on the E-lead only when it receives voice packets from the network. When no packets are detected on the network, the seize signal is removed from the E-lead.

Command Default

seize

Command Modes

Voice-port configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

The **lmr e-lead** command has an effect on an ear and mouth (E&M) voice port only if the signal type for that port is LMR. The **lmr e-lead** command is effective only if the attached LMR device operates under E-lead control. Use the **lmr e-lead** command to configure the voice port when using private line, automatic ringdown (PLAR) connections. The E-lead connects to the Push To Talk (PTT) of the LMR system.

Examples

In the following example, packet transmission from the E&M voice port on a Cisco 3745 to an attached LMR radio system is disabled:

```
lmr e-lead inactive
```

Related Commands

Command	Description
lmr m-lead	Defines the use of the M-lead in signaling between the E&M voice port on the router and the attached LMR device.

lmr ip-vad

To configure the Land Mobile Radio (LMR) digital signal processor (DSP) on a Cisco 2800 series integrated services router to report a voice packet arrival event only if the packet contains voice energy, use the **lmr ip-vad** command in voice-port configuration mode. To disable this feature, use the **no** form of this command.

lmr ip-vad

no lmr ip-vad

Syntax Description

This command has no arguments or keywords.

Command Default

Any voice packet received from the IP network side triggers the DSP to report a voice packet arrival event to the Cisco IOS software.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.4(6)T	This command was introduced.

Usage Guidelines

The **lmr ip-vad** command applies to a voice interface card (VIC) in a Cisco 2800 series integrated services router if the VIC is one of the following types of ear and mouth (E&M) interfaces:

- VIC2-2E/M with signal type LMR
- ds0-group created with signal type e&m-lmr under an E1 or T1 controller

The **lmr ip-vad** command configures the LMR DSP to report voice activity detection (VAD) status change events (rather than voice packet arrival events) for a supported voice interface in a Cisco 2800 series integrated services router.

Examples

The following example shows a sequence of commands that can be used to configure a voice port so that a voice packet arrival event is reported to the Cisco IOS software on the router only if the packet contains voice energy.

```
Router(config)# voice-port 1/1/0
Router(config-voiceport)# signal lmr
Router(config-voiceport)# lmr ip-vad
```

Related Commands

Command	Description
signal	Configures the type of signaling to be used for a voice port.
voice-port	Enters voice-port configuration mode.

lmr led-on

To use the ear and mouth (E&M) LED to indicate the E-lead and M-lead status, use the **lmr led-on** command in voice-port configuration mode. To return to the default use of the E&M LED, use the **no** form of this command.

lmr led-on

no lmr led-on

Syntax Description

This command has no arguments or keywords.

Command Default

The E&M LED indicates voice port activity only.

Command Modes

Voice-port configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

The **lmr e-lead** command is available on an E&M voice port only if the signal type for that port is Land Mobile Radio (LMR). This command enables the use of the E&M LED to indicate the E-lead and M-lead status as follows:

- Red—E-lead active
- Green—M-lead active
- Yellow—Both E-lead and M-lead active

The default behavior of the E&M LED is to light up when there is activity on the voice port and to turn off when there is no activity.

Examples

The following example specifies that the E&M LED is used to indicate the E-lead and M-lead status:

```
voice-port 1/0/0
 lmr led-on
```

lmr m-lead

To define the use of the M-lead in signaling between the ear and mouth (E&M) voice port on the router and the attached Land Mobile Radio (LMR) device, use the **lmr m-lead** command in voice-port configuration mode. To return to the default use of the M-lead, use the **no** form of this command.

lmr m-lead {**inactive** | **audio-gate-in** | **dialin**}

no lmr m-lead {**inactive** | **audio-gate-in** | **dialin**}

Syntax Description

inactive	The router ignores signals sent by voice on the M-lead. The flow of voice packets is determined by voice activity detection (VAD). The router sends voice received from the LMR device. This is the default.
audio-gate-in	The router generates VoIP packets when a seize signal is detected on the M-lead. The router stops generating VoIP packets when the seize signal is removed from the M-lead.
dialin	When the LMR device is not involved in a VoIP connection, the first seize signal detected on the M-lead triggers the router to set up a VoIP connection. Once the connection is made, the router behaves as in the **audio-gate-in** option.

Command Default

inactive

Command Modes

Voice-port configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

The **lmr m-lead** command has an effect on an ear and mouth (E&M) voice port only if the signal type for that port is LMR. The **lmr e-lead** command is effective only if the attached LMR device operates under M-lead control. The M-lead corresponds to the Carrier Operated Relay (COR) of the LMR system, which indicates receive activity on the LMR system.

Examples

In the following example, an LMR radio system attached to the E&M voice port on a Cisco 3745 is allowed to transmit audio by first raising the E-lead, then transmitting:

```
lmr m-lead dialin
```

Related Commands

Command	Description
lmr e-lead	Defines the use of the E-lead in signaling between the E&M voice port on the router and the attached LMR device.

load-balance

To configure load balancing, use the **load-balance** command in gatekeeper configuration mode. To disable load balancing, use the **no** form of this command.

load-balance [**endpoints** *max-endpoints*] [**calls** *max-calls*] [**cpu** *max-%cpu*] [**memory** *max-%mem-used*]

no load-balance [**endpoints** *max-endpoints*] [**calls** *max-calls*] [**cpu** *max-%cpu*] [**memory** *max-%mem-used*]

Syntax Description

endpoints *max-endpoints*	(Optional) Maximum number of endpoints.
calls *max-calls*	(Optional) Maximum number of calls.
cpu *max-%cpu*	(Optional) Maximum percentage of CPU utilization.
memory *max-%mem-used*	(Optional) Maximum percentage of memory used.

Command Default

Load balancing is performed by the gatekeeper.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.1(2)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XB1	This command was implemented on the Cisco AS5850.

Usage Guidelines

Load balancing occurs when one gatekeeper reaches the default or the configured load level. Upon reaching the load-level threshold, the gatekeeper begins sending alternate gatekeeper information in Registration, Admission, and Status (RAS) messages, and the gateways then attempt to migrate from the loaded gatekeeper to its least busy alternate. The move is permanent; endpoints are not actively moved back to the original gatekeeper if it stabilizes. However, they may return to that gatekeeper if the new gatekeeper reaches a load threshold and transfers them again. The gatekeepers share the load, but they may not have equal shares. The process of load balancing allows for more effective zone management.

Examples

The following example configures load balancing:

```
load-balance endpoints 200 calls 100 cpu 75 memory 80
```

Related Commands

Command	Description
zone cluster local	Configures alternate gatekeepers for each zone.

local

To define the local domain, including the IP address and port that the border element (BE) should use for interacting with remote BEs, use the **local** command in Annex G configuration mode. To reset to the default, use the **no** form of this command.

local ip *ip-address* [**port** *local-port*]

no local ip

Syntax Description

ip *ip-address*	IP address of the local border element.
port *local-port*	(Optional) Port number of the local border element, which is used for exchanging Annex G messages. Default is 2099.

Command Default Port number: 2099

Command Modes Annex G configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 in this release.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines The local IP address can be a virtual Hot Standby Routing Protocol (HSRP) address for high reliability and availability. You can configure multiple gatekeepers and BEs identically and use HSRP to designate a primary BE and other standby BEs. If the primary BE is down, a standby BE operates in its place.

Examples The following example sets the IP address and port that the BE should use. (Note that this example uses a nonstandard port number. If you do not want to use a nonstandard port number, use the default value of 2099.)

```
Router(config)# call-router h323-annexg be20
Router(config-annexg)# local ip 121.90.10.80 port 2010
```

Related Commands

Command	Description
call-router	Enables the Annex G border element configuration commands.
show call-router status	Displays the Annex G BE status.

localhost

To globally configure Cisco IOS voice gateways, Cisco Unified Border Elements (Cisco UBEs), or Cisco Unified Communications Manager Express (Cisco Unified CME) to substitute a Domain Name System (DNS) hostname or domain as the localhost name in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers in outgoing messages, use the **localhost** command in voice service SIP configuration mode. To remove a DNS localhost name and disable substitution for the physical IP address, use the **no** form of this command.

localhost dns:[*hostname.*]*domain* [**preferred**]

no localhost

Syntax Description

dns:[*hostname.*]*domain*	Alphanumeric value representing the DNS domain (consisting of the domain name with or without a specific hostname) in place of the physical IP address that is used in the host portion of the From, Call-ID, and Remote-Party-ID headers in outgoing messages. This value can be the hostname and the domain separated by a period (**dns:***hostname.domain*) or just the domain name (**dns:***domain*). In both case, the **dns:** delimiter must be included as the first four characters.
preferred	(Optional) Designates the specified DNS hostname as preferred.

Command Default

The physical IP address of the outgoing dial peer is sent in the host portion of the From, Call-ID, and Remote-Party-ID headers in outgoing messages.

Command Modes

Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(2)T	This command was introduced.
15.0(1)XA	This command was modified. The **preferred** keyword was added to specify the preferred localhost if multiple registrars are configured on a SIP trunk.
IOS Release XE 2.5	This command was integrated into Cisco IOS XE Release 2.5.
15.1(1)T	This command was integrated into Cisco IOS Release 5.1(1)T.

Usage Guidelines

Use the **localhost** command in voice service SIP configuration mode to globally configure a DNS localhost name to be used in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages on Cisco IOS voice gateways, Cisco UBEs, or Cisco Unified CME. When multiple registrars are configured you can then use the **localhost preferred** command to specify which host is preferred.

To override the global configuration and specify DNS localhost name substitution settings for a specific dial peer, use the **voice-class sip localhost** command in dial peer voice configuration mode. To remove a globally configured DNS localhost name and use the physical IP address in the From, Call-ID, and Remote-Party-ID headers in outgoing messages, use the **no localhost** command.

Examples

The following example shows how to globally configure a preferred DNS localhost name using only the domain for use in place of the physical IP address in outgoing messages on all dial peers:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# localhost dns:example.com preferred
```

The following example shows how to globally configure a preferred DNS localhost name by specifying the hostname along with the domain for use in place of the physical IP address in outgoing messages on all dial peers:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# localhost dns:MyHostname.example.com preferred
```

Related Commands

Command	Description
authentication (dial peer)	Enables SIP digest authentication on an individual dial peer.
authentication (SIP UA)	Enables SIP digest authentication.
credentials (SIP UA)	Configures a Cisco UBE to send a SIP registration message when in the UP state.
registrar	Enables Cisco IOS SIP gateways to register E.164 numbers on behalf of FXS, EFXS, and SCCP phones with an external SIP proxy or SIP registrar.
voice-class sip localhost	Configures settings for substituting a DNS localhost name in place of the physical IP address in the From, Call-ID, and Remote-Party-ID headers of outgoing messages on an individual dial peer, overriding the global setting.

loopback (controller)

To set the loopback method for testing a T1 or E1 interface, use the **loopback** command in controller configuration mode. To reset to the default, use the **no** form of this command.

loopback {**diagnostic** | **local** {**payload** | **line**} | **remote** {**v54 channel-group** *channel-number* | **iboc** | **esf** {**payload** | **line**}}}

no loopback

Syntax Description

diagnostic	Loops the outgoing transmit signal back to the receive signal.
local	Places the interface into local loopback mode.
payload	Places the interface into external loopback mode at the payload level.
line	Places the interface into external loopback mode at the line level.
remote	Keeps the local end of the connection in remote loopback mode.
v54 channel-group	Activates a V.54 channel-group loopback at the remote end. Available for both T1 and E1 facilities.
channel-number	Channel number for the V.54 channel-group loopback. Range is from 0 to 1.
iboc	Sends an inband bit-oriented code to the far end to cause it to go into line loopback.
esf	T1 or E1 frame type of Extended Super Frame (ESF). Only available under T1 or E1 controllers when ESF is configured on the controller. The following are keywords: • **payload**—Activates remote payload loopback by sending Facility Data Link (FDL) code. FDL is a 4-kbps out-of-band signaling channel in ESF. • **line**—Activates remote line loopback by sending FDL code.

Command Default No loopback is configured.

Command Modes Controller configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced as a controller configuration command for the Cisco MC3810.
12.0(5)T and 12.0(5)XK	The command was introduced as an ATM interface configuration command for the Cisco 2600 series and Cisco 3600 series.
12.0(5)XE	The command was introduced as an ATM interface configuration command for the Cisco 7200 series and Cisco 7500 series.
12.0(5)XK and 12.0(7)T	The command was introduced as a controller configuration command for the Cisco 2600 series and Cisco 3600 series.
12.1(1)T	The command was modified as a controller configuration command for the Cisco 2600 series.

Usage Guidelines

You can use a loopback test on lines to detect and distinguish equipment malfunctions caused either by the line and channel service unit/digital service unit (CSU/DSU) or by the interface. If correct data transmission is not possible when an interface is in loopback mode, the interface is the source of the problem.

Examples

The following example sets the diagnostic loopback method on controller T1 0/0:

```
controller t1 0/0
 loopback diagnostic
```

The following example sets the payload loopback method on controller E1 0/0:

```
controller e1 0/0
 loopback local payload
```

loop-detect

To enable loop detection for T1, use the **loop-detect** command in controller configuration mode. To cancel loop detection, use the **no** form of this command.

loop-detect

no loop-detect

Syntax Description

This command has no arguments or keywords.

Command Default

Loop detection is disabled.

Command Modes

Controller configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.

Usage Guidelines

This command applies to Voice over Frame Relay and Voice over ATM.

Examples

The following example configures loop detection for controller T1 0:

```
controller t1 0
 loop-detect
```

Related Commands

Command	Description
loopback (interface)	Diagnoses equipment malfunctions between an interface and a device.

loss-plan

To specify the analog-to-digital gain offset for an analog Foreign Exchange Office (FXO) or Foreign Exchange Station (FXS) voice port, use the **loss-plan** command in voice-port configuration mode. To reset to the default, use the **no** form of this command.

loss-plan {**plan1** | **plan2** | **plan3** | **plan4** | **plan5** | **plan6** | **plan7** | **plan8** | **plan9**}

no loss-plan

Syntax Description

plan1	FXO: A-D gain = 0 dB, D-A gain = 0 dB. FXS: A-D gain = –3 dB, D-A gain = –3 dB.
plan2	FXO: A-D gain = 3 dB, D-A gain = 0 dB. FXS: A-D gain = 0 dB, D-A gain = –3 dB.
plan3	FXO: A-D gain = –3 dB, D-A gain = 0 dB. FXS: Not applicable.
plan4	FXO: A-D gain = –3 dB, D-A gain = –3 dB. FXS: Not applicable.
plan5	FXO: Not applicable. FXS: A-D gain = –3 dB, D-A gain = –10 dB.
plan6	FXO: Not applicable. FXS: A-D gain = 0 dB, D-A gain = –7 dB.
plan7	FXO: A-D gain = 7 dB, D-A gain = 0 dB. FXS: A-D gain = 0 dB, D-A gain = –6 dB.
plan8	FXO: A-D gain = 5 dB, D-A gain = –2 dB. FXS: Not applicable.
plan9	FXO: A-D gain = 6 dB, D-A gain = 0 dB. FXS: Not applicable.

Command Default

FXO: A-D gain = 0 dB, D-A gain = 0 dB (loss plan 1)
FXS: A-D gain = –3 dB, D-A gain = –3 dB (loss plan 1)

Command Modes

Voice-port configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810.
12.0(7)XK	The following additional signal level choices were added: plan 3, plan 4, plan 8, and plan 9.
12.1(2)T	This command was integrated into Cisco IOS Release 12.1(2)T.

Usage Guidelines

This command sets the analog signal level difference (offset) between the analog voice port and the digital signal processor (DSP). Each loss plan specifies a level offset in both directions—from the analog voice port to the DSP (A-D) and from the DSP to the analog voice port (D-A).

Use this command to obtain the required levels of analog voice signals to and from the DSP.

Examples

The following example configures FXO voice port 1/6 for a –3 dB offset from the voice port to the DSP and for a 0 dB offset from the DSP to the voice port:

```
voice-port 1/6
 loss-plan plan3
```

The following example configures FXS voice port 1/1 for a 0 dB offset from the voice port to the DSP and for a –7 dB offset from the DSP to the voice port:

```
voice-port 1/1
 loss-plan plan6
```

Related Commands

Command	Description
impedance	Specifies the terminating impedance of a voice port interface.
input gain	Specifies the gain applied by a voice port to the input signal from the PBX or other customer premises equipment.
output attenuation	Specifies the attenuation applied by a voice port to the output signal toward the PBX or other customer premises equipment.

lrq e164 early-lookup

To start the E.164 registered endpoint matching before via-zone routing is processed in the location request (LRQ) routing process, use the **lrq e164 early-lookup** command in gatekeeper configuration mode. To return to the default behavior, use the **no** form of this command.

lrq e164 early-lookup

no lrq e164 early-lookup

Syntax Description This command has no arguments or keywords.

Command Default The E.164 endpoint matching is done at the last stage of LRQ routing.

Command Modes Gatekeeper configuration (config-gk)

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines The default gatekeeper algorithm for IP-to-IP gateway selection is based on the via-zone prefix and tech-prefix match. Use the **lrq e164 early-lookup** command to start the E.164 matching process before via-zone routing to block nonregistered endpoints.

Examples The following example causes the gatekeeper to notify the sending gatekeeper on receipt of an LRQ message that no terminating endpoints are available:

```
Router(config)# gatekeeper
Router(config-gk)# lrq e164 early-lookup
```

lrq forward-queries

To enable a gatekeeper to forward location request (LRQ) messages that contain E.164 addresses that match zone prefixes controlled by remote gatekeepers, use the **lrq forward-queries** command in gatekeeper configuration mode. To disable this function, use the **no** form of this command.

lrq forward-queries

no lrq forward-queries

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Gatekeeper configuration

Command History

Release	Modification
12.0(3)T	This command was introduced on the following platforms: Cisco 2500 series, Cisco 3600 series, and Cisco MC3810.

Usage Guidelines LRQ forwarding is dependent on a Cisco nonstandard field that first appeared in Cisco IOS Release 12.0(3)T. This means that any LRQ message received from a non-Cisco gatekeeper or any gatekeeper running a Cisco IOS software image prior to Cisco IOS Release 12.0(3)T is not forwarded.

The routing of E.164-addressed calls is dependent on the configuration of zone prefix tables (for example, area code definitions) on each gatekeeper. Each gatekeeper is configured with a list of prefixes controlled by itself and by other remote gatekeepers. Calls are routed to the zone that manages the matching prefix. Thus, in the absence of a directory service for such prefix tables, you, the network administrator, may have to define extensive lists of prefixes on all the gatekeepers in your administrative domain.

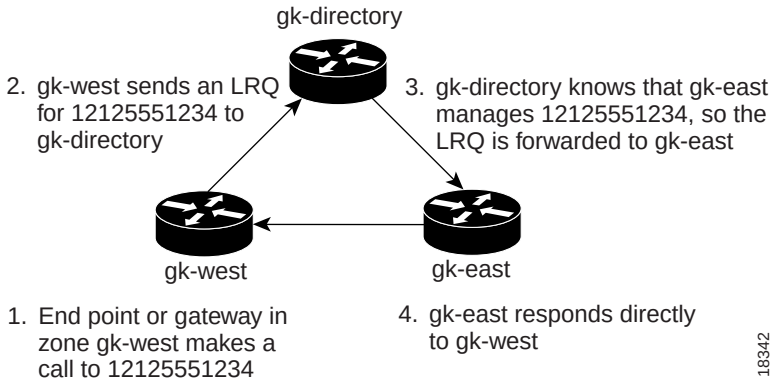
To simplify this task, you can select one of your gatekeepers as the "directory" gatekeeper and configure that gatekeeper with the complete list of prefixes and the **lrq forward-queries** command. You can then simply configure all the other gatekeepers with their own prefixes and the wildcard prefix "*" for your directory gatekeeper.

This command affects only the forwarding of LRQ messages for E.164 addresses. LRQ messages for H.323-ID addresses are never forwarded.

Examples

The following example selects one gatekeeper as the directory gatekeeper. See Figure 6.

Figure 6 Example Scenario with Directory Gatekeeper and Two Remote Gatekeepers



Configuration on gk-directory

On the directory gatekeeper called gk-directory, identify all the prefixes for all the gatekeepers in your administrative domain:

```
zone local gk-directory cisco.com
zone remote gk-west cisco.com 172.16.1.1
zone remote gk-east cisco.com 172.16.2.1

zone prefix gk-west 1408.......
zone prefix gk-west 1415.......
zone prefix gk-west 1213.......
zone prefix gk-west 1650.......

zone prefix gk-east 1212.......
zone prefix gk-east 1617.......

lrq forward-queries
```

Configuration on gk-west

On the gatekeeper called gk-west, configure all the locally managed prefixes for that gatekeeper:

```
zone local gk-west cisco.com
zone remote gk-directory cisco.com 172.16.2.3

zone prefix gk-west 1408.......
zone prefix gk-west 1415.......
zone prefix gk-west 1213.......
zone prefix gk-west 1650.......
zone prefix gk-directory *
```

Configuration on gk-east

On the gatekeeper called gk-east, configure all the locally managed prefixes for that gatekeeper:

```
zone local gk-east cisco.com
zone remote gk-directory cisco.com 172.16.2.3

zone prefix gk-east 1212.......
zone prefix gk-east 1617.......
zone prefix gk-directory *
```

When an endpoint or gateway in zone gk-west makes a call to 12125551234, gk-west sends an LRQ message for that E.164 address to gk-directory, which forwards the message to gk-east. Gatekeeper gk-east responds directly to gk-west.

Related Commands

Command	Description
lrq reject-unknown-prefix	Enables the gatekeeper to reject all LRQ messages for zone prefixes that are not configured.

lrq lrj immediate-advance

To enable the Cisco IOS gatekeeper to immediately send a sequential location request (LRQ) message to the next zone after it receives a location reject (LRJ) message from a gatekeeper in the current zone, use the **lrq lrj immediate-advance** command in gatekeeper configuration mode. To disable this function, use the **no** form of this command.

lrq lrj immediate-advance

no lrq lrj immediate-advance

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(4)T	This command was introduced. This command does not support the Cisco AS5300, Cisco AS5350, and Cisco AS5400 series in this release.

Usage Guidelines

In a network in which LRQ messages are forwarded through multiple gatekeepers along a single path, a single LRQ message sent from a gatekeeper could solicit multiple LRJ and location confirmation (LCF) responses. If an LRJ response is received first, a potentially unnecessary LRQ message could be sent to the next zone, increasing traffic.

To avoid this problem, perform the following:

- Configure the zone prefix to send sequential LRQ messages rather than to use the **blast** option, using the **zone prefix** command.
- Configure the sequential timer on each gatekeeper along the path, using the **timer lrq seq delay** command.

Examples

The following example enables the gatekeeper to immediately send a sequential LRQ message to the next zone after it receives an LRJ message from a gatekeeper in the current zone.

```
lrq lrj immediate-advance
```

Related Commands

Command	Description
timer lrq seq delay	Defines the time interval between successive sequential LRQ messages.
timer lrq window	Defines the time window during which the gatekeeper collects responses to one or more outstanding LRQ messages.
zone prefix	Adds a prefix to the gatekeeper zone list.

lrq reject-resource-low

To configure a gatekeeper to notify a sending gatekeeper on receipt of a location request (LRQ) message that no terminating endpoints are available, use the **lrq reject-resource-low** command in gatekeeper configuration mode. To disable this function, use the **no** form of this command.

lrq reject-resource-low

no lrq reject-resource-low

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 2500 series, Cisco 2600 series, Cisco 3600 series, Cisco 3700 series, Cisco 7200 series, and Cisco 7400 series.

Examples

The following example causes the gatekeeper to notify the sending gatekeeper on receipt of an LRQ message that no terminating endpoints are available:

```
Router(config)# gatekeeper
Router(config-gk)# lrq reject-resource-low
```

lrq reject-unknown-circuit

To enable the gatekeeper to reject a location request (LRQ) message that contains an unknown destination circuit, use the **lrq reject-unknown-circuit** command in gatekeeper configuration mode. To disable the rejection, use the **no** form of this command.

lrq reject-unknown-circuit

no lrq reject-unknown-circuit

Syntax Description

This command has no keywords or arguments.

Command Default

Disabled

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

The gatekeeper checks the destination circuit field in each LRQ message. If the field contains a circuit unknown to the gatekeeper and this command is entered, the gatekeeper rejects the LRQ request. If this command is disabled, the gatekeeper tries to resolve the alias without considering the circuit.

Examples

The following example causes the gatekeeper to reject unknown carriers in an LRQ request:

```
Router(config)# gatekeeper
Router(config-gk)# lrq reject-unknown-circuit
```

Related Commands

Command	Description
endpoint circuit-id h323id	Assigns a circuit to a non-Cisco endpoint.
show gatekeeper endpoint circuits	Displays the information of all registered endpoints for a gatekeeper.

lrq reject-unknown-prefix

To enable the gatekeeper to reject all location request (LRQ) messages for zone prefixes that are not configured, use the **lrq reject-unknown-prefix** command in gatekeeper configuration mode. To reenable the gatekeeper to accept and process all incoming LRQ messages, use the **no** form of this command.

lrq reject-unknown-prefix

no lrq reject-unknown-prefix

Syntax Description

This command has no arguments or keywords.

Command Default

The gatekeeper accepts and processes all incoming LRQ messages.

Command Modes

Gatekeeper configuration

Command History

Release	Modification
11.3(6)NA2	This command was introduced on the Cisco 2500 series and Cisco 3600 series.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

Usage Guidelines

Use this command to configure the gatekeeper to reject any incoming LRQ messages for a destination E.164 address that does not match any of the configured zone prefixes.

Whether or not you use this command, the following is true when the E.164 address matches a zone prefix:

- If the matching zone prefix is local (that is, controlled by this gatekeeper), the LRQ message is serviced.
- If the matching zone prefix is remote (that is, controlled by some other gatekeeper), the LRQ message is rejected.

If you do not use this command and the target address does not match any known local or remote prefix, the default behavior is to attempt to service the call using one of the local zones. If this default behavior is not suitable for your site, use this command on your router to force the gatekeeper to reject such requests.

Examples

Consider the following gatekeeper configuration:

```
zone local gk408 cisco.com
zone local gk415 cisco.com
zone prefix gk408 1408.......
zone prefix gk415 1415.......
lrq reject-unknown-prefix
```

In this sample configuration, the gatekeeper is configured to manage two zones. One zone contains gateways with interfaces in the 408 area code, and the second zone contains gateways in the 415 area code. Then using the **zone prefix** command, the gatekeeper is configured with the appropriate prefixes so that calls to those area codes hop off in the optimal zone.

Now say some other zone has been erroneously configured to route calls to the 212 area code to this gatekeeper. When the LRQ message for a number in the 212 area code arrives at this gatekeeper, the gatekeeper fails to match the area code, and the message is rejected.

If this was your only site that had any gateways in it and you wanted your other sites to route all calls that require gateways to this gatekeeper, you can undo the **lrq reject-unknown-prefix command** by simply using the **no lrq reject-unknown-prefix command.**Now when the gatekeeper receives an LRQ message for the address 12125551234, it attempts to find an appropriate gateway in either one of the zones gk408 or gk415 to service the call.

Related Commands

Command	Description
lrq forward-queries	Enables a gatekeeper to forward LRQ messages that contain E.164 addresses that match zone prefixes controlled by remote gatekeepers.

lrq timeout blast window

To configure the timeout window for use when sending multiple location request (LRQ) messages (either sequentially or simultaneously), use the **lrq timeout blast window** command in gatekeeper configuration mode. To reset to the default, use the **no** form of this command.

lrq timeout blast window *seconds*

no lrq timeout blast window

Syntax Description

seconds	Duration of the window, in seconds. Range is from 1 to 10. Default is 6.

Command Default

6 seconds

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.1(2)T	This command was introduced on the following platforms: Cisco 2500 series, Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco MC3810.

Examples

The following example sets the window to 3 seconds:

```
lrq timeout blast window 3
```

Related Commands

Command	Description
gatekeeper gw-type-prefix	Sets the gatekeepers responsible for each technology prefix.
zone prefix	Adds a prefix to a gatekeeper's zone list.

lrq timeout seq delay

To configure the delay for use when sending location request (LRQ) messages sequentially, use the **lrq timeout seq delay** command in gatekeeper configuration mode. To reset to the default, use the **no** form of this command.

lrq timeout seq delay *value*

no lrq timeout seq delay

Syntax Description

value	Duration of the delay, in 100-millisecond units.Range is from 1 to 10. The default is 5 (500 ms or 0.5 seconds).

Command Default

Five 100-millisecond units (500 ms or 0.5 seconds)

Command Modes

Gatekeeper configuration

Command History

Release	Modification
12.1(2)T	This command was introduced on the following platforms: Cisco 2500 series, Cisco 2600 series, Cisco 3600 series, Cisco 7200 series, and Cisco MC3810.

Examples

The following example sets the window to 300 milliseconds:

```
lrq timeout seq delay 3
```

Related Commands

Command	Description
gatekeeper gw-type-prefix	Sets the gatekeepers responsible for each technology prefix.
zone prefix	Adds a prefix to a gatekeeper's zone list.

Cisco IOS Voice Commands: M

This chapter contains commands to configure and maintain Cisco IOS voice applications. The commands are presented in alphabetical order. Some commands required for configuring voice may be found in other Cisco IOS command references. Use the master index of commands or search online to find these commands.

For detailed information on how to configure these applications and features, refer to the *Cisco IOS Voice Configuration Library.*

map q850-cause

To play a customized tone to PSTN callers if a call disconnects with a specific Q.850 call-disconnect cause code and release source, use the **map q850-cause** command in voice-service configuration mode. To disable the code-to-tone mapping, use the **no** form of this command.

map q850-cause *code-id* **release-source** {**local** | **remote** | **all**} **tone** *tone-id*

no map q850-cause *code-id* **release-source** {**local** | **remote** | **all**} **tone** *tone-id*

Syntax Description

code-id	Q.850 call-disconnect cause code. Range: 1 to 15, 17 to 127 (16 is not allowed).
release-source	Source from which the cause code is generated. Choices are the following: • **local**—Originating gateway or gatekeeper • **remote**—Terminating gateway or gatekeeper • **all**—Any gateway or gatekeeper
tone *tone-id*	Tone to play for this cause code. Choices are the following: • **1**—Busy tone • **2**—Congestion tone • **3**—Special-information tone (a three-tone sequence at 950, 1400, and 1800 MHz) (not supported on IP phones)

Command Default

No mapping occurs.

Command Modes

Voice-service

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Use this command to cause a particular tone to play when a call disconnects for a particular reason.

The tone plays to callers only if the call-disconnect and wait-to-release timers are set to values greater than 0 by entering the **timeouts call-disconnect** and **timeouts wait-release** commands.

Examples

The following example maps Q.850 call-disconnect cause code 21 to tone 3 on the local gateway and to tone 2 on the remote gateway:

```
Router(config)# voice service pots
Router(conf-voi-serv)# map q850-cause 21 release-source local tone 3
Router(conf-voi-serv)# map q850-cause 21 release-source remote tone 2
```

Related Commands

Command	Description
progress_ind	Sets a specific PI in call setup, progress, or connect messages from an H.323 VoIP gateway.
q850-cause	Maps a Q.850 call-disconnect cause code to a different Q.850 call-disconnect cause code.
scenario-cause	Configures new Q.850 call-disconnect cause codes for use if an H.323 call fails.
timeouts call-disconnect	Configures the delay timeout before an FXO voice port disconnects an incoming call after disconnect tones are detected.
timeouts wait-release	Configures the delay timeout before the system starts the process for releasing voice ports.

map resp-code

To globally configure a Cisco Unified Border Element (Cisco UBE) to map specific received Session Initiation Protocol (SIP) provisional response messages to a different SIP provisional response message on the outgoing SIP dial peer, use the **map resp-code** command in voice service SIP configuration mode. To disable mapping of received SIP provisional response messages, use the **no** form of this command.

map resp-code 181 to 183

no map resp-code 181

Syntax Description

181	The code representing the specific incoming SIP provisional response messages to be mapped and replaced.
to	The designator for specifying that the specified incoming SIP provisional response message should be mapped to and replaced with a different SIP provisional response message on the outgoing SIP dial peer.
183	The code representing the specific SIP provisional response message on the outgoing dial peer to which incoming SIP message responses should be mapped.

Command Default

Incoming SIP provisional response messages are passed, as is to the outgoing SIP leg.

Command Modes

Voice service SIP configuration (conf-serv-sip)

Command History

Release	Modification
15.0(1)XA	This command was introduced.
15.1(1)T	This command was integrated into Cisco IOS Release 5.1(1)T.

Usage Guidelines

Use the **map resp-code** command in voice service SIP configuration mode to globally enable a Cisco UBE to map incoming SIP 181 provisional response messages to SIP 183 provisional response messages on the outgoing SIP dial peer.

Note If the **block** command is configured for incoming SIP 181 messages, either globally or at the dial-peer level, the messages may be dropped before they can be passed or mapped to a different message—even when the **map resp-code** command is enabled. To globally configure whether and when incoming SIP 181 messages are dropped, use the **block** command in voice service SIP configuration mode (or use the **voice-class sip block** command in dial peer voice configuration mode to configure drop settings on individual dial peers).

To configure mapping of SIP provisional response messages for an individual dial peer on a Cisco UBE, use the **voice-class sip map resp-code** command in dial peer voice configuration mode. To disable mapping of SIP 181 message globally on a Cisco UBE, use the **no map resp-code** command in voice service SIP configuration mode.

As an example, to enable interworking of SIP endpoints that do not support the handling of SIP 181 provisional response messages, you could use the **block** command to configure a Cisco UBE to drop SIP 181 provisional response messages received on the SIP trunk or you can use the **map resp-code** command to configure the Cisco UBE to map the incoming messages to and send out, instead, SIP 183 provisional response messages to the SIP line in Cisco Unified Communications Manager Express (Cisco Unified CME).

Note This command is supported only for SIP-to-SIP calls and will have no effect on H.323-to-SIP or time-division multiplexing (TDM)-to-SIP calls.

Examples

The following example shows how to configure mapping of incoming SIP 181 provisional response messages on the Cisco UBE to SIP 183 provisional response messages on the outbound dial peer:

```
Router> enable
Router# configure terminal
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# map resp-code 181 to 183
```

Related Commands

Command	Description
block	Configures global settings for dropping specific SIP provisional response messages on a Cisco IOS voice gateway or Cisco UBE.
voice-class sip block	Configures an individual dial peer on a Cisco IOS voice gateway or Cisco UBE to drop specified SIP provisional response messages.
voice-class sip map resp-code	Configures a specific dial peer on a Cisco UBE to map specific incoming SIP provisional response messages to a different SIP response message.

max1 lookup

To enable Domain Name System (DNS) lookup for a new call-agent address when the suspicion threshold value is reached, use the **max1 lookup** command in MGCP profile configuration mode. To disable lookup, use the **no** form of this command.

max1 lookup

no max1 lookup

Syntax Description This command has no arguments or keywords.

Command Default Lookup is enabled.

Command Modes MGCP profile configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines This command is used when configuring values for a Media Gateway Control Protocol (MGCP) profile.

Call-agent redundancy can be provided when call agents are identified by DNS name rather than by IP address in the **call-agent** command, because each DNS name can have more than one IP address associated with it.

When the active call agent does not respond to a message from the media gateway, the gateway tests to determine whether the call agent is out of service. The gateway retransmits the message to the call agent for the number of times specified in the **max1 retries** command; this is known as the suspicion threshold. If there is no response and the **max1 lookup** command is enabled, the gateway examines the DNS lookup table to find the IP address of another call agent. If a second call agent is listed, the gateway retransmits the message to the second call agent until a response is received or the number of retries specified in the **max1 retries** command is reached.

This process is repeated for each IP address in the DNS table until the final address is reached. For the final address, the number of retries is specified by the **max2 retries** command; this number is known as the disconnect threshold. If the number of retries specified in the **max2 retries** command is reached and there is still no response and the **max2 lookup** command is enabled, the gateway performs one final DNS lookup. If any new IP addresses have been added, the gateway starts the retransmission process again. Otherwise, the gateway places the endpoint in a disconnected state.

Examples

The following example enables DNS lookup and sets the suspicion retransmission counter to 7:

```
Router(config)# mgcp profile nyc-ca
Router(config-mgcp-profile)# call-agent igloo.northpole.net
Router(config-mgcp-profile)# max1 lookup
Router(config-mgcp-profile)# max1 retries 7
```

Related Commands

Command	Description
call-agent	Specifies a call-agent address and protocol for an MGCP profile.
max1 retries	Sets the MGCP suspicion threshold value.
max2 lookup	Enables DNS lookup for an MGCP call agent when the disconnect threshold is reached.
max2 retries	Sets the MGCP disconnect threshold value.
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints or to configure the default profile.

max1 retries

To set the Media Gateway Control Protocol (MGCP) suspicion threshold value (the number of attempts to retransmit messages to a call agent address before performing a new lookup for retransmission), use the **max1 retries** command in MGCP profile configuration mode. To reset to the default, use the **no** form of this command.

max1 retries *number*

no max1 retries

Syntax Description

number	Number of times to attempt to resend messages. Range is from 3 to 30. The default is 5.

Command Default 5 attempts

Command Modes MGCP profile configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced and replaces the **mgcp request retries** command, which is no longer supported.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850 platforms. The maximum number of retries was increased to 30.

Usage Guidelines This command is used when configuring values for an MGCP profile.

Call-agent redundancy can be provided when call agents are identified by Domain Name System (DNS) name rather than by IP address in the **call-agent** command, because each DNS name can have more than one IP address associated with it.

When the active call agent does not respond to a message from the media gateway, the gateway tests to determine whether the call agent is out of service. The gateway retransmits the message to the call agent for the number of times specified in the **max1 retries** command; this is known as the suspicion threshold. If there is no response and the **max1 lookup** command is enabled, the gateway examines the DNS lookup table to find the IP address of another call agent.

If a second call agent is listed, the gateway retransmits the message to the second call agent until a response is received or the number of retries specified in the **max1 retries** command is reached. This process is repeated for each IP address in the DNS table until the final address is reached. For the final address, the number of retries is specified by the **max2 retries** command; this is known as the disconnect threshold. If the number of retries specified in the **max2 retries** command is reached and there is still no response and the **max2 lookup** command is enabled, the gateway performs one final DNS lookup. If any new IP addresses have been added, the gateway starts the retransmission process again. Otherwise, the gateway places the endpoint in a disconnected state.

Examples

The following example enables DNS lookup and sets the suspicion retransmission counter to 7:

```
Router(config)# mgcp profile nyc-ca
Router(config-mgcp-profile)# call-agent igloo.northpole.net
Router(config-mgcp-profile)# max1 lookup
Router(config-mgcp-profile)# max1 retries 7
```

Related Commands

Command	Description
call-agent	Specifies a call-agent address and protocol for an MGCP profile.
max1 lookup	Enables DNS lookup for an MGCP call agent when the suspicion threshold is reached.
max2 lookup	Enables DNS lookup for an MGCP call agent when the disconnect threshold is reached.
max2 retries	Sets the MGCP disconnect threshold value.

mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints, or to configure the default profile.

max2 lookup

To enable Domain Name System (DNS) lookup for a new call-agent address after the disconnect threshold timeout value is reached, use the **max2 lookup** command in MGCP profile configuration mode. To disable DNS lookup, use the **no** form of this command.

max2 lookup

no max2 lookup

Syntax Description This command has no arguments or keywords.

Command Default Lookup is enabled.

Command Modes MGCP profile configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines This command is used when configuring values for a Media Gateway Control Protocol (MGCP) profile.

Call-agent redundancy can be provided when call agents are identified by DNS name rather than by IP address in the **call-agent** command, because each DNS name can have more than one IP address associated with it.

When the active call agent does not respond to a message from the media gateway, the gateway tests to determine whether the call agent is out of service. The gateway retransmits the message to the call agent for the number of times specified in the **max1 retries** command; this is known as the *suspicion threshol*d. If there is no response and the **max1 lookup** command is enabled, the gateway examines the DNS lookup table to find the IP address of another call agent. If a second call agent is listed, the gateway retransmits the message to the second call agent until a response is received or the number of retries specified in the **max1 retries** command is reached.

This process is repeated for each IP address in the DNS table until the final address is reached. For the final address, the number of retries is specified by the **max2 retries** command; this is known as the *disconnect threshold*. If the number of retries specified in the **max2 retries** command is reached and there is still no response and the **max2 lookup** command is enabled, the gateway performs one final DNS lookup. If any new IP addresses have been added, the gateway starts the retransmission process again. Otherwise, the gateway places the endpoint in a disconnected state.

Examples

The following example enables DNS lookup and sets the disconnect retransmission counter to 9:

```
Router(config)# mgcp profile nyc-ca
Router(config-mgcp-profile)# call-agent ca1@exp.example.com
Router(config-mgcp-profile)# max2 lookup
Router(config-mgcp-profile)# max2 retries 9
```

Related Commands

Command	Description
call-agent	Specifies a call-agent address and protocol for an MGCP profile.
max1 lookup	Enables DNS lookup for an MGCP call agent when the suspicion threshold is reached.
max1 retries	Sets the MGCP suspicion threshold value.
max2 retries	Sets the MGCP disconnect threshold value.
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints, or to configure the default profile.

max2 retries

To set the Media Gateway Control Protocol (MGCP) disconnect threshold value (the number of attempts to retransmit messages to a call agent address before performing a new lookup for further retransmission), use the **max2 retries** command in MGCP profile configuration mode. To disable the disconnect threshold or to return the number of retries to the default, use the **no** form of this command.

max2 retries *number*

no max2 retries

Syntax Description

number	Number of times to attempt to resend messages. Range is from 3 to 30. The default is 7.

Command Default 7 attempts

Command Modes MGCP profile configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced and replaced the **mgcp request retries** command, which is no longer supported.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850. The maximum number of retries was increased to 30.

Usage Guidelines This command is used when configuring values for an MGCP profile.

Call-agent redundancy can be provided when call agents are identified by Domain Name System (DNS) name rather than by IP address in the **call-agent** command, because each DNS name can have more than one IP address associated with it.

When the active call agent does not respond to a message from the media gateway, the gateway tests to determine whether the call agent is out of service. The gateway retransmits the message to the call agent for the number of times specified in the **max1 retries** command; this is known as the suspicion threshold. If there is no response and the **max1 lookup** command is enabled, the gateway examines the DNS lookup table to find the IP address of another call agent. If a second call agent is listed, the gateway retransmits the message to the second call agent until a response is received or the number of retries specified in the **max1 retries** command is reached.

This process is repeated for each IP address in the DNS table until the final address is reached. For the final address, the number of retries is specified by the **max2 retries** command; this is known as the disconnect threshold. If the number of retries specified in the **max2 retries** command is reached and there is still no response and the **max2 lookup** command is enabled, the gateway performs one final DNS lookup. If any new IP addresses have been added, the gateway starts the retransmission process again. Otherwise, the gateway places the endpoint in a disconnected state.

Examples

The following example sets the disconnect retransmission counter to 9:

```
Router(config)# mgcp profile nyc-ca
Router(config-mgcp-profile)# call-agent igloo.northpole.net
Router(config-mgcp-profile)# max2 retries 9
```

Related Commands

Command	Description
call-agent	Specifies a call-agent address and protocol for an MGCP profile.
max1 lookup	Enables DNS lookup for an MGCP call agent after the suspicion threshold value is reached.
max1 retries	Sets the MGCP suspicion threshold value.
max2 lookup	Enables DNS lookup for an MGCP call agent after the disconnect threshold value is reached.
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp profile	Initiates MGCP profile mode to create and configure a named MGCP profile associated with one or more endpoints, or to configure the default profile.

max-calls

To set the maximum number of calls that a trunk group can handle, use the **max-calls** command in trunk group configuration mode. To reset to the default, use the **no** form of this command.

max-calls {**any** | **data** | **voice**} *number* [**direction** [**in** | **out**]]

no max-calls {**any** | **data** | **voice**} *number* [**direction** [**in** | **out**]]

Syntax Description

any	Assigns the maximum number of calls that the trunk group can handle, regardless of the type of call.
data	Assigns the maximum number of data calls to the trunk group.
voice	Assigns the maximum number of voice calls to the trunk group.
number	Range is from 0 to 1000.
direction	(Optional) Specifies direction of calls.
in	(Optional) Allows only incoming calls.
out	(Optional) Allows only outgoing calls.

Command Default

No limit when the command is not set.

Command Modes

Trunk group configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

Use this command to set the maximum number of calls to be handled by the trunk group. If the command is not set the maximum is infinite.

If the maximum is reached, the trunk group becomes unavailable for more calls. When the number of calls falls below the maximum, the trunk group will accept more calls.

Examples

The following example assigns a maximum number of 500 calls of any type to trunk group gw15:

```
Router(config)# trunk group gw15
Router(config-trunk-group)# max-calls any 500
```

The following example assigns a maximum of 200 data calls and 750 voice calls to trunk group 32:

```
Router(config)# trunk group 32
Router(config-trunk-group)# max-calls data 200
Router(config-trunk-group)# max-calls voice 750
```

Related Commands

Command	Description
show trunk group	Displays the configuration of one or more trunk groups.
trunk group	Initiates a trunk group definition.

max-conn (dial peer)

To specify the maximum number of incoming or outgoing connections for a particular Multimedia Mail over IP (MMoIP), plain old telephone service (POTS), Voice over Frame Relay (VoFR), or Voice over IP (VoIP) dial peer, use the **max-conn** command in dial peer configuration mode. To set an unlimited number of connections for this dial peer, use the **no** form of this command.

max-conn *number*

no max-conn

Syntax Description

number	Maximum number of connections for this dial peer. Range is from 1 to 2147483647. Default is an unlimited number of connections.

Command Default

The **no** form of this command is the default, meaning an unlimited number of connections

Command Modes

Dial peer configuration

Command History

Release	Modification
11.3(1)T	This command was introduced.
12.0(4)XJ	This command was modified for store-and-forward fax.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

Use this command to define the maximum number of connections used simultaneously to send or receive fax-mail. This command applies to off-ramp store-and-forward fax functions.

Examples

The following example configures a maximum of 5 connections for VoIP dial peer 10:

```
dial-peer voice 10 voip
 max-conn 5
```

Related Commands

Command	Description
mta receive maximum-recipients	Specifies the maximum number of recipients for all SMTP connections.

max-connection

To set the maximum number of simultaneous connections to be used for communication with a settlement provider, use the **max-connection** command in settlement configuration mode. To reset to the default, use the **no** form of this command.

max-connection *number*

no max-connection *number*

Syntax Description

number	Maximum number of HTTP connections to a settlement provider.

Command Default 10 connections

Command Modes Settlement configuration

Command History

Release	Modification
12.0(4)XH1	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Examples The following command sets the maximum number of simultaneous connections to 10:

```
settlement 0
 max-connection 10
```

Related Commands

Command	Description
connection-timeout	Configures the time that a connection is maintained after completing a communication exchange.
customer-id	Sets the customer identification.
device-id	Specifies a gateway associated with a settlement provider.
encryption	Sets the encryption method to be negotiated with the provider.
response-timeout	Configures the maximum time to wait for a response from a server.
retry-delay	Sets the time between attempts to connect with the settlement provider.
retry-limit	Sets the maximum number of connection attempts to the provider.
session-timeout	Sets the interval for closing the connection when there is no input or output traffic.
settlement	Enters settlement configuration mode and specifies the attributes specific to a settlement provider.
shutdown	Brings up the settlement provider.

Command	Description
type	Configures an SAA-RTR operation type.
url	Configures the ISP address.

max-forwards

To globally set the maximum number of hops, that is, proxy or redirect servers that can forward the Session Initiation Protocol (SIP) request, use the **max-forwards** command in SIP user-agent configuration mode. To reset the default number of hops, use the **no** form of this command.

max-forwards *number-of-hops*

no max-forwards *number-of-hops*

Syntax Description

number-of-hops	Number of hops. Range is from 1 to 70. Default is 70.

Command Default

70 hops

Command Modes

SIP user-agent configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.2(2)XA	This command was implemented on Cisco AS5350 and AS5400 platforms.
12.2(2)XB1	This command was introduced on the Cisco AS5850.
12.2(8)T	This command was implemented on Cisco 7200 series routers. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.
12.3(8)T	This command was enhanced with a greater configurable range and a higher default value (compliant with RFC 3261).

Usage Guidelines

To reset this command to the default value, you can also use the **default** command.

Examples

The following example sets the number of forwarding requests to 65:

```
sip-ua
 max-forwards 65
```

Related Commands

Command	Description
max-redirects	Sets the maximum number of redirects that the user agent allows.

max-redirects

To set the maximum number of redirect servers that the *n_* allows, use the **max-redirects** command in dial peer configuration mode. To reset to the default, use the **no** form of this command.

max-redirects *number*

no max-redirects

Syntax Description

number	Maximum number of redirect servers that a call can traverse. Range is from 1 to 10. The default is 1.

Command Default 1 redirect

Command Modes Dial peer configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco AS5300.
12.2(2)XA	This command was implemented on the Cisco AS5400 and Cisco AS5350 platforms.
12.2(2)XB1	This command was implemented on the Cisco AS5850.
12.2(8)T	This command was implemented on the Cisco 7200 series. This command does not support the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 in this release.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Examples The following is an example of setting the maximum number of redirect servers that the user agent allows:

```
dial-peer voice 102 voip
 max-redirects 2
```

Related Commands

Command	Description
dial-peer voice	Enters dial peer configuration mode and specifies the method of voice-related encapsulation.

max-subscription

To set the maximum number of concurrent watch sessions that are allowed, use the **max-subscription** command in presence configuration mode. To return to the default, use the **no** form of this command.

max-subscription *number*

no max-subscription

Syntax Description

number	Maximum watch sessions. Range: 100 to 500. Default: 100.

Command Default

Maximum subscriptions is 100.

Command Modes

Presence (config-presence)

Command History

Release	Modification
12.4(11)XJ	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

This command sets the maximum number of concurrent presence subscriptions for both internal and external subscribe requests.

Examples

The following example shows the maximum subscriptions set to 150:

```
Router(config)# presence
Router(config-presence)# max-subscription 150
```

Related Commands

Command	Description
allow watch	Allows a directory number on a phone registered to Cisco Unified CME to be watched in a presence service.
allow subscribe	Allows internal watchers to monitor external presence entities (directory numbers).
presence	Enables presence service on the router and enters presence configuration mode.
presence enable	Allows incoming presence requests from SIP trunks.
server	Specifies the IP address of a presence server for sending presence requests from internal watchers to external presence entities.
watcher all	Allows external watchers to monitor internal presence entities (directory numbers).

maximum buffer-size

To set the maximum size of the file accounting buffer, use the **maximum buffer-size** command in gateway accounting file configuration mode. To reset to the default, use the **no** form of this command.

maximum buffer-size *kbytes*

no maximum buffer-size

Syntax Description

kbytes	Maximum buffer size, in kilobytes. Range: 6 to 40. Default: 20.

Command Default

Maximum buffer size is 20 kilobytes.

Command Modes

Gateway accounting file configuration (config-gw-accounting-file)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

The file accounting process writes call detail records (CDRs) to a memory buffer instead of writing each record independently to the accounting file. Two buffers are allocated for file accounting and their size is set by this command. After the accounting records in the buffer reach the size limit set by this command, the system flushes the first buffer and writes the records to the accounting file. While the first buffer is busy being flushed, the system uses the second buffer to hold new data. After the flush process, the buffer is available again.

The buffer size must be large enough to accommodate incoming CDRs without the system filling up both buffers completely.

Examples

The following example sets the maximum buffer size to 25 kilobytes:

```
gw-accounting file
 primary ftp server1/cdrtest1 username bob password temp
 secondary ifs flash:cdrtest2
 maximum buffer-size  25
 maximum retry-count 3
 maximum fileclose-timer 720
 cdr-format compact
```

Related Commands

Command	Description
cdr-format	Selects the format of the CDRs generated for file accounting.
file-acct flush	Manually flushes the CDRs from the buffer to the accounting file.

Command	Description
maximum fileclose-timer	Sets the maximum time for saving records to an accounting file before closing the file and creating a new one.
primary	Sets the primary location for storing the CDRs generated for file accounting.
secondary	Sets the backup location for storing CDRs if the primary location becomes unavailable.

maximum cdrflush-timer

To set the maximum time to hold call records in the buffer before appending the records to the accounting file, use the **maximum cdrflush-timer** command in gateway accounting configuration mode. To reset to the default, use the **no** form of this command.

maximum cdrflush-timer *minutes*

no maximum cdrflush-timer

Syntax Description

minutes	Maximum time, in minutes, to hold call records in the accounting buffer. Range: 1 to 1,435. Default: 60 (1 hour).

Command Default

Records are held in the buffer for 60 minutes (1 hour).

Command Modes

Gateway accounting file configuration (config-gw-accounting-file)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

After the time period set with this command expires, the router flushes the buffer and writes the call detail records (CDRs) to the accounting file.

The file accounting process sends CDRs to a memory buffer instead of writing each record independently to the accounting file. The system flushes the buffer automatically either after this timer expires or when the records in the buffer reach the size set by the **maximum buffer-size** command.

Set this flush timer to at least five minutes less than the file close timer set with the **maximum fileclose-timer** command.

To manually flush the CDRs from the buffer to the accounting file, use the **file-acct flush** command.

Examples

The following example shows that call records are held in the accounting file for three hours, after which the records are appended to the accounting file:

```
gw-accounting file
 primary ftp server1/cdrtest1 username bob password temp
 secondary ifs flash:cdrtest2
 maximum buffer-size  25
 maximum retry-count 3
 maximum fileclose-timer 720
 cdr-format compact
```

Related Commands

Command	Description
file-acct flush	Manually flushes the CDRs from the buffer to the accounting file.
maximum buffer-size	Sets the maximum size of the file accounting buffer.
maximum fileclose-timer	Sets the maximum time for saving records to an accounting file before closing the file and creating a new one.
primary	Sets the primary location for storing the CDRs generated for file accounting.
secondary	Sets the backup location for storing CDRs if the primary location becomes unavailable.

maximum conference-participants

To configure the maximum number of conference participants allowed in each meet-me conference, use the **maximum conference-participants** command in DSP farm profile configuration mode. To reset the maximum to the default number, use the **no** form of this command.

maximum conference-participants *max-participants* [**video-cap-class** *number*]

no maximum conference-participants *max-participants* [**video-cap-class** *number*]

Syntax Description

max-participants	Maximum number of participants allowed in each meet-me conference session. One DSP can support the following maximums: • G.711—32 participants • G.729—16 participants • Video (H.263 or H.264)—4, 8, or 16 participants
video-cap-class *number*	(Optional) Reserves the DSP resources needed to support a video participant requiring video format conversion. The range for video port number is from 2 to 4. The default is 2.

Command Default

The default maximum number of participants for a video conference is 4. The default maximum number of participants for an audio conference is 8.

Command Modes

DSP farm profile configuration (config-dspfarm-profile)

Command History

Release	Modification
12.4(11)XJ2	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
15.1(4)M	This command was modified. The **video-cap-class** keyword was added.

Usage Guidelines

The maximum number of participants allowed for hardware conferencing is dependent on the codec used in the DSP farm profile. Use the **codec** command in DSP farm profile configuration mode to specify the codecs supported by the DSP farm profile. Use the **show dspfarm profile** command to display the DSP farm profile.

Examples

The following example configures a DSP farm profile that has a maximum of 16 participants for hardware conferences using the G.711 codec:

```
Router(config)# dspfarm profile conference 1
Router(config-dspfarm-profile)# maximum conference-participants 16
Router(config-dspfarm-profile)# codec g711alaw
```

Related Commands

Command	Description
codec (DSP Farm profile)	Specifies the codecs supported by a DSP farm profile.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
maximum sessions	Specifies the maximum number of sessions that are supported by the profile.
show dspfarm profile	Displays configured DSP farm profile information.

maximum fileclose-timer

To set the maximum time for writing call detail records (CDRs) to an accounting file before closing the file and creating a new one, use the **maximum fileclose-timer** command in gateway accounting configuration mode. To reset to the default, use the **no** form of this command.

maximum fileclose-timer *minutes*

no maximum fileclose-timer

Syntax Description

minutes	Maximum time, in minutes, to write records to an accounting file. Range: 60 (1 hour) to 1,440 (24 hours). Default: 1,440.

Command Default

Records are saved to an accounting file for 1,440 minutes (24 hours).

Command Modes

Gateway accounting file configuration (config-gw-accounting-file)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

After the timer set with this command expires, the current accounting file is closed and a new file with a new time stamp is opened to write CDRs. The name and location of the accounting file is set by the **primary** command, or the **secondary** command if in failover mode.

Set this file close timer to at least five minutes longer than the flush timer set with the **maximum cdrflush-timer** command.

To manually flush the CDRs from the buffer to the accounting file, use the **file-acct flush** command.

Examples

The following example shows that call records are saved to the currently open accounting file for 12 hours, after which a new accounting file is created:

```
gw-accounting file
 primary ftp server1/cdrtest1 username bob password temp
 secondary ifs flash:cdrtest2
 maximum buffer-size  25
 maximum retry-count 3
 maximum fileclose-timer 720
 cdr-format compact
```

Related Commands

Command	Description
file-acct flush	Manually flushes the CDRs from the buffer to the accounting file.
maximum buffer-size	Sets the maximum size of the file accounting buffer.
maximum cdrflush-timer	Sets the maximum time to hold call records in the buffer before appending the records to the accounting file.
primary	Sets the primary location for storing the CDRs generated for file accounting.
secondary	Sets the backup location for storing CDRs if the primary location becomes unavailable.

maximum retry-count

To set the maximum number of times the router attempts to connect to the primary file device before switching to the secondary device, use the **maximum retry-count** command in gateway accounting file configuration mode. To reset to the default value, use the **no** form of this command.

maximum retry-count *number*

no maximum retry-count

Syntax Description

number	Number of connection attempts. Range: 1 to 5. Default: 2.

Command Default

Maximum connection attempts is 2.

Command Modes

Gateway accounting file configuration (config-gw-accounting-file)

Command History

Release	Modification
12.4(15)XY	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

This command specifies the number of times that the router attempts to connect to the primary file device defined in the **primary** command before it attempts to connect to the backup file device specified with the **secondary** command.

Examples

The following example shows the maximum retries set to 3:

```
gw-accounting file
 primary ftp server1/cdrtest1 username bob password temp
 secondary ifs flash:cdrtest2
 maximum buffer-size  25
 maximum retry-count 3
 cdr-format compact
```

Related Commands

Command	Description
file-acct reset	Manually switches back to the primary device for file-based accounting.
primary	Sets the primary location for storing the call detail records generated for file accounting.
secondary	Sets the backup location for storing CDRs if the primary location becomes unavailable.

maximum sessions (DSP farm profile)

To specify the maximum number of sessions that are supported by the profile, use the **maximum sessions** command in DSP farm profile configuration mode. To reset to the default, use the **no** form of this command.

Command Syntax When Conferencing or Transcoding Is Configured

maximum sessions *number*

no maximum sessions

Command Syntax When MTP Is Configured

maximum sessions {**hardware** | **software**} *number*

no maximum sessions

Syntax Description

number	Number of session supported by the profile. Range is 0 to *x*. Default is 0. The *x* value is determined at run time depending on the number of resources available with the resource provider.
hardware	Number of sessions that media termination points (MTP) hardware resources will support.
software	Number of sessions that MTP software resources will support.

Command Default

The maximum number of supported sessions is 0.

Command Modes

DSP farm profile configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.
12.4(22)T	Support for IPv6 was added.

Usage Guidelines

When using the MTP service type, you must specify the number of sessions separately for software MTP and hardware MTP. The hardware MTP needs digital signal processor (DSP) resources. Use hardware MTP when the codecs are the same and the packetization period is different.

Active profiles must be shut down before any parameters can be changed.

Note The syntax of the command will vary based on the type of profile that you are configuring. The keywords work only when MTP is configured.

Examples

The following example shows that four sessions are supported by the DSP farm profile:

```
Router(config-dspfarm-profile)# maximum sessions
```

Related Commands

Command	Description
associate application	Associates the SCCP protocol to the DSP farm profile.
codec (dspfarm-profile)	Specifies the codecs supported by a DSP farm profile.
description (dspfarm-profile)	Includes a specific description about the DSP farm profile.
dspfarm profile	Enters DSP farm profile configuration mode and defines a profile for DSP farm services.
shutdown (dspfarm-profile)	Allocates DSP farm resources and associates with the application.
voice-card	Enters voice-card configuration mode.

mdn

To request that a message disposition notification (MDN) be generated when a message is processed (opened), use the **mdn** command in dial peer configuration mode. To disable generation of an MDN, use the **no** form of this command.

mdn

no mdn

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Dial peer configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.0(4)T	This command was integrated into Cisco IOS Release 12.0(4)T.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(4)T	This command was implemented on the Cisco 1750 access router.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines Message disposition notification is an e-mail message that is generated and sent to the sender when the message is opened by the receiver. Use this command to request that an e-mail response message be sent to the sender when the e-mail that contains the fax TIFF image has been opened.

This command applies to on-ramp store-and-forward fax functions.

Examples The following example requests that a message disposition notification be generated by the recipient:

```
dial-peer voice 10 mmoip
 mdn
```

Related Commands

Command	Description
mta receive generate-mdn	Specifies that the off-ramp gateway process a response MDN from an SMTP server.
mta send return-receipt-to	Specifies the address to which MDNs are sent.

media

To enable media packets to pass directly between the endpoints, without the intervention of the Cisco Unified Border Element (Cisco UBE) and to enable signaling services, enter the **media** command in dial peer voice, voice class, or voice service configuration mode. To return to the default behavior, use the **no** form of this command.

media [**flow-around | flow-through | forking | monitoring** [*max-calls*] **| statistics | transcoder high-density | anti-trombone | sync-streams**]

no media [**flow-around | flow-through | forking | monitoring** [*max-calls*] **| statistics | transcoder high-density | anti-trombone | sync-streams**]

Syntax Description

flow-around	(Optional) Enables media packets to pass directly between the endpoints, without the intervention of the Cisco UBE. The media packet is to flow around the gateway.
flow-through	(Optional) Enables media packets to pass through the endpoints, without the intervention of the Cisco UBE.
forking	(Optional) Enables the media forking feature for all calls.
monitoring	(Optional) Enables the monitoring feature for all calls or a maximum number of calls.
max-calls	(Optional) The maximum number of calls that are monitored.
statistics	(Optional) Enables media monitoring.
transcoder high-density	(Optional) Converts media codecs from one voice standard to another to facilitate the interoperability of devices using different media standards.
anti-trombone	(Optional) Enables media anti-trombone for all calls. Media trombones are media loops in SIP entity due to call transfer or call forward.
sync-streams	(Optional) Specifies that both audio and video streams go through the DSP farms on Cisco UBE and Cisco Unified CME.

Command Default

The default behavior of the Cisco UBE is to receive media packets from the inbound call leg, terminate them, and then reoriginate the media stream on an outbound call leg.

Command Modes

Dial peer voice configuration (config-dial-peer)
Voice class configuration (config-class)
Voice service configuration (config-voi-serv)

Command History

Release	Modification
12.3(1)T	This command was introduced.
12.4(11)XJ2	This command was modified. The **statistics** keyword was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
12.4(20)T	This command was modified. The **transcoder** and **high-density** keywords were introduced.

Release	Modification
15.0(1)M	This command was modified. The **forking** and **monitoring** keywords and the *max-calls* argument were introduced.
15.1(3)T	This command was modified. The **anti-trombone** keyword was introduced.
15.1(4)M	This command was modified. The **sync-stream** keyword was added.

Usage Guidelines

With the default configuration, the Cisco UBE receives media packets from the inbound call leg, terminates them, and then reoriginates the media stream on an outbound call leg. Media flow-around enables media packets to be passed directly between the endpoints, without the intervention of the Cisco UBE. The Cisco UBE continues to handle routing and billing functions. Media flow-around for SIP-to-SIP calls is not supported.

Note The Cisco UBE must be running Cisco IOS Release 12.3(1) or a later release to support media flow-around.

You can specify media flow-around for a voice class, all VoIP calls, or individual dial peers.

The **transcoder high-density** keyword can be enabled in any of the configuration modes with the same command format. If you are configuring the **transcoder high-density** keyword for dial peers, make sure that the **media transcoder high-density** command is configured on both the in and Out-Legs.

Note The software does not support configuring the **transcoder high-density** keyword on any dial peer that is to handle video calls. The following scenarios are not supported:

- Dial peers used for video at any time. Configuring the **media transcoder high-density** command directly under the dial-peer or a voice-class media configuration mode is not supported.
- Dial peers configured on a Cisco UBE used for video calls at any time. The global configuration of the **media transcoder high-density** command under voice service configuration mode is not supported.

To enable the **media** command on a Cisco 2900 or Cisco 3900 series Unified Border Element voice gateway, you must first enter the **mode border-element** command. This enables the **media forking** and **media monitoring** commands. Do not configure the **mode border-element** command on the Cisco 2800 or Cisco 3800 series platform.

You can specify media anti-trombone for a voice class, all VoIP calls, or individual dial peers.

The **anti-trombone** keyword can be enabled only when no media interworking is required in both the Out-Legs. Antitrombone will not work if call leg is flow-through and another call leg is flow-around.

Examples

Media Flow-around Examples

The following example shows media flow-around configured on a dial peer:

```
Router(config)# dial-peer voice 2 voip
Router(config-dial-peer)# media flow-around
```

The following example shows media flow-around configured for all VoIP calls:

```
Router(config)# voice service voip
Router(config-voi-serv)# media flow-around
```

The following example shows media flow-around configured for voice class calls:

```
Router(config)# voice class media 1
Router(config-class)# media flow-around
```

Media Flow-through Examples

The following example shows media flow-through configured on a dial peer:

```
Router(config)# dial-peer voice 2 voip
Router(config-dial-peer)# media flow-through
```

The following example shows media flow-through configured for all VoIP calls:

```
Router(config)# voice service voip
Router(config-voi-serv)# media flow-through
```

The following example shows media flow-through configured for voice class calls:

```
Router(config)# voice class media 2
Router(config-class)# media flow-through
```

Media Statistics Examples

The following example shows media monitoring configured for all VoIP calls:

```
Router(config)# voice service voip
Router(config-voi-serv) media statistics
```

The following example shows media monitoring configured for voice class calls:

```
Router(config)# voice class media 1
Router(config-class) media statistics
```

Media Transcoder High-density Examples

The following example shows the **media transcoder** command configured for all VoIP calls:

```
Router(config)# voice service voip
Router(conf-voi-serv)# media transcoder high-density
```

The following example shows the **media transcoder** command configured for voice class calls:

```
Router(config)# voice class media 1
Router(config-voice-class)# media transcoder high-density
```

The following example shows the **media transcoder** command configured on a dial peer:

```
Router(config)# dial-peer voice 36 voip
Router(config-dial-peer)# media transcoder high-density
```

Media Monitoring on a Cisco UBE Platform

The following example shows how to configure audio call scoring for a maximum of 100 calls:

```
mode border-element
media monitoring 100
```

Media Antitrombone Examples

The following example shows the **media anti-trombone** command configured for all VoIP calls:

```
Router(config)# voice service voip
Router(conf-voi-serv)# media anti-trombone
```

The following example shows the **media anti-trombone** command configured for voice class calls:

```
Router(config)# voice class media 1
Router(config-voice-class)# media anti-trombone
```

The following example shows the **media anti-trombone** command configured on a dial peer:

```
Router(config)# dial-peer voice 36 voip
Router(config-dial-peer)# media anti-trombone
```

Media Transcoder Examples

The following example specifies that both audio and video RTP streams go through the DSP farms when either audio or video transcoding is needed:

```
Router(config)# voice service voip
Router(config-voi-serv)# media transcoder sync-streams
```

The following example specifies that both audio and video RTP streams go through the DSP farms when either audio or video transcoding is needed and the RTP streams flow around Cisco Unified Border Element.

```
Router(config)# voice service voip
Router(config-voi-serv)# media transcoder high-density sync-streams
```

Related Commands

Command	Description
dial-peer voice	Enters dial peer voice configuration mode.
mode border-element	Enables the media monitoring capability of the **media** command.
voice class	Enters voice class configuration mode.
voice service	Enters voice service configuration mode.

mediacard

To enter mediacard configuration mode and configure a Communications Media Module (CMM) media card, use the **mediacard** command in global configuration mode.

mediacard *slot*

Syntax Description

slot	Specifies the slot number for the media card to be configured. Valid values are from 1 to 4.

Command Default

No default behavior or values

Command Modes

Global configuration mode

Command History

Release	Modification
12.3(8)XY	This command was introduced on the Communication Media Module.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T.
12.4(3)	This command was integrated into Cisco IOS Release 12.4(3).

Usage Guidelines

Mediacard configuration mode is used to configure parameters related to the selected media card, such as digital signal processor (DSP) resource pools.

Examples

The following example shows how you configure DSP resources on the media card in slot 1:

```
mediacard 1
```

Related Commands

Command	Description
debug mediacard	Displays debugging information for Digital Signal Processor Resource Manager (DSPRM).
show mediacard	Displays information about the selected media card.

media-inactivity-criteria

To specify the mechanism for detecting media inactivity (silence) on a voice call, use the **media-inactivity-criteria** command in gateway configuration mode. To disable detection, use the **no** form of this command.

media-inactivity-criteria {**rtp** | **rtcp** | **all**}

no media-inactivity-criteria

Syntax Description

rtp	Real-Time Transport Protocol (RTP) (default)
rtcp	RTP Control Protocol (RTCP)
all	Both RTP and RTCP

Command Default

Media-inactivity detection is performed by means of RTP.

Command Modes

Gateway

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

Use this command to specify the mechanism for detecting silence on a voice call. After doing so, you can configure silent calls to disconnect by entering the related commands listed below.

Use this command, in conjunction with the **application**, **package callfeature**, **param**, and **paramspace** commands, to configure callfeature parameters at the package level and to override them as needed for specific applications or dial peers.

The mechanism that you explicitly specify with this command takes precedence over any mechanism that you might implicitly have specified with the **ip rtcp report interval** command in combination with the **timer media-inactive** or **timer receive-rtcp** command.

Examples

The following example specifies the use of RTCP for silence detection:

```
Router(config)# gateway
Router(config-gateway)# media-inactivity-criteria rtcp
```

The following example shows a configuration that might result from the use of this and related commands:

```
voice service pots
map q850-cause 44 release-source local tone 3

application
 package callfeature
  param med-inact-disc-cause 44
  param med-inact-det enable
  param med-inact-action disconnect
ip rtcp report interval 9000
dial-peer voice 5 voip
destination-pattern .T
 progress_ind disconnect enable 8
 session target ras
 codec g711ulaw
gateway
 media-inactivity-criteria rtcp
 timer media-inactive 5
```

Related Commands

Command	Description
application	Enables a specific application on a dial peer.
ip rtcp report interval	Configures the average reporting interval between subsequent RTCP report transmissions.
package callfeature	Enters application-parameter configuration mode.
param	Loads and configures parameters in a package or a service (application) on the gateway.
paramspace	Enables an application to use parameters from the local parameter space of another application.
timer media-inactive	Sets the media-inactivity disconnect timer.
timer receive-rtcp	Sets the RTCP timer and configures a multiplication factor for the RTCP timer interval for SIP or H.323 calls.

meetme-conference

To define a feature code for a Feature Access Code (FAC) to initiate an SCCP Meet-Me Conference, use the **meetme-conference** command in STC application feature access-code configuration mode. To return the feature code to its default, use the **no** form of this command.

meetme-conference *keypad-character*

no meetme-conference

Syntax Description

keypad-character	Character string that can be dialed on a telephone keypad (0-9, *, #). Default: 5. The string can be any of the following: • A single character (0-9, *, #) • Two digits (00-99) • Two to four characters (0-9, *, #) and the leading or ending character must be an asterisk (*) or number sign (#) In Cisco IOS Release 15.0(1)M and later releases, the string can also be any of the following: • Three digits (000-999) • Four digits (0000-9999)

Command Default The default value of the feature code is 5.

Command Modes STC application feature access-code configuration (config-stcapp-fac)

Command History

Release	Modification
12.4(20)YA	This command was introduced.
12.4(22)T	This command was integrated into Cisco IOS Release 12.4(22)T.
15.0(1)M	This command was modified.

Usage Guidelines

This command changes the value of the feature code for SCCP Meet-Me Conference from the default (5) to the specified value.

If the length of the *keypad-character* argument is at least two characters and the leading or ending character of the string is an asterisk (*) or a number sign (#), phone users are not required to dial a prefix to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 55#, the phone user dials only 55#, without the FAC prefix, to access the corresponding feature.

In Cisco IOS Release 15.0(1)M and later releases, if the length of the keypad-character argument is three or four digits, phone users are not required to dial a prefix or any special characters to access this feature. Typically, phone users dial a special feature access code (FAC) consisting of a prefix plus a feature code, for example **2. If the feature code is 788, the phone user dials only 788, without the FAC prefix, to access the corresponding feature.

If you attempt to configure this command with a value that is already configured for another FAC, speed-dial code, or the Redial FSD, you receive a message. If you configure a duplicate code, the system implements the first matching feature in the order of precedence shown in the output of the **show stcapp feature codes** command.

If you attempt to configure this command with a value that precludes or is precluded by another FAC, speed-dial code, or the Redial FSD, you receive a message. If you configure a feature code to a value that precludes or is precluded by another code, the system always executes the call feature with the shortest code and ignores the longer code. For example, #1 will always preclude #12 and #123. You must configure a new value for the precluded code in order to enable phone user access to that feature.

To display a list of all FACs, use the **show stcapp feature codes** command.

Examples

The following example shows how to change the value of the feature code for SCCP Meet-Me Conference from the default (5). This configuration also changes the value of the prefix for all FACs from the default (**) to ##. With this configuration, a phone user must press ##9 on the phone keypad to cancel all-call forwarding.

```
Router(config)# stcapp feature access-code
Router(config-stcapp-fac)# prefix ##
Router(config-stcapp-fac)# meetme-conference 9
Router(config-stcapp-fac)# exit
```

Related Commands

Command	Description
prefix (stcapp-fac)	Defines the prefix for feature access codes (FACs).
show stcapp feature codes	Displays all feature access codes (FACs).
stcapp feature access-code	Enables feature access codes (FACs) and enters STC application feature access-code configuration mode for changing values of the prefix and features codes from the default.

member (dial peer cor list)

To add a member to a dial peer class of restrictions (COR) list, use the **member** command in dial peer COR list configuration mode. To remove a member from a list, use the **no** form of this command.

member *class-name*

no member *class-name*

Syntax Description

class-name	Class name previously defined in dial peer COR custom configuration mode by using of the **name** command.

Command Default No default behavior or values.

Command Modes Dial peer COR list configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.

Examples The following example adds three members to the COR list named list3:

```
dial-peer cor list list3
 member 900_call
 member 800_call
 member catchall
```

Related Commands

Command	Description
dial-peer cor list	Defines a COR list name.

method

To set a specific accounting method list, use the **method** command in gateway accounting AAA configuration mode.

method *acctMethListName*

Syntax Description

acctMethListName	Name of the accounting method list.

Command Default

H.323 is the default accounting method list.

Command Modes

Gateway accounting AAA configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 3660, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, and Cisco AS5850.

Usage Guidelines

- For information on setting AAA network security for your network, including setting method lists, refer to the *Authentication, Authorization, and Accounting Cisco IOS Security Configuration Guide, Release 12.2*.
- The **method** command sets the accounting method globally (not for a dial peer). To initially define the AAA method list name for accounting, use the **aaa accounting** command.
- The method list name used is the same name used to define the method list name under the **aaa accounting** command.

Examples

The following example uses the method list named “klz_aaa6” that was previously defined using the AAA commands.

```
aaa new-model
!
aaa group server radius sg6
server 1.6.30.70 auth-port 1708 acct-port 1709
!
aaa authentication login klz_aaa6 group sg6
! klz_aaa6 is defined as the method list name.
aaa authorization exec klz_aaa6 group sg6
aaa accounting connection klz_aaa6 start-stop group sg6
!
gw-accounting aaa
method klz_aaa6
! The same method list named klz_aaa6 is used.
```

Related Commands

Command	Description
aaa accounting	Enables accounting of requested services for billing or security purposes.
gw-accounting aaa	Enables VoIP gateway accounting.

mgcp

To allocate resources for the Media Gateway Control Protocol (MGCP) and start the MGCP daemon, use the **mgcp** command in global configuration mode. To terminate all calls, release all allocated resources, and stop the MGCP daemon, use the **no** form of this command.

mgcp [*port*]

no mgcp

Syntax Description

port	(Optional) User Datagram Protocol (UDP) port for the MGCP gateway. Range is from 1025 to 65535. The default is UDP port 2427.

Command Default UDP port 2427

Command Modes Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 3660, Cisco uBR924, and Cisco 2600 series.
12.1(5)XM	This command was added to Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines Once you start the MGCP daemon using the **mgcp** command, you can suspend it (for example, for maintenance) by using the **mgcp block-newcalls** command. When you are ready to resume normal MGCP operations, use the **no mgcp block-newcalls** command. Use the **no mgcp** command only if you intend to terminate all MGCP applications and protocols.

When the MGCP daemon is not active, all MGCP messages are ignored.

If you want to change the UDP port while MGCP is running, you must stop the MGCP daemon using the **no mgcp** command, and then restart it with the new port number using the **mgcp** *port* command.

Examples The following example initiates the MGCP daemon:

```
Router(config)# mgcp
```

The following example enables the MGCP daemon on port 4204:

```
Router(config)# mgcp 4204
```

Related Commands

Command	Description
application	Enables debugging on MGCP.
debug mgcp	Enables debugging on MGCP.
mgcp block-newcalls	Gracefully terminates all MGCP activity.
mgcp ip-tos	Enables or disables the IP ToS for MGCP connections.
mgcp request retries	Specifies the number of times to retry sending the **mgcp** command.
show mgcp	Displays the MGCP parameter settings.

mgcp behavior

To configure a gateway to alter the Media Gateway Control Protocol (MGCP) behavior, use the **mgcp behavior** command in global configuration mode. To resume using the standard protocol version behavior that is specified in the configuration, use the **no** form of this command.

mgcp behavior *category version*

no mgcp behavior *category version*

Syntax Description

category	MGCP behavior category. For valid values, see Table 33.
version	MGCP version for the behavior category. For valid values, see Table 34.

Command Default

The gateway follows the rules and guidelines that are specified by the configured MGCP protocol version.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.3(2)T1	This command was introduced.
12.3(4)T	This command was modified. The **signals v0.1** keyword was added.
12.3(8)T	This command was modified. The **dlcx-clear-signals** keyword was added.
12.3(11)T	This command was modified. The **ack-init-rsip disable** and **init-rsip-per-insvc legacy** keywords were added.
12.3(14)T	This command was modified. The **q-mode-enduring legacy** keyword was added.
12.3(16)	This command was modified. The **mdcx-sdp ack-with-sdp** keyword was added.
12.4(4)T	This command was modified. The **rsip-range** keyword was added.
12.4(24)T	This command was modified. The default behavor of the mode parameter in the SDP was given higher preference to the mode present in the M: line of the MGCP message. The **digit-collect-stuck play-reorder**, **fxs-gs emulate-ls-disconnect**, **mode-attrb-in-sdp disable,** **private-localhost**, and **transient-state-response enable** keywords were added.
15.1(1)T	This command was modified. The **dynamically-change-codec-pt disable** keyword was added.
15.1(3)T	This command was modified. The **negotiate-nse enable** keyword was added.

Usage Guidelines

Table 33 describes the MGCP behavior category keywords.

Table 33 MGCP Behavior Category Keywords

Keywords	Description
ack-init-rsip disable	Forces the gateway to accept commands from the call agent before its initial ReStart In Progress (RSIP) messages are acknowledged; that is, 405 error codes do not occur. The gateway also behaves in this way if it is configured for MGCP Version 1.0 and earlier versions. By default, or when the **no** form of this command is issued, if the gateway is configured for MGCP Version RFC 3435-1.0 or later versions, it responds to call agent commands with a 405 error code until its initial RSIPs are acknowledged by the call agent.
digit-collect-stuck play-reorder	Forces the gateway to play a reorder tone to the user when 60 seconds have passed and when MGCP is in the process of collecting the digits. By default, or when the **no** form of this command is issued, if the MGCP application does not get a connection or gets disconnected within a specific time when the endpoint is in the off-hook state, then the endpoint may be busy in the digit collection state.
dlcx-clear-signals all	Forces the gateway to turn off or clear all signals when it receives a Delete Connection (DLCX) message from the call agent even if there is no S: line in the message. By default, and as specified by RFC 3435, the gateway maintains current endpoint signals if a DLCX has no S: line. The MGCP gateway clears signals only when the call agent explicitly turns off each signal or sends an empty S: line to clear all signals.
dynamically-change-codec-pt disable	Forces the gateway not to change the codec payload type when it is dynamically changed in the incoming Session Description Protocol (SDP). By default, or when **no** form of this command is issued, MGCP dynamically changes the payload, if the incoming SDP has a different codec.
fxs-gs emulate-ls-disconnect	Forces the gateway not to disconnect the call even when the gateway receives a DLCX for a ground-start enabled endpoint. The gateway plays the busy tone as the call does not get disconnected. By default, or when **no** form of this command is issued, MGCP disconnects the call when it receives a DLCX.

Table 33 MGCP Behavior Category Keywords (continued)

Keywords	Description
init-rsip-per-insvc legacy	Forces the gateway to always use the restart method of Restart for its initial RSIP messages, regardless of the service state of the endpoints. Wildcard demotion may occur as needed, based on configuration. By default, or when the **no** form of this command is issued, if the MGCP gateway is running Version RFC 3435-1.0, the default restart method for initial RSIPs depends on the service state of the endpoint. For in-service endpoints, the restart method is Restart. For out-of-service endpoints, the restart method is Forced. Additionally, regardless of the protocol version, the gateway always attempts to use a wildcard RSIP * message to minimize the number of messages that are sent to the call agent. The gateway sends the fully wildcarded RSIP * message as long as the following requirements are met: • MGCP is configured for a single profile (or the default profile) only. • A single DS0 group is configured for each DS1. • The single DS0 group includes all the possible DS0s. • All endpoints are in the same service state (when the MGCP call agent is configured for Version RFC 3435-1.0 and the **no** form of this command is issued). If any one of these requirements is not met, the initial RSIP * message is demoted and sent as multiple RSIP messages to the call agent. When demoting, the gateway continues to attempt to minimize the number of RSIP messages.
mdcx-sdp ack-with-sdp	Forces the gateway to generate a SDP in response to a modify connection (MDCX) message that contains an SDP. The response contains the SDP only if the MDCX is responded to with a positive (200) acknowledgment. By default, or when the **no** form of this command is issued, the positive acknowledgment reply generates an SDP only if any of the parameters have changed from the previous SDP that was generated by the gateway. With this command, even if all the parameters are the same as the previous SDP, the SDP is still generated. This enables operation with a SIP gateway that expects an SDP response to every CRCX or MDCX message.
mode-attrb-in-sdp disable	Forces the gateway to take connection mode M in Create Connection (CRCX). By default, or when **no** form of this command is issued, preference is given to the connection mode present in SDP. This is only when the mode is present in SDP.
negotiate-nse enable	Makes MGCP gateway aware of the remote side's Named Signaling Event (NSE) capabilities by examining the remote SDP for NSE capabilities. By default, or when the **no** form of this command is issued, NSE is disabled on the gateway. Cisco Unified Call Manager (UCM) does not support modem or fax passthrough. This feature should not be enabled when Cisco UCM is the call agent.

Table 33 MGCP Behavior Category Keywords (continued)

Keywords	Description
private-localhost	Requires the outgoing messages from the gateway, like Notify (NTFY), RSIP, DLCX, have the private-localhost appended to the endpoint ID. By default, or when the **no** form of this command is issued, the outgoing messages from the gateway have the global router name appended to the endpoint ID. This is applicable for MGCP 0.1 and MGCP 1.0 versions.
q-mode-enduring legacy	Allows the gateway to keep the current quarantine mode when a request notification (RQNT) does not contain a Q: line. Operation reverts to legacy behavior, which is the following: **Note** Only the first bulleted item results in modified behavior. • No Q: line—Makes no changes to the quarantine mode (whatever mode was set in the previous command persists). • Empty Q: line—Resets the quarantine mode to the default. • Valid Q: line—Sets the quarantine mode per command. • Invalid Q: line—Generates an error. **Note** The quarantine mode is set with the **mgcp quarantine mode** command, and the default is discarded. This is the configuration mode used if the quarantine mode is not specified in the RQNT or embedded request for events. By default, or when the **no** form of this command is issued, MGCP behaves according to both MGCP Version 0.1 and MGCP Version 1.0 specifications—that is, the MGCP gateway resets the quarantine mode to the default in the running configuration if no Q: line is present.
rsip-range	Determines whether the gateway can generate RSIP messages with endpoint ranges for versions other than Trunking Gateway Control Protocol (TGCP). By default, endpoint ranges are generated in RSIP messages for TGCP only. The following *category* and *version* values can be configured: • **rsip-range all**—Allows the gateway to generate endpoint ranges in RSIP messages for all MGCP versions. • **rsip-range none**—Prevents the gateway from generating endpoint ranges for all MGCP versions, including TGCP. • **rsip-range tgcp-only**—Allows the gateway to generate endpoint ranges in RSIP messages only if the configured protocol is TGCP. This is the default value. TGCP specifications require support for endpoint ranges in RSIP messages. Not all call agents may support this functionality however. In such cases, selecting **none** allows the gateway to interoperate with these call agents. Conversely, if a non-TGCP call agent supports endpoint ranges, selecting **all** allows the gateway to take advantage of this functionality.

Table 33 MGCP Behavior Category Keywords (continued)

Keywords	Description
transient-state-response enable	Forces the gateway to send 400 responses for an MGCP message even if the endpoint is in a transient state. By default, or when **no** form of this command is issued, the gateway does not respond to MGCP messages even if the endpoint is in a transient or disconnecting state.

Table 34 describes the MGCP behavior version keywords.

Table 34 MGCP Behavior Version Keywords

Keywords	Description
auep v0.1	Forces the gateway to reply to an Audit Endpoint (AUEP) command according to the MGCP Version 0.1 specification. This behavior applies specifically to the case in which the endpoint being audited is out of service. If this command is used, an AUEP command on an out-of-service endpoint returns error code of 501. By default, or when the **no** form of this command is issued, MGCP Version 1.0 behavior occurs—that is, response code 200 is sent for all valid endpoints, regardless of their service state, and requested audit information follows. In either case, the configured MGCP version is ignored.
signals v0.1	Forces the gateway to handle call signaling tones such as ringback, network congestion, reorder, busy, and off-hook warning tones according to the MGCP Version 0.1 specification. The MGCP Version 0.1 specification treats some call signaling tones as on-off tones, which terminate only after a specific MGCP message has been received to stop the signal. By default, or when the **no** form of this command is issued, RFC 3660 is followed, which treats the call signaling tones as timeout tones that terminate when the appropriate timeout expires. In either case, the configured MGCP version is ignored.

Examples

The following example shows how the gateway sends MGCP 0.1 responses to AUEP commands:

```
Router(config)# mgcp behavior auep v0.1
```

The following example shows how the gateway provides MGCP 0.1 treatment of call signaling tones:

```
Router(config)# mgcp behavior signals v0.1
```

The following example shows how to disable the requirement that the RSIP be acknowledged before a call agent command is accepted:

```
Router(config)# mgcp behavior ack-init-rsip disable
```

The following example show how to configure the gateway to not demote initial RSIPs based on the service state of the endpoints:

```
Router(config)# mgcp behavior init-rsip-per-insvc legacy
```

The following example shows how to configure the gateway to turn off all signals on receipt of a DLCX:

```
Router(config)# mgcp behavior dlcx-clear-signals all
```

The following examples show how to set quarantine mode to legacy:

```
Router(config)# mgcp behavior q-mode-enduring legacy
```

The following example shows how to force the gateway to generate an SDP in the response to an MDCX with SDP:

```
Router(config)# mgcp behavior mdcx-sdp ack-with-sdp
```

The following example shows how to force the gateway to generate endpoint ranges for all MGCP versions:

```
Router(config)# mgcp behavior rsip-range all
```

The following example shows how to force the gateway not to change the codec payload type when it is dynamically changed in the incoming SDP for all MGCP versions:

```
Router(config)# mgcp behavior dynamically-change-codec-pt disable
```

The following example shows how to force the gateway not to disconnect when it receives DLCX:

```
Router(config)# mgcp behavior fxs-gs emulate-ls-disconnect
```

The following example shows how forces the gateway to send responses for MGCP messages even if the endpoint is in a transient state:

```
Router(config)# mgcp behavior transient-state-response enable
```

The following example shows how to force the gateway to take connection mode M in CRCX:

```
Router(config)# mgcp behavior mode-attrb-in-sdp disable
```

The following example shows how to force the outgoing messages to have the configured private–localhost appended to the endpoint ID for MGCP 0.1 and MGCP 1.0 versions:

```
Router(config)# mgcp behavior private-localhost cisco.com
```

The following example shows how to force the gateway to play a reorder tone when MGCP is still stuck trying to collect digits:

```
Router(config)# mgcp behavior digit-collect-stuck play-reorder
```

The following example shows how to allow the gateway to be aware of NSE capabilities:

```
Router(config)# mccp behavior negotiate-nse enable
```

Use the following commands to display the MGCP behavior and versions settings:

```
Router# show running-config | include behavior

mgcp behavior auep v0.1
mgcp behavior signals v0.1
mgcp behavior ack-init-rsip disable
mgcp behavior init-rsip-per-insvc legacy
mgcp behavior q_mode-enduring legacy
mgcp behavior dlcx-clear-signals all
mgcp behavior mdcx-sdp ack-with-sdp
mgcp behavior rsip-range all
mgcp behaviour dynamically-change-codec-pt disable
mgcp behavior fxs-gs emulate-ls-disconnect
mgcp behavior transient-state-response enable
mgcp behavior mode-attrb-in-sdp-disable
```

```
mgcp behavior private-localhost cisco.com
mgcp behavior digit-collect-stuck- play-reorder
mgcp behavior negotiate-nse enable

Router# show running-config | include call-agent

mgcp call-agent ca123.example.net 4040 service-type mgcp version rfc3435-1.0
```

Related Commands

Command	Description
mgcp	Allocates resources for MGCP and starts the MGCP daemon.
mgcp call-agent	Specifies the address and protocol for the MGCP call agent.
mgcp quarantine mode	Configures the mode for MGCP quarantined events.
show mgcp	Displays values for MGCP parameters.
show running-config	Displays the contents of the currently running configuration file.

mgcp behavior comedia-check-media-src

To force IP address and port detection from the first RTP packet received for the entire Media Gateway Control Protocol (MGCP) gateway and enable the callback function selected by MGCP, use the **mgcp behavior comedia-check-media-src** command in global configuration mode.

mgcp behavior comedia-check-media-src {**enable** | **disable**}

Syntax Description

enable	Forces ip address and port detection.
disable	Disables ip address and port detection.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines Use the **mgcp behavior comedia-check-media-src** command to force IP address and port detection from the first rtp packet received for the entire MGCP gateway. This command also enables the callback function selected by MGCP, and with the configuration of the **mgcp behavior comedia-role** command contributes to the determination of whether to populate the SDP direction attribute.

Examples The following example shows IP address and port detection being enabled for the entire MGCP gateway:

```
Router(config)# mgcp behavior comedia-check-media-src enable
```

Related Commands

Field	Description
mgcp	Allocates resources for the MGCP and starts the daemon.
mgcp behavior comedia-role	Specifies the location of the configured MGCP gateway.
mgcp behavior comedia-sdp-force	Forces the SDP to place the direction attribute in the SDP using the command as a reference.
show mgcp connection	Displays information for active MGCP-controlled connections.

mgcp behavior comedia-role

To specify the location of the configured Media Gateway Control Protocol (MGCP) gateway, use the **mgcp behavior comedia-role** command in global configuration mode.

mgcp behavior comedia-role {**active** | **passive** | **none**}

Syntax Description

active	Specifies MGCP gateways located inside NAT.
passive	Specifies MGCP gateways located outside of NAT.
none	Specifies gateway behavior be as in releases prior to Cisco IOS Release 12.4(11)T.

Command Default

none

Command Modes

Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

This command will specify the location of the configured MGCP gateway and its role in solving the NAT media traversal. A comedia role of **active** is configured for MGCP gateways inside NAT. For gateways located outside of NAT a comedia role of **passive** is configured. Configuring the **none** keyword specifies gateway behavior before the **mgcp behavior comedia-role** command was introduced.

The **mgcp behavior comedia-role** and **mgcp behavior comedia-check-media-src** commands are used to determine when to populate the sdp direction attribute.

Examples

The following example shows the location of the MGCP gateway configured for MGCP gateways inside NAT:

```
Router(config)# mgcp behavior comedia-role active
```

Related Commands

Field	Description
mgcp behavior comedia-check-media-src	Enables ip address and port detection from the first rtp packet received for the entire MGCP gateway.
mgcp behavior comedia-sdp-force	Forces the SDP to place the direction attribute in the SDP using the command as a reference.
mgcp	Allocates resources for the MGCP and starts the daemon.
show mgcp	Displays the entire mgcp configuration.
show mgcp connection	Displays information for active MGCP-controlled connections.

mgcp behavior comedia-sdp-force

To force MGCP to place the direction attribute in the Session Description Protocol (SDP), use the **mgcp behavior comedia-sdp-force** command in global configuration mode.

mgcp behavior comedia-sdp-force {**enable** | **disable**}

Syntax Description

enable	Forces MGCP to place the direction attribute in the SDP.
disable	Allows the **mgcp behavior comedia-role**, and **mgcp behavior comedia-check-media-src** commands and the remote descriptor to determine if the direction attribute is added to the SDP.

Command Default

Disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

This command will force the MGCP to always place the direction attribute in the SDP using the **mgcp behavior comedia-sdp-force** command as a reference. When the **mgcp behavior comedia-sdp-force** command is configured with the **disable** keyword, the **mgcp behavior comedia-role** and **mgcp behavior comedia-check-media-src** commands and the remote descriptor determine if the direction is added to the SDP. If the role is not configured, this command has no effect.

Examples

The following example configuration forces the direction attribute to be placed in the SDP:

```
Router(config)# mgcp behavior comedia-sdp-force enable
```

Related Commands

Field	Description
mgcp	Allocates resources for the MGCP and starts the daemon.
mgcp behavior comedia-check-media-src	Enables ip address and port detection from the first rtp packet received for the entire MGCP gateway.
mgcp behavior comedia-role	Specifies the location of the configured MGCP gateway.
show mgcp connection	Displays information for active MGCP-controlled connections.

mgcp behavior g729-variants static-pt

To change the default from dynamic to static Real-time Transport Protocol (RTP) payload type on G.729 voice codecs, use the **mgcp behavior g729-variants static-pt** command in global configuration mode. To return the default to dynamic, use the **no** form of this command.

mgcp behavior g729-variants static-pt

no mgcp behavior g729-variants static-pt

Syntax Description

This command has no arguments or keywords.

Command Default

This command is enabled by default, so the RTP payload type on G.729 voice codecs is static.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(11)T	This command was introduced.
12.4(22)T2 12.4(24)T1	This command was modified to be enabled by default.

Usage Guidelines

Prior to Cisco IOS Releases 12.4(22)T2 and 12.4(24)T1, the negotiated value (dynamic) payload type was not set in RTP packets. If you upgraded the Cisco IOS software on your network voice gateways (with existing Cisco Unified Communications Manager) and calls were going between Skinny Client Control Protocol (SCCP) phones controlled by Cisco Unified Communications Manager and public switched telephone network (PSTN) phones connected to a Cisco gateway, a condition of “no audio” could occur. The **mgcp behavior g729-variants static-pt** command changes the default from dynamic to static RTP payload type on G.729 voice codecs and eliminates the “no audio” condition.

Examples

The following example shows how to set the RTP payload type to static for G.729 voice codecs:

```
Router(config)# mgcp behavior g729-variants static-pt
```

Related Commands

Command	Description
mgcp codec	Selects the default codec type and its optional packetization period value.
mgcp rtp payload-type	Specifies use of the correct RTP payload type for backward compatibility in MGCP networks.

mgcp bind

To configure the source address for signaling and media packets to the IP address of a specific interface, use the **mgcp bind** command in global configuration mode. To disable binding, use the **no** form of this command.

mgcp bind {**control** | **media**} **source-interface** *interface-id*

no mgcp bind {**control** | **media**}

Syntax Description

control	Binds only Media Gateway Control Protocol (MGCP) control packets.
media	Binds only media packets.
source-interface	Specifies an interface as the source address of MGCP or Session Initiation Protocol (SIP) packets. **Note** The MGCP Gateway Support for the mgcp bind Command feature does not support SIP.
interface-id	Specifies the interface for source address of MGCP packets. The following are valid source addresses: • **Async**—Async interface • **BVI**—Bridge-Group Virtual Interface • **CTunnel**—CTunnel interface • **Dialer**—Dialer interface • **FastEthernet**—Fast Ethernet IEEE 802.3 • **Lex**—Lex interface • **Loopback**—Loopback interface • **MFR**—Multilink Frame Relay bundle interface • **Multilink**—Multilink-group interface • **Null**—Null interface • **Serial**—Serial • **Tunnel**—Tunnel interface • **Vif**—PGM Multicast Host interface • **Virtual-Template**—Virtual Template interface • **Virtual-TokenRin**g—Virtual Token Ring

Command Default Binding is disabled.

Command Modes Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced for MGCP on the Cisco 2400 series, Cisco 2600 series, Cisco 3600 series, Cisco 3700 series, Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5850, Cisco IAD2421, Cisco MC3810, and Cisco VG200.

Usage Guidelines

If the **mgcp bind** command is not enabled, the IP layer still provides the best local address.

A warning message is displayed if any of the following situations occur:

- When there are active MGCP calls on the gateway, the **mgcp bind** command is rejected for both control and media.
- If the bind interface is not up, the command is accepted but does not take effect until the interface comes up.
- If the IP address is not assigned on the bind interface, the **mgcp bind** command is accepted but takes effect only after a valid IP address is assigned. During this time, if MGCP calls are up, the **mgcp bind** command is rejected.
- When the bound interface goes down, either because of a manual shutdown on the interface or because of operational failure, the bind activity is disabled on that interface.
- When bind is not configured on the media gateway controller (MGC), the IP address used for sourcing MGCP control and media is the best available IP address.

Examples

The following example shows how the configuration of bind interfaces is shown when **show running-config** information is viewed:

```
.
.
.
mgcp bind control source-interface FastEthernet0
mgcp bind media source-interface FastEthernet0
.
.
.
```

Related Commands

Command	Description
show mgcp	Displays values for MGCP parameters.

mgcp block-newcalls

To block new calls while maintaining existing calls, use the **mgcp block-newcalls** command in global configuration mode. To resume media gateway control protocol (MGCP) operation, use the **no** form of this command.

mgcp block-newcalls

no mgcp block-newcalls

Syntax Description

This command has no arguments or keywords.

Command Default

New call are not blocked.

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

This command is valid only if the **mgcp** command is enabled.

Once you issue this command, all requests for new connections (CreateConnection requests) are denied. All existing calls are maintained until participants terminate them or you use the **no mgcp** command. When the last active call is terminated, the MGCP daemon is terminated and all resources that are allocated to it are released. The **no mgcp block-newcalls** command returns the router to normal MGCP operations.

Examples

The following example prevents the gateway from receiving new calls:

```
Router(config)# mgcp block-newcalls
```

Related Commands

Command	Description
mgcp	Allocates resources for the MGCP and starts the daemon.

mgcp call-agent

To configure the address and protocol of the call agent for Media Gateway Control Protocol (MGCP) endpoints on a media gateway, use the **mgcp call-agent** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp call-agent {*host-name* | *ip-address*} [*port*] [**service-type** *type* [**version** *protocol-version*]]

no mgcp call-agent

Syntax Description

host-name	Fully qualified domain name (including host portion) for the call agent; for example, ca123.example.net.
ip-address	IP address for the call agent.
port	(Optional) User Datagram Protocol (UDP) port over which the gateway sends messages to the call agent. Range is from 1025 to 65535.
service-type *type*	(Optional) Type of Gateway control service protocol. It can be one of the following values: • **mgcp**—Media Gateway Control Protocol • **ncs**—Network Communication Server • **sgcp**—Simple Gateway Control Protocol • **tgcp**—Trunking Gateway Control Protocol
version *protocol-version*	(Optional) Version of gateway control service protocol. It can be one of the following values: • For **service-type mgcp**: 0.1, 1.0, rfc3435-1.0 – 0.1—Version 0.1 of MGCP (Internet Draft) – 1.0—Version 1.0 of MGCP (RFC2705 Version 1.0) – rfc3435-1.0—Version 1.0 of MGCP (RFC3435 Version 1.0) **Note** This configuration value is used to allow the router to tailor the MGCP application behavior to be compatible based on the RFC2705 or RFC3435 definitions. • For **service-type ncs**: 1.0 • For **service-type sgcp**: 1.1, 1.5 • For **service-type tgcp**: 1.0

Command Default

Call-agent UDP port: 2727 for MGCP 1.0, NCS 1.0, and TGCP 1.0
Call-agent UDP port: 2427 for MGCP 0.1 and SGCP
Call-agent UDP port: 2427 for Cisco CallManager
Service type and version: mgcp 0.1
Service type for Cisco CallManager: mgcp

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	The **service-type** *type* keyword and argument were added.
12.1(5)XM	The **version** *protocol-version* keyword and argument were added.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(2)XA	New service types (**ncs** and **tgcp**) and appropriate versions were added. Version 1.0 was added for the **mgcp** service type. This command was implemented on Cisco 2600 series and Cisco 3600 series routers.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(2)XN	This command was implemented to provide enhanced MGCP voice gateway interoperability on Cisco CallManager Version 3.1 for the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco VG200.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 3.2 and implemented on the Cisco IAD2420 series and Cisco AS5850.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T and implemented on the Cisco AS5300, Cisco AS5350, and Cisco AS5400.
12.3(8)T 1	This command was modified by adding the RFC3435-1.0 option to the command.

Usage Guidelines

Global call-agent configuration (with this command) and call-agent configuration for an MGCP profile (with the **mgcp profile call-agent** command) are mutually exclusive; the first to be configured on an endpoint blocks configuration of the other on the same endpoint.

Identifying call agents by Domain Name System (DNS) name rather than by IP address in the **mgcp call-agent** and **mgcp profile call-agent** commands provides call-agent redundancy, because a DNS name can have more than one IP address associated with it. If a call agent is identified by DNS name and a message from the gateway fails to reach the call agent, the **max1 lookup** and **max2 lookup** commands enable a search from the DNS lookup table for a backup call agent at a different IP address.

The *port* argument configures the call-agent port number (the UDP port over which the gateway sends messages to the call agent). The reverse (the gateway port number, or the UDP port over which the gateway receives messages from the call agent) is configured by specifying a port number in the **mgcp** command.

When the service type is set to **mgcp**, the call agent processes the restart in progress (RSIP) error messages sent by the gateway if the **mgcp sgcp restart notify** command is enabled. When the service type is set to **sgcp**, the call agent ignores the RSIP messages.

Use this command on any platform and media gateway.

The **mgcp** service type supports the RSIP error messages sent by the gateway if the **mgcp sgcp restart notify** command is enabled.

Examples

The following examples illustrate several formats for specifying the call agent (use any one of these formats):

```
Router(config)# mgcp call-agent 209.165.200.225 service-type mgcp version 1.0
Router(config)# mgcp call-agent 10.0.0.1 2427 service-type mgcp version rfc3435-1.0
Router(config)# mgcp call-agent igloo.northpole.net service-type ncs
Router(config)# mgcp call-agent igloo.northpole.net 2009 service-type sgcp version 1.5
Router(config)# mgcp call-agent 209.165.200.225 5530 service-type tgcp
```

Related Commands

Command	Description
call-agent	Specifies a call-agent address and protocol for an MGCP profile.
debug mgcp events	Displays debug messages for MGCP events.
max1 lookup	Enables DNS lookup of the MGCP call agent address when the suspicion threshold is reached.
max2 lookup	Enables DNS lookup of the MGCP call agent address when the disconnect threshold is reached.
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp profile	Initiates MGCP profile mode to create and configure an MGCP profile associated with one or more endpoints, or to configure the default profile.
mgcp sgcp restart notify	Starts RSIP message processing in the MGCP application.mgcp
sgcp restart notify	Enables the MGCP application to process SGCP-type RSIP messages.

mgcp codec

To select the codec type and its optional packetization period value, use the **mgcp codec** command in global configuration mode. To set the codec to its default value of G711 u-law, use the **no** form of this command.

mgcp codec *type* [**packetization-period** *value*]

no mgcp codec

Syntax Description

type	Type of codec supported. Valid codecs include the following: G711alaw, G711ulaw, G723ar53, G723ar63, G723r53, G723r63, G729ar8, G729br8, and G729r8.
packetization-period *value*	(Optional) Packetization period. This value is useful when the preferred compression algorithm and packetization period parameter is not provided by the media gateway controller. The range depends on the type of codec selected: • Range for **G729** is 10 to 220 in increments of 10. • Range for **G711** is 10 to 20 in increments of 10. • Range for **G723** is 30 to 330 in increments of 10.

Command Default **G711 u-law codec**

Command Modes Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.1(5)XM	This command was implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5850.

Examples The following example specifies the codec type:

```
Router(config)# mgcp codec g711alaw
```

The following example sets the codec type and packetization period:

```
Router(config)# mgcp codec g729r8 packetization-period 150
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp codec gsmamr-nb

To specify the Global System for Mobile Adaptive Multi-Rate Narrow Band (GSMAMR-NB) codec for an MGCP dial peer, use the **mgcp codec gsmamr-nb** command in dial peer voice configuration mode. To disable the GSMAMR-NB codec, use the **no** form of this command.

mgcp codec gsmamr-nb [**packetization-period 20**] [**encap rfc3267**] [**frame-format** {**bandwidth-efficient** | **octet-aligned** [**crc** | **no-crc**]}] [**modes** *modes-value*]

no mgcp codec gsmamr-nb

Syntax Description

packetization-period 20	(Optional) Sets the packetization period at 20 ms.
encap rfc3267	(Optional) Sets the encapsulation value to comply with RFC 3267.
frame-format	(Optional) Specifies a frame format. Supported values are **octet-aligned** and **bandwidth-efficient**. The default is **octet-aligned**.
crc | **no-crc**	(Optional) CRC is applicable only for **octet-aligned** frame format. If you enter **bandwidth-efficient** frame format, the **crc** | **no-crc** options are not available because they are inapplicable.
modes	(Optional) The eight speech-encoding modes (bit rates between 4.75 and 12.2 kbps) available in the GSMAMR-NB codec.
modes-value	(Optional) Valid values are from 0 to 7. You can specify modes as a range (for example, 0-2), or individual modes separated by commas (for example, 2,4,6), or a combination of the two (for example, 0-2,4,6-7).

Command Default

Packetization period is **20** ms.
Encapsulation is **rfc3267**.
Frame format is **octet-aligned**.
CRC is **no-crc**.
Modes value is **0-7**.

Command Modes

Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.4(11)XW	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

Use the **mgcp codec gsmamr-nb** command to configure the GSMAMR-NB codec and its parameters on the Cisco AS5350XM and Cisco AS5400XM platforms.

Examples

The following example shows how to set the codec to **gsmamr-nb** and set the parameters:

```
Router(config-dial-peer)# mgcp codec gsmamr-nb packetization-period 20 encap rfc3267
frame-format octet-aligned crc
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp codec ilbc

To specify the internet Low Bandwidth Codec (iLBC) for an MGCP dial peer, use the **mgcp codec ilbc** command in dial peer voice configuration mode. To disable the iLBC, use the **no** form of this command.

mgcp codec ilbc mode *frame_size* [**packetization-period** *value*]

no mgcp codec ilbc

Syntax Description

mode *frame_size*	Specifies the iLBC operating frame mode that is encapsulated in each packet in milliseconds (ms). Valid entries are the following: • 20—20, 40, 60, 80, 100 or 120 ms frames for 15.2 kbps bit rate. Default is 20. • 30—30, 60, 90, or 120 ms frames for 13.33 kbps bit rate. Default is 30.
packetization-period *value*	(Optional) Packetization period. This value is useful when the preferred compression algorithm and packetization period parameter are not provided by the media gateway controller. The range is 20 to120 in increments of 10.

Command Default

20ms frames for a 15.2 kbps bit rate.

Command Modes

Dial peer voice configuration (config-dial-peer)

Command History

Release	Modification
12.4(11)XW	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

The iLBC is only supported on Cisco AS5350XM and Cisco AS5400XM Universal Gateways with Voice Feature Cards (VFCs) and IP-to-IP gateways with no transcoding and conferencing.

Examples

The following example shows how to set the MGCP codec to **ilbc** and set the parameters:

```
Router(config-dial-peer)# mgcp codec ilbc mode 20 packetization-period 60
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp crypto rfc-preferred

To enable support for the media-level Session Description Protocol (SDP) a=crypto attribute on Cisco IOS Media Gateway Control Protocol (MGCP) gateways, use the **mgcp crypto rfc-preferred** command in global configuration mode. To disable support for the a=crypto attribute, use the **no** form of this command.

mgcp crypto rfc-preferred

no mgcp crypto rfc-preferred

Syntax Description

This command has no arguments or keywords.

Command Default

Support for the a=crypto attribute is not enabled on Cisco IOS MGCP gateways.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(22)YB2	This command was introduced.

Usage Guidelines

Cryptographic parameters for Secure RTP (SRTP) media sessions are signalled and negotiated using the crypto attribute in the SDP. Some versions of the crytpo attribute syntax set the crypto attribute name to the X-crypto keyword (a=X-crypto). RFC 4568 *Session Description Protocol (SDP) Security Descriptions for Media Streams,* defines the crypto attribute syntax, where the attribute name is set to the crypto keyword (a=crypto). You use the **mgcp crypto rfc-preferred** command to enable support for the a=crypto attribute on Cisco MGCP gateways.

When support for a=crypto is enabled, the system can choose to use the a=crypto or a=X-crypto notation, depending on the SDP received. By default, if a remote SDP is not present, all SDPs generated by the gateway use the a=crypto notation.

If the command is disabled, the gateway can understand both a=crypto or a=X-crypto in any SDP it receives. However, all SDPs generated by the gateway use the a=X-crypto notation.

You must configure the command based on the notation used by the call agent. For example, the Cisco public switched telephone network (PSTN) gateway (PGW) uses the a=crypto notation and Cisco Unified Call Manager uses the a=X-crypto notation.

Examples

The following example enables support for the SDP a=crypto attribute on the Cisco IOS MGCP gateway:

```
Router(config)# mgcp crypto rfc-preferred
```

The following is sample output from the **show mgcp** command when support for the SDP a=crypto attribute is enabled on the Cisco IOS MGCP gateway:

```
Router(config)# show mgcp

MGCP rsip-range is enabled for TGCP only.
MGCP Comedia role is NONE
MGCP Comedia check media source is DISABLED
MGCP Comedia SDP force is DISABLED
MGCP Guaranteed scheduler time is DISABLED
MGCP Disconnect delay error recovery DISABLED
MGCP support for a:crypto RFC notation is ENABLED
MGCP DNS stale threshold is 30 seconds
```

Related Commands

Command	Description
debug mgcp	Enables debug traces for MGCP errors, events, media, packets, parser, and CAC.
max1 retries	Sets the MGCP suspicion threshold value (the number of attempts to retransmit messages to a call agent address before performing a new lookup for retransmission).
max2 retries	Set the MGCP disconnect threshold value (the number of attempts to retransmit messages to a call agent address before performing a new lookup for further retransmission).
mgcp	Allocates resources for the MGCP and starts the MGCP daemon.
mgcp block-newcalls	Blocks new calls while maintaining existing calls.
mgcp ip-tos	Enables or disables the IP ToS for MGCP connections.
mgcp profile	Creates and configures an MGCP profile to be associated with one or more MGCP endpoints or configures the default MGCP profile.
show mgcp	Displays values for MGCP parameters.

mgcp dns stale threshold

To configure the Media Gateway Control Protocol (MGCP) Domain Name System (DNS) stale threshold, use the **mgcp dns stale threshold** command in global configuration mode. To disable the stale threshold configuration, use the **no** form of this command.

mgcp dns stale threshold *seconds*

no mgcp dns stale threshold

Syntax Description

seconds	The threshold time in seconds, that MGCP DNS values are considered stale. The range is from 0 to 600. The default is 300.

Command Default

The MGCP DNS threshold value is set to 300 seconds.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(24)T	This command was introduced in a release earlier than Cisco IOS Release 12.4(24)T.

Examples

The following example shows how to set the threshold stale time to 44 seconds:

```
Router(config)# mgcp dns stale threshold 44
```

Related Commands

Command	Description
show mgcp	Displays MGCP parameter details.

mgcp debug-header

To enable the display of Media Gateway Control Protocol (MGCP) module-dependent information in the debug header, use the **mgcp debug-header** command in global configuration mode. To disable the MGCP module-dependent information, use the **no** form of this command.

mgcp debug-header

no mgcp debug-header

Syntax Description

This command has no arguments or keywords.

Command Default

MGCP module-dependent information in the debug header is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.4(4)T	This command was introduced.

Usage Guidelines

This command determines whether MGCP module-dependent information is displayed in the standard header for debug output.

Examples

The following example enables MGCP module-dependent information in debug headers:

```
Router(config)# mgcp debug-header
```

Related Commands

Command	Description
debug mgcp all	Enables all debug traces for MGCP.
debug mgcp endpoint	Enables debug traces for a specific MGCP endpoint.
mgcp	Starts the MGCP daemon.
show debugging	Displays the types of debugging that are enabled.
show mgcp	Displays the MGCP parameter settings.
voice call debug	Specifies the format of the debug header.

mgcp default-package

To configure the default package capability type for the media gateway, use the **mgcp default-package** command in global configuration mode. This command does not have a **no** form. To change the default package, use the **mgcp default-package** command with a different, actively supported package.

Residential Gateways

mgcp default-package {**dt-package** | **dtmf-package** | **fxr-package** | **gm-package** | **hs-package** | **line-package** | **ms-package** | **rtp-package**}

Business Gateways

mgcp default-package {**atm-package** | **dt-package** | **dtmf-package** | **fxr-package** | **gm-package** | **hs-package** | **line-package** | **ms-package** | **rtp-package** | **trunk-package**}

Trunking Gateways

mgcp default-package {**as-package** | **atm-package** | **dt-package** | **dtmf-package** | **gm-package** | **hs-package** | **md-package** | **mo-package** | **ms-package** | **nas-package** | **rtp-package** | **script-package** | **trunk-package**}

Syntax Description

as-package	Announcement server package.
atm-package	ATM package.
dtmf-package	DTMF package.
dt-package	DTMF trunk package (for Channel Associated Signaling (CAS) endpoints).
fxr-package	FXR package for fax transmissions.
gm-package	Generic media package.
hs-package	Handset package.
line-package	Line package.
md-package	MD package for Feature Group D (FGD) Exchange Access North American (EANA) signaling.
mo-package	MF operator services package (for CAS endpoints).
ms-package	MF wink/immediate start package (for CAS endpoints).
nas-package	Network access server package.
rtp-package	RTP package.
script-package	Script package.
trunk-package	Trunk package.

Command Default

For residential gateways: line-package
For trunking gateways: trunk-package

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	The **line-package** keyword and a distinction between residential and trunking gateways were added.
12.1(5)XM	This command was implemented on the Cisco MC3810 and Cisco 3600 series. The **atm-package**, **hs-package**, **ms-package**, **dt-package**, and **mo-package** keywords were added.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.
12.3(1)	The **fxr-package** keyword was added.
12.4(4)T	The **md-package** keyword was added.

Usage Guidelines

This command is helpful when the Media Gateway Controller does not provide the package capability to be used for the specific connection.

Before selecting a package as the default, use the **show mgcp** command to ensure that the package is actively supported. If the package you want does not appear in the display, use the **mgcp package-capability** command to add the package to the supported list.

Note The CAS packages (**dt-package**, **md-package**, **mo-package**, and **ms-package**) are available only as default package options. They do not appear as options in the **mgcp package-capability** command. This is because the non-CAS packages are configured on a per-gateway basis, whereas the CAS packages are defined on a per-trunk basis. Each trunk is defined using the **ds0-group** command.

If only one package is actively supported, it becomes the default package.

When the FXR package is the default, the call agent omits the "fxr/" prefix on two types of requests in CRCX, MDCX, DLCX, and RQNT messages: requests to detect events ("R:<pkg>/<evt>") and requests to generate events ("S:<pkg>/<evt>"). For example, to ask for T.38 detection, the call agent sends "R:t38" in an RQNT message rather than "R:fxr/t38." Note that the "fxr/fx:" parameter to the Local Connection Options is not affected by selection of FXR as the default package and always needs the "fxr/" prefix.

Examples

The following example sets the default package:

```
Router(config)# mgcp default-package as-package
! The announcement server package type will be the new default package type.
```

Related Commands

Command	Description
ds0-group	Specifies the DS0 time slots that make up a logical voice port
mgcp	Starts the MGCP daemon.
mgcp package-capability	Includes a specific MGCP package that is supported by the gateway.
show mgcp	Displays values for MGCP parameters.

mgcp disconnect-delay

To configure the MGCP disconnect delay error recovery mechanism, use the **mgcp disconnect-delay** command in global configuration mode. To disable error recovery, use the **no** form of this command.

mgcp disconnect-delay [**timeout** *seconds*]

no mgcp disconnect-delay

Syntax Description

timeout	(Optional) User defined timeout before the error recovery procedure is initiated.
seconds	Length of timeout, in seconds before the error recovery procedure is initiated. The range is from 2 to 15. There is no default.

Command Default

Disconnect delay error recovery is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)T8, 12.4(20)T2	This command was introduced.
12.4(22)T1	This command was integrated into Cisco IOS Release 12.4(22)T1.

Usage Guidelines

When the FXS telephony endpoint disconnect request exceeds the configured timeout value for completion, the call agent continues to send MGCP messages, which cause the FXS endpoint to eventually block or unregister the gateway. To avoid this situation, configure the gateway with the **mgcp disconnect-delay** command so that the MGCP application initiates the disconnect delay error recovery procedure when the disconnect request takes too long to complete.

When the **mgcp disconnect-delay timeout** command is configured without the optional **timeout** keyword the disconnect delay error recovery mechanism is set to 7 seconds.

Examples

The following example shows the disconnect delay error recovery mechanism set to the default timeout of 7 seconds:

```
Router(config)# mgcp disconnect-delay
```

The following example shows the disconnect delay error recovery mechanism set with a user-defined 15 seconds:

```
Router(config)# mgcp disconnect-delay timeout 15
```

mgcp dtmf-relay

To ensure accurate forwarding of digits on compressed codecs, use the **mgcp dtmf-relay** command in global configuration mode. To disable this process for uncompressed codecs, use the **no** form of this command.

Voice over IP (VoIP)

mgcp dtmf-relay voip codec {**all** | **low-bit-rate**} **mode** {**cisco** | **disabled** | **nse** | **out-of-band** | **nte-gw** | **nte-ca**}

no mgcp dtmf-relay voip

Voice over AAL2 (VoAAL2)

mgcp dtmf-relay voaal2 codec [**all** | **low-bit-rate**]

no mgcp dtmf-relay voaal2

Syntax Description

voip	Specifies VoIP calls.
voaal2	Specifies voice over AAL2 (VoAAL2) calls (using Annex K type 3 packets).
codec	Specifies the MGCP DTMF relay codec configuration.
all	Specifies that dual-tone multifrequency (DTMF) relay is to be used with all voice codecs.
low-bit-rate	Specifies that the DTMF relay is to be used with only low-bit-rate voice codecs, such as G.729.
mode	Sets MGCP DTMF relay mode.
cisco	Specifies that Real-time Transport Protocol (RTP) digit events are encoded using a proprietary format similar to Frame Relay as described in the FRF.11 specification. The events are transmitted in the same RTP stream as nondigit voice samples, using payload type 121.
disabled	Sets MGCP DTMF relay mode to be disabled. This keyword is available only for the **all** keyword.
nse	Specifies that named signaling event (NSE) RTP digit events are encoded using the format specified in RFC 2833, Section 3.0, and are transmitted in the same RTP stream as nondigit voice samples, using the payload type that is configured using the **mgcp tse payload** command.
out-of-band	Specifies that Media Gateway Control Protocol (MGCP) digit events are sent using Notify (NTFY) messages to the call agent, which plays them on the remote gateway using Request Notification (RQNT) messages with **S:** (signal playout request).
nte-gw	Specifies that RTP digit events are encoded using the named telephony event (NTE) format specified in RFC 2833, Section 3.0, and are transmitted in the same RTP stream as nondigit voice samples. The payload type is negotiated by the gateways before use. The configured value for payload type is presented as the preferred choice at the beginning of the negotiation.
nte-ca	Behaves similar to the **nte-gw** keyword except that the call agent's local connection options **a:** line is used to enable or disable DTMF relay.

Defaults

For the Cisco 7200 series router, the command is disabled.
For all other platforms, noncompressed codecs are disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.1(5)XM	This command was integrated into Cisco IOS Release 12.1(5)XM and implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series. The **voaal2** keyword was added.
12.2(2)XB	This command was modified. The **nte-gw** and **nte-ca** keywords were added to this command.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(2)XN	This command was integrated into Cisco IOS Release 12.2(2)XN and implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco Voice Gateway 200 (Cisco VG200).
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and Cisco CallManager Version 2.0. This command was implemented on the following platforms: Cisco AS5300, Cisco AS5400, Cisco AS5850, and Cisco IAD2420.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T and implemented on the Cisco 1751 and Cisco 1760.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **disabled** keyword was added.

Usage Guidelines

Use this command to access an announcement server or a voice-mail server that cannot decode RTP packets containing DTMF digits. When the **mgcp dtmf-relay** command is active, the DTMF digits are removed from the voice stream and carried so that the server can decode the digits.

Only VoIP supports the **mode** keyword for forwarding digits on codecs.

Examples

The following example shows how to remove the DTMF tone from the voice stream and send FRF.11 with a special payload for the DTMF digits:

```
Router(config)# mgcp dtmf-relay codec mode cisco
```

The following example shows how to configure a low-bit-rate codec using VoIP in NSE mode:

```
Router(config)# mgcp dtmf-relay voip codec low-bit-rate mode nse
```

The following example shows how to configurev a codec for VoAAL2:

```
Router(config)# mgcp dtmf-relay voaal2 codec all
```

The following example shows how to configure a low-bit-rate codec using VoIP in NSE mode:

```
Router(config)# mgcp dtmf-relay voip codec low-bit-rate mode nse
```

The following example shows how to set the DTMF relay codec and mode to gateway:

```
Router(config)# mgcp dtmf-relay codec mode nte-gw
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp endpoint offset

To enable incrementing of the POTS or DS0 portion of an endpoint name when using the Network-based Call Signaling (NCS) 1.0 profile of Media Gateway Control Protocol (MGCP), use the **mgcp endpoint offset** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp endpoint offset

no mgcp endpoint offset

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

This command is used with NCS 1.0 to increment the POTS or DS0 portion of an endpoint name by 1 to minimize potential interoperability problems with call agents (media gateway controllers).

NCS 1.0 mandates that the port number of an endpoint be based on 1, and port numbering on some gateway platforms is based on 0.

When this command is configured, it offsets all endpoint names on the gateway. For example, an endpoint with a port number of aaln/0 is offset to aaln/1, and a DS0 group number of 0/0:0 is offset to 0/0:1.

Examples

The following example enables incrementing the port number portion of an endpoint name:

```
Router(config)# mgcp endpoint offset
```

Related Commands

Command	Description
mgcp	Starts and allocates resources for the MGCP daemon.

mgcp explicit hookstate

To enable detection of explicit hookstates, use the **mgcp explicit hookstate** command in global configuration mode. To disable hookstate detection, use the **no** form of this command.

mgcp explicit hookstate

no mgcp explicit hookstate

Syntax Description

This command has no arguments or keywords.

Command Default

Hookstate detection is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

Explicit hookstate detection is enabled by default. In this state, the gateway returns a “401 endpoint already off hook” or “402 endpoint already on hook” NACK (Not Acknowledged) response to R:hu or R:hd event requests.

If you turn hookstate detection off with the **no** form of the **mgcp explicit hookstate** command, the hookstate is not checked when the gateway receives R:hu or R:hd event requests. The gateway acknowledges (ACK) these event requests.

Examples

The following example enables hookstate detection:

```
Router(config)# mgcp explicit hookstate
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp fax rate

To establish the maximum fax rate for Media Gateway Control Protocol (MGCP) T.38 sessions, use the **mgcp fax rate** command in global configuration mode. To reset MGCP endpoints to their default fax rate, use the **no** form of this command.

mgcp fax rate {**2400** | **4800** | **7200** | **9600** | **12000** | **14400** | **voice**}

no mgcp fax rate

Syntax Description

2400	Maximum fax transmission speed of 2400 bits per second (bps).
4800	Maximum fax transmission speed of 4800 bps.
7200	Maximum fax transmission speed of 7200 bps.
9600	Maximum fax transmission speed of 9600 bps.
12000	Maximum fax transmission speed of 12,000 bps.
14400	Maximum fax transmission speed of 14,400 bps.
voice	Highest possible transmission speed allowed by the voice codec. This is the default.

Command Default

MGCP fax rate is set to the highest possible transmission speed allowed by the voice codec (**mgcp fax rate voice**).

Command Modes

Global configuration

Command History

Release	Modification
12.3(8)T	This command was introduced.

Usage Guidelines

Use this command to specify the maximum fax transmission rate for all MGCP endpoints in the gateway.

The values for this command apply only to the fax transmission speed and do not affect the quality of the fax itself. The higher transmission speed values (14,400 bps) provide a faster transmission speed but use a significantly large portion of the available bandwidth. A lower transmission speed value (2400 bps, for example) provides a slower transmission speed but uses a smaller portion of the available bandwidth.

Note MGCP fax rate does not support call admission and control or bandwidth allocation.

When the MGCP fax rate is set to the highest possible transmission speed allowed by the voice codec (**mgcp fax rate voice**), all MGCP endpoints limit T.38 fax calls to this speed. For example, if the voice codec is G.711, fax transmission may occur up to 14,400 bps because 14,400 bps is less than the 64-kbps voice rate. If the voice codec is G.729 (8 kbps), the fax transmission speed is limited to the nearest fax rate of 7200 bps.

Tip If the fax rate transmission speed is set higher than the codec rate in the same dial peer, the data sent over the network for fax transmission will be greater than the bandwidth reserved for Resource Reservation Protocol (RSVP). The **mgcp fax rate** command sets a maximum fax rate for T.30 negotiation (DIS/DCS). Fax machines can negotiate a lower rate, but not a higher rate.

Only values other than the default value appear in the saved gateway configuration.

Examples

The following example configures a maximum fax rate transmission speed of 9600 bps for MGCP T.38 fax relay sessions:

```
Router(config)# mgcp fax rate 9600
```

The following example configures the maximum fax rate transmission speed to 12,000 bps for MGCP T.38 fax relay sessions:

```
Router(config)# mgcp fax rate 12000
```

Related Commands

Command	Description
show call active fax	Displays the maximum fax rate for the current T.38 fax session.
show mgcp	Displays the current configuration for the MGCP fax rate.

mgcp fax-relay

To allow for the suppression of tones from the fax machine side so that Super Group 3 (SG3) fax machines can negotiate down to G3 speeds for Media Gateway Control Protocol (MGCP) fax relay, use the **mgcp fax-relay** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp fax-relay {**ans-disable** | **sg3-to-g3**}

no mgcp fax-relay {**ans-disable** | **sg3-to-g3**}

Syntax Description

ans-disable	Suppresses ANS tones from originating SG3 fax machines so that these machines can operate at G3 speeds using fax relay.
sg3-to-g3	Allows SG3 machines to negotiate down to G3 speeds using fax relay.

Command Default

If this command is not enabled, modem upspeed can occur when ANS tones are detected and SG3-to-SG3 fax relay communication is not supported and probably will fail.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(4)T	This command was introduced as the **mgcp fax-relay sg3-to-g3** command.
12.4(6)T	This command was implemented on the Cisco 1700 series and Cisco 2800 series.
12.4(20)T1	The **ans-disable** keyword was added.
12.4(24)T	This command was integrated into Cisco IOS Release 12.4(24)T.

Usage Guidelines

When the **mgcp fax-relay ans-disable** command is entered, modem upspeed does not occur when an ANS tone is detected. When the **ans-disable** keyword is entered, the modem-related sessions will fail because the ANS tones are squelched at the digital signal processor (DSP) level by the TI C5510 DSP.

When the **mgcp fax-relay sg3-to-g3** command is entered, the DSP fax-relay firmware suppresses the V.8 CM tone and the fax machines negotiate down to G3 speeds for the fax stream.

Examples

The following global configuration output shows V.8 fax CM message suppression being enabled on the voice dial peer for MGCP signaling types:

```
Router(config)# mgcp fax-relay sg3-to-g3
```

Related Commands

Command	Description
fax-relay(voice-service)	Allows ANS tones to be disabled for SG3 machines to operate at G3 speeds using fax relay and to enable the fax stream between two SG3 fax machines to negotiate down to G3 speeds on a VoIP dial peer.
mgcp fax t38	Specifies MGCP fax T.38 parameters.

mgcp fax t38

To configure MGCP fax T.38 parameters, use the **mgcp fax t38** command in global configuration mode. return a parameter to its default, use the **no** form of this command.

mgcp fax t38 {**ecm | gateway force | hs_redundancy** *factor* **| inhibit | ls_redundancy** *factor* **| nsf** *hexcode*}

no mgcp fax t38 {**ecm | gateway force | hs_redundancy | inhibit | ls_redundancy | nsf**}

Syntax Description

ecm	Enables error correction mode (ECM) for the gateway. By default, ECM is not enabled.
gateway force	Forces gateway-controlled T.38 fax relay using Cisco-proprietary named signaling events (NSEs) even if the capability to use T.38 and NSEs cannot be negotiated by the MGCP call agent at call setup time. The default is that force is not enabled.
hs_redundancy *factor*	Sends redundant T.38 fax packets. Refers to data redundancy in the high-speed V.17, V.27, and V.29 T.4 or T.6 fax machine image data. For the **hs_redundancy** parameter, the *factor* range is from 0 through 2. The default is 0 (no redundancy). **Note** Setting the **hs_redundancy** parameter to a value greater than 0 causes a significant increase in the network bandwidth consumed by the fax call.
inhibit	Disables use of T.38 for the gateway. By default, T.38 is enabled. **Note** If the MGCP gateway uses the auto-configuration function, the **mgcp fax t38 inhibit** command is automatically configured on the gateway each time a new configuration is downloaded. Beginning with Cisco IOS Software Release 12.4T, the auto-configuration of this command is removed. For MGCP gateways using auto-cofiguration and running Cisco IOS version 12.4T or later, you must manually configure the **mgcp fax t38 inhibit** command to use T.38 fax relay.
ls_redundancy *factor*	Sends redundant T.38 fax packets. The **ls_redundancy** parameter refers to data redundancy in the low-speed V.21-based T.30 fax machine protocol. For the **ls_redundancy** parameter, the *factor* range is from 0 through 2. Default is 0 (no redundancy).
nsf *hexcode*	Overrides the nonstandard facilities (NSF) code with the code provided using the *hexcode* argument. The *word* argument is a two-digit hexadecimal country code and a four-digit hexadecimal manufacturer code. By default, the NSF code is not overridden.

Command Default

ecm—disabled
gateway force—disabled
hs_redundancy—0
inhibit—disabled (T.38 is enabled. See note in above table.)
ls_redundancy—0
nsf—not overridden

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T and implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 7200 series. Support for the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850 is not included in this release.
12.2(11)T	This command was applicable to the Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5800 in this release.
12.2(11)T2	This command was modified. The **gateway force** keyword pair was introduced.
12.2(15)T	This command was implemented on the Cisco 1751 and Cisco 1760.
12.4T	This command was modified. The **mgcp fax t38 inhibit** command was no longer configured by default for MGCP gateways that use the auto-configuration function.

Usage Guidelines Nonstandard facilities (NSF) are capabilities a particular fax manufacturer has built into a fax machine to distinguish products from each other.

To disable T.38 fax relay, use the **mgcp fax t38 inhibit** command.

Some MGCP call agents do not properly pass those portions of Session Description Protocol (SDP) messages that advertise T.38 and NSE capabilities. As a result, gateways that are controlled by these call agents are unable to use NSEs to signal T.38 fax relay to other gateways that use NSEs. The **mgcp fax t38 gateway force** command provides a way to ensure gateway-controlled T.38 fax relay and use of NSEs between an MGCP gateway and another gateway. The other gateway can be an H.323, Session Initiation Protocol (SIP), or MGCP gateway. Both gateways must be configured to use NSEs to signal T.38 fax relay mode switchover. On H.323 and SIP gateways, use the **fax protocol t38 nse force** command to specify the use of NSEs for T.38 fax relay. On MGCP gateways, use the **mgcp fax t38 gateway force** command.

Examples The following example configures the gateway to use NSEs for gateway-controlled T.38 fax relay signaling:

```
Router(config)# mgcp fax t38 gateway force
```

The following example shows that MGCP T.38 fax relay and ECM are enabled, NSF override is disabled, and low- and high-speed redundancy are set to the default value of 0:

```
Router(config)# mgcp fax t38 ecm
Router(config)# exit
Router# show mgcp

MGCP Admin State ACTIVE, Oper State ACTIVE - Cause Code NONE

The following example shows that NSF is overridden:

```
MGCP T.38 Fax NSF Override is ENABLED: AC04D3
```

Related Commands

Command	Description
fax protocol	Specifies fax protocol parameters on H.323 and SIP gateways.

mgcp ip qos dscp

To configure Differentiated Services Code Point (DSCP) for Media Gateway Control Protocol (MGCP) packets, use the **mgcp ip qos dscp** command in global configuration mode. To disable the configuration, use the **no** form of this command.

mgcp ip qos dscp {*dscp-value* | *af-number* | *cs-number* | **default** | **ef**} {**media** | **signaling**}

no mgcp ip qos dscp {*dscp-value* | *af-number* | *cs-number* | **default** | **ef**} {**media** | **signaling**}

Syntax Description

dscp-value	DSCP value. The range is from 0 to 63.
af-number	Assured forwarding bit pattern. The assure forwarding bit patterns are as follows: • **af11** • **af12** • **af13** • **af21** • **af22** • **af23** • **af31** • **af32** • **af33** • **af41** • **af42** • **af43** For more information, use the question mark (?) online help function.
cs-number	Class selector code point. The class selector code points are as follows: • **cs1** • **cs2** • **cs3** • **cs4** • **cs5** • **cs6** • **cs7** For more information, use the question mark (?) online help function.
default	Sets the DSCP to the default bit pattern. For more information, use the question mark (?) online help function.
ef	Sets the DSCP to the expedited forwarding bit pattern. For more information, use the question mark (?) online help function.
media	Applies DSCP to media payload packets.
signaling	Applies DSCP to signaling packets.

Command Default DSCP is applied to media payload packets and signaling packets.

Command Modes Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines The **mgcp ip qos dscp** command is used to set the DSCP for the quality of service. This command provides voice and signaling traffic priorities.

Examples The following example shows how to configure DSCP for MGCP packets:

```
Router# configure terminal
Router(config)# mgcp ip qos dscp af31 signaling
```

Related Commands

Command	Description
show mgcp	Displays values for MGCP parameters.

mgcp ip-tos

To enable or disable the IP type of service (ToS) for media gateway control protocol (MGCP) connections, use the **mgcp ip-tos** command in global configuration mode. To restore the default, use the **no** form of this command.

mgcp ip-tos {**high-reliability** | **high-throughput** | **low-cost** | **low-delay** | **rtp precedence** *value* | **signaling precedence** *value*}

no mgcp ip-tos {**high-reliability** | **high-throughput** | **low-cost** | **low-delay** | **rtp precedence** *value* | **signaling precedence** *value*}

Syntax Description

high-reliability	High-reliability ToS.
high-throughput	High-throughput ToS.
low-cost	Low-cost ToS.
low-delay	Low-delay ToS.
rtp precedence *value*	Value of the Real-Time Transport Protocol (RTP) IP precedence bit. Range is from 0 to 7. The default is 3. **Note** In Cisco IOS Release 12.1(3)T, this parameter was **precedence** *value*.
signaling precedence *value*	IP precedence value for MGCP User Datagram Protocol (UDP) and Real-Time Transport Protocol Control Protocol (RTCP) signaling packets. Range is from 0 to 7. The default is 3.

Command Default

Services are disabled.
RTP precedence: 3
Signaling precedence: 3

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.1(5)XM	This command was implemented on the Cisco MC3810. The **precedence** parameter was changed to **rtp precedence** and the **signaling precedence** parameter was added.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

Only one of the keywords in the group **high-reliability**, **high-throughput**, **low-cost**, and **low-delay** can be enabled at any given time. Enabling one keyword disables any other that was active. Enabling one of these keywords has no effect on the **precedence** value.

The **no** form of the **mgcp ip-tos** command disables the first four keywords and sets **the precedence value** back to 3.

When you configure a new value for **precedence**, the old value is erased.

Examples

The following example activates the **low-delay** keyword and disables the previous three keywords:

```
Router(config)# mgcp ip-tos high-rel
Router(config)# mgcp ip-tos high-throughput
Router(config)# mgcp ip-tos low-cost
Router(config)# mgcp ip-tos low-delay
Router(config)# mgcp ip-tos rtp precedence 4
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp lawful-intercept

To enable the lawful-intercept feature for the Media Gateway Control Protocol (MGCP), use the **mgcp lawful-intercept** command in global configuration mode. To disable the feature in mgcp, use the **no** form of this command.

mgcp lawful-intercept

no mgcp lawful-intercept

Syntax Description

This command has no arguments or keywords.

Defaults

Lawful Intercept feature is enabled in mgcp.

Command Modes

Global configuration

Command History

Release	Modification
12.4(20)T	This command was introduced.

Usage Guidelines

The Lawful Intercept feature is the process law enforcement agencies conduct electronic surveillance of circuit and packet-mode communications as authorized by judicial or administrative order. By default the **lawful-intercept** feature is enabled in mgcp. The **no mgcp lawful-intercept** command is used to disable the lawful-intercept feature in mgcp.

Examples

The following example shows the electronic surveillance being disabled:

```
Router(config)# no mgcp lawful-intercept
```

Related Commands

Command	Description
debug mgcp	Enables debugging on MGCP.
show mgcp	Displays the MGCP parameter settings.

mgcp max-waiting-delay

To specify the media gateway control protocol (MGCP) maximum waiting delay (MWD), use the **mgcp max-waiting-delay** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp max-waiting-delay *milliseconds*

no mgcp max-waiting-delay

Syntax Description

milliseconds	Time, in milliseconds, to wait after restart. Range is from 0 to 600000 (600 seconds). The default is 3000 (3 seconds).

Command Default 3000 ms

Command Modes Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines Use this command to send out an Restart in Progress (RSIP) message to the call agent with the restart method. This command helps prevent traffic bottlenecks caused by MGCP gateways all trying to connect at the same time after a restart.

Examples The following example sets the MGCP maximum waiting delay to 600 ms:

```
Router(config)# mgcp max-waiting-delay 600
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp restart-delay	Configures the graceful teardown method sent in the RSIP message.

mgcp modem passthrough codec

To select the codec that enables the gateway to send and receive modem and fax data in VoIP and VoATM adaptation layer 2 (VoAAL2) configurations, use the **mgcp modem passthrough codec** command in global configuration mode. To disable support for modem and fax data, use the **no** form of this command.

mgcp modem passthrough {**voip** | **voaal2**} **codec** {**g711alaw** | **g711ulaw**}

no mgcp modem passthrough {**voip** | **voaal2**}

Syntax Description

voip	VoIP voice protocol.
voaal2	VoAAL2 voice protocol.
g711alaw	G.711 a-law codec for changing speeds during modem and fax switchover.
g711ulaw	G.711 u-law codec for changing speeds during modem and fax switchover.

Command Default **The g711 u-law** codec for both VOIP and VOAAL2

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.1(5)XM	This command was implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines Use this command for fax pass-through because the answer tone can come from either modem or fax transmissions. Selecting a codec dynamically changes the codec type and speed to meet network conditions.

Examples The following example enables a gateway to send and receive VoAAL2 modem or fax data using the G711 a-law codec:

```
Router(config)# mgcp modem passthrough voaal2 codec g711alaw
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp modem passthrough mode	Sets the method for changing speeds for modem and fax transmissions on the gateway.

Command	Description
mgcp quarantine persistent-events disable	Enables redundancy for VoIP modem and fax transmissions.
mgcp tse payload	Enables the TSE payload for modem and fax operation.

mgcp modem passthrough mode

To set the method for changing speeds that enables the gateway to send and receive modem and fax data in VoIP and VoATM adaptation layer 2 (VoAAL2) configurations, use the **mgcp modem passthrough mode** command in global configuration mode. To disable support for modem and fax data, use the **no** form of this command.

mgcp modem passthrough {**voip** | **voaal2**} **mode** {**cisco** | **nse**}

no mgcp modem passthrough {**voip** | **voaal2**}

Syntax Description

voip	VoIP.
voaal2	Voice over AAL2 calls using Annex K type 3 packets.
cisco	Cisco-proprietary method for changing modem speeds, based on the protocol.
nse	Named signaling event (NSE)-based method for changing modem speeds. For VoAAL2 configurations, AAL2 Annex K (type 3) is used.

Defaults

NSE-based method

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.1(5)XM	This command was implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series router.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

Use this command for fax pass-through because the answer tone can come from either modem or fax transmissions.

Upspeed is the method used to change the codec type and speed dynamically to meet network conditions.

If you use the **nse** keyword, you must also use the **mgcp tse payload** command.

If you use the default **nse** keyword and the **voip** or **voaal2** keyword, the **show run** command does not display the **mgcp modem passthrough mode** command in the configuration output, although the command is displayed for the **cisco** keyword. The **show mgcp** command displays settings for both the **nse** and **cisco** keywords.

Examples

The following example enables a gateway to send and receive VoIP modem or fax data using the NSE modem-speed-changing method:

```
Router(config)# mgcp modem passthrough voip mode nse
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp modem passthrough codec	Selects the codec to use for modem and fax transmissions on the gateway.
mgcp quarantine persistent-events disable	Enables redundancy for VoIP modem and fax transmissions.
mgcp tse payload	Enables the TSE payload for modem and fax operation.

mgcp modem passthrough voip redundancy

To enable redundancy on a gateway that sends and receives modem and fax data in VoIP configurations, use the **mgcp modem passthrough voip redundancy** command in global configuration mode. To disable redundancy, use the **no** form of this command.

mgcp modem passthrough voip redundancy [**sample-duration** [**10** | **20**]] [**maximum-sessions** *number*]

no mgcp modem passthrough voip redundancy [**sample-duration** [**10** | **20**]] [**maximum-sessions** *number*]

Syntax Description

sample-duration	(Optional) Specifies the time length of the largest Real-time Transport Protocol (RTP) packet when packet redundancy is active, in milliseconds (ms).
10 | **20**	(Optional) Specifies the redundancy sample duration in milliseconds (ms). The default sample duration is 10.
maximum-sessions	(Optional) Specifies the maximum number of redundant sessions that can run simultaneously on each subsystem.
number	Number of maximum modem passthrough sessions on each module. The range is from 1 to 30.

Command Default

The default redundancy sample duration is 10 milliseconds (ms).

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T and implemented on the Cisco AS5300 and Cisco AS5850.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The *number* argument and the following keywords were added: • **sample-duration** • **10** | **20** • **maximum-sessions**

Usage Guidelines

Use the **modem passthrough voip redundancy** command for fax pass-through because the answer tone can come from either modem or fax transmissions. This command enables a single repetition of packets (using RFC 2198) to improve reliability by protecting against packet loss. When redundancy is on, all calls on the gateway are affected.

Upspeed is the method used to dynamically change the codec type and speed to meet network conditions.

Examples

The following example shows how to enable redundancy for VoIP modem and fax transmissions on a gateway:

```
Router(config)# mgcp modem passthrough voip redundancy sample-duration 20
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp modem passthrough codec	Selects the codec for modem and fax transmissions.
mgcp modem passthrough mode	Sets the method for changing speeds for modem and fax transmissions on the gateway.
mgcp tse payload	Enables the TSE payload for modem and fax operation.

mgcp modem passthru

To enable the gateway to send and receive modem and fax data, use the **mgcp modem passthru** command in global configuration mode. To disable support for modem and fax data, use the **no** form of this command.

mgcp modem passthru {**cisco** | **ca**}

no mgcp modem passthru

Syntax Description

cisco	When the gateway detects a modem/fax tone, it switches the codec to G.711 to allow the analog data to pass through.
ca	When the gateway detects a modem/fax tone, it alerts the call agent to switch the codec to G.711 to allow the analog data to pass through.

Command Default **ca**

Command Modes Global configuration

Command History

Release	Modification
12.1(3)T	This command was added to MGCP.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

When the **cisco** keyword is activated and the gateway detects a modem/fax tone, the gateway switches the codec to G.711 then sends the analog data to a remote gateway. The remote gateway also switches the codec on its side of the call to G.711 to allow the analog data to pass through.

When the **ca** keyword is activated and the gateway detects a modem/fax tone, the gateway alerts the call agent to switch the codec to G.711 to allow the analog data to pass through. The call agent must send an MDCX signal to the G.711 codec for successful data pass-through.

Examples

The following example configures a gateway to send and receive modem or fax data:

```
Router(config)# mgcp modem passthru cisco
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp modem relay voip gateway-xid

To enable in-band negotiation of compression parameters between two VoIP gateways using Media Gateway Control Protocol (MGCP), use the **mgcp modem relay voip gateway-xid** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp modem relay voip gateway-xid [**compress** {**backward** | **both** | **forward** | **no**}] [**dictionary** *value*] [**string-length** *value*]

no mgcp modem relay voip gateway-xid

Syntax Description

compress	(Optional) Direction in which data flow is compressed. For normal dialup, compression should be enabled in both directions. You may want to disable compression in one or more directions. This is normally done during testing and perhaps for gaming applications, but not for normal dialup when compression is enabled in both directions. • **backward**—Enables compression only in the backward direction. • **both**—Enables compression in both directions. For normal dialup, this is the preferred setting. This is the default. • **forward**—Enables compression only in the forward direction. • **no**—Disables compression in both directions.
dictionary *value*	(Optional) V.42bis parameter that specifies characteristics of the compression algorithm. Range is from 512 to 2048. Default is 1024. **Note** Your modem may support values higher than this range. A value acceptable to both sides is negotiated during modem call setup.
string-length *value*	(Optional) V.42bis parameter that specifies characteristics of the compression algorithm. Range is from 16 to 32. Default is 32. **Note** Your modem may support values higher than this range. A value acceptable to both sides is negotiated during modem call setup.

Command Default

Command: enabled
Compress: both
Dictionary: 1024
String length: 32

Command Modes

Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, Cisco 7200 series, and Cisco AS5300.

Usage Guidelines

This command enables XID negotiation for modem relay. By default it is enabled.

This command affects only VoIP calls and not Voice over ATM adaption layer 2 (VoAAL2) calls. This is because MGCP supports VoAAL2 calls for voice and fax/modem, but not for modem relay.

If this command is enabled on both VoIP gateways of a network, the gateways determine whether they need to engage in in-band negotiation of various compression parameters. The remaining keywords in this command specify the negotiation posture of this gateway in the subsequent in-band negotiation (assuming that in-band negotiation is agreed on by the two gateways).

The **compress**, **dictionary**, and **string-length** keywords are digital-signal-processor (DSP)-specific and related to xid negotiation. If this command is disabled, they are all irrelevant. The application (MGCP or H.323) just passes these configured values to the DSPs, and it is the DSP that requires them.

Examples

The following example enables in-band negotiation of compression parameters on the VoIP gateway, with compression in both directions, dictionary size of 1024, and string length of 32 for the compression algorithm:

```
mgcp modem relay voip gateway-xid compress both dictionary 1024 string-length 32
```

Related Commands

Command	Description
mgcp modem relay voip mode	Enables modem relay mode support in a gateway for MGCP VoIP calls.
mgcp modem relay voip sprt retries	Sets the maximum number of times that the SPRT protocol tries to send a packet before disconnecting.
modem relay gateway-xid	Enables in-band negotiation of compression parameters between two VoIP gateways that use MBCP.
mgcp tse payload	Enables TSEs for communications between gateways, which are required for modem relay over VoIP using MGCP.

mgcp modem relay voip latency

To optimize the Modem Relay Transport Protocol and the estimated one-way delay across the IP network using Media Gateway Control Protocol (MGCP), use the **mgcp modem relay voip latency** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp modem relay voip latency *value*

no mgcp modem relay voip latency

Syntax Description

value	Estimated one-way delay across the IP network, in milliseconds. Range is from 100 to 1000. Default is 200.

Command Default 200 ms

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, Cisco 7200 series, and Cisco AS5300.

Usage Guidelines Use this command to adjust the retransmission timer of the Simple Packet Relay Transport (SPRT) protocol, if required, by setting the value to the estimated one-way delay (in milliseconds) across the IP network. Changing this value may affect the throughput or delay characteristics of the modem relay call. The default value of 200 does not need to be changed for most networks.

Examples The following example sets the estimated one-way delay across the IP network to 100 ms.

```
mgcp modem relay voip latency 100
```

Related Commands

Command	Description
mgcp modem relay voip mode	Enables modem relay mode support in a gateway for MGCP VoIP calls.
mgcp modem relay voip sprt retries	Sets the maximum number of times that the SPRT protocol tries to send a packet before disconnecting.
mgcp tse payload	Enables TSEs for communications between gateways, which are required for modem relay over VoIP using MGCP.

Command	Description
modem relay gateway-xid	Enables in-band negotiation of compression parameters between two VoIP gateways that use MBCP.
modem relay latency	Optimizes the Modem Relay Transport Protocol and the estimated one-way delay across the IP network.

mgcp modem relay voip mode

To enable named signaling event (NSE) based modem relay mode for VoIP calls on a Media Gateway Control Protocol (MGCP) gateway, use the **mgcp modem relay voip mode** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp modem relay voip mode [**nse**] **codec** [**g711alaw** | **g711ulaw**] [**redundancy**] **gw-controlled**

no mgcp modem relay voip mode

Syntax Description

nse	(Optional) Instructs the gateway to use NSE mode for upspeeding.
codec	(Optional) Specifies a codec to use for upspeeding: • **g711alaw**—G.711 a-law 64,000 bits per second (bps) for E1. • **g711ulaw**—G.711 mu-law 64,000 bps for T1. This is the default.
redundancy	(Optional) Specifies packet redundancy for modem traffic during modem pass-through. By default, redundancy is disabled.
gw-controlled	Specifies the gateway-configured method for establishing modem relay parameters.

Command Default

Modem relay in NSE mode is disabled. All modem calls go through as pass-through calls, which are less reliable and use more bandwidth than modem relay calls, provided that pass-through is enabled.
The G.711 mu-law codec is used for upspeeding.
Redundancy is disabled and no duplicate data packets are sent while the gateway is in modem/fax pass-through mode.

Command Modes

Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, Cisco 7200 series, and Cisco AS5300.
12.4(2)T	Usage guidelines were added for the **nse** keyword.
12.4(4)T	The **gw-controlled** keyword was added.
12.4(6)T	This feature was implemented on the Cisco 1700 series and Cisco 2800 series.

Usage Guidelines

The **mgcp modem relay voip mode** command enables non secure modem relay mode for MGCP VoIP calls. By default, NSE modem relay mode is disabled. This command configures upspeeding, which is needed because modem pass-through is an intermediate step while the gateway switches from handling voice calls to handling modem relay calls.

The **mgcp modem relay voip mode nse** command is not supported on the TI C2510 digital signal processor (DSP), formerly known as the TI C5510 DSP; only the TI C549 DSP supports negotiation of NSE parameters. If Cisco CallManager is used as the call agent, the **mgcp modem relay voip mode nse** command is not supported.

Redundancy causes the gateway to generate duplicate (redundant) data packets for fax/modem pass-through calls as per RFC 2198. For these calls to be more reliable, redundant packets transmission is needed to make up for excessive loss of packets in VoIP networks. Even if one of the gateways is configured with redundancy, calls go through. Gateways can handle asymmetric (one-way) redundancy.

To enable secure voice and data calls between Secure Telephone Equipment (STE) and IP-STE endpoints using the state signaling events (SSE) protocol, use the **mgcp modem relay voip mode sse** command. Before configuring SSE parameters, you must use the **mgcp package-capability mdste** command to enable modem relay capabilities and SSE protocol support.

The **gw-controlled** keyword specifies that modem transport parameters are configured directly on the gateway instead of being negotiated by the call agent.

Examples

The following example enables MGCP modem relay and specifies the following: NSE mode for upspeeding, G.711 mu-law codec, packet redundancy, and gateway-controlled for modem traffic during modem pass-through:

```
Router(config)# mgcp modem relay voip mode nse codec g711ulaw redundancy gw-controlled
```

Related Commands

Command	Description
mgcp modem relay voip gateway-xid	Optimizes the modem relay transport protocol and the estimated one-way delay across the IP network.
mgcp modem relay voip mode sse	Enables SSE-based modem relay.
mgcp package-capability mdste	Enables MGCP gateway support for processing events and signals for modem connections over a secure communication path between IP-STE and STE.
mgcp tse payload	Enables TSEs for communications between gateways, which are required for modem relay over VoIP using MGCP.

mgcp modem relay voip mode sse

To enable State Signaling Event (SSE) based modem relay mode and to configure SSE parameters on the MGCP gateway, use the **mgcp modem relay voip mode sse** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp modem relay voip mode sse [**redundancy** [{**interval** *number* | **packet** *number*}]][**retries** *value*] [**t1** *time*]

no mgcp modem relay voip mode sse

Syntax Description

redundancy	(Optional) Packet redundancy for modem traffic during modem pass-through. By default redundancy is disabled.
interval *milliseconds*	(Optional) Specifies the timer in milliseconds (ms) for redundant transmission of SSEs. Range is 5 - 50 ms. Default is 20 ms.
packet *number*	(Optional) Specifies the SSE packet retransmission count before disconnecting. Range is 1- 5 packets. Default is 3 packets.
retries *value*	(Optional) Specifies the number of SSE packet retries, repeated every t1 interval, before disconnecting. Range is 0 - 5 retries. Default is 5 retries.
t1 *milliseconds*	(Optional) Specifies the repeat interval, in milliseconds, for initial audio SSEs used for resetting the SSE protocol state machine (clearing the call) following error recovery. Range is 500 - 3000 ms. Default is 1000 ms.

Command Default

SSE mode is enabled by default, using default parameter values.

Command Modes

Global configuration

Command History

Release	Modification
12.4(2)T	This command was introduced

Usage Guidelines

Use the **mgcp modem relay voip mode sse** command to configure state signaling events (SSE) parameters for secure MGCP voice and data calls between Secure Telephone Equipment (STE) and IP STE endpoints using the SSE protocol, a subset of the V.150.1 standard for modem relay. SSEs, which are Real-Time Transport Protocol (RTP) encoded event messages, are used to coordinate transitions between the different media states, secure and nonsecure. Before configuring SSE parameters, you must use the **mgcp package-capability mdste** command to enable modem relay capabilities and SSE protocol support.

Examples

The following examples configure SSE parameters for redundancy interval redindancy packet count, number of retries and the **t1** timer interval:

```
Router(config)# mgcp modem relay voip mode sse redundancy interval 20
Router(config)# mgcp modem relay voip mode sse redundancy packet 4
Router(config)# mgcp modem relay voip mode sse retries 5
Router(config)# mgcp modem relay voip mode sse t1 1000
```

Related Commands

Command	Description
mgcp package-capability mdste	Enables MGCP gateway support for processing events and signals for modem connections over a secure communication path between IP-STE and STE.

mgcp modem relay voip sprt retries

To set the maximum number of times that the Simple Packet Relay Transport (SPRT) protocol tries to send a packet before disconnecting, use the **mgcp modem relay voip sprt retries** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp modem relay voip sprt retries *value*

no mgcp modem relay voip sprt retries

Syntax Description

value	Maximum number of times that the SPRT protocol tries to send a packet before disconnecting. Range is from 6 to 30. The default is 12.

Command Default 12 times

Command Modes Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco 2600 series, Cisco 3620, Cisco 3640, Cisco 3660, Cisco 7200 series, and Cisco AS5300.

Examples The following example sets 15 as the maximum number of times that the SPRT protocol tries to send a packet before disconnecting:

```
mgcp modem relay voip sprt retries 15
```

Related Commands

Command	Description
mgcp modem relay voip gateway-xid	Optimizes the Modem Relay Transport Protocol and the estimated one-way delay across the IP network.
mgcp modem relay voip mode	Enables modem relay mode support in a gateway for MGCP VoIP calls.
mgcp tse payload	Enables TSEs for communications between gateways, which are required for modem relay over VoIP using MGCP.
modem relay gateway-xid	Enables in-band negotiation of compression parameters between two VoIP gateways that use MBCP.

mgcp modem relay voip sprt v14

To configure V.14 modem relay parameters for packets sent by the Simple Packet Relay Transport (SPRT) protocol, use the **mgcp modem relay voip sprt v14** command in global configuration mode. To disable this function, use the **no** form of this command.

mgcp modem relay voip sprt v14 [**receive playback hold-time** *milliseconds* | **transmit hold-time** *milliseconds* | **transmit maximum hold-count** *characters*]

no mgcp modem relay voip sprt v14

Syntax Description

receive playback hold-time *milliseconds*	Configures the time in milliseconds (ms) to hold incoming data in the V.14 receive queue. Range is 20 to 250 ms. Default is 50 ms.
transmit hold-time *milliseconds*	Configures the time to wait, in ms, after the first character is ready before sending the SPRT packet. Range is 10 to 30 ms. Default is 20 ms.
transmit maximum hold-count *characters*	Configures the number of V.14 characters to be received on the ISDN public switched telephone network (PSTN) interface that will trigger sending the SPRT packet. Range is 8 to 128. Default is 16.

Command Default

V.14 modem relay parameters are enabled by default, using default parameter values.

Command Modes

Global configuration

Command History

Release	Modification
12.4(2)T	This command was introduced.

Usage Guidelines

The maximum size of receive buffers is set at 500 characters, a nonprovisionable limit. Use the **mgcp modem relay voip sprt v14 receive playback hold-time** *milliseconds* command to configure the minimum holding time before characters can be removed from the receive queue. Characters received on the PSTN or ISDN interface may be collected for a configurable collection period before being sent out on SPRT channel 3, potentially resulting in variable size SPRT packets. To configure V.14 transmit parameters for SPRT packets, use the **mgcp modem relay voip sprt v14 transmit hold-time** *milliseconds* and the **mgcp modem relay voip sprt v14 transmit maximum hold-count** *characters* commands.

Parameter changes do not take effect during existing calls; they affect new calls only.

SPRT transport channel 1 is not supported.

Examples

The following example sets 200 ms as the receive playback hold time, 25 ms as the transmit hold time, and 10 characters as the transmit hold count parameters:

```
Router(config)# mgcp modem relay voip sprt v14 receive playback hold-time 200
Router(config)# mgcp modem relay voip sprt v14 transmit hold-time 25
Router(config)# mgcp modem relay voip sprt v14 transmit maximum hold-count 10
```

Related Commands

Command	Description
debug voip ccapi inout	Traces the execution path through the call control API.
debug vtsp all	Displays all VTSP debugging except statistics, tone, and event.
mgcp package-capability mdste-package	Enables MGCP gateway support for processing events and signals for modem connections over a secure communication path between IP-STE and STE.
mgcp modem relay voip mode sse	Enables MGCP gateway SSE based modem relay mode support for VoIP calls.

mgcp package-capability

To specify the MGCP package capability type for a media gateway, use the **mgcp package-capability** command in global configuration mode. To remove a specific MGCP package capability from the list of capabilities, use the **no** form of this command.

mgcp package-capability *package*

no mgcp package-capability *package*

Syntax Description

package	One of the following package capabilities (available choices vary according to platform and release version; check the CLI help for a list): • **as-package**—Announcement server package. • **atm-package**—ATM package. MGCP for VoATM using ATM adaptation layer 2 (AAL2) permanent virtual circuit (PVC) and a subset of ATM extensions specified by Cisco is supported. Switched virtual circuit (SVC)-based VoAAL2 is not supported. • **dt-package**—Dual Tone(DT) package. Events and signals for immediate-start and basic dual tone multifrequency (DTMF) and dial-pulse trunks. • **dtmf-package**—DTMF package. Events and signals for DTMF relay. • **fxr-package**—Fax Transmission (FXR) package for fax transmissions. • **gm-package**—Generic media package. Events and signals for several types of endpoints, such as trunking gateways, access gateways, or residential gateways. • **hs-package**—Handset package. An extension of the line package, to be used when the gateway can emulate a handset. • **it-package**—PacketCable Trunking Gateway Control Protocol (TGCP) ISDN User Part (ISUP) trunk package. • **lcs-package**—MGCP Line Control Signaling (LCS) package. • **line-package**—Line package. Events and signals for residential lines. This is the default for residential gateways. • **md-package**—MD package. Provides support for Feature Group D (FGD) Exchange Access North American (EANA) protocol signaling. • **mdste-package**—Modem relay Secure Telephone Equipment (STE) package. Events and signals for modem connections enabling a secure communication path between IP-STE and STE. • **mf-package**—Multifrequency (MF) tone package. Events and signals for MF relay. • **mo-package**—Multifrequency Operations (MO) package. Events and signals for Operator Service Signaling protocol for FGD.

- **ms-package**—MS package. Events and signals for MF single-stage dialing trunks, including wink-start and immediate-start PBX Direct Inward Dialing (DID) and Direct Outward Dialing (DOD), basic R1, and FGD Terminating Protocol.
- **nas-package**—Network Access Server (NAS) Package. Accepts NAS requests from the call agent.

Note For Cisco IOS Release 12.4(4)T and later releases, the **nas-package** is not enabled by default.

- **script-package**—Script package. Events and signals for script loading.
- **srtp-package**—Secure RTP (SRTP) package. Enables the MGCP gateway to process SRTP packages. The default is disabled.
- **tone-package**—Tone package. Disabled by default. Enables the MGCP gateway to play secure call tone during midcall.
- **trunk-package**—Trunk package. Events and signals for trunk lines. This is the default for trunking gateways.

Command Default The **line-package** is configured by default for residential gateways and the **trunk package** is configured by default for trunk gateways.

Command Modes Global configuration (config)

Command History

Release	Modification
12.0(7)XR2	This command was introduced on the Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.1(3)T	This command was implemented on the following platforms: Cisco uBR924, Cisco 2600 series, and Cisco 3660. The **line-package**, **rtp-package**, and **script-package** keywords were added and a distinction was made between residential and trunking gateways.
12.1(5)XM	This command was implemented on the Cisco 3600 series and Cisco MC3810. The **atm-package**, **dt-package, hs-package**, **mo-package,** and **ms-package** keywords were added.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(2)XB	This command was modified. The **nat-package** and **res-package** keywords were added.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5300, Cisco AS5350, Cisco AS5400, and Cisco AS5850.
12.3(1)	This command was modified. The **fxr-package** keyword was added.
12.3(8)T	This command was modified. The **lcs-package** keyword was added.
12.3(8)XY	This command was modified. The **pre-package** keyword was added.
12.3(11)T	This command was modified. The **srtp-package** keyword was added.

Release	Modification
12.4(2)T	This command was modified. The **mdste-package** keyword was added.
12.4(4)T	This command was modified. The **md-package** keyword was added. The **nas-package** keyword was not enabled by default.
15.1(4)M	This command was modified. The **tone-package** keyword was added.

Usage Guidelines

Events specified in the MGCP messages from the call agent must belong to one of the supported packages. Otherwise, connection requests are refused by the gateway.

By default, certain packages are configured as supported on each platform type. Using the **mgcp-package capability** command, you can configure additional package capability only for packages that are supported by your call agent. You can also disable support for a package with the **no** form of this command. Enter each package you want to add as a separate command.

Note Beginning in Cisco IOS Release12.4(4)T the **nas-package** keyword is not enabled by default.

The **md-package** keyword is enabled automatically when a T1 interface is configured to use FGD EANA signaling with the **ds0-group** command.

Use the **show mgcp** command to display the packages that are supported on the gateway.

Use this command before specifying a default package with the **mgcp default-package** command. Specify at least one default package.

Packages that are available to be configured with this command vary by platform and type of gateway. Use the CLI help to ascertain the packages available on your gateway. This example shows the CLI help output for a Cisco 3660:

```
Router# mgcp package-capability ?
as-package     Select the Announcement Server Package
atm-package    Select the ATM Package
dtmf-package   Select the DTMF Package
gm-package     Select the Generic Media Package
hs-package     Select the Handset Package
line-package   Select the Line Package
mf-package     Select the MF Package
res-package    Select the RES Package
rtp-package    Select the RTP Package
trunk-package  Select the Trunk Package
tone-package  Select the Tone Package
```

Note The Channel Associated Signaling (CAS) packages configured using the **dt-package**, **md-package**, **mo-package**, and **ms-package** keywords are available only as default packages using the **mgcp default-package** command. They do not appear as keywords in the **mgcp package-capability** command because all the other packages are configured on a per-gateway basis, whereas the CAS packages are defined on a per-trunk basis. The per-trunk specification is made when the trunk is configured using the **ds0-group** command.

When the **lcs-package** keyword is used on the Cisco Integrated Access Device (IAD), the named telephony events (NTEs) associated with the line control signaling (LCS) package are enabled automatically. NTEs are used by a media gateway to transport telephony tones and trunk events across a packet network. See RFC 2833.

Note Using NTE in the LCS package requires a successful MGCP/Session Definition Protocol (SDP) negotiation during call setup. The call agent must use the Line Connection Option's FMTP parameter keyword, **telephone-event**, to indicate which LCS NTEs will be used. If the IAD has been configured to use the LCS package, the IAD will answer with an SDP containing the requested LCS NTE events.

Examples

The following example enables the modem relay STE package, trunk package, DTMF package, script package, and tone package on the gateway, and then names the trunk package as the default package for the gateway:

```
Router(config)# mgcp package-capability mdste-package
Router(config)# mgcp package-capability trunk-package
Router(config)# mgcp package-capability dtmf-package
Router(config)# mgcp package-capability script-package
Router(config)# mgcp package-capability tone-package
Router(config)# mgcp default-package trunk-package
```

Related Commands

Command	Description
ds0-group	Specifies the DS0 time slots that make up a logical voice port
mgcp	Starts the MGCP daemon.
mgcp default-package	Configures the default package capability type for the media gateway.
show mgcp	Displays the supported MGCP packages.

mgcp persistent

To configure the sending of persistent events from the Media Gateway Control Protocol (MGCP) gateway to the call agent, use the **mgcp persistent** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp persistent {**hookflash** | **offhook** | **onhook**}

no mgcp persistent {**hookflash** | **offhook** | **onhook**}

Syntax Description

hookflash	Sends persistent hookflash events to the call agent.
offhook	Sends persistent off-hook events to the call agent.
onhook	Sends persistent on-hook events to the call agent.

Command Default

The **hookflash** keyword is disabled for persistence. The **offhook** keyword is enabled for persistence. The **onhook** keyword is disabled for persistence.

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

Persistent events are those events that, once they are detected, are defined as reportable to the call agent whether or not the call agent has explicitly requested to be notified of their occurrence; that is, even if they are not included in the list of RequestedEvents that the gateway is asked to detect and report. Such events can include fax tones, continuity tones, and on-hook transition. Each event has an associated action for the gateway to take.

Use this command for each type of persistent event that should override the default behavior.

Examples

The following example configures the gateway to send persistent on-hook events to the call agent:

```
Router(config)# mgcp persistent onhook
```

Related Commands

Command	Description
mgcp	Starts and allocates resources for the MGCP daemon.

mgcp piggyback message

To enable piggyback messages, use the **mgcp piggyback message** command in global configuration mode. To disable piggyback messages, use the **no** form of this command.

mgcp piggyback message

no mgcp piggyback message

Syntax Description This command has no arguments or keywords.

Command Default Piggyback messages are enabled

Command Modes Global configuration

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines If the network gateway cannot handle piggyback messages, us e the **no** form of this command to disable the piggyback messages and to enable Media Gateway Control Protocol (MGCP) 1.0, Network-based Call Signaling (NCS), and Trunking Gateway Control Protocol (TGCP). Piggyback messaging is not available to Simple Gateway Control Protocol (SGCP) and MGCP 0.1.

The term piggyback message refers to a situation in which a gateway or a call agent sends more than one MGCP message in the same User Datagram Protocol (UDP) packets. The recipient processes the messages individually, in the order received. However, if a message must be retransmitted, the entire datagram is resent. The recipient must be capable of sorting out the messages and keeping track of which messages have been handled or acknowledged.

Piggybacking is used during retransmission of a message to send previously unacknowledged messages to the call agent. This maintains the order of events the call agent receives and makes sure that RestartInProgress (RSIP) messages are always received first by a call agent.

Examples The following example disables piggyback messages:

```
Router(config)# no mgcp piggyback message
```

Related Commands

Command	Description
mgcp	Starts and allocates resources for the MGCP daemon.

mgcp playout

To tune the jitter-buffer packet size attempted for MGCP-controlled connections, use the **mgcp playout** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp playout {**adaptive** *init-milliseconds min-milliseconds max-milliseconds* | **fax** *milliseconds* | **fixed** *milliseconds* [**no-timestamps**]}

no mgcp playout {**adaptive** | **fax** | **fixed**}

Syntax Description

adaptive *init-milliseconds min-milliseconds max-milliseconds*	Sets the range, in milliseconds (ms), for the jitter-buffer packet size. Range for each value is 4 to 250. Note that *init-milliseconds* must be between *min-milliseconds* and *max-milliseconds*. Default: 60 4 200.
fax *milliseconds*	Sets the value for the fax playout buffer size. Range: 1 to 700. Default: 300. **Note** The range and default value might vary with different platforms. See the platform digital signal processor (DSP) specifications before setting this value.
fixed *milliseconds*	Sets the fixed size, in milliseconds, for the jitter-buffer packet size. Range: 4 to 1000. There is no default value.
no-timestamps	(Optional) Fixes the jitter buffer at a constant delay without time stamps.

Command Default

The MGCP jitter playout-delay buffer is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.2(11)T	This command was implemented on the Cisco AS5850.
12.2(13)T	This command was modified. The **fax** keyword was added.
15.1(1.8)T	This command was modified. The **no-timestamps** keyword was added and the fixed range value was increased from 250 to 1000.

Examples

The following example configures a jitter buffer to an initial playout of 100 ms, minimum buffer size of 50 ms, and maximum buffer size of 150 ms:

```
Router(config)# mgcp playout adaptive 100 50 150
```

The following example configures a fax playout buffer size of 200 ms.

```
Router(config)# mgcp playout fax 200
```

The following example configures a jitter buffer to a fixed playout of 120 ms:

```
Router(config)# mgcp playout fixed 120
```

The following example configures a jitter buffer to a fixed playout of 65 ms delay without time stamps:

```
Router(config)# mgcp playout fixed 65 no-timestamps
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
playout-delay	Tunes the playout buffer on DSPs to accommodate packet jitter caused by switches in the WAN.
playout-delay mode	Selects fixed or adaptive mode for playout delay from the jitter buffer on DSPs.

mgcp profile

To create and configure a Media Gateway Control Protocol (MGCP) profile to be associated with one or more MGCP endpoints or to configure the default MGCP profile, use the **mgcp profile** command in global configuration mode. To delete the profile, use the **no** form of this command.

mgcp profile {*profile-name* | **default**}

no mgcp profile {*profile-name* | **default**}

Syntax Description

profile-name	Identifying name for the user-defined profile to be configured. The name can be a maximum of 32 characters.
default	The default profile is to be configured.

Command Default If this command is not used, there are no MGCP profiles created.

Command Modes Global configuration (config)

Command History

Release	Modification
12.2(2)XA	This command was introduced.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.
12.4(24)T3	The maximum number of MGCP profiles that can be configured was increased from 13 (12 plus 1 default) to 29 (28 plus 1 default).

Usage Guidelines An MGCP profile is a subset of endpoints on a media gateway. More than one MGCP profile can be configured on a gateway at the same time. Prior to Cisco IOS Release 12.2(24)T3, the maximum number of MGCP profiles was 13 (12 plus 1 default). Beginning in Cisco IOS Release 12.2(24)T3, the maximum number of MGCP profiles is 29 (28 plus 1 default). The **voice-port** command in MGCP profile configuration mode associates endpoints with the profile.

There are two types of MGCP parameters: global and profile-related. The parameters that are configured in MGCP profile configuration mode are the profile-related parameters. However, endpoints do not need to belong to an MGCP profile. When endpoints are not associated with any MGCP profile, values for the profile-related MGCP parameters are provided by a *default profile*. Although all of the parameters for the default profile have default values, they can also be configured in the same way that an MGCP profile is configured by simply using the **default** keyword instead of a profile name. The main difference between a default profile and a user-defined profile is that there is no voice-port or call-agent association in the default profile, but they are required in user-defined profiles. When configuring the default profile, do not use the **call-agent** command or the **voice-port** command.

This command initiates MGCP profile configuration mode, in which you create an MGCP profile for an endpoint or a set of endpoints on a media gateway, and you set parameters for that profile or for the default profile.

Examples

The following example shows the definition of the MGCP profile named newyork:

```
Router(config)# mgcp profile newyork
Router(config-mgcp-profile)# call-agent 10.14.2.200 4000 service-type mgcp version 1.0
Router(config-mgcp-profile)# voice-port 0:1

Related Commands

Command	Description
call-agent	Defines the call agent for an MGCP profile.
mgcp	Starts and allocates resources for the MGCP daemon.
voice-port	Enters voice-port configuration mode.

mgcp quality-threshold

To set the jitter buffer size threshold, latency threshold, and packet-loss threshold parameters, use the **mgcp quality-threshold** command in global configuration mode. To reset to the defaults, use the **no** form of this command.

mgcp quality-threshold {**hwm-cell-loss** *value* | **hwm-jitter-buffer** *value* | **hwm-latency** *value* | **hwm-packet-loss** *value* | **lwm-cell-loss** *value* | **lwm-jitter-buffer** *value* | **lwm-latency** *value* | **lwm-packet-loss** *value*}

no mgcp quality-threshold {**hwm-cell-loss** *value* | **hwm-jitter-buffer** *value* | **hwm-latency** *value* | **hwm-packet-loss** *value* | **lwm-cell-loss** *value* | **lwm-jitter-buffer** *value* | **lwm-latency** *value* | **lwm-packet-loss** *value*}

Syntax Description

hwm-cell-loss *value*	High-water-mark cell loss count, when the ATM package is enabled. Range is from 5000 to 25000. Default is 10000.
hwm-jitter-buffer *value*	High-water-mark jitter buffer size, in milliseconds. Range is from 100 to 200. Default is 150.
hwm-latency *value*	High-water-mark latency value, in milliseconds. Range is from 250 to 400. Default is 300.
hwm-packet-loss *value*	High-water-mark packet loss value, in milliseconds. Range is from 5000 to 25,000. Default is 10000.
lwm-cell-loss *value*	Low-water-mark cell loss count, when the ATM package is enabled. Range is from 1 to 3000. Default is 1000.
lwm-jitter-buffer *value*	Low-water-mark jitter buffer size, in milliseconds. Range is from 4 to 60. Default is 30.
lwm-latency *value*	Low-water-mark latency value, in milliseconds. Range is from 125 to 200. Default is 150.
lwm-packet-loss *value*	Low-water-mark packet-loss value, in milliseconds. Range is from 1 to 3000. Default is 1000.

Command Default

High-water-mark cell loss count: 10000 cells
High-water-mark jitter buffer size: 150 ms
High-water-mark latency value: 300 ms
High-water-mark packet loss value: 10000 ms
Low-water-mark cell loss count: 1000 cells
Low-water-mark jitter buffer size: 30 ms
Low-water-mark latency value: 150 ms
Low-water-mark packet-loss value: 1000 ms

Command Modes

Command History

Release	Modification
11.3(3)T	The default was changed to 100 milliseconds.
12.1(1)T	This command was implemented on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.1(5)XM	This command was implemented on the Cisco MC3810. The **hwm-cell-loss** and **lwm-cell-loss** keywords were added.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

The following impact the quality of voice calls:

- **Cell loss** (the number of ATM cells lost during transmission)
- **Jitter buffer** (storage area containing active call voice packets that have been received from the network and are waiting to be decoded and played)
- **Latency** (network delay in sending and receiving packets)
- **Packet loss** (number of packets lost per 100,000 packets for a given call)

For good voice quality, the system should perform below the low water mark values. As the values go higher, voice quality degrades. The system generates a report when the values go above the high water marks levels. Set the high water marks and low water marks values sufficiently apart so that you receive reports on poor performance, but not so close together that you receive too much feedback.

Enter each parameter as a separate command.

Examples

The following example sets various keywords to new values:

```
Router(config)# mgcp quality-threshold hwm-jitter-buffer 100
Router(config)# mgcp quality-threshold hwm-latency 250
Router(config)# mgcp quality-threshold hwm-packet-loss 5000
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp package-capability	Activates various packages on the gateway.
mgcp playout	Tunes the jitter buffer packet size.

mgcp quarantine mode

To configure the mode for Media Gateway Control Protocol (MGCP) quarantined events, use the **mgcp quarantine mode** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp quarantine mode [**discard** | **process**] [**loop** | **step**]

no mgcp quarantine mode

Syntax Description

discard	Enables discarding of quarantined events instead of processing. Observed events are not reported to the call agent, even if the call agent is ready to receive them.
loop	Enables loop mode for quarantined events instead of stepping. After receiving a request from the call agent, the gateway reports the observed events to the call agent in multiples without waiting for subsequent requests.
process	Enables processing of quarantined events instead of discarding. Observed events are reported to the call agent when the call agent is ready to receive them.
step	Enables step mode for quarantined events instead of looping. After receiving a request from the call agent, the gateway reports observed events individually to the call agent, one for each request.

Command Default

If no event is specified the default is **step**.

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200.
12.2(2)XA	This command was modified to support MGCP.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

Quarantine events are defined as events that have been detected by the gateway before the arrival of the MGCP NotificationRequest command but that have not yet been notified to the call agent. They are held in the quarantine buffer until receipt of the MGCP NotificationRequest command, when the gateway is expected to generate either one notification (step by step) or multiple notifications (loop) in response to this request (the default is exactly one), based on the configuration of the **mgcp quarantine mode** command.

This command supports backward compatibility with SGCP implementations running under the MGCP application. SGCP does not have a way to allow the call agent to control the quarantine mode. MGCP has this functionality.

When the gateway is in the notification state, the interdigit timer (Tcrit) is not started.

When the gateway receives an unsuccessful NotificationRequest, the current RequestEventList and SignalEventList are emptied. The ObservedEventList and quarantine buffer are also emptied.

Changes to the quarantine mode only take effect when the gateway is rebooted or the MGCP application is restarted.

Examples

The following example starts the MGCP application:

```
Router(config)# mgcp
```

The following example stops the MGCP application:

```
Router(config)# no mgcp
```

The following example turns on processing of quarantined events and sends observed events to the call agent:

```
Router(config)# mgcp quarantine mode process
```

The following example turns off processing of quarantined events:

```
Router(config)# no mgcp quarantine mode discard
```

The following example sends observed events to the call agent in loop mode:

```
Router(config)# mgcp quarantine mode process loop
```

Related Commands

Command	Description
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp quarantine persistent-event disable	Disables handling of persistent call events in the quarantine buffer.

mgcp quarantine persistent-event disable

To disable handling of persistent call events in the Media Gateway Control Protocol (MGCP) quarantine buffer, use the **mgcp quarantine persistent-events disable** command in global configuration mode. To reset to the default state, use the **no** form of this command.

mgcp quarantine persistent-event disable

no mgcp quarantine persistent-event disable

Syntax Description

This command has no arguments or keywords.

Command Default

Persistent events are held in the events buffer.

Command Modes

Global configuration

Command History

Release	Modification
12.1(5)XM	This command was introduced.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200.
12.2(2)XA	This command was modified to support MGCP.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

This command enables the reporting of persistent events immediately to the call agent rather than holding the events in quarantine. Persistent events are events defined as reportable whether or not the call agent explicitly has requested to be notified of their occurrence. Quarantining means that the gateway observes events but does not report them to the call agent until the call agent indicates readiness to receive notifications. By default, all events, including persistent events, are quarantined when they are detected, even when the gateway is in a notification state. When the **mgcp quarantine persistent-event disable** command is configured, however, persistent events are reported to the call agent immediately by an MGCP Notify command.

Examples

The following example disables quarantine buffer handling of persistent events:

```
Router(config)# mgcp quarantine persistent-event disable
```

Related Commands

Command	Description
mgcp	Starts and allocates resources for the MGCP daemon.
mgcp quarantine mode	Configures MGCP event quarantine buffer handling mode.

mgcp request retries

This command was added in Cisco IOS Release 12.1(1)T. Beginning in Cisco IOS Release 12.2(2)XA and Cisco IOS Release 12.2(4)T, this command is supported no longer. It has been replaced by the MGCP profile **max1 retries** and **max2 retries** commands.

mgcp request timeout

To specify how long a Media Gateway Control Protocol (MGCP) gateway waits for a call-agent response to a request before retransmitting the request, use the **mgcp request timeout** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp request timeout {*timeout-value* | **max** *maxtimeout-value*}

no mgcp request timeout [**max**]

Syntax Description

timeout-value	Time, in milliseconds, to wait for a response to a request. Range is 1 to 10000. Default is 500.
max *maxtimeout-value*	Maximum timeout, in milliseconds. Default is 4000.

Command Default

timeout-value: 500 ms
maxtimeout-value: 4000 ms

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.1(5)XM	This command was implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200.
12.2(2)XA	The **max** keyword was added to this command.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T and implemented on the Cisco uBR925.
12.2(11)T	This command was implemented on the Cisco AS5850.

Usage Guidelines

The request timeout value sets the initial time period that an MGCP gateway waits for a response from the call agent before retransmitting the message. The interval doubles with each retransmission. The request timeout maximum value sets an upper limit on the timeout interval.

Examples

The following example sets a router to wait 40 ms for a reply to the first request before retransmitting and limits subsequent interval maximums to 10,000 ms (10 seconds):

```
Router(config)# mgcp request timeout 40
Router(config)# mgcp request timeout max 10000
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp request retries	Specifies the number of times to retry sending the **mgcp** command.

mgcp restart-delay

To select the delay value sent in the Restart in Progress (RSIP) graceful teardown, use the **mgcp restart-delay** command in global configuration mode. To reset to the default, use the **no** form of this command.

mgcp restart-delay *value*

no mgcp restart-delay

Syntax Description

value	Restart delay value, in seconds. Range is 0 to 600. The default is 0.

Command Default 0 seconds

Command Modes Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.1(5)XM	This command was implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines Use this command to send an RSIP message indicating when the connection in the gateway is to be torn down.

Examples The following example sets the restart delay to 30 seconds:

```
Router(config)# mgcp restart-delay 30
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp smax-waiting-delay	Specifies the MGCP maximum waiting delay after a restart.

mgcp rtp payload-type

To specify use of the correct Real-time Transport Protocol (RTP) payload type for backward compatibility in Media Gateway Control Protocol (MGCP) networks, use the **mgcp rtp payload-type** command in global configuration mode. To restore default values for payload types, use the **no** form of this command.

Fax and Modem Codecs

mgcp rtp payload-type {**cisco-codec-fax-ack** | **cisco-codec-fax-ind** | **cisco-pcm-switch-over-alaw127** | **cisco-pcm-switch-over-ulaw 126**}

no mgcp rtp payload-type {**cisco-codec-fax-ack** | **cisco-codec-fax-ind** | **cisco-pcm-switch-over-alaw127** | **cisco-pcm-switch-over-ulaw 126**}

Named Signaling and Telephony Events

mgcp rtp payload-type {**nse** | **nte**} *number*

no mgcp rtp payload-type {**nse** | **nte**}

Voice Codecs

mgcp rtp payload-type {**clear-channel** | **g726r16** | **g726r24**} **static**

no mgcp rtp payload-type {**clear-channel** | **g726r16** | **g726r24**}

Syntax Description

cisco-codec-fax-ack	Payload type for Cisco codec fax acknowledgment.
cisco-codec-fax-ind	Payload type for Cisco codec fax indication.
cisco-pcm-switch-over-alaw 127	Payload type for upspeed to the G.711 a-law codec.
cisco-pcm-switch-over-ulaw 126	Payload type for upspeed to the G.711 mu-law codec.
nse	Payload type for named signaling events (NSE).
nte	Payload type for named telephony events (NTE).
number	Indicates the payload-type value. The valid range for NSE and NTE payload is from 96 to127. Default for NSE is 100. Default for NTE is 99.
clear-channel	Payload type for clear channel codec.
g726r16	Payload type for the G.726 codec at a bit rate of 16 kbps.
g726r24	Payload type for the G.726 codec at a bit rate of 24 kbps.
static	Static payload type.

Defaults

Fax and modem codecs: static RTP payload type
Voice codecs: dynamic RTP payload range from 96 to 127 (default for NSE is 100; default for NTE is 99)

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(11)T	This command was introduced on the following platforms: Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5400HPX, and Cisco AS5850.
12.4(6)T	The **nse** and **nte** named signalling and telephony events keywords were added.
12.4(15)T5	The **cisco-codec-fax-ack** and **cisco-codec-fax-ind** keywords were added.
12.4(18a)	The **cisco-codec-fax-ack** and **cisco-codec-fax-ind** keywords were added.
12.4(13f)	The **cisco-codec-fax-ack** and **cisco-codec-fax-ind** keywords were added.

Usage Guidelines

Cisco IOS Release 12.2(11)T introduced an RTP payload type negotiation for MGCP VoIP calls different from previous Cisco IOS images. To ensure interoperability between gateways using different Cisco IOS images, follow these guidelines:

- For fax and modem codecs—If either the originating or terminating MGCP gateway is running Cisco IOS Release 12.2(11)T or a later release and the other gateway is running a release earlier than Cisco IOS Release 12.2(11)T, use the **mgcp rtp payload-type** command on the gateway with the later release.
- For voice codecs—If you are using a Clear Channel, G.726R16, or G.726R24 codec, and either the originating or terminating MGCP gateway is running Cisco IOS Release 12.2(11)T or a later release and the other gateway is running a release earlier than Cisco IOS Release 12.2(11)T, use the **mgcp rtp payload-type** command on the gateway with the later release.

If both the originating and terminating gateways are using Cisco IOS Release 12.2(11)T or a later release, this command is not required.

The **cisco-codec-fax-ack** and **cisco-codec-fax-ind** keywords are used to change the default dynamic payload type for the Cisco fax relay feature to a different dynamic payload type.

Note NSE and NTE cannot be configured to use the same value. An error message will be generated by the command parser if the same value is entered.

Examples

The following example specifies use of dynamic RTP payload type for fax and modem calls for mu-law pulse code modulation (PCM) calls in an MGCP network in which the other gateway is running a release of Cisco IOS software that is earlier than Release 12.2(11)T:

```
Router# mgcp rtp payload-type cisco-pcm-switch-over-ulaw 126
```

The following example specifies use of a static RTP payload type for a G.726R16 codec in an MGCP network in which the other gateway is running a release of Cisco IOS software that is earlier than Release 12.2(11)T:

```
Router# mgcp rtp payload-type g726r16 static
```

The following examples configure the gateway to use RTP payload 104 for NSE events and payload 108 for NTE events. These payload types are used when the gateway is advertising capabilities via the Session Definition Protocol (SDP). If the gateway is recieving the SDP, the payload types configured in the remote SDP will be used instead.

```
Router# mgcp rtp payload-type nse 104
Router# mgcp rtp payload-type nte 108
```

Related Commands

Command	Description
mgcp codec	Selects the default codec type and its optional packetization period value.

mgcp rtp unreachable timeout

To enable detection of an unreachable remote VoIP endpoint, use the **mgcp rtp unreachable timeout** command in global configuration mode. To disable detection, use the **no** form of this command.

mgcp rtp unreachable timeout *timer-value*

no mgcp rtp unreachable timeout

Note This command replaces the previously hidden **mgcp rtp icmp timeout** command.

Syntax Description

timer-value	Time, in milliseconds, that the system waits for voice packets from the unreachable endpoint. Range is 500 to 10000.

Command Default Detection is disabled.

Command Modes Global configuration

Command History

Release	Modification
12.2(2)T	This command was introduced.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines This command is useful for preventing calls from remaining open when the remote endpoint is no longer available.

For example, suppose an IP phone makes a call through a gateway to another IP phone. During the call, the call agent goes down and the remote IP phone hangs up. Normally, the call agent would tell the gateway to tear down the call. In this case, the gateway continues to treat the call as active and sends more voice packets to the remote IP phone. The remote IP phone returns Internet Control Message Protocol (ICMP) port unreachable messages to the gateway. If the **mgcp rtp unreachable timeout** command is enabled, the gateway tears down the call. If the command is disabled, the call is left open.

The *timer-value* argument tells the gateway how long to wait before tearing down the call. After receiving the ICMP the unreachable message, the gateway starts a timer. If the gateway does not receive any voice packets by the end of the timer-value period, the gateway tears down the call. If some voice packets arrive before the end of the timer-value period, the gateway resets the timer and leaves the call in active state.

Examples The following example sets the Real-Time Transport Protocol (RTP) unreachable timer to 1500 ms:

```
Router(config)# mgcp rtp unreachable timeout 1500
```

Related Commands

Command	Description
mgcp	Initiates the MGCP daemon.
mgcp timer	Configures RTP stream host detection.

mgcp rtrcac

To enable Media Control Gateway Protocol (MGCP) Service Assurance (SA) Agent Call Admission Control (CAC) on an MGCP gateway supporting VoIP, use the **mgcp rtrcac** command in global configuration mode. To disable SA Agent checking on the gateway, use the **no** form of this command.

mgcp rtrcac

no mgcp rtrcac

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(11)T	This command was implemented on the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Usage Guidelines

Use this command to initiate or disable MGCP SA Agent CAC on the MGCP gateway.

Examples

The following example enables MGCP SA Agent CAC:

```
Router(config)# mgcp rtrcac
```

Related Commands

Command	Description
call fallback active	Enables a call request to fall back to alternate dial peers in case of network congestion.
mgcp	Starts and allocates resources for the MGCP daemon.
rtr responder	Enables the SA Agent Responder feature.

mgcp sched-time

To configure the scheduled timer value for Media Gateway Control Protocol (MGCP), use the **mgcp sched-time** command in global configuration mode. To disable the configuration, use the **no** form of this command.

mgcp sched-time *milliseconds*

no mgcp sched-time

Syntax Description

milliseconds	Schedule timer value, in milliseconds (ms). The range is from 12 to 40.

Command Default

The scheduled timer value for MGCP is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines

The **mgcp sched-time** command is used to configure the MGCP process a specified time to run before it yields to a process of a lower or the same priority. The schedule timer value must be from 12 to 40 ms, the minimum and maximum time, respectively, a process can run. This ensures that the MGCP process is not suspending too often.

Examples

The following example shows how to configure the scheduled timer value for MGCP:

```
Router# configure terminal
Router(config)# mgcp sched-time 15
```

Related Commands

Command	Description
show mgcp	Displays values for MGCP parameters.

mgcp sdp

To specify parameters for Session Definition Protocol (SDP) operation in Media Gateway Control Protocol (MGCP), use the **mgcp sdp** command in global configuration mode. To disable the parameters, use the **no** form of this command.

mgcp sdp {**notation undotted** | **simple** | **xpc-codec**}

no mgcp sdp {**notation undotted** | **simple** | **xpc-codec**}

Syntax Description

notation undotted	Enables undotted SDP notation for the codec string in SDP.
simple	Enables simple mode of SDP operation for MGCP.
xpc-codec	Enables initial generation of the X-pc-codec field, which is used during codec negotiation in SDP for Network-based Call Signaling (NCS) and Trunking Gateway Control Protocol (TGCP).

Command Default

notation undotted: disabled
simple: disabled
xpc-codec: disabled

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced.
12.2(2)XA	The **notation undotted** and **xpc-codec** keywords were added.
12.2(2)T	This command was implemented on the Cisco 7200.
12.2(4)T	This command was integrated into Cisco IOS Release 12.2(4)T.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

This command allows you to configure SDP fields to meet the requirements of your call agent.

The **notation undotted** keyword is for the G.726-16 and G.729 codecs. The codec strings G.726-16 and G.729 are dotted notation. The codec notation format is selected dynamically in the following order of preference:

1. The notation used in SDP for MGCP packets from the call agent.
2. The notation used in the a: parameter of the Local connection option for MGCP packets from the call agent.
3. The notation set by the **mgcp sdp notation undotted** command.

The **simple** keyword, when enabled, causes the gateway not to generate the following SDP fields: o (origin and session identifier), s (session name), and t (session start time and stop time). Certain call agents require this modified SDP to send data through the network.

The **xpc-codec** keyword, in TGCP and NCS, defines a new field (X-pc-codec) in the SDP for codec negotiation. To be backward compatible with non-packet-cable SDPs, the initial generation of the X-pc-codec field is suppressed by default. However, if a received SDP contains this field, the X-pc-codec field is read and generated in response to continue with the codec negotiation.

Examples

The following example configures simple mode for SDP:

```
Router(config)# mgcp sdp simple
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp sgcp disconnect notify

To enable enhanced endpoint synchronization after a disconnected procedure in a Simple Gateway Control Protocol (SGCP) version 1.5 network, use the **mgcp sgcp disconnect notify** command in global configuration mode. To disable this feature, use the **no** form of this command.

mgcp sgcp disconnect notify

no mgcp sgcp disconnect notify

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(11)T	This command was introduced.

Usage Guidelines

This command is used with SGCP version 1.5 to provide enhanced messaging capability for an endpoint that undergoes the disconnected procedure. It does not apply to gateways that run Media Control Gateway Protocol (MGCP) or other versions of SGCP.

An SGCP endpoint may lose communication with its call agent because the call agent is temporarily off line or because of faults in the network. When a gateway recognizes that an endpoint has lost its communication with the call agent (has become disconnected), it attempts to restore contact. If contact is not established before the disconnected timer expires, the disconnected procedure is initiated.

The disconnected procedure consists of the endpoint sending a Restart In Progress (RSIP) message to the call agent, stating that the endpoint was disconnected and is now trying to reestablish connectivity. If the **mgcp sgcp disconnect notify** command has been configured on the gateway, a special disconnected RSIP message is sent. When contact is reestablished, the call agent may decide to audit the endpoint using an Audit Endpoint (AUEP) command with additional I, ES, and RM parameters, which are defined as follows:

- I—List of connection identifiers for current connections on the endpoint
- ES—Event state of the endpoint (off-hook or on-hook)
- RM—Restart method reason for the last RSIP (graceful, forced, restart, or disconnected)

Endpoint synchronization with the call agent is achieved by the exchange of the disconnected RSIP message and the endpoint audit.

Examples

The following example enables disconnected RSIP messaging between SGCP endpoints and a call agent:

```
Router(config)# mgcp sgcp disconnect notify
```

Related Commands

Command	Description
mgcp sgcp restart notify	Enables the MGCP application to process SGCP-type RSIP messages.
show mgcp	Displays information for MGCP and SGCP parameters.

mgcp sgcp restart notify

To trigger the Media Gateway Control Protocol (MGCP) application to process Simple Gateway Control Protocol (SGCP)-type restart in progress (RSIP) messages, use the **mgcp sgcp restart notify** command in global configuration mode. To cancel the trigger, use the **no** form of this command.

mgcp sgcp restart notify

no mgcp sgcp restart notify

Syntax Description

This command has no arguments or keywords.

Command Default

SGCP does not send any RSIP messages when the protocol type is configured as SGCP.

Command Modes

Global configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco 3600 series.
12.1(5)XM	This command was modified for MGCP and implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

This command is used to send RSIP messages from the router to the SGCP call agent. The RSIP messages are used to indicate whether the T1 controller is up or down so that the call agent can synchronize with the router. RSIP messages are also sent when the **mgcp** command is entered, enabling the MGCP daemon.

Examples

The following example specifies that the system sends an RSIP notification to the SGCP call agent when the T1 controller state changes:

```
Router(config)# mgcp sgcp restart notify
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp src-cac

To enable System Resource Check (SRC) Call Admission Control (CAC) on a Media Gateway Control Protocol (MGCP) gateway supporting VoIP, use the **mgcp src-cac** command in global configuration mode. To disable system resource checking on the gateway, use the **no** form of this command.

mgcp src-cac

no mgcp src-cac

Syntax Description

This command has no arguments or keywords.

Command Default

System resource checking is disabled.

Command Modes

Global configuration

Command History

Releases	Modification
12.2(2)XB	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(11)T	This command was implemented on the the following platforms: Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Usage Guidelines

When this command is entered, all system-resource checks of CPU utilization, memory utilization, and maximum number of calls are performed for every call setup or modification request received from the call agent.

Examples

The following example enables MGCP VoIP SRC CAC:

```
Router(config)# mgcp src-cac
```

Related Commands

Command	Description
call threshold global	Sets threshold values for SRC CAC parameters.
mgcp	Starts and allocates resources for the MGCP daemon.

mgcp timer

To configure how a gateway detects the Real-Time Transport Protocol (RTP) stream host, use the **mgcp timer** command in global configuration mode. To reset to the defaults, use the **no** form of this command.

mgcp timer {**receive-rtcp** *timer* | **net-cont-test** *timer* | **nse-response t38** *timer*}

no mgcp timer {**receive-rtcp** | **net-cont-test** }

Syntax Description

receive-rtcp *timer*	Multiples of the RTCP report transmission interval, in milliseconds. Range is 1 to 100. Default is 5.
net-cont-test *timer*	Continuity-test timeout interval for VoIP and VoATM adaptation layer 2 (VoAAL2) calls, in milliseconds. Range is from 100 to 3000. The default is 200. **Note** This keyword was previously called **rtp-nse**.
nse-response t38 *timer*	Timeout period, in milliseconds, for awaiting T.38 named signaling event (NSE) responses from a peer gateway. Range is from 100 to 3000. The default is 200.

Defaults

receive-rtcp *timer*: 5 ms
net-cont-test *timer*: 200 ms
nse-response t38 *timer*: 200 ms

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(5)T	This command was introduced for Simple Gateway Control Protocol (SGCP) on the Cisco AS5300.
12.0(7)XK	This command was implemented on the Cisco MC3810 and Cisco 3600 series (except for the Cisco 3620).
12.1(5)XM	This command was modified to support Media Gateway Control Protocol (MGCP). The **rtp-nse** keyword was changed to the **net-cont-test** keyword without change of functionality.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200.
12.2(2)XB	This command was modified. The **nse-response t38** option was added to support MGCP T.38.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(11)T	This command was implemented on the Cisco AS5300, Cisco AS5400, and Cisco AS5850.
12.2(15)T	This command was implemented on the Cisco 1751 and Cisco 1760.

Usage Guidelines

Use this command to specify the RTP Control Protocol (RTCP) transmission interval for VoIP calls and the continuity-test timeout interval for VoIP and VoATM adaptation layer 2 (VoAAL2) calls.

The **receive-rtcp** keyword is the timer used by a gateway to disconnect a VoIP call when IP connectivity is lost with the remote gateway. After receiving each RTP or RTCP packet from the remote gateway, the receiving gateway starts a timer. The period of the timer is determined by multiplying the value configured using the **mgcp timer receive-rtcp** command with the value configured using **ip rtcp report interval** command. If the timer expires before the next packet is received from the remote gateway, the receiving gateway disconnects the call and notifies the call agent.

The **net-cont-test** keyword uses the terminating gateway to verify the network connectivity with the originating gateway before ringing the called party. To do this, the terminating gateway sends a command packet to the originating gateway and starts a timed for the timer period. If the timer expires before any acknowledgement from the originating gateway is received, the terminating gateway does not ring the called party, but instead disconnects the call and alerts the call agent.

The **nse-response t38** option sets the timer for awaiting T.38 NSE responses. This timer is configured to tell the terminating gateway how long to wait for an NSE from a peer gateway. The NSE from the peer gateway can either acknowledge the switch and its readiness to accept packets or indicate that it cannot accept T.38 packets.

Examples

The following example sets the multiplication factor to 10 (or x*10, where x is the interval that is set with the ip rtcp report interval command):

```
Router(config)# mgcp timer receive-rtcp 10
```

The following example sets the net-cont-test timer to 1500 ms (1.5 seconds):

```
Router(config)# mgcp timer net-cont-test 1500
```

The following example enables MGCP fax relay and sets the gateway wait time to 300 ms for an NSE from a peer gateway:

```
Router(config)# mgcp timer nse-response t38 300
```

Related Commands

Command	Description
ip rtcp report interval	Configures the minimum interval for RTCP report transmissions.
mgcp	Starts the MGCP daemon.
mgcp modem passthrough mode	Sets the method for changing speeds for modem and fax transmissions on the gateway.
mgcp tse payload	Sets the TSE payload for fax and modem calls.

mgcp tse payload

To enable inband telephony signaling events (TSEs) and specify the payload value to be used during fax and modem pass-through and network continuity tests, use the **mgcp tse payload** command in global configuration mode. To disable these signaling events, use the **no** form of this command.

mgcp tse payload *value*

no mgcp tse payload

Syntax Description

value	TSE payload value. Range is from 98 to 119. The default is 100.

Command Default 100

Command Modes Global configuration

Command History

Release	Modification
12.0(7)XK	This command was introduced for Simple Gateway Control Protocol (SGCP) on the Cisco MC3810 and on the Cisco 3600 series (except the Cisco 3620).
12.1(5)XM	This command was modified to support Media Gateway Control Protocol (MGCP).
12.2(2)T	This command was integrated into Cisco IOS release 12.2(2)T and implemented on the Cisco 7200 series router.
12.2(11)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3620 series, and Cisco 5300.

Usage Guidelines Because this command is disabled by default, you must specify a TSE payload value. Both gateways must have the same payload value.

If you configure the **mgcp modem passthrough mode** command using the **nse** keyword, you must configure this command.

Examples The following example sets NSE mode for VoIP modem pass-through and sets the TSE payload:

```
Router(config)# mgcp modem passthrough voip mode nse
Router(config)# mgcp tse payload 100
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.
mgcp modem passthrough mode	Sets the method for changing speeds for modem and fax transmissions on the gateway.

mgcp vad

To enable voice activity detection (VAD) silence suppression for Media Gateway Control Protocol (MGCP), use the **mgcp vad** command in global configuration mode. To disable VAD silence suppression, use the **no** form of this command.

mgcp vad

no mgcp vad

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.1(1)T	This command was introduced on the Cisco AS5300.
12.1(3)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3660, and Cisco uBR924.
12.1(5)XM	This command was implemented on the Cisco MC3810.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.

Usage Guidelines

Use this command to tell the MGCP gateway to turn VAD silence suppression on or off.

If VAD silence suppression is turned on, silence is not sent over the network, only audible speech. Sound quality is slightly degraded but the connection monopolizes much less bandwidth.

Examples

The following example turns VAD silence suppression on:

```
Router(config)# mgcp vad
```

Related Commands

Command	Description
mgcp	Starts the MGCP daemon.

mgcp validate call-agent source-ipaddr

To enable the Media Gateway Control Protocol (MGCP) application to validate that packets are received from a configured call agent, use the **mgcp validate call-agent source-ipaddr** command in global configuration mode. To disable the validation feature, use the **no** form of this command.

mgcp validate call-agent *source-ipaddr*

no mgcp validate call-agent *source-ipaddr*

Syntax Description This command has no arguments or keywords.

Command Default No validation occurs.

Command Modes Global configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines This command verifies that incoming packets are received from MGCP or Cisco CallManager configured call agents only. When the command is enabled, all MGCP messages received from call agents that are not configured in MGCP or Cisco CallManager are dropped. Use the **mgcp validate call-agent source-ipaddr** command in place of access lists to filter out packets from unconfigured call agents. Use the **mgcp bind control source-interface** *interface* command to restrict the MGCP application from responding to unconfigured call agent requests on nonsecure interfaces. Use the **ccm-manager config server** *server address* command to configure the Cisco CallManager address to be used when verifying incoming packets.

Examples The following example shows that MGCP call-agent validation is enabled:

```
Router(config)# mgcp validate call-agent source-ipaddr
```

Related Commands

Command	Description
ccm-manager config server	Configures the Cisco CallManager address used in verifying incoming packets.
mgcp bind control source-interface	Restricts the MGCP application from responding to unconfigured call agent requests on nonsecure interfaces.

Command	Description
mgcp call-agent	Configures the IP address for the primary or default Cisco CallManager server and designates the optional destination UDP port number for the specified Cisco CallManager server.
show mgcp srtp	Displays active MGCP SRTP calls.

mgcp validate domain-name

To enable validation of a hostname and domain (or a specific IP address) received as part of the endpoint name in MGCP messages against those configured on the gateway, use the **mgcp validate domain-name** command in global configuration mode. To disable Media Gateway Control Protocol (MGCP) endpoint validation, use the **no** form of this command.

mgcp validate domain-name

no mgcp validate domain-name

Syntax Description

This command has no arguments or keywords.

Defaults

Hostname and domain (or IP address) validation is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.
12.3(17)	The default state of this command was changed to disabled.
12.3(11)T8; 12.3(14)T5	The default state of this command was changed to disabled.
12.4(1c); 12.4(3b); 12.4(5)	The default state of this command was changed to disabled.
12.4(2)T2; 12.4(4)T1; 12.4(6)T	The default state of this command was changed to disabled.

Usage Guidelines

The **mgcp validate domain-name** command enables validation of a hostname and domain (or specific IP address) received as part of the endpoint name sent from the call agent (CA) or Cisco Unified Communications Manager against those configured on the gateway. If the hostname or domain (or IP address) is not valid, the system returns a 500 error with appropriate comment.

Use the **mgcp validate domain-name** command before configuring MGCP globally in a VoIP network. (See the *Cisco Unified CallManager and Cisco IOS Interoperability Guide* for global MGCP configuration information.)

Note Only MGCP messages received from the CA or Cisco Unified Communications Manager are validated.

You can display the current setting for MGCP domain name validation using the **show running-config** command. To show only MGCP information, limit the display output to the section on MGCP (see the "Examples" section).

Note When MGCP domain name validation is disabled, the output of the **show running-config** command does not include this command—it displays only when domain name validation is enabled. However, if your system is running a software image released before the default for this feature was changed, MGCP domain name validation is turned on by default and will appear in the **show running-config** command output only if validation is disabled.

Once you enable the MGCP validate domain name feature, you should verify that the appropriate endpoint name is included as part of incoming MGCP messages. Performing this verification helps to ensure that incoming messages with invalid hostnames, domain names, and IP addresses are rejected while valid incoming messages are still allowed to reach their target endpoint (host). Enabling this validation feature without verifying this information can cause all incoming messages, even those using valid names or addresses, to be rejected (see the "Examples" section).

Examples

The following examples show how to enable MGCP domain name validation, how to verify that validation is enabled in the running configuration, and how to verify and match the hostname, domain name, or IP address specified in incoming MGCP messages to the gateway configuration.

Use the following command to enable MGCP domain name validation:

```
Router(config)# mgcp validate domain-name
```

Use the following command to verify that MGCP domain name validation is enabled:

```
Router(config)# show running-config | section mgcp
```

or

```
Router(config)# show running-config | include mgcp validate

mgcp validate domain-name
Router(config)#
```

Use the following commands and processes to verify that hostname and domain name are configured so that all and only valid incoming messages are accepted by the gateway.

After enabling domain name validation, enable debug tracing for MGCP packets:

```
Router# debug mgcp packets

Media Gateway Control Protocol packets debugging for all endpoints is on
Router#
```

Generate a call to the gateway from a CA or Cisco Unified Communications Manager. That call will generate debug messages on the gateway so that you can view the endpoint information included in the incoming MGCP message and the response from the gateway to the CA (or Cisco Unified Communications Manager):

```
Router#
*Mar 14 02:29:11.512: MGCP Packet received from 192.0.2.135:2427--->
RQNT 3 aaln/S2/SU0/0@Router2821.example.com MGCP 0.1
R: L/hd(N)
X:1
<---
```

```
*Mar 14 02:29:11.512: MGCP Packet sent to 192.0.2.135:2427--->
500 3 Endpoint name contains an invalid host or domain
<---
```

Because the hostname in the incoming message (aaln/S2/SU0/0@*Router2821*.example.com) does not match the hostname of the gateway (*Router*), the message was rejected (replied to with a NACK). To resolve this, change the hostname of the gateway:

```
Router# config terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# hostname Router2821
Router2821(config)# end
Router2821#
```

Generate another call to the gateway from the CA or Cisco Unified Communications Manager. That call will generate more debug messages so that you can view the endpoint information included in the incoming MGCP message and the response from the gateway to the CA (or Cisco Unified Communications Manager):

```
*Mar 14 03:01:12.480: MGCP Packet received from 192.0.2.135:2427--->
RQNT 3 aaln/S2/SU0/0@Router2821.example.com MGCP 0.1
R: L/hd(N)
X:1
<---

*Mar 14 03:01:12.480: MGCP Packet sent to 192.0.2.135:2427--->
200 3 OK
<---
```

The validation is successful and an ACK (positive response) is sent back to the CA or Cisco Unified Communications Manager because the hostname now matches. This same process also applies to validation for the domain name. Use the following commands to set the domain name for the gateway and to view current configuration for domain name and hostname:

```
Router2821# config terminal

Enter configuration commands, one per line.  End with CNTL/Z.
Router2821(config)# ip domain-name example.com
Router2821(config)# end
Router2821# show running-config

Building configuration...
.
.
.
hostname Router2821
.
.
.
ip domain name example.com
.
.
.
.
Router2821#
```

Use the following commands and processes to verify that the IP address for the gateway is configured so that all and only valid incoming messages are accepted by the gateway:

```
Router2821# show ip interface brief

Interface                  IP-Address       OK?    Method    Status    Protocol
GigabitEthernet0/0         192.0.2.189    YES    NVRAM     up        up
Router2821#
```

Generate a call to the gateway from the CA or Cisco Unified Communications Manager. That call will generate debug messages so that you can view the endpoint information included in the incoming MGCP message and the response from the gateway to the CA (or Cisco Unified Communications Manager). If the MGCP message is directed to a specific IP address instead of a domain or hostname, you will see debug messages similar to the following:

```
*Mar 14 03:16:52.356: MGCP Packet received from 192.0.2.135:2427--->
RQNT 3 aaln/S2/SU0/0@[192.0.2.190] MGCP 0.1
R: L/hd(N)
X:1
<---

*Mar 14 03:16:52.356: MGCP Packet sent to 192.0.2.135:2427--->
500 3 Endpoint name contains an invalid host or domain
<---
```

Because the IP address specified in the incoming message (aaln/S2/SU0/0@*192.0.2.190*) does not match the IP address of the GigE 0/0 interface (*192.0.2.189*), the message was rejected (replied to with a NACK). To resolve this, change the IP address specified by the CA or Cisco Unified Communications Manager for this gateway and generate another call to this gateway. If the IP addresses match, you will see debug messages similar to the following:

```
*Mar 14 03:16:10.360: MGCP Packet received from 192.0.2.135:2427--->
RQNT 3 aaln/S2/SU0/0@[192.0.2.189] MGCP 0.1
R: L/hd(N)
X:1
<---

*Mar 14 03:16:10.364: MGCP Packet sent to 192.0.2.135:2427--->
200 3 OK
<---
```

Because the IP address now specified in the incoming MGCP message matches the IP address of the gateway, the message was accepted and replied to with an ACK (positive response).

Related Commands

Command	Description
mgcp call-agent	Configures the IP address for the primary or default Cisco Unified Communications Manager server and designates the optional destination UDP port number for the specified Cisco Unified Communications Manager server.
show ccm-manager	Displays a list of Cisco Unified Communications Manager servers and their current status and availability.

mgcp voice-quality-stats

To enable voice-quality statistics reporting for the Media Gateway Control Protocol (MGCP), use the **mgcp voice-quality-stats** command in global configuration mode. To turn off voice-quality statistics reporting, use the no form of this command.

mgcp voice-quality-stats [**priority**<*value*>] | [**all**]

no mgcp voice-quality-stats [**priority**<*value*>] | [**all**]

Syntax Description

priority<*value*>	Selects numeric parameters to indicate priority.
all	Selects all VQ parameters.

Command Default Voice-quality statistics reporting is turned off.

Command Modes Global configuration

Command History

Release	Modification
12.3(3)	This command was introduced.
12.4(4)T	The **priority** and **all** keywords were introduced.

Usage Guidelines

- The request for digital signal processor (DSP) statistics is controlled by the RTP Control Protocol (RTCP) statistics polling interval. The polling interval is configurable by entering the **ip rtcp report interval** command. Statistics are polled every 5 seconds by default.

Note The Cisco PGW 2200 must have a patch the supports DSP statistics in order to collect data in the call detail records (CDRs).

- This command does not generate any output on the console; it adds additional quality statistics parameters in the MGCP Delete Connection (DLCX) ACK message that is sent to the call agent.
- The keyword **priority** uses a value of 1 or 2 to indicate the priority of the parameters.

The corresponding set of VQ parameters are sent in the MGCP DLCX message based on the priority selected. Cisco IOS Release 12.4(4)T supports only priority levels 1 and 2.

Examples The following example enables voice-quality statistics reporting for MGCP:

```
Router> enable
Router# configure terminal
Router(config)# mgcp voice-quality-stats
Router(config)# end
```

The following example shows the VQ parameters selected for priority 1:

```
mgcp voice-quality-stats priority 1

16:38:20.461771 10.0.5.130:2427 10.0.5.133:2427 MGCP..... -> 250 1133 OK
P: PS=0, OS=0, PR=0, OR=0, PL=0, JI=65, LA=0
DSP/TX: PK=118, SG=0, NS=1, DU=28860, VO=2350

Related Commands

Command	Description
debug mgcp	Enables debug traces for MGCP errors, events, media, packets, parser, and CAC.
ip rtcp report interval	Configures the RTCP statistics polling interval.

microcode reload controller

To reload the firmware and field programmable gate array (FPGA) without reloading the Cisco IOS image, use the **microcode reload controller** command in privileged EXEC mode.

microcode reload controller {**t1** | **e1**| **j1**} {*x*/*y*}

Syntax Description

t1	T1
e1	E1
j1	J1 controller.
x/*y*	Controller slot and unit numbers. The slash must be typed.

Command Default No microcode reload activity is initiated.

Command Modes Privileged EXEC

Command History

Release	Modification
12.1(2)XH	This command was introduced on the Cisco 2600 series and Cisco 3600 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.
12.2(8)T	The **j1** keyword was added.

Usage Guidelines Loopbacks in the running configuration are restored after this command is entered. If the controller is in a looped state before this command is issued, the looped condition is dropped. You have to reinitiate the loopbacks from the remote end by entering the **no loop** command from the controller configuration.

Examples The following example shows how to start the microcode reload activity:

```
Router# microcode reload controller j1 3/0

TDM-connections and network traffic will be briefly disrupted.
Proceed with reload microcode?[confirm]
Router#

*Mar  3 209.165.200.229: clk_src_link_up_down: Status of this CLK does not matter

*Mar  3 209.165.200.229: clk_src_link_up_down: Status of this CLK does not matter
```

midcall-signaling

To configure the method used for signaling messages, use the **midcall-signaling** command in SIP configuration mode. To disable the midcall-signaling feature, use the **no** form of this command.

midcall-signaling passthru

no midcall-signaling

Syntax Description

passthru	Passes SIP messages from one IP leg to another IP leg.

Command Default

Midcall-signaling is disabled.

Command Modes

SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.4(15)XZ	This command was introduced.
12.4(20)T	This command was integrated into Cisco IOS Release 12.4(20)T.

Usage Guidelines

The **midcall-signaling** command distinguishes between the way Cisco Unified Communications Express and Cisco Unified Border Element handle signaling messages. Most SIP-to-SIP video and SIP-to-SIP reinvite based supplementary services require the **midcall-signaling** command to be configured before configuring other supplementary services. Supplementary service features that are functional without configuring **midcall-signaling** include: session refresh, fax, and refer-based supplementary services. The **midcall-signaling** command is for SIP-to-SIP calls only. All other calls (H323-to-SIP, and H323-to-H323) do not require the **midcall-signaling** command be configured. The **allow-connections sip-to-sip** command must be configured before the **midcall-signaling** command.

Configuring the Session Refresh with Reinvites feature on a dial-peer basis is not supported.

Examples

The following example shows SIP messages configured to passthrough from one IP leg to another IP leg:

```
Router(config)#voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# midcall-signaling passthru
```

Related Commands

Command	Description
allow-connections	Allows connections between specific types of endpoints in a Cisco Unified BE.

min-se (SIP)

To change the minimum session expiration (Min-SE) header value for all calls that use the Session Initiation Protocol (SIP) session timer, use the **min-se** command in SIP configuration mode. To reset to the default, use the **no** form of this command.

min-se *time* **session-expires** *interval*

no min-se

Syntax Description

time	Length of time, in seconds. Range: 90 to 86400 (1 day). Default: 1800.
session-expires *interval*	Indicates the session expires time interval. Range is 90 to 86400. Default:1800.

Command Default 1800 seconds (30 minutes)

Command Modes SIP configuration (conf-serv-sip)

Command History

Release	Modification
12.2(11)T	This command was introduced.
12.4(9)T	This command was modified. The default time was changed from 90 to 1800 seconds.
IOS Release XE 2.5	This command was integrated into Cisco IOS XE Release 2.5.
15.1(2)T	This command was modified. The **session-expires** keyword was added.

Usage Guidelines A proxy, user-agent client, and user-agent server can all have a configured minimum value indicating the smallest session interval that they accept. If they all happen to have a different configured minimum value, the highest minimum value is used. This command sets the minimum timer that is conveyed in the Min-SE header in the initial INVITE request.

The recommended value for this command is 1800 seconds (30 minutes), which is the default value. The value cannot be set below 90 seconds because excessive INVITEs create problems for routers. Once set, the value affects all calls originated by the router.

If you do not configure the session expires interval and configure only the min-se value then the session expires interval takes the value that is configured for the min-se.

Examples The following example sets the expiration timer to 90 seconds:

```
Router(config)# voice service voip
Router(conf-voi-serv)# sip
Router(conf-serv-sip)# min-se 90 session-expires 1800
```

Related Commands

Command	Description
show sip-ua min-se	Shows the current value of the Min-SE header.

mmoip aaa global-password

To define a password to be used with CiscoSecure for Microsoft Windows NT when using store and forward fax, use the **mmoip aaa global-password** command in global configuration mode. To reset to the default, use the **no** form of this command.

mmoip aaa global-password *password*

no mmoip aaa global-password *password*

Syntax Description

password	Password for CiscoSecure for Windows NT to be used with store and forward fax. The maximum length is 64 alphanumeric characters.

Command Default

No password is defined

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Usage Guidelines

CiscoSecure for Windows NT might require a separate password in order to complete authentication, no matter what security protocol you use. This command defines the password to be used with CiscoSecure for Windows NT. All records on the Microsoft Windows NT server use this defined password.

This command applies to on-ramp store and forward fax functions when using a modem card. It is not used with voice feature cards.

Examples

The following example specifies a password (password) when CiscoSecure for Microsoft Windows NT is used with store and forward fax:

```
mmoip aaa global-password password
```

mmoip aaa method fax accounting

To define the name of the method list to be used for authentication, authorization, and accounting (AAA) accounting with store-and-forward fax, use the **mmoip aaa method fax accounting** command in global configuration mode. To reset to the undefined state, use the **no** form of this command.

mmoip aaa method fax accounting *method-list-name*

no mmoip aaa method fax accounting *method-list-name*

Syntax Description

method-list-name	List of accounting methods to be used with store-and-forward fax.

Command Default No AAA accounting method list is defined

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines This command defines the name of the AAA accounting method list to be used with store-and-forward fax. The method list itself, which defines the type of accounting services provided for store-and-forward fax, is defined using the **aaa accounting** command in global configuration mode. Unlike standard AAA (in which each defined method list can be applied to specific interfaces and lines), the AAA accounting method lists used in store-and-forward fax are applied globally.

After the accounting method lists have been defined, they are enabled by using the **mmoip aaa receive-accounting enable** command.

This command applies to both on-ramp and off-ramp store-and-forward fax functions when a modem card is used. It is not used with voice feature cards.

Examples The following example specifies a AAA accounting method list (called “list3”) to be used with store-and-forward fax:

```
aaa new-model
mmoip aaa method fax accounting list3
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when RADIUS or TACACS+ is used.
mmoip aaa receive-accounting enable	Enables on-ramp store-and-forward fax for AAA accounting services.

mmoip aaa method fax authentication

To define the name of the method list to be used for authentication, authorization, and accounting (AAA) authentication with store and forward fax, use the **mmoip aaa method fax authentication** command in global configuration mode. To reset to the default, use the **no** form of this command.

mmoip aaa method fax authentication *method-list-name*

no mmoip aaa method fax authentication *method-list-name*

Syntax Description

method-list-name	List of authentication methods to be used with store and forward fax.

Command Default

No AAA authentication method list is defined

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced on the Cisco AS5300.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.

Usage Guidelines

This command defines the name of the AAA authentication method list to be used with store and forward fax. The method list itself, which defines the type of authentication services provided for store and forward fax, is defined using the **aaa authentication** global configuration command. Unlike standard AAA (where each defined method list can be applied to specific interfaces and lines), AAA authentication method lists used with store and forward fax are applied globally on the Cisco AS5300 universal access server.

After the authentication method lists have been defined, they are enabled by using the **mmoip aaa receive-authentication enable** command.

This command applies to both on-ramp and off-ramp store and forward fax functions.

Examples

The following example specifies a AAA authentication method list (called xyz) to be used with store and forward fax:

```
aaa new-model
mmoip aaa method fax authentication xyz
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
mmoip aaa receive-authentication enable	Enables on-ramp store and forward fax AAA authentication services.

mmoip aaa receive-accounting enable

To enable on-ramp authentication, authorization, and accounting (AAA) services, use the **mmoip aaa receive-accounting enable** command in global configuration mode. To disable on-ramp AAA services, use the **no** form of this command.

mmoip aaa receive-accounting enable

no mmoip aaa receive-accounting enable

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was introduced on the Cisco 1750.

Usage Guidelines This command enables AAA services if an accounting method list has been defined using both the **aaa accounting** command and the **mmoip aaa method fax accounting** command.

This command applies to on-ramp store-and-forward fax functions.

Examples The following example specifies an AAA method list (called xyz) to be used with inbound store-and-forward fax. In this example, store-and-forward fax is configured to track start and stop connection accounting records.

```
aaa new-model
mmoip aaa method fax accounting xyz
aaa accounting connection sherman stop-only radius
mmoip aaa receive-accounting enable
```

Related Commands

Command	Description
aaa accounting	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS or TACACS+.
mmoip aaa method fax accounting	Defines the name of the method list to be used for AAA accounting with store-and-forward fax.

mmoip aaa receive-authentication enable

To enable on-ramp authentication, authorization, and accounting (AAA) services, use the **mmoip aaa receive-authentication enable** command in global configuration mode. To disable on-ramp AAA services, use the **no** form of this command.

mmoip aaa receive-authentication enable

no mmoip aaa receive-authentication enable

Syntax Description This command has no arguments or keywords.

Command Default Disabled

Command Modes Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was introduced on the Cisco 1750.

Usage Guidelines This command enables AAA services if an AAA method list has been defined using both the **aaa authentication** command and the **mmoip aaa method fax authentication** command.

This command applies to on-ramp store-and-forward fax functions.

Examples The following example specifies an AAA method list (called xyz) to be used with inbound store-and-forward fax. In this example, RADIUS authentication (and if the RADIUS server fails, then local authentication) is configured for store-and-forward fax.

```
aaa new-model
mmoip aaa method fax authentication xyz
aaa authentication login peabody radius local
mmoip aaa receive-authentication enable
```

Related Commands

Command	Description
aaa authentication	Enables AAA of requested services for billing or security purposes when you use RADIUS or TACACS+.
mmoip aaa method fax authentication	Defines the name of the method list to be used for AAA authentication with store-and-forward fax.

mmoip aaa receive-id primary

To specify the primary location from which the authentication, authorization, and accounting (AAA) protocol retrieves its account identification information for on-ramp faxing, use the **mmoip aaa receive-id primary** command in global configuration mode. To remove the definition of the account identification source, use the **no** form of this command.

mmoip aaa receive-id primary {**ani** | **dnis** | **gateway** | **redialer-id** | **redialer-dnis**}

no mmoip aaa receive-id primary {**ani** | **dnis** | **gateway** | **redialer-id** | **redialer-dnis**}

Syntax Description

ani	AAA uses the calling party telephone number (automatic number identification [ANI]) as the AAA account identifier.
dnis	AAA uses the called party telephone number (dialed number identification service [DNIS]) as the AAA account identifier.
gateway	AAA uses the router-specific name derived from the host name and domain name as the AAA account identifier, displayed in the following format: *router-name.domain-name*.
redialer-id	AAA uses the account string returned by the external redialer device as the AAA account identifier. In this case, the redialer ID is either the redialer serial number or the redialer account number.
redialer-dnis	AAA uses the called party telephone number (dialed number identification service [DNIS]) as the AAA account identifier that is captured by the redialer if a redialer device is present.

Command Default

dial peer
No account identification source is defined

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was implemented on the Cisco 1750.
12.2(8)T	This command was implemented on the following platforms: Cisco 1751, Cisco 2600 series, Cisco 3600 series, Cisco 3725, and Cisco 3745.

Usage Guidelines

Normally, when AAA is being used for simple user authentication, AAA uses the username information defined in the user profile for authentication. With store-and-forward fax, you can specify that the ANI, DNIS, gateway ID, redialer ID, or redialer DNIS be used to identify the user for authentication. This command defines what AAA uses for the primary identifier for inbound or on-ramp user authentication with store-and-forward fax.

Store-and-forward fax allows you to define either a primary or a secondary identifier. You configure the secondary identifier using the **mmoip aaa receive-id secondary** command.

AAA does not use these methods sequentially. If the primary identifier is defined and AAA cannot authenticate the primary identifier information, it does not use the secondary identifier for authentication. Authentication simply fails.

Defining only the secondary identifier enables you to service two different scenarios simultaneously—for example, if you are offering fax services to two different companies, one of which uses redialers and the other does not. In this case, configure the **mmoip aaa receive-id primary** command to use the redialer DNIS, and configure the **mmoip aaa receive-id secondary** command to use ANI. With this configuration, when a user dials in and the redialer DNIS is not null, the redialer DNIS is used as the authentication identifier. If a user dials in and the redialer DNIS is null, ANI is used as the authentication identifier.

This command applies to on-ramp store-and-forward fax functions.

Examples

The following example defines the DNIS captured by the redialer as the primary AAA authentication identifier for store-and-forward fax:

```
aaa new-model
mmoip aaa receive-id primary redialer-dnis
```

Related Commands

Command	Description
mmoip aaa receive-id secondary	Specifies the secondary location from which AAA retrieves its account identification information for on-ramp faxing if the primary identifier has not been defined.

mmoip aaa receive-id secondary

To specify the secondary location where the authentication, authorization, and accounting (AAA) protocol retrieves its account identification information for on-ramp faxing if the primary identifier has not been defined, use the **mmoip aaa receive-id secondary** command in global configuration mode. To remove the definition of the account identification source, use the **no** form of this command.

mmoip aaa receive-id secondary {**ani** | **dnis** | **gateway** | **redialer-id** | **redialer-dnis**}

no mmoip aaa receive-id secondary {**ani** | **dnis** | **gateway** | **redialer-id** | **redialer-dnis**}

Syntax Description

ani	AAA uses the calling party telephone number (automatic number identification or ANI) as the AAA account identifier.
dnis	AAA uses the called party telephone number (dialed number identification service or DNIS) as the AAA account identifier.
gateway	AAA uses the router-specific name derived from the host name and domain name as the AAA account identifier, displayed in the following format: *router-name.domain-name*.
redialer-id	AAA uses the account string returned by the external redialer device as the AAA account identifier. In this case, the redialer ID is either the redialer serial number or the redialer account number.
redialer-dnis	AAA uses the called party telephone number (dialed number identification service or DNIS) as the AAA account identifier that is captured by the redialer if a redialer device is present.

Command Default

No account identification source is defined

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was introduced on the Cisco 1750.

Usage Guidelines

Normally, when AAA is being used for simple user authentication, AAA uses the username information defined in the user profile for authentication. With store-and-forward fax, you can specify that the ANI, DNIS, gateway ID, redialer DNIS, or redialer ID be used to identify the user for authentication. This command defines what AAA uses for the secondary identifier for inbound or on-ramp user authentication with store-and-forward fax if the primary identifier has not been defined.

Store-and-forward fax allows you to define either a primary or a secondary identifier. You configure the primary identifier using the **mmoip aaa receive-id primary** command.

AAA does not use these methods sequentially—meaning that if the primary identifier is defined and AAA cannot match the primary identifier information, it does not use the secondary identifier for authentication. Authentication simply fails.

Defining only the secondary identifier enables you to service two different scenarios simultaneously—for example, if you are offering fax services to two different companies, one of which uses redialers and the other does not. In this case, configure the **mmoip aaa receive-id primary** command to use the redialer DNIS, and configure the **mmoip aaa receive-id secondary** command to use ANI. With this configuration, when a user dials in and the redialer DNIS is not null, the redialer DNIS is used as the authentication identifier. If a user dials in and the redialer DNIS is null, ANI is used as the authentication identifier.

This command applies to on-ramp store-and-forward fax functions.

Examples

The following example defines the DNIS captured by the redialer as the secondary AAA authentication identifier for store-and-forward fax:

```
aaa new-model
mmoip aaa receive-id secondary redialer-dnis
```

mmoip aaa send-id primary

To specify the primary location where the authentication, authorization, and accounting (AAA) protocol retrieves its account identification information for off-ramp faxing, use the **mmoip aaa send-id primary** command in global configuration mode. To remove the definition of the account identification source, use the **no** form of this command.

mmoip aaa send-id primary {**account-id** | **envelope-from** | **envelope-to** | **gateway**}

no mmoip aaa send-id primary {**account-id** | **envelope-from** | **envelope-to** | **gateway**}

Syntax Description

account-id	AAA uses the account username from the originating fax-mail system as the AAA account identifier. This means that the off-ramp gateway uses the account identifier in the X-account ID field of the e-mail header. Using this attribute offers end-to-end authentication and accounting tracking.
envelope-from	AAA uses the account username from the fax-mail header as the AAA account identifier.
envelope-to	AAA uses the recipient derived from the fax-mail header as the AAA account identifier.
gateway	AAA uses the router-specific name derived from the host name and domain name as the AAA account identifier, displayed in the following format: *router-name.domain-name*.

Command Default

No account identification source is defined

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was implemented on the Cisco 1750.

Usage Guidelines

Normally, when AAA is being used for simple user authentication, AAA uses the username information defined in the user profile for authentication. With store-and-forward fax, you can specify that the account ID, username, or recipient name from the e-mail header information be used to identify the user for authentication. This command defines what AAA uses for the primary identifier for outbound or off-ramp user authentication with store-and-forward fax.

Store-and-forward fax allows you to define either a primary or a secondary identifier. You configure the secondary identifier using the **mmoip aaa send-id secondary** command. AAA extracts the authentication identifier information from the defined sources. If the field is blank (meaning undefined), AAA uses the secondary identifier source if configured. The secondary identifier is used only when the primary identifier is null. In this case, when AAA sees that the primary identifier is null, it checks to see if a secondary identifier has been defined and use that value for user authentication.

AAA does not use these methods sequentially—meaning that if the primary identifier is defined and AAA cannot authenticate the primary identifier information, it does not use the secondary identifier for authentication. Authentication simply fails.

When you enable authentication, the on-ramp gateway inserts whatever value you configure for the **mmoip aaa receive-id primary** command in the X-account ID field of the e-mail header. This X-account ID field contains the value that is used for authentication and accounting by the on-ramp gateway. For example, if the **mmoip aaa receive-id primary** command is set to **gateway**, the on-ramp gateway name (for example, hostname.domain-name) is inserted in the X-account ID field of the e-mail header of the fax-mail message.

If you want to use this configured gateway value in the X-account ID field, you must configure the **mmoip aaa send-id primary** command with the **account-id** keyword. This particular keyword enables store-and-forward fax to generate end-to-end authentication and accounting tracking records. If you do not enable authentication on the on-ramp gateway, the X-account ID field is left blank.

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example specifies the recipient name as defined in the envelope-to field of the e-mail header to be used as the AAA authentication identifier for store-and-forward fax:

```
aaa new-model
mmoip aaa send-id primary envelope-to
```

Related Commands

Command	Description
mmoip aaa receive-id primary	Specifies the primary location where AAA retrieves its account identification information for off-ramp faxing.
mmoip aaa send-id secondary	Specifies the secondary location where AAA retrieves its account identification information for off-ramp faxing.

mmoip aaa send-id secondary

To specify the secondary location where the authentication, authorization, and accounting (AAA) protocol retrieves its account identification information for off-ramp faxing, use the **mmoip aaa send-id secondary** command in global configuration mode. To remove the definition of the account identification source, use the **no** form of this command.

mmoip aaa send-id secondary {**account-id** | **envelope-from** | **envelope-to** | **gateway**}

no mmoip aaa send-id secondary {**account-id** | **envelope-from** | **envelope-to** | **gateway**}

Syntax Description

account-id	AAA uses the account username from the originating fax-mail system as the AAA account identifier. This means that the off-ramp gateway uses the account identifier in the X-account ID field of the e-mail header. Using this attribute offers end-to-end authentication and accounting tracking.
envelope-from	AAA uses the account username from the fax-mail header as the AAA account identifier.
envelope-to	AAA uses the recipient derived from the fax-mail header as the AAA account identifier.
gateway	AAA uses the router-specific name derived from the host name and domain name as the AAA account identifier, displayed in the following format: *router-name.domain-name*.

Command Default

No account identification source is defined

Command Modes

Global configuration

Command History

Release	Modification
12.0(4)XJ	This command was introduced.
12.1(1)T	This command was integrated into Cisco IOS Release 12.1(1)T.
12.2(4)T	This command was implemented on the Cisco 1750.

Usage Guidelines

Normally, when AAA is being used for simple user authentication, AAA uses the username information defined in the user profile for authentication. With store-and-forward fax, you can specify that the account ID, username, or recipient name from the e-mail header information be used to identify the user for authentication. This command defines what AAA uses for the secondary identifier for outbound or off-ramp user authentication with store-and-forward fax.

Store-and-forward fax allows you to define either a primary or a secondary identifier. You configure the primary identifier using the **mmoip aaa send-id primary** command. AAA extracts the authentication identifier information from the defined sources. If the field is blank (meaning undefined), AAA uses the secondary identifier source if configured. The secondary identifier is used only when the primary identifier is null. In this case, when AAA sees that the primary identifier is null, it checks to see if a secondary identifier has been defined and use that value for user authentication.

AAA does not use these methods sequentially—meaning that if the primary identifier is defined and AAA cannot match the primary identifier information, it does not use the secondary identifier for authentication. Authentication simply fails.

When you enable authentication, the on-ramp gateway inserts whatever value you configure for the **mmoip aaa receive-id secondary** command in the X-account ID field of the e-mail header (if store-and-forward fax uses the defined secondary identifier). This X-account ID field contains the value that is used for authentication and accounting by the on-ramp gateway. For example, if the **mmoip aaa receive-id secondary** command is set to **gateway**, the on-ramp gateway name (for example, hostname.domain-name) is inserted in the X-account ID field of the e-mail header of the fax-mail message.

If you want to use this configured gateway value in the X-account ID field, you must configure the **mmoip aaa send-id secondary** command with the **account-id** keyword. This particular keyword enables store-and-forward fax to generate end-to-end authentication and accounting tracking records. If you do not enable authentication on the on-ramp gateway, the X-account ID field is left blank.

This command applies to off-ramp store-and-forward fax functions.

Examples

The following example specifies the recipient name as defined in the envelope-to field of the e-mail header to be used as the AAA authentication identifier for store-and-forward fax:

```
aaa new-model
mmoip aaa send-id secondary envelope-to
```

Related Commands

Command	Description

no mode atm

Cisco 1700 Series, Cisco 2600XM Platform,

mode {**atm** | **t1** | **e1**}

no mode {**atm** | **t1** | **e1**}

Cisco IAD2430

mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}

no mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}

Syntax Description

atm	Sets the controller into ATM mode and creates an ATM interface (ATM 0). When ATM mode is enabled, no channel groups, DS0 groups, PRI groups, or time-division multiplexing (TDM) groups are allowed, because ATM occupies all the DS0s on the T1/E1 trunk. When you set the controller to ATM mode, the controller framing is automatically set to extended super frame (ESF) for T1 or cyclic redundancy check type 4 (CRC4) for E1. The line code is automatically set to binary 8-zero substitution (B8ZS) for T1 or high-density bipolar C (HDBC) for E1. When you remove ATM mode by entering the **no mode atm** command, ATM interface 0 is deleted. **Note** The **mode atm** command without the **aim** keyword uses software to perform ATM segmentation and reassembly (SAR). This is supported on Cisco 2600 series WIC slots only; it is not supported on network module slots.
aim	(Optional) The configuration on this controller uses the Advanced Integration Module (AIM) in the specified slot for ATM SAR. The **aim** keyword does not apply to the Cisco IAD2430 series IAD.
aim-slot	(Optional) AIM slot number on the router chassis: • Cisco 2600 series—0. • Cisco 3660—0 or 1.

cas	(Cisco 2600 series WIC slots only) Channel-associated signaling (CAS) mode. The T1 or E1 in this WIC slot is mapped to support T1 or E1 voice (that is, it is configured in a DS0 group or a PRI group). CAS mode is supported on both controller 0 and controller 1. On the Cisco IAD2430 series IAD, CAS mode is not supported.
t1	Sets the controller into T1 mode and creates a T1 interface. When you set the controller to T1 mode, the controller framing is automatically set to ESF for T1. The line code is automatically set to B8ZS for T1.
e1	Sets the controller into E1 mode and creates an E1 interface. When you set the controller to E1 mode, the controller framing is automatically set to CRC4 for E1. The line code is automatically set to HDB3 for E1.

Command Default The controller mode is disabled.

Command Modes Controller configuration

Command History

Release	Modification
11.3 MA	This command was introduced on the Cisco MC3810.
12.1(5)XM	Support for this command was extended to the merged SGCP/MGCP software.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T for the Cisco IAD2420 IADs.
12.2(2)XB	Support was extended to the Cisco 2600 series and Cisco 3660. The keyword **aim** and the argument *aim-slot* were added. The parenthetical modifier for the command was changed from "Voice over ATM" to "T1/E1 controller."
12.2(15)T	This command was implemented on the Cisco 2691 and the Cisco 3700 series.
12.3(4)XD	This command was integrated into Cisco IOS Release 12.3(4)XD on Cisco 2600 series and Cisco 3700 series routers to configure DSL Frame mode and to add T1/E1 Framed support.
12.3(4)XG	This command was integrated into Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.

Usage Guidelines

When a DSL controller is configured in ATM mode, the mode must be configured identically on both the CO and CPE sides. Both sides must be set to ATM mode.

Note If using the **no mode atm** command to leave ATM mode, the router must be rebooted immediately to clear the mode.

When configuring a DSL controller in T1 or E1 mode, the mode must be configured identically on the CPE and CO sides.

Examples

ATM Mode Example

The following example configures ATM mode on the DSL controller.

```
Router(config)# controller dsl 3/0
Router(config-controller)# mode atm
```

T1 Mode Example

The following example configures T1 mode on the DSL controller.

```
Router(config)# controller dsl 3/0
Router(config-controller)# mode t1
```

Related Commands

Command	Description
channel-group	Configures a list of time slots for voice channels on controller T1 0 or E1 0.
tdm-group	Configures a list of time slots for creating clear channel groups (pass-through) for time-division multiplexing (TDM) cross-connect.

mode (T1/E1 controller)

To set the T1 or E1 controller into asynchronous transfer mode (ATM) and create an ATM interface, to set the T1 or E1 controller into T1 or E1 mode and create a logical T1 or E1 controller, or to set the T1 or E1 controller into channel-associated signaling (CAS) mode, use the **mode** command in controller configuration mode. To disable the current mode and prepare to change modes, use the **no** form of this command.

mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}

no mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}

Syntax Description

atm	Sets the controller into ATM mode and creates an ATM interface (ATM 0). When ATM mode is enabled, no channel groups, DS0 groups, PRI groups, or time-division multiplexing (TDM) groups are allowed, because ATM occupies all the DS0s on the T1/E1 trunk. When you set the controller to ATM mode, the controller framing is automatically set to extended super frame (ESF) for T1 or cyclic redundancy check type 4 (CRC4) for E1. The line code is automatically set to binary 8-zero substitution (B8ZS) for T1 or high-density bipolar C (HDB3) for E1. When you remove ATM mode by entering the **no mode atm** command, ATM interface 0 is deleted. On the Cisco MC3810, ATM mode is supported only on controller 0 (T1 or E1 0). **Note** The **mode atm** command without the **aim** keyword uses software to perform ATM segmentation and reassembly (SAR). This is supported on Cisco 2600 series WIC slots only and is not supported on network module slots.
aim	(Optional) The configuration on this controller uses the Advanced Integration Module (AIM) in the specified slot for ATM SAR. The **aim** keyword does not apply to the Cisco MC3810 and the Cisco IAD2420 series IAD.
aim-slot	(Optional) AIM slot number on the router chassis. For the Cisco 2600 series, the AIM slot number is 0; for the Cisco 3660, the AIM slot number is 0 or 1.
cas	(CAS mode on Cisco 2600 series WIC slots only) The T1 or E1 in this WIC slot is mapped to support T1 or E1 voice (it is configured in a DS0 group or a PRI group). CAS mode is supported on both controller 0 and controller 1.

t1	(Cisco 2600XM series using the G.SHDSL WIC only) Sets the controller into T1 mode and creates a T1 interface. When you set the controller to T1 mode, the controller framing is automatically set to ESF for T1. The line code is automatically set to B8ZS for T1.
e1	(Cisco 2600XM series using the G.SHDSL WIC only) Sets the controller into E1 mode and creates an E1 interface. When you set the controller to E1 mode, the controller framing is automatically set to CRC4 for E1. The line code is automatically set to HDB3 for E1.

Command Default No controller mode is configured.

Command Modes Controller configuration

Command History

Release	Modification
11.3 MA	This command was introduced on the Cisco MC3810.
12.1(5)XM	Support for this command was extended to Simple Gateway Control Protocol (SGCP) and Media Gateway Control Protocol (MGCP).
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(2)XB	Support was extended to the Cisco 2600 series and Cisco 3660. The **aim** keyword and the *aim-slot* argument were added. The parenthetical modifier for the command was changed from "Voice over ATM" to "T1/E1 controller."
12.2(8)T	This command was implemented on the Cisco IAD2420 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.
12.2(15)T	This command was implemented on the Cisco 2691 and the Cisco 3700 series.
12.3(4)XD	Support was extended on Cisco 2600 series and Cisco 3700 series routers to configure DSL Frame mode and to add T1/E1 Framed support.
12.3(7)T	The support that was added in Cisco IOS Release 12.3(4)XD was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines This command has the following platform-specific usage guidelines:

- Cisco 2600 series, Cisco 3660 routers, or Cisco 3700 series that use an AIM for ATM processing must use the **mode atm aim** *aim-slot* command.
- Cisco 2600 series routers that use an AIM for DSP processing and specify DS0 groups must use the **mode cas** command if they are using WIC slots for voice. This command does not apply if network modules are being used.
- Cisco 3660 routers or Cisco 3700 series that use an AIM only for DSP resources should not use this command.

- On Cisco 2600 series routers that use WIC slots for voice, the **mode atm** command without the **aim** keyword specifies software ATM segmentation and reassembly. When the **aim** keyword is used with the **mode atm** command, the AIM performs ATM segmentation and reassembly.
- Cisco MC3810 routers cannot use the **aim** keyword.
- Cisco MC3810 routers with digital voice modules (DVMs) use some DS0s exclusively for different signaling modes. The DS0 channels have the following limitations when mixing different applications (such as voice and data) on the same network trunk:
  - On E1 controllers, DS0 16 is used exclusively for either CAS or common channel signaling (CCS), depending on which mode is configured.
  - On T1 controllers, DS0 24 is used exclusively for CCS.
- Cisco MC3810—When no mode is selected, channel groups and clear channels (data mode) can be created using the **channel group** and **tdm-group** commands, respectively.
- Cisco MC3810 is not supported in the AIM-ATM, AIM-VOICE-30, and AIM-ATM-VOICE-30 on the Cisco 2600 Series, Cisco 3660, and Cisco 3700 Series feature.
- On Cisco 2600 series and Cisco 3700 series routers when configuring a DSL controller in ATM mode, the mode must be set to the same mode on both the CO and CPE sides. Both sides must be set to ATM mode.
  - If the **no mode atm** command is used to leave ATM mode, the router must be rebooted immediately to clear the mode.
- On Cisco 2600 series and Cisco 3700 series routers when configuring a DSL controller in T1 or E1 mode, the mode must be configured identically on the CO and CPE sides.

Examples

The following example configures ATM mode on controller T1 0. This step is required for Voice over ATM.

```
Router(config)# controller T1 0
Router(config-controller)# mode atm
```

The following example configures ATM mode on controller T1 1/ 0 on a Cisco 2600 series router using an AIM in slot 0 for ATM segmentation and reassembly:

```
Router(config)# controller t1 1/0
Router(config-controller)# mode atm aim 0
```

The following example configures CAS mode on controller T1 1 on a Cisco 2600 series router:

```
Router(config)# controller T1 1
Router(config-controller)# mode cas
```

The following example configures ATM mode on the DSL controller.

```
Router(config)# controller dsl 3/0
Router(config-controller)# mode atm
```

The following example configures T1 mode on the DSL controller.

```
Router(config)# controller dsl 3/0
Router(config-controller)# mode t1
```

Related Commands

Command	Description
channel-group	Defines the time slots for voice channels on controller T1 0 or E1 0.
tdm-group	Configures a list of time slots for creating clear channel groups (pass-through) for TDM cross-connect.

mode bles

To set Broadband Loop Emulation Services (BLES) mode to independent or slave mode, use the **mode bles** command in dial peer configuration mode. To disable BLES mode, use the **no** form of this command.

mode bles [**slave**]

no mode bles

Syntax Description

slave	(Optional) Acts in slave mode.

Command Default

The default mode for this command is independent mode. Using the **slave** keyword sets the mode to slave mode.

Command Modes

Dial peer configuration

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco IAD2420 series.

Usage Guidelines

This command activates BLES mode. BLES mode activates the dynamic call admission control (CAC) resource allocation and implicit channel activation and deactivation. Use the **mode bles** command to activate independent mode and the **mode bles slave** command to activate slave mode.

Examples

The following example configures BLES mode:

```
voice service voatm
session protocol aal2
mode bles
```

The following example configures slave mode in BLES mode:

```
voice service voatm
session protocol aal2
mode bles slave
```

Related Commands

Command	Description
mode atm	Places the controller into ATM mode and creates an ATM interface (ATM 0).
mode cas	Places the controller into CAS mode, which allows you to create channel groups, CAS groups, and clear channels (both data and CAS modes).

mode border-element

To enable the set of commands used in border-element configuration on the Cisco 2900 and Cisco 3900 series platforms, use the **mode border-element** command in voice service configuration mode. To disable the set of commands used in border-element configuration, use the **no** form of this command.

mode border-element

no mode border-element

Syntax Description This command has no arguments or keywords.

Command Default The **mode border-element** command is disabled by default, so the commands specific to border-element configuration are unavailable on the Cisco 2900 and Cisco 3900 series platforms.

Command Modes Voice service configuration (conf-voi-serv)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines Use this command to enable the commands used in border-element configuration on Cisco 2900 and Cisco 3900 series platforms with a universal feature set. These commands are part of the **media** command. For more information about these commands, see the **media** command in the *Cisco IOS Voice Command Reference.*

If the **mode border-element** command is not entered, border-element-related commands are not available for Cisco Unified Border Element voice connections on the Cisco 2900 and Cisco 3900 series platforms with a universal feature set. The **mode border-element** command is not available on any other platforms.

For the **mode border-element** or the **no mode border-element** command to take effect, you need to save the running-config file and reload the router after you enter the command. The command-line interface (CLI) displays the following reminder after the command is entered:

```
You need to save and reload the router for this configuration change to be effective.
```

If you do not reload the router, the **mode border-element** or **no mode border-element** command does not take effect, and the availability of the commands used in border-element configuration is not affected.

Note The **show running-config** command displays the **mode border-element** or **no mode border-element** command in its output, even if a reload has not been done and either command is not in effect.

Exampless

The following example shows how to configure mode border-element and media-monitoring capability for a maximum of 200 Cisco Unified Border Element calls:

```
Router(config)# voice service voip
Router(conf-voi-serv)# mode border-element
Router(conf-voi-serv)# media monitoring 200
```

The following example shows how to configure the **media transcoder** command for high density on all VoIP calls:

```
Router(config)# voice service voip
Router(conf-voi-serv)# mode border-element
Router(conf-voi-serv)# media transcoder high-density
```

The following example shows how to configure the mode border-element and media flow-around for all VoIP calls:

```
Router(config)# voice service voip
Router(conf-voi-serv)# mode border-element
Router(config-voi-serv) media flow-around
```

Related Commands

Command	Description
codec (voice port)	Specifies voice compression.
codec complexity	Specifies call density and codec complexity based on the codec used.
media	Enables media packets to pass directly between the endpoints without the intervention of the IP-to-IP gateway and enables the incoming and outgoing IP-IP call gain/loss feature for audio call scoring on either the incoming dial peer or the outgoing dial peer.
show dial peer voice	Displays the codec setting for dial peers.
show running-config	Displays the contents of the currently running configuration file on the router.

mode ccs

To configure the T1/E1 controller to support common channel signaling (CCS) cross-connect or CCS frame forwarding, use the **mode ccs** command in global configuration mode. To disable support for CCS cross-connect or CCS frame forwarding on the controller, use the **no** form of this command.

mode ccs {**cross-connect** | **frame-forwarding**}

no mode ccs {**cross-connect** | **frame-forwarding**}

Syntax Description

cross-connect	Enables CCS cross-connect on the controller.
frame-forwarding	Enables CCS frame forwarding on the controller.

Command Default

No CCS mode is configured

Command Modes

Global configuration

Command History

Release	Modification
12.0(2)T	This command was introduced on the Cisco MC3810.
12.1(2)XH	This command was implemented on the Cisco 2600 series and Cisco 3600 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.

Usage Guidelines

On Cisco 2600 Series routers and Cisco 2600XM Series routers with the AIM-ATM, AIM-VOICE-30 or AIM-ATM-VOICE-30 module installed, the channel group configuration must be removed before the **no mode ccs frame-forwarding** command is entered. This restriction does not apply to the Cisco 3600 Series routers or the Cisco 3700 Series routers.

Examples

To enable CCS cross-connect on controller T1 1, enter the following commands:

```
controller T1 1
 mode ccs cross-connect
```

To enable CCS frame forwarding on controller T1 1, enter the following commands:

```
controller T1 1
 mode ccs frame-forwarding
```

Related Commands

Command	Description
ccs connect	Configures a CCS connection on an interface configured to support CCS frame forwarding.

modem passthrough (dial peer)

To enable modem pass-through over VoIP for a specific dial peer, use the **modem passthrough** command in dial peer configuration mode. To disable modem pass-through for a specific dial peer, use the **no** form of this command.

modem passthrough {**system** | **nse** [**payload-type** *number*] **codec** {**g711ulaw** | **g711alaw**} [**redundancy**]}

no modem passthrough

Syntax Description

system	Defaults to the global configuration.
nse	Specifies that named signaling events (NSEs) are used to communicate codec switchover between gateways.
payload-type *number*	(Optional) NSE payload type. Range varies by platform, but is from 96 to 119 on most platforms. For details, refer to command-line interface (CLI) help. Default is 100.
codec	Codec selections for upspeeding.
g711ulaw	Codec G.711 u-law 64000 bits per second for T1.
g711alaw	Codec G.711 a-law 64000 bits per second for E1.
redundancy	(Optional) Enables a single repetition of packets (using RFC 2198) to improve reliability by protecting against packet loss.

Defaults

payload-type *number*:100

Command Modes

Dial peer configuration

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco AS5300.
12.2(11)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 3700 series, Cisco AS5350, Cisco AS5400, and Cisco AS5850.

Usage Guidelines

Use this command to enable fax pass-through over VoIP individually for a single dial peer. Use the same values for all options on originating and terminating gateways.

Fax pass-through occurs when incoming T.30 fax data is not demodulated or compressed for its transit through the packet network. On detection of a fax tone on an established VoIP call, the gateways switch into fax pass-through mode by suspending the voice codec and configuration and loading the pass-through parameters for the duration of the fax session. The switchover of codec is known as upspeeding, and it changes the bandwidth needed for the call to the equivalent of G.711.

The **system** keyword overrides the configuration for the dial peer and directs that the values from the global configuration are to be used for this dial peer. When the **system** keyword is used, the following parameters are not available: **nse**, **payload-type**, **codec**, and **redundancy**.

The **modem passthrough (voice service)** command can be used to set pass-through options globally on all dial peers at one time. If the **modem passthrough (voice service)** command is used to set pass-through options for all dial peers and the **modem passthrough (dial peer)** command is used on a specific dial peer, the dial peer configuration takes precedence over the global configuration for that dial peer.

Examples

The following example configures fax pass-through over VoIP for a specific dial peer:

```
dial-peer voice 25 voip
 modem passthrough nse codec g711ulaw redundancy
```

Related Commands

Command	Description
dial-peer voice	Enters dial-peer configuration mode.
modem passthrough (voice service)	Enables fax or modem pass-through over VoIP globally for all dial peers.

modem passthrough (voice-service)

To enable fax or modem pass-through over VoIP globally for all dial peers, use the **modem passthrough** command in voice-service configuration mode. To disable fax or modem pass-through, use the **no** form of this command.

Cisco 2600 Series, Cisco 3600 Series, Cisco 3700 Series, Cisco AS5300

modem passthrough nse [**payload-type** *number*] **codec** {**g711ulaw** | **g711alaw**} [**redundancy** [**maximum-sessions** *sessions*]]

no modem passthrough

Cisco AS5350, Cisco AS5400, Cisco AS5850, Cisco AS5350XM, Cisco AS5400XM, Cisco VGD 1T3

modem passthrough {**nse** | **protocol**} [**payload-type** *number*] **codec** {**g711ulaw** | **g711alaw**} [**redundancy** [**maximum-sessions** *sessions*] [**sample-duration** [**10** | **20**]]]

no modem passthrough

Syntax Description

nse	Named signaling events (NSEs) are used to communicate codec switchover between gateways.
payload-type *number*	(Optional) NSE payload type. Range varies, but is from 96 to 119 on most platforms. For details, see the command-line interface (CLI) help. Default is 100.
codec	Codec selections for upspeed.
g711ulaw	Codec G.711 mu-law, 64000 bits per second for T1.
g711alaw	Codec G.711 A-law, 64000 bits per second for E1.
redundancy	(Optional) A single repetition of packets (using RFC 2198) to improve reliability by protecting against packet loss.
maximum-sessions *sessions*	(Optional) Maximum number of simultaneous pass-through sessions. Ranges and defaults vary by platform. For details, see the CLI help.
sample-duration	(Optional) Time, in milliseconds, of the largest Real-time Transport Protocol (RTP) packet when packet redundancy is active. Keywords vary by platform, but are either **10** or **20**. Default is 10.
protocol	Session Initiation Protocol (SIP)/H.323 protocol is used to signal modem pass-through.

Command Default

The command is disabled, so no fax or modem pass-through occurs.

Command Modes

Voice-service configuration (conf-voi-serv)

Command History

Release	Modification
12.1(3)T	This command was introduced on the Cisco AS5300.
12.2(11)T	This command was implemented on the following platforms: Cisco 2600 series, Cisco 3600 series, Cisco 3700 series, Cisco AS5350, Cisco AS5400, and Cisco AS5850. The **sample-duration** keyword was added.
12.4(24)T	This command was implemented on the following platforms: Cisco AS5350XM, Cisco AS5400XM, and Cisco VGD 1T3. The **protocol** keyword was added.

Usage Guidelines

Use this command to enable fax or modem pass-through over VoIP globally for all dial peers. Use the same values for all options on originating and terminating gateways.

In Cisco IOS Release 12.4(24)T, the **modem passthrough protocol** command is supported only on SIP signaling.

Note The **modem passthrough protocol** and **fax protocol** commands cannot be configured at the same time. If you enter either one of these commands when the other is already configured, the command-line interface returns an error message.

The error message serves as a confirmation notice because the **modem passthrough protocol** command is internally treated the same as the **fax protocol passthrough** command by the Cisco IOS software. For example, no other mode of fax protocol (for example, fax protocol T.38) can operate if the **modem passthrough protocol** command is configured.

Note Even though the **modem passthrough protocol** and **fax protocol passthrough** commands are treated the same internally, be aware that if you change the configuration from the **modem passthrough protocol** command to the **modem passthrough nse** command, the configured **fax protocol passthrough** command is not automatically reset to the default. If default settings are required for the **fax protocol** command, you have to specifically configure the **fax protocol** command.

Fax pass-through occurs when incoming T.30 fax data is not demodulated or compressed for its transit through the packet network. On detection of a fax tone on an established VoIP call, the gateways switch into fax pass-through mode by suspending the voice codec and configuration and loading the pass-through parameters for the duration of the fax session. The switchover of codec is known as upspeeding, and it changes the bandwidth needed for the call to the equivalent of G.711.

When using the **voice service voip** and **modem passthrough nse** commands on a terminating gateway to globally set up fax or modem pass-through with NSEs, you must also ensure that each incoming call will be associated with a VoIP dial peer to retrieve the global fax or modem configuration. You associate calls with dial peers by using the **incoming called-number** command to specify a sequence of digits that incoming calls can match. You can ensure that all calls will match at least one dial peer by using the following commands:

```
Router(config)# dial-peer voice tag voip
Router(config-dial-peer)# incoming called-number .
```

The **modem passthrough (dial peer)** command can be used to set pass-through options on individual dial peers. If the **modem passthrough (voice-service)** command is used to set pass-through options for all dial peers and the **modem passthrough (dial peer)** command is used on a specific dial peer, the dial-peer configuration takes precedence over the global configuration for that specific dial peer.

Examples

The following example configures modem pass-through for NSE payload type 101 using the G.711 mu-law codec:

```
voice service voip
 modem passthrough nse payload-type 101 codec g711ulaw redundancy maximum-sessions 1
```

Related Commands

Command	Description
fax protocol (voice-service)	Specifies the global default fax protocol to be used for all VoIP dial peers.
incoming called-number	Defines an incoming called number to match a specific dial peer.
modem passthrough (dial peer)	Enables fax or modem pass-through over VoIP for a specific dial peer.
voice service voip	Enters voice-service configuration mode and specifies the voice encapsulation type.

modem relay (dial peer)

To configure modem relay over VoIP for a specific dial peer, use the **modem relay** command in dial peer configuration mode. To disable modem relay over VoIP for a specific dial peer, use the **no** form of this command.
