#### CHAPTER 6 Implementing Lawful Intercept 89

Information About Lawful Intercept Implementation 89
Prerequisites for Implementing Lawful Intercept <b>90</b>
Restrictions for Implementing Lawful Intercept <b>90</b>
Lawful Intercept Topology <b>91</b>
Benefits of Lawful Intercept <b>92</b>
Installing Lawful Intercept (LI) Package 93
Installing and Activating the LI Package 93
Deactivating the LI RPM <b>93</b>
How to Configure SNMPv3 Access for Lawful Intercept <b>93</b>
Disabling SNMP-based Lawful Intercept <b>93</b>
Configuring the Inband Management Plane Protection Feature 94
Enabling the Lawful Intercept SNMP Server Configuration 95

Additional Information on Lawful Intercept 95
Interception Mode 95
Data Interception 95
Scale or Performance Values 96
Intercepting IPv4 and IPv6 Packets 96
Lawful Intercept Filters 96
Encapsulation Type Supported for Intercepted Packets 97
High Availability for Lawful Intercept 97
Preserving TAP and MD Tables during RP Fail Over 97
Replay Timer 97

# **Configuring AAA Services**

This module describes the implementation of the administrative model of *task-based authorization* used to control user access in the software system. The major tasks required to implement task-based authorization involve configuring user groups and task groups.

User groups and task groups are configured through the software command set used for authentication, authorization and accounting (AAA) services. Authentication commands are used to verify the identity of a user or principal. Authorization commands are used to verify that an authenticated user (or principal) is granted permission to perform a specific task. Accounting commands are used for logging of sessions and to create an audit trail by recording certain user- or system-generated actions.

AAA is part of the software base package and is available by default.

Configuring AAA Services, on page 1

# **Configuring AAA Services**

This module describes the implementation of the administrative model of *task-based authorization* used to control user access in the software system. The major tasks required to implement task-based authorization involve configuring user groups and task groups.

User groups and task groups are configured through the software command set used for authentication, authorization and accounting (AAA) services. Authentication commands are used to verify the identity of a user or principal. Authorization commands are used to verify that an authenticated user (or principal) is granted permission to perform a specific task. Accounting commands are used for logging of sessions and to create an audit trail by recording certain user- or system-generated actions.

AAA is part of the software base package and is available by default.

# **Prerequisites for Configuring AAA Services**

The following are the prerequisites to configure AAA services:

- You must be in a user group associated with a task group that includes the proper task IDs. The command reference guides include the task IDs required for each command. If you suspect user group assignment is preventing you from using a command, contact your AAA administrator for assistance.
- Establish a root system user using the initial setup dialog. The administrator may configure a few local users without any specific AAA configuration. The external security server becomes necessary when user accounts are shared among many routers within an administrative domain. A typical configuration

would include the use of an external AAA security server and database with the local database option as a backup in case the external server becomes unreachable.

# **Restrictions for Configuring AAA Services**

This section lists the restrictions for configuring AAA services.

#### Compatibility

Compatibility is verified with the Cisco freeware TACACS+ server and FreeRADIUS only.

#### Interoperability

Router administrators can use the same AAA server software and database (for example, CiscoSecure ACS) for the router and any other Cisco equipment that does not currently run the Cisco software. To support interoperability between the router and external TACACS+ servers that do not support task IDs, see the "Task IDs for TACACS+ and RADIUS Authenticated Users, on page 38" section.

# **Configure Task group**

Task-based authorization employs the concept of a *task ID* as its basic element. A task ID defines the permission to execute an operation for a given user. Each user is associated with a set of permitted router operation tasks identified by task IDs. Users are granted authority by being assigned to user groups that are in turn associated with task groups. Each task group is associated with one or more task IDs. The first configuration task in setting up an authorization scheme to configure the task groups, followed by user groups, followed by individual users.

Specific task IDs can be removed from a task group by specifying the **no** prefix for the **task** command.

The task group itself can be removed. Deleting a task group that is still referred to elsewhere results in an error.

#### Before you begin

Before creating task groups and associating them with task IDs, you should have some familiarity with the router list of task IDs and the purpose of each task ID. Use the **show aaa task supported** command to display a complete list of task IDs.

Note Only users with write permissions for the AAA task ID can configure task groups.

Step 1 configure

Example:

RP/0/# configure

Enters mode.

#### **Step 2 taskgroup** *taskgroup-name*

#### Example:

RP/0/(config) # taskgroup beta

Creates a name for a particular task group and enters task group configuration submode.

• Specific task groups can be removed from the system by specifying the **no** form of the **taskgroup** command.

#### Step 3 description string

#### Example:

RP/0/(config-tg) # description this is a sample task group description

(Optional) Creates a description of the task group named in Step 2.

**Step 4 task** {read | write | execute | debug} *taskid-name* 

#### Example:

RP/0/(config-tg) # task read bgp

Specifies a task ID to be associated with the task group named in Step 2.

- Assigns **read** permission for any CLI or API invocations associated with that task ID and performed by a member of the task group.
- Specific task IDs can be removed from a task group by specifying the **no** prefix for the **task** command.

**Step 5** Repeat for each task ID to be associated with the task group named in Step 2.

**Step 6** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

#### What to do next

After completing configuration of a full set of task groups, configure a full set of user groups as described in the Configuring User Groups section.

# **Configure User Groups**

User groups are configured with the command parameters for a set of users, such as task groups. Entering the **usergroup** command accesses the user group configuration submode. Users can remove specific user groups

by using the **no** form of the **usergroup** command. Deleting a usergroup that is still referenced in the system results in a warning.

#### Before you begin

**Note** Only users associated with the WRITE:AAA task ID can configure user groups. User groups cannot inherit properties from predefined groups, such as owner-sdr.

#### Procedure

Step 1 configure

#### Example:

RP/0/# configure

Enters mode.

#### **Step 2 usergroup** *usergroup-name*

#### Example:

RP/0/(config) # usergroup beta

Creates a name for a particular user group and enters user group configuration submode.

• Specific user groups can be removed from the system by specifying the **no** form of the **usergroup** command.

#### **Step 3** description *string*

#### **Example:**

```
RP/0/(config-ug)#
description this is a sample user group description
```

(Optional) Creates a description of the user group named in Step 2.

#### **Step 4 inherit usergroup** *usergroup-name*

#### Example:

RP/0/(config-ug)#
inherit usergroup sales

• Explicitly defines permissions for the user group.

#### **Step 5 taskgroup** taskgroup-name

#### Example:

RP/0/(config-ug) # taskgroup beta

Associates the user group named in Step 2 with the task group named in this step.

• The user group takes on the configuration attributes (task ID list and permissions) already defined for the entered task group.

L

- **Step 6** Repeat Step for each task group to be associated with the user group named in Step 2.
- **Step 7** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel Remains in the configuration session, without committing the configuration changes.

# **Configure Users**

Perform this task to configure a user.

Each user is identified by a username that is unique across the administrative domain. Each user should be made a member of at least one user group. Deleting a user group may orphan the users associated with that group. The AAA server authenticates orphaned users but most commands are not authorized.

#### Procedure

Step 1	configure
	Example:
	RP/0/# configure
	Enters mode.
Step 2	username user-name
	Example:
	RP/0/(config)# username user1
	Creates a name for a new user (or identifies a current user) and enters username configuration submode.
	• The <i>user-name</i> argument can be only one word. Spaces and quotation marks are not allowed.
Step 3	Do one of the following:
	• password {0   7} password • secret {0   5} secret
	Example:
	RP/0/(config-un)# password 0 pwd1
	or
	RP/0/(config-un)# secret 0 sec1
	Specifies a password for the user named in step 2.

- Use the secret command to create a secure login password for the user names specified in step 2.
- Entering **0** following the **password** command specifies that an unencrypted (clear-text) password follows. Entering **7** following the **password** command specifies that an encrypted password follows.
- Entering **0** following the **secret** command specifies that a secure unencrypted (clear-text) password follows. Entering **5** following the **secret** command specifies that a secure encrypted password follows.
- Type **0** is the default for the **password** and **secret** commands.

#### **Step 4** group group-name

#### Example:

RP/0/(config-un) # group sysadmin

Assigns the user named in step 2 to a user group that has already been defined through the **usergroup** command.

- The user takes on all attributes of the user group, as defined by that user group's association to various task groups.
- Each user must be assigned to at least one user group. A user may belong to multiple user groups.
- **Step 5** Repeat step 4 for each user group to be associated with the user specified in step 2.

**Step 6** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

# **Configure Router to RADIUS Server Communication**

This task configures router to RADIUS server communication. The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (CiscoSecure ACS), Livingston, Merit, Microsoft, or another software provider. Configuring router to RADIUS server communication can have several components:

- · Hostname or IP address
- Authentication destination port
- Accounting destination port
- Retransmission value
- · Timeout period
- · Key string

RADIUS security servers are identified on the basis of their hostname or IP address, hostname and specific User Datagram Protocol (UDP) port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port numbers creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as an automatic switchover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order they are configured.)

A RADIUS server and a Cisco router use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the router.

The timeout, retransmission, and encryption key values are configurable globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the router, use the three unique global commands: **radius-server timeout**, **radius-server retransmit**, and **radius-server key**. To apply these values on a specific RADIUS server, use the **radius-server host** command.

Note

You can configure both global and per-server timeout, retransmission, and key value commands simultaneously on the same Cisco network access server. If both global and per-server functions are configured on a router, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands.

#### Procedure

#### Step 1 configure

#### Example:

RP/0/# configure

Enters mode.

**Step 2** radius-server host {hostname | ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string]

#### Example:

RP/0//CPU0:router(config)# radius-server host host1

Specifies the hostname or IP address of the remote RADIUS server host.

- Use the **auth-port** *port-number* option to configure a specific UDP port on this RADIUS server to be used solely for authentication.
- Use the **acct-port** *port-number* option to configure a specific UDP port on this RADIUS server to be used solely for accounting.
- To configure the network access server to recognize more than one host entry associated with a single IP address, simply repeat this command as many times as necessary, making sure that each UDP port

number is different. Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host.

- If no timeout is set, the global value is used; otherwise, enter a value in the range 1 to 1000. If no retransmit value is set, the global value is used; otherwise enter a value in the range 1 to 100. If no key string is specified, the global value is used.
- **Note** The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the **radius-server host** command syntax because the leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks themselves are part of the key.

#### Step 3 radius-server retransmit retries

#### Example:

RP/0/(config) # radius-server retransmit 5

Specifies the number of times the software searches the list of RADIUS server hosts before giving up.

• In the example, the number of retransmission attempts is set to 5.

#### **Step 4** radius-server timeout seconds

#### Example:

RP/0/(config) # radius-server timeout 10

Sets the number of seconds a router waits for a server host to reply before timing out.

- In the example, the interval timer is set to 10 seconds.
- **Step 5** radius-server key {0 clear-text-key | 7 encrypted-key | clear-text-key}

#### Example:

RP/0/(config) # radius-server key 0 samplekey

Sets the authentication and encryption key for all RADIUS communications between the router and the RADIUS daemon.

**Step 6** radius source-interface type instance [vrf vrf-id]

#### Example:

RP/0/(config) # radius source-interface 0/3/0/1

(Optional) Forces RADIUS to use the IP address of a specified interface or subinterface for all outgoing RADIUS packets.

• The specified interface or subinterface must have an IP address associated with it. If the specified interface or subinterface does not have an IP address or is in the down state, then RADIUS reverts to the default. To avoid this, add an IP address to the interface or subinterface or bring the interface to the up state.

The **vrf** keyword enables the specification on a per-VRF basis.

- **Step 7** Repeat step 2 through step 6 for each external server to be configured.
- **Step 8** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- **Cancel**—Remains in the configuration session, without committing the configuration changes.

#### **Step 9** show radius

#### Example:

```
RP/0/# show radius
```

(Optional) Displays information about the RADIUS servers that are configured in the system.

#### **Radius Summary Example**

```
radius source-interface Mgm0/rp0/cpu0/0 vrf default
radius-server timeout 10
radius-server retransmit 2
1
! OOB RADIUS
radius-server host 123.100.100.186 auth-port 1812 acct-port 1813
key cisco123
timeout 10
retransmit 2
radius-server host 123.100.100.187 auth-port 1812 acct-port 1813
kev cisco123
timeout 10
retransmit 2
1
aaa group server radius radgrp
server 123.100.100.186 auth-port 1812 acct-port 1813
server 123.100.100.187 auth-port 1812 acct-port 1813
!
aaa authorization exec radauthen group radgrp local
aaa authentication login radlogin group radgrp local
line template vty
authorization exec radauthen
login authentication radlogin
timestamp disable
exec-timeout 0 0
1
vty-pool default 0 99 line-template vty
```

### **Configure RADIUS Dead-Server Detection**

The RADIUS Dead-Server Detection feature lets you configure and determine the criteria that is used to mark a RADIUS server as dead. If no criteria is explicitly configured, the criteria is computed dynamically on the basis of the number of outstanding transactions. The RADIUS dead-server detection configuration results in the prompt detection of RADIUS servers that have stopped responding. The prompt detection of nonresponding RADIUS servers and the avoidance of swamped and dead-to-live-to-dead-again servers result in less deadtime and quicker packet processing.

You can configure the minimum amount of time, in seconds, that must elapse from the time that the router last received a valid packet from the RADIUS server to the time the server is marked as dead. If a packet has not been received since the router booted, and there is a timeout, the time criterion is treated as though it was met.

In addition, you can configure the number of consecutive timeouts that must occur on the router before the RADIUS server is marked as dead. If the server performs both authentication and accounting, both types of packets are included in the number. Improperly constructed packets are counted as though they are timeouts. Only retransmissions are counted, not the initial transmission. For example, each timeout causes one retransmission to be sent.

Note Both the time criterion and the tries criterion must be met for the server to be marked as dead.

The **radius-server deadtime** command specifies the time, in minutes, for which a server is marked as dead, remains dead, and, after this period, is marked alive even when no responses were received from it. When the dead criteria are configured, the servers are not monitored unless the **radius-server deadtime** command is configured

#### Procedure

#### Step 1 configure

#### Example:

RP/0/# configure

Enters mode.

#### Step 2 radius-server deadtime minutes

#### Example:

RP/0/(config) # radius-server deadtime 5

Improves RADIUS response times when some servers might be unavailable and causes the unavailable servers to be skipped immediately.

#### **Step 3** radius-server dead-criteria time seconds

#### Example:

RP/0/(config) # radius-server dead-criteria time 5

Establishes the time for the dead-criteria conditions for a RADIUS server to be marked as dead.

# Step 4 radius-server dead-criteria tries tries

#### Example:

RP/0/(config) # radius-server dead-criteria tries 4

Establishes the number of tries for the dead-criteria conditions for a RADIUS server to be marked as dead.

**Step 5** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel Remains in the configuration session, without committing the configuration changes.

 Step 6
 show radius dead-criteria host ip-addr [auth-port auth-port] [acct-port acct-port]

 Example:

RP/0/# show radius dead-criteria host 172.19.192.80

(Optional) Displays dead-server-detection information that has been requested for a RADIUS server at the specified IP address.

# **Configure TACACS+ Server**

This task configures a TACACS+ server.

The port, if not specified, defaults to the standard port number, 49. The **timeout** and **key** parameters can be specified globally for all TACACS+ servers. The **timeout** parameter specifies how long the AAA server waits to receive a response from the TACACS+ server. The **key** parameter specifies an authentication and encryption key shared between the AAA server and the TACACS+ server.

#### Procedure

```
Step 1 configure
```

Example:

RP/0/# configure

Enters mode.

#### Step 2 tacacs-server host host-name port port-number

#### Example:

RP/0/(config)# tacacs-server host 209.165.200.226 port 51 RP/0/(config-tacacs-host)#

Specifies a TACACS+ host server and optionally specifies a server port number.

• This option overrides the default, port 49. Valid port numbers range from 1 to 65535.

**Step 3** tacacs-server host host-name timeout seconds

#### **Example:**

```
RP/0/(config-tacacs-host) # tacacs-server host 209.165.200.226 timeout 30
RP/0/(config) #
```

Specifies a TACACS+ host server and optionally specifies a timeout value that sets the length of time the AAA server waits to receive a response from the TACACS+ server.

• This option overrides the global timeout value set with the **tacacs-server timeout** command for only this server. The timeout value is expressed as an integer in terms of timeout interval seconds. The range is from 1 to 1000.

#### **Step 4** tacacs-server host host-name key [0 | 7] auth-key

#### Example:

RP/0/(config)# tacacs-server host 209.165.200.226 key 0 a secret

Specifies a TACACS+ host server and optionally specifies an authentication and encryption key shared between the AAA server and the TACACS+ server.

- The TACACS+ packets are encrypted using this key. This key must match the key used by TACACS+ daemon. Specifying this key overrides the global key set by the **tacacs-server key** command for only this server.
- (Optional) Entering **0** indicates that an unencrypted (clear-text) key follows.
- (Optional) Entering 7 indicates that an encrypted key follows.
- The *auth-key* argument specifies the encrypted or unencrypted key to be shared between the AAA server and the TACACS+ server.

#### Step 5 tacacs-server host host-name single-connection

#### Example:

RP/0/(config)# tacacs-server host 209.165.200.226 single-connection

Prompts the router to multiplex all TACACS+ requests to this server over a single TCP connection. By default, a separate connection is used for each session.

#### **Step 6 tacacs source-interface** type instance

#### Example:

RP/0/(config) # tacacs source-interface 0/4/0/0

(Optional) Specifies the source IP address of a selected interface for all outgoing TACACS+ packets.

- The specified interface or subinterface must have an IP address associated with it. If the specified interface or subinterface does not have an IP address or is in the down state, then TACACS+ reverts to the default interface. To avoid this, add an IP address to the interface or subinterface or bring the interface to the up state.
- The **vrf** option specifies the Virtual Private Network (VPN) routing and forwarding (VRF) reference of an AAA TACACS+ server group.

**Step 7** Repeat step 2 through step 5 for each external server to be configured.

**Step 8** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

#### Step 9 show tacacs

#### Example:

RP/0/# show tacacs

(Optional) Displays information about the TACACS+ servers that are configured in the system.

#### **Tacacs Summary Example:**

```
! OOB TAC
tacacs-server host 123.100.100.186 port 49
kev lm51
Т
tacacs-server host 123.100.100.187 port 49
key lm51
aaa group server tacacs+ tacgrp
server 123.100.100.186
server 123.100.100.187
1
aaa group server tacacs+ eem
server 123.100.100.186
server 123.100.100.187
1
aaa authorization exec tacauthen group tacgrp local
aaa authentication login taclogin group tacgrp local
line console
authorization exec tacauthen
login authentication taclogin
timeout login response 30
timestamp
exec-timeout 0 0
session-timeout 15
1
vty-pool default 0 99 line-template console
```

# **Configure RADIUS Server Groups**

This task configures RADIUS server groups.

The user can enter one or more **server** commands. The **server** command specifies the hostname or IP address of an external RADIUS server along with port numbers. When configured, this server group can be referenced from the AAA method lists (used while configuring authentication, authorization, or accounting).

#### Before you begin

For configuration to succeed, the external server should be accessible at the time of configuration.

#### Procedure

Step 1 configure

#### Example:

RP/0/# configure

Enters mode.

#### Step 2 aaa group server radius group-name

#### Example:

RP/0/(config) # aaa group server radius radgroup1

Groups different server hosts into distinct lists and enters the server group configuration mode.

#### **Step 3** server {hostname | ip-address} [auth-port port-number] [acct-port port-number]

#### Example:

RP/0/(config-sg-radius) # server 192.168.20.0

Specifies the hostname or IP address of an external RADIUS server.

- After the server group is configured, it can be referenced from the AAA method lists (used while configuring authentication, authorization, or accounting).
- **Step 4** Repeat step 4 for every external server to be added to the server group named in step 3.

#### **Step 5 deadtime** *minutes*

#### Example:

RP/0/(config-sg-radius)# deadtime 1

Configures the deadtime value at the RADIUS server group level.

• The *minutes* argument specifies the length of time, in minutes, for which a RADIUS server is skipped over by transaction requests, up to a maximum of 1440 (24 hours). The range is from 1 to 1440.

The example specifies a one-minute deadtime for RADIUS server group radgroup1 when it has failed to respond to authentication requests for the **deadtime** command

**Note** You can configure the group-level deadtime after the group is created.

**Step 6** Use the **commit** or **end** command.

commit —Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.

• Cancel —Remains in the configuration session, without committing the configuration changes.

#### Step 7 show radius server-groups [group-name [detail]]

#### Example:

RP/0/# show radius server-groups

(Optional) Displays information about each RADIUS server group that is configured in the system.

#### What to do next

After configuring RADIUS server groups, define method lists by configuring authentication, authorization, and accounting.

## **Configure TACACS+ Server Groups**

This task configures TACACS+ server groups.

You can enter one or more **server** commands. The **server** command specifies the hostname or IP address of an external TACACS+ server. Once configured, this server group can be referenced from the AAA method lists (used while configuring authentication, authorization, or accounting).

#### Before you begin

For successful configuration, the external server should be accessible at the time of configuration. When configuring the same IP address for global and vrf configuration, server-private parameters are required (see *Configure Per VRF TACACS+ Server Groups* section).

#### Procedure

```
Step 1 configure
```

Example:

RP/0/# configure

Enters mode.

#### **Step 2 aaa group server tacacs**+ group-name

#### Example:

RP/0/(config) # aaa group server tacacs+ tacgroup1

Groups different server hosts into distinct lists and enters the server group configuration mode.

#### **Step 3** server {*hostname* | *ip-address*}

#### Example:

RP/0/(config-sg-tacacs+)# server 192.168.100.0

Specifies the hostname or IP address of an external TACACS+ server.

• When configured, this group can be referenced from the AAA method lists (used while configuring authentication, authorization, or accounting).

Step 4	Repeat	step 3 for every external server to be added to the server group named in step 2.		
Step 5	server-private {hostname   ip-address in IPv4 or IPv6 format} [port port-number] [timeout seconds] [key string]			
	Example:			
	Route	Router(config-sg-tacacs+)# server-private 10.1.1.1 key a_secret		
	Configures the IP address of the private TACACS+ server for the group server.			
	Note	If private server parameters are not specified, global configurations are used. If global configurations are not specified, default values are used.		
Step 6	(Option	nal) <b>vrf</b> vrf-id		
	Examp	le:		
	Route	r(config-sg-tacacs+)# vrf test-vrf		
		Soption specifies the Virtual Private Network (VPN) routing and forwarding (VRF) reference of an ACACS+ server group.		
Step 7	Use the	e commit or end command.		
	commi	t —Saves the configuration changes and remains within the configuration session.		
	end —	Prompts user to take one of these actions:		
	• Ye	2s — Saves configuration changes and exits the configuration session.		
	• N	<b>o</b> —Exits the configuration session without committing the configuration changes.		
	• Ca	ancel — Remains in the configuration session, without committing the configuration changes.		
Step 8	show ta	acacs server-groups		
	Examp	le:		

RP/0/# show tacacs server-groups

(Optional) Displays information about each TACACS+ server group that is configured in the system.

# **Configure Per VRF TACACS+ Server Groups**

The Cisco IOS XR software supports per VRF AAA to be configured on TACACS+ server groups. You must use the **server-private** and **vrf** commands as listed below to configure this feature.

The global server definitions can be referred from multiple server groups, but all references use the same server instance and connect to the same server. In case of VRF, you do not need the global configuration because the server status, server statistics and the key could be different for different VRFs. Therefore, you must use the server-private configuration if you want to configure per VRF TACACS+ server groups. If you have the same server used in different groups with different VRFs, ensure that it is reachable through all those VRFs.

If you are migrating the servers to a VRF, then it is safe to remove the global server configuration with respect to that server.

#### **Prerequisites**

You must ensure these before configuring per VRF on TACACS+ server groups:

- Be familiar with configuring TACACS+, AAA, per VRF AAA, and group servers.
- Ensure that you have access to the TACACS+ server.
- Configure the VRF instance before configuring the specific VRF for a TACACS+ server and ensure that the VRF is reachable.

#### **Configuration Example**

#### Router#configure

 $/\star$  Groups different server hosts into distinct lists and enters the server group configuration mode.

You can enter one or more server commands. The server command specifies the hostname or IP address of an external TACACS+ server.

Once configured, this server group can be referenced from the AAA method lists (used while configuring authentication, authorization, or accounting). \*/

#### Router(config) # aaa group server tacacs+ tacgroup1

/\* Configures the IP address and the secret key of the private TACACS+ server that is
reachable through specific VRF.
You can have multiple such server configurations which are reachable through the same VRF.\*/

Router(config-sg-tacacs+) # server-private 10.1.1.1 port 49 key a secret

/\* The vrf option specifies the VRF reference of a AAA TACACS+ server group \*/
Router(config-sg-tacacs+)# vrf test-vrf
Router(config-sg-tacacs+)# commit

#### **Running Configuration**

```
aaa group server tacacs+ tacgroup1
vrf test-vrf
server-private 10.1.1.1 port 49
key 7 0822455D0A16
!
server-private 10.1.1.2 port 49
key 7 05080F1C2243
!
server-private 2001:db8:1::1 port 49
key 7 045802150C2E
!
server-private 2001:db8:1::2 port 49
key 7 13061E010803
!
!
```

#### Verify Per VRF TACACS+ Server Groups

```
Router#show tacacs
Fri Sep 27 11:14:34.991 UTC
```

```
Server: 10.1.1.1/49 vrf=test-vrf [private]
opens=0 closes=0 aborts=0 errors=0
```

packets in=0 packets out=0 status=up single-connect=false family=IPv4 Server: 10.1.1.2/49 vrf=test-vrf [private] opens=0 closes=0 aborts=0 errors=0 packets in=0 packets out=0 status=up single-connect=false family=IPv4 Server: 2001:db8:1::1/49 vrf=test-vrf [private] opens=0 closes=0 aborts=0 errors=0 packets in=0 packets out=0 status=up single-connect=false family=IPv6 Server: 2001:db8:1::2/49 vrf=test-vrf [private] opens=0 closes=0 aborts=0 errors=0 packets in=0 packets out=0 status=up single-connect=false family=IPv6

#### **Associated Commands**

server-private

• vrf

# **Create Series of Authentication Methods**

Authentication is the process by which a user (or a principal) is verified. Authentication configuration uses *method lists* to define an order of preference for the source of AAA data, which may be stored in a variety of data sources. You can configure authentication to define more than one method list and applications (such as login) can choose one of them. For example, console ports may use one method list and the vty ports may use another. If a method list is not specified, the application tries to use a default method list.

Note

e Applications should explicitly refer to defined method lists for the method lists to be effective.

The authentication can be applied to tty lines through use of the **login authentication** line configuration submode command. If the method is RADIUS or TACACS+ servers, rather than server group, the RADIUS or TACACS+ server is chosen from the global pool of configured RADIUS and TACACS+ servers, in the order of configuration. Servers from this global pool are the servers that can be selectively added to a server group.

The subsequent methods of authentication are used only if the initial method returns an error, not if the request is rejected.

#### Before you begin

**Note** The default method list is applied for all the interfaces for authentication, except when a non-default named method list is explicitly configured, in which case the named method list is applied.

The group radius, group tacacs+, and group *group-name* forms of the aaa authentication command refer to a set of previously defined RADIUS or TACACS+ servers. Use the radius server-host or tacacs-server host command to configure the host servers. Use the aaa group server radius or aaa group server tacacs+ command to create a named group of servers.

#### Procedure

Step 1 configure

Example:

RP/0/# configure

Enters mode.

#### **Step 2** aaa authentication {login} {default | *list-name*} method-list

#### Example:

RP/0//CPU0:router(config) # aaa authentication login default group tacacs+

Creates a series of authentication methods, or a method list.

- Using the **login** keyword sets authentication for login. Using the **ppp** keyword sets authentication for Point-to-Point Protocol.
- Entering the **default** keyword causes the listed authentication methods that follow this keyword to be the default list of methods for authentication.
- Entering a *list-name* character string identifies the authentication method list.
- Entering a *method-list* argument following the method list type. Method list types are entered in the preferred sequence. The listed method types are any one of the following options:
  - group tacacs+—Use a server group or TACACS+ servers for authentication
  - group radius—Use a server group or RADIUS servers for authentication
  - group named-group—Use a named subset of TACACS+ or RADIUS servers for authentication
  - local—Use a local username or password database for authentication
  - line—Use line password or user group for authentication
- The example specifies the **default** method list to be used for authentication.

**Step 3** Use the **commit** or **end** command.

commit ---Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

**Step 4** Repeat Step 1 through Step 3 for every authentication method list to be configured.

# **Create Series of Authorization Methods**

Method lists for authorization define the ways authorization will be performed and the sequence in which these methods will be performed. A method list is a named list describing the authorization methods to be used (such as TACACS+), in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system if the initial method fails. The software uses the first method listed to authorize users for specific network services; if that method fails to respond, the software selects the next method listed in the method list. This process continues until there is successful communication with a listed authorization method, or until all methods defined have been exhausted.

#### Note

The software attempts authorization with the next listed method only when there is no response or an error response (not a failure) from the previous method. If authorization fails at any point in this cycle—meaning that the security server or local username database responds by denying the user services—the authorization process stops and no other authorization methods are attempted.

When you create a named method list, you are defining a particular list of authorization methods for the indicated authorization type. When defined, method lists must be applied to specific lines or interfaces before any of the defined methods are performed. Do not use the names of methods, such as TACACS+, when creating a new method list.

"Command" authorization, as a result of adding a command authorization method list to a line template, is separate from, and is in addition to, "task-based" authorization, which is performed automatically on the router. The default behavior for command authorization is none. Even if a default method list is configured, that method list has to be added to a line template for it to be used.

The **aaa authorization commands** command causes a request packet containing a series of attribute value (AV) pairs to be sent to the TACACS+ daemon as part of the authorization process. The daemon can do one of the following:

- Accept the request as is.
- Refuse authorization.

Use the **aaa authorization** command to set parameters for authorization and to create named method lists defining specific authorization methods that can be used for each line or interface.

#### Procedure

Step 1 configure

Example:

RP/0/# configure

Enters mode.

# Step 2 aaa authorization {commands | eventmanager | exec | network} {default | list-name} {none | local | group {tacacs+ | radius | group-name}}

#### Example:

RP/0//CPU0:router(config) # aaa authorization commands listname1 group tacacs+

Creates a series of authorization methods, or a method list.

- The **commands** keyword configures authorization for all shell commands. Command authorization applies to the EXEC mode commands issued by a user. Command authorization attempts authorization for all commands.
- The **eventmanager** keyword applies an authorization method for authorizing an event manager (fault manager).
- The **exec** keyword configures authorization for an interactive () session.
- The network keyword configures authorization for network services like PPP or IKE.
- The **default** keyword causes the listed authorization methods that follow this keyword to be the default list of methods for authorization.
- A *list-name* character string identifies the authorization method list. The method list itself follows the method list name. Method list types are entered in the preferred sequence. The listed method list types can be any one of the following:
  - none—The network access server (NAS) does not request authorization information. Authorization
    always succeeds. No subsequent authorization methods will be attempted. However, the task ID
    authorization is always required and cannot be disabled.
  - local—Uses local database for authorization.
- group tacacs+—Uses the list of all configured TACACS+ servers for authorization. The NAS exchanges authorization information with the TACACS+ security daemon. TACACS+ authorization defines specific rights for users by associating AV pairs, which are stored in a database on the TACACS+ security server, with the appropriate user.
- group radius—Uses the list of all configured RADIUS servers for authorization.
- group group-name—Uses a named server group, a subset of TACACS+ or RADIUS servers for authorization as defined by the aaa group server tacacs+ or aaa group server radius command.

#### **Step 3** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

## **Create Series of Accounting Methods**

Use the **aaa accounting** command to create default or named method lists defining specific accounting methods that can be used for each line or interface.

Currently, the software supports both the TACACS+ and RADIUS methods for accounting. The router reports user activity to the TACACS+ or RADIUS security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.

Method lists for accounting define the way accounting is performed, enabling you to designate a particular security protocol to be used on specific lines or interfaces for particular types of accounting services. When naming a method list, do not use the names of methods, such as TACACS+.

For minimal accounting, include the **stop-only** keyword to send a "stop accounting" notice at the end of the requested user process. For more accounting, you can include the **start-stop** keyword, so that the external AAA server sends a "start accounting" notice at the beginning of the requested process and a "stop accounting" notice at the end of the process. In addition, you can use the **aaa accounting update** command to periodically send update records with accumulated information. Accounting records are stored only on the TACACS+ or RADIUS server.

When AAA accounting is activated, the router reports these attributes as accounting records, which are then stored in an accounting log on the security server.

#### Procedure

#### Step 1 configure

#### Example:

RP/0/# configure

Enters mode.

#### **Step 2** Do one of the following:

- aaa accounting {commands | exec | network} {default | *list-name*} {start-stop | stop-only}
- {none | method}

#### Example:

RP/0//CPU0:router(config) # aaa accounting commands default stop-only group tacacs+

**Note** Command accounting is not supported on RADIUS, but supported on TACACS.

Creates a series of accounting methods, or a method list.

- The commands keyword enables accounting for shell commands.
- The exec keyword enables accounting for an interactive () session.
- The network keyword enables accounting for all network-related service requests, such as Point-to-Point Protocol (PPP).
- The **default** keyword causes the listed accounting methods that follow this keyword to be the default list of methods for accounting.
- A list-name character string identifies the accounting method list.
- The **start-stop** keyword sends a "start accounting" notice at the beginning of a process and a "stop accounting" notice at the end of a process. The requested user process begins regardless of whether the "start accounting" notice was received by the accounting server.
- The **stop-only** keyword sends a "stop accounting" notice at the end of the requested user process.
- The **none** keyword states that no accounting is performed.
- The method list itself follows the **start-stop** keyword. Method list types are entered in the preferred sequence. The method argument lists the following types:
  - group tacacs+---Use the list of all configured TACACS+ servers for accounting.
  - group radius—Use the list of all configured RADIUS servers for accounting.
  - group group-name—Use a named server group, a subset of TACACS+ or RADIUS servers for accounting as defined by the aaa group server tacacs+ or aaa group server radius command.
- The example defines a **default** command accounting method list, in which accounting services are provided by a TACACS+ security server, with a stop-only restriction.
- **Step 3** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

# **Generate Interim Accounting Records**

This task enables periodic interim accounting records to be sent to the accounting server. When the **aaa accounting update** command is activated, software issues interim accounting records for all users on the system.

Note

Interim accounting records are generated only for network sessions, such as Internet Key Exchange (IKE) accounting, which is controlled by the **aaa accounting** command with the **network** keyword. System, command, or EXEC accounting sessions cannot have interim records generated.

#### Procedure

#### Step 1 configure

**Example:** 

RP/0/# configure

Enters mode.

#### **Step 2** aaa accounting update {newinfo | periodic *minutes*}

#### Example:

RP/0//CPU0:router(config)# aaa accounting update periodic 30

Enables periodic interim accounting records to be sent to the accounting server.

- If the **newinfo** keyword is used, interim accounting records are sent to the accounting server every time there is new accounting information to report. An example of this report would be when IPCP completes IP address negotiation with the remote peer. The interim accounting record includes the negotiated IP address used by the remote peer.
- When used with the **periodic** keyword, interim accounting records are sent periodically as defined by the argument number. The interim accounting record contains all the accounting information recorded for that user up to the time the interim accounting record is sent.

**Caution** The **periodic** keyword causes heavy congestion when many users are logged in to the network.

**Step 3** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end — Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

# Apply Method List

After you use the **aaa authorization** command to define a named authorization method list (or use the default method list) for a particular type of authorization, you must apply the defined lists to the appropriate lines in

I

order for authorization to take place. Use the **authorization** command to apply the specified method lists (or, if none is specified, the default method list) to the selected line or group of lines.

#### Procedure

configure
Example:
RP/0/# configure
Enters mode.
<pre>line { console   default   template template-name}</pre>
Example:
RP/0//CPU0:router(config)# line console
Enters line template configuration mode.
authorization {commands   exec} {default   <i>list-name</i> }
Example:
RP/0//CPU0:router(config-line)# authorization commands listname5
Enables AAA authorization for a specific line or group of lines.
• The <b>commands</b> keyword enables authorization on the selected lines for all commands.
• The <b>exec</b> keyword enables authorization for an interactive () session.
• Enter the <b>default</b> keyword to apply the name of the default method list, as defined with the <b>aaa authorization</b> command.
• Enter the name of a list of authorization methods to use. If no list name is specified, the system uses t default. The list is created with the <b>aaa authorization</b> command.
• The example enables command authorization using the method list named listname5.
Use the <b>commit</b> or <b>end</b> command.
commit —Saves the configuration changes and remains within the configuration session.
end —Prompts user to take one of these actions:
• Yes — Saves configuration changes and exits the configuration session.
• No —Exits the configuration session without committing the configuration changes.

• Cancel —Remains in the configuration session, without committing the configuration changes.

#### What to do next

After applying authorization method lists by enabling AAA authorization, apply accounting method lists by enabling AAA accounting.

# **Enable Accounting Services**

This task enables accounting services for a specific line of group of lines.

	configure
	Example:
	RP/0/# configure
	Enters mode.
	line { console   default   template template-name}
	Example:
	RP/0//CPU0:router(config)# line console
	Enters line template configuration mode.
	accounting {commands   exec} {default   <i>list-name</i> }
	Example:
	RP/0//CPU0:router(config-line)# accounting commands listname7
	Enables AAA accounting for a specific line or group of lines.
	• The commands keyword enables accounting on the selected lines for all shell commands.
	• The <b>exec</b> keyword enables accounting for an interactive () session.
	• Enter the <b>default</b> keyword to apply the name of the default method list, as defined with the <b>aaa accoun</b> command.
	• Enter the name of a list of accounting methods to use. If no list name is specified, the system uses t default. The list is created with the <b>aaa accounting</b> command.
	• The example enables command accounting using the method list named listname7.
	Use the <b>commit</b> or <b>end</b> command.
	commit —Saves the configuration changes and remains within the configuration session.
	end —Prompts user to take one of these actions:
	• Yes — Saves configuration changes and exits the configuration session.
	• No —Exits the configuration session without committing the configuration changes.

System Security Configuration Guide for Cisco NCS 540 Series Routers, IOS XR Release 6.3.x

• Cancel —Remains in the configuration session, without committing the configuration changes.

#### What to do next

After applying accounting method lists by enabling AAA accounting services, configure login parameters.

# **Configure Login Parameters**

This task sets the interval that the server waits for reply to a login.

Procedure
configure
Example:
RP/0/# configure
Enters mode.
line template template-name
Example:
RP/0//CPU0:router(config)# line template alpha
Specifies a line to configure and enters line template configuration mode.
timeout login response seconds
Example:
RP/0//CPU0:router(config-line)# timeout login response 20
Sets the interval that the server waits for reply to a login.
• The seconds argument specifies the timeout interval (in seconds) from 0 to 300. The default is 30 second
• The example shows how to change the interval timer to 20 seconds.
Use the <b>commit</b> or <b>end</b> command.
commit —Saves the configuration changes and remains within the configuration session.
end —Prompts user to take one of these actions:
• Yes — Saves configuration changes and exits the configuration session.
• No —Exits the configuration session without committing the configuration changes.
• <b>Cancel</b> — Remains in the configuration session, without committing the configuration changes.

### Task Maps

For users who are authenticated using an external TACACS+ server and RADIUS server, Cisco IOS XR software AAA supports a method to define task IDs remotely.

#### Format of the Task String

The task string in the configuration file of the TACACS+ server consists of tokens delimited by a comma (,). Each token contains either a task ID name and its permissions or the user group to include for this particular user, as shown in the following example:

task = " permissions : taskid name , # usergroup name , ..."

Note

Cisco IOS XR software allows you to specify task IDs as an attribute in the external RADIUS or TACACS+ server. If the server is also shared by non-Cisco IOS XR software systems, these attributes are marked as optional as indicated by the server documentation. For example, CiscoSecure ACS and the freeware TACACS+ server from Cisco require an asterisk (\*) instead of an equal sign (=) before the attribute value for optional attributes. If you want to configure attributes as optional, refer to the TACACS+ server documentation.

For example, to give a user named user1 BGP read, write, and execute permissions and include user1 in a user group named operator, the username entry in the external server's TACACS+ configuration file would look similar to the following:

```
user = user1{
member = some-tac-server-group
opap = cleartext "lab"
service = exec {
task = "rwx:bgp,#operator"
}
```

The r,w,x, and d correspond to read, write, execute and debug, respectively, and the pound sign (#) indicates that a user group follows.

**Note** The optional keyword must be added in front of "task" to enable interoperability with systems based on Cisco IOS software.

If CiscoSecure ACS is used, perform the following procedure to specify the task ID and user groups:

#### Procedure

Step 1	Enter your username and password.
Step 2	Click the Group Setup button to display the Group Setup window.
Step 3	From the Group drop-down list, select the group that you want to update.
Step 4	Click the Edit Settings button.
Step 5	Use the scroll arrow to locate the Shell (exec) check box.
Step 6	Check the Shell (exec) check box to enable the custom attributes configuration.

**Step 7** Check the **Custom attributes** check box.

**Step 8** Enter the following task string without any blank spaces or quotation marks in the field:

#### Example:

task=rwx:bgp,#netadmin

**Step 9** Click the **Submit + Restart** button to restart the server.

The following RADIUS Vendor-Specific Attribute (VSA) example shows that the user is part of the sysadmin predefined task group, can configure BGP, and can view the configuration for OSPF:

#### Example:

```
user Auth-Type := Local, User-Password == lab
Service-Type = NAS-Prompt-User,
Reply-Message = "Hello, %u",
Login-Service = Telnet,
Cisco-AVPair = "shell:tasks=#sysadmin,rwx:bgp,r:ospf"
```

After user1 successfully connects and logs in to the external TACACS+ server with username user1 and appropriate password, the **show user tasks** command can be used in to display all the tasks user1 can perform. For example:

#### Example:

```
Username:user1
Password:
RP/0/# show user tasks
Task:
        basic-services :READ
                               WRITE
                                         EXECUTEDEBUG
Task:
                    bgp :READ
                                WRITE
                                         EXECUTE
                   cdp :READ
Task:
Task:
                  diag :READ
Task:
             ext-access :READ
                                         EXECUTE
Task:
                logging :READ
```

Alternatively, if a user named user2, who does not have a task string, logs in to the external server, the following information is displayed:

#### Example:

```
Username:user2
Password:
RP/0/# show user tasks
No task ids available
```

# **References for AAA Services**

This section lists all the conceptual information that a software user must understand before configuring user groups and task groups through AAA or configuring Remote Authentication Dial-in User Service (RADIUS) or TACACS+ servers. Conceptual information also describes what AAA is and why it is important.

#### User, User Groups, and Task Groups

User attributes form the basis of the Cisco software administrative model. Each router user is associated with the following attributes:

• User ID (ASCII string) that identifies the user uniquely across an administrative domain

- Length limitation of 253 characters for passwords and one-way encrypted secrets
- List of user groups (at least one) of which the user is a member (thereby enabling attributes such as task IDs).

#### User Categories

Router users are classified into the following categories:

- Root Secure Domain Router (SDR) user (specific SDR administrative authority)
- SDR user (specific SDR user access)

#### Root System Users

The root system user is the entity authorized to "own" the entire router chassis. The root system user functions with the highest privileges over all router components and can monitor all secure domain routers in the system. At least one root system user account must be created during router setup. Multiple root system users can exist.

The root system user can perform any configuration or monitoring task, including the following:

- Configure secure domain routers.
- Create, delete, and modify root SDR users (after logging in to the secure domain router as the root system user).
- Create, delete, and modify secure domain router users and set user task permissions (after logging in to the secure domain router as the root system user).
- Access fabric racks or any router resource not allocated to a secure domain router, allowing the root system user to authenticate to any router node regardless of the secure domain router configurations.

#### Root SDR Users

A root SDR user controls the configuration and monitoring of a particular SDR. The root SDR user can create users and configure their privileges within the SDR. Multiple root SDR users can work independently. A single SDR may have more than one root SDR user.

A root SDR user can perform the following administrative tasks for a particular SDR:

- Create, delete, and modify secure domain router users and their privileges for the SDR.
- Create, delete, and modify user groups to allow access to the SDR.
- Manage nearly all aspects of the SDR.

A root SDR user cannot deny access to a root system user.

#### Secure Domain Router (SDR) Users

A SDR user has restricted access to an SDR as determined by the root SDR user. The SDR user performs the day-to-day system and network management activities. The tasks that the secure domain router user is allowed to perform are determined by the task IDs associated with the user groups to which the SDR user belongs. Multiple SDRs in a chasis are not supported.

#### User Groups

A *user group* defines a collection of users that share a set of attributes, such as access privileges. Cisco software allows the system administrator to configure groups of users and the job characteristics that are common in groups of users. Users are not assigned to groups by default hence the assignment needs to be done explicitly. A user can be assigned to more than one group.

Each user may be associated with one or more user groups. User groups have the following attributes:

- A user group consists of the list of task groups that define the authorization for the users. All tasks, except cisco-support, are permitted by default for root system users.
- Each user task can be assigned read, write, execute, or debug permission.

#### Predefined User Groups

The Cisco software provides a collection of user groups whose attributes are already defined. The predefined groups are as follows:

- cisco-support: This group is used by the Cisco support team.
- netadmin: Has the ability to control and monitor all system and network parameters.
- operator: A demonstration group with basic privileges.
- root-lr: Has the ability to control and monitor the specific secure domain router.
- **sysadmin:** Has the ability to control and monitor all system parameters but cannot configure network protocols.
- serviceadmin: Service administration tasks, for example, Session Border Controller (SBC).

#### User-Defined User Groups

Administrators can configure their own user groups to meet particular needs.

#### User Group Inheritance

A user group can derive attributes from another user group. (Similarly, a task group can derive attributes from another task group). For example, when user group A inherits attributes from user group B, the new set of task attributes of the user group A is a union of A and B. The inheritance relationship among user groups is dynamic in the sense that if group A inherits attributes from group B, a change in group B affects group A, even if the group is not reinherited explicitly.

#### Task Groups

Task groups are defined by lists of permitted task IDs for each type of action (such as read, write, and so on). The task IDs are basically defined in the router system. Task ID definitions may have to be supported before task groups in external software can be configured.

Task IDs can also be configured in external TACACS+ or RADIUS servers.

#### Predefined Task Groups

The following predefined task groups are available for administrators to use, typically for initial configuration:

- cisco-support: Cisco support personnel tasks
- netadmin: Network administrator tasks

- operator: Operator day-to-day tasks (for demonstration purposes)
- root-lr: Secure domain router administrator tasks
- sysadmin: System administrator tasks
- serviceadmin: Service administration tasks, for example, SBC

#### User-Defined Task Groups

Users can configure their own task groups to meet particular needs.

#### Group Inheritance

Task groups support inheritance from other task groups. (Similarly, a user group can derive attributes from another user group. For example, when task group A inherits task group B, the new set of attributes of task group A is the union of A and B.

#### **Command Access in XR and Admin Modes**

The XR user group and task is mapped to the System Admin VM group when the System Admin mode is accessed from XR mode using **admin** command. The corresponding access permission on System Admin VM is available to the user. Currently, only aaa, admin task and root-lr groups are mapped to System Admin VM group or task. The other tasks like protocols are not mapped as these services are not supported in System Admin VM. The disaster-recovery user of System Admin VM is synced with the Host VM.

XR Task or Group	Sysadmin VM Group	Access	Example
root-lr	Root-system group	Full access to the system configuration.	<pre>RP/0/RP0/CPU0:ios#show user group Mon Nov 3 13:48:54.536 UTC root-lr, cisco-support RP/0/RP0/CPU0:ios#show user tasks   inc root-lr Mon Nov 3 13:49:06.495 UTC Task: root-lr : READ WRITE EXECUTE DEBUG (reserved) RP/0/RP0/CPU0:ios#admin sysadmin-vm:0_RP0# show aaa user-group Mon Nov 3 13:48:00.790 UTC User group : root-system</pre>

XR Task or Group	Sysadmin VM Group	Access	Example
Admin-r/w/x/d	Admin-r	Read only commands on Sysadmin VM	<pre>taskgroup tg-admin-write task write admin task execute admin ! usergroup ug-admin-write taskgroup tg-admin-write ! username admin-write group ug-admin-write password admin-write ! RP/0/RP0/CPU0:ios#show user group Mon Nov 3 14:09:29.676 UTC ug-admin-write RP/0/RP0/CPU0:ios#show user tasks Mon Nov 3 14:09:35.244 UTC Task: admin : READ WRITE EXECUTE RP/0/RP0/CPU0:ios#admin Mon Nov 3 14:09:40.401 UTC admin-write connected from 127.0.0.1 using console on xr-vm_node0_RP0_CPU0 sysadmin-vm:0_RP0# show aaa user-group Mon Nov 3 13:53:00.790 UTC User group : admin-r</pre>
Netadmin or sysadmin group Admin-r/ wx /d, aaa -r/w/x/d	Aaa -r and admin -r	Read only commands on Sysadmin VM	<pre>RP/0/RP0/CPU0:ios#show user group Mon Nov 3 13:44:39.176 UTC netadmin RP/0/RP0/CPU0:ios#show user tasks   inc aaa Mon Nov 3 13:45:00.999 UTC Task: aaa : READ RP/0/RP0/CPU0:ios#show user tasks   inc admin Mon Nov 3 13:45:09.567 UTC Task: admin : READ RP/0/RP0/CPU0:ios#admin Mon Nov 3 13:46:21.183 UTC netadmin connected from 127.0.0.1 using console on xr-vm_node0_RP0_CPU0 sysadmin-vm:0_RP0# show aaa user-group Mon Nov 3 13:44:23.939 UTC User group : admin-r,aaa-r sysadmin-vm:0_RP0#</pre>

#### **Administrative Model**

The router operates in two planes: the administration (admin) plane and secure domain router (SDR) plane. The admin (shared) plane consists of resources shared across all SDRs, while the SDR plane consists of those resources specific to the particular SDR.

Each SDR has its own AAA configuration including, local users, groups, and TACACS+ and RADIUS configurations. Users created in one SDR cannot access other SDRs unless those same users are configured in the other SDRs.

#### Administrative Access

Administrative access to the system can be lost if the following operations are not well understood and carefully planned.

• Configuring authentication that uses remote AAA servers that are not available, particularly authentication for the console.

Ŋ				
Not	The <b>none</b> option without any other method list is not supported.			
	• Configuring command authorization or authorization on the console should be done with extreme care, because TACACS+ servers may not be available or may deny every command, which locks the user out. This lockout can occur particularly if the authentication was done with a user not known to the TACACS+ server, or if the TACACS+ user has most or all the commands denied for one reason or another.			
	To avoid a lockout, we recommend one or both of the following:			
	• Before turning on TACACS+ command authorization or authorization on the console, make sure that the user who is configuring the authorization is logged in using the appropriate user permissions in the TACACS+ profile.			
	• If the security policy of the site permits it, use the <b>none</b> option for command authorization or authorization so that if the TACACS+ servers are not reachable, AAA rolls over to the <b>none</b> method, which permits the user to run the command.			
AAA Database				
	The AAA database stores the users, groups, and task information that controls access to the system. The AAA database can be either local or remote. The database that is used for a specific situation depends on the AAA configuration.			
Local Database				
	AAA data, such as users, user groups, and task groups, can be stored locally within a secure domain router. The data is stored in the in-memory database and persists in the configuration file. The stored passwords are encrypted.			
Not	The database is local to the specific secure domain router (SDR) in which it is stored, and the defined users or groups are not visible to other SDRs in the same system.			
	You can delete the last remaining user from the local database. If all users are deleted when the next user logs in, the setup dialog appears and prompts you for a new username and password.			
Not	The setup dialog appears only when the user logs into the console.			
Remote Database				

AAA data can be stored in an external security server, such as CiscoSecure ACS. Security data stored in the server can be used by any client (such as a network access server [NAS]) provided that the client knows the server IP address and shared secret.

#### Remote AAA Configuration

Products such as CiscoSecure ACS can be used to administer the shared or external AAA database. The router communicates with the remote AAA server using a standard IP-based security protocol (such as TACACS+ or RADIUS).

Client Configuration	
	The security server should be configured with the secret key shared with the router and the IP addresses of the clients.
User Groups	
	User groups that are created in an external server are not related to the user group concept that is used in the context of local AAA database configuration on the router. The management of external TACACS+ server or RADIUS server user groups is independent, and the router does not recognize the user group structure. The remote user or group profiles may contain attributes that specify the groups (defined on the router) to which a user or users belong, as well as individual task IDs.
	Configuration of user groups in external servers comes under the design of individual server products. See the appropriate server product documentation.
Task Groups	
	Task groups are defined by lists of permitted task IDs for each type of action (such as read, write, and so on). The task IDs are basically defined in the router system. Task ID definitions may have to be supported before task groups in external software can be configured.
	Task IDs can also be configured in external TACACS+ or RADIUS servers.
AAA Configuration	
	This section provides information about AAA configuration.
Method Lists	
	AAA data may be stored in a variety of data sources. AAA configuration uses <i>method lists</i> to define an order of preference for the source of AAA data. AAA may define more than one method list and applications (such as login) can choose one of them. For example, console ports may use one method list and the vty ports may use another. If a method list is not specified, the application tries to use a default method list. If a default method list does not exist, AAA uses the local database as the source.
Rollover Mechanism	
	AAA can be configured to use a prioritized list of database options. If the system is unable to use a database, it automatically rolls over to the next database on the list. If the authentication, authorization, or accounting request is rejected by any database, the rollover does not occur and the request is rejected.
	The following methods are available:
	• Local: Use the locally configured database (not applicable for accounting and certain types of authorization)
	• TACACS+: Use a TACACS+ server (such as CiscoSecure ACS)

- RADIUS: Use a RADIUS server
- Line: Use a line password and user group (applicable only for authentication)
- None: Allow the request (not applicable for authentication)

#### Server Grouping

Instead of maintaining a single global list of servers, the user can form server groups for different AAA protocols (such as RADIUS and TACACS+) and associate them with AAA applications (such as PPP and ).

#### Authentication

Authentication is the most important security process by which a principal (a user or an application) obtains access to the system. The principal is identified by a username (or user ID) that is unique across an administrative domain. The applications serving the user (such as or Management Agent) procure the username and the credentials from the user. AAA performs the authentication based on the username and credentials passed to it by the applications. The role of an authenticated user is determined by the group (or groups) to which the user belongs. (A user can be a member of one or more user groups.)

#### Authentication of Non-Owner Secure Domain Router User

When logging in from a non-owner secure domain router, the root system user must add the "@admin" suffix to the username. Using the "@admin" suffix sends the authentication request to the owner secure domain router for verification. The owner secure domain router uses the methods in the list-name **remote** for choosing the authentication method. The **remote** method list is configured using the **aaa authentication login remote** *method1 method2*... command.

#### Authentication of Owner Secure Domain Router User

An owner secure domain router user can log in only to the nodes belonging to the specific secure domain router associated with that owner secure domain router user. If the user is member of a root-sdr group, the user is authenticated as an owner secure domain router user.

#### Authentication of Secure Domain Router User

Secure domain router user authentication is similar to owner secure domain router user authentication. If the user is not found to be a member of the designated owner secure domain router user group, the user is authenticated as a secure domain router user.

#### Authentication Flow of Control

AAA performs authentication according to the following process:

- **1.** A user requests authentication by providing a username and password (or secret).
- 2. AAA verifies the user's password and rejects the user if the password does not match what is in the database.
- 3. AAA determines the role of the user (root SDR user, or SDR user).
  - If the user has been configured as a member of an owner secure domain router user group, then AAA authenticates the user as an owner secure domain router user.
  - If the user has not been configured as a member of an owner secure domain router user group, AAA authenticates the user as a secure domain router user.

Clients can obtain a user's permitted task IDs during authentication. This information is obtained by forming a union of all task group definitions specified in the user groups to which the user belongs. Clients using such information typically create a session for the user (such as an API session) in which the task ID set remains static. Both the and external API clients can use this feature to optimize their operations. can avoid displaying the commands that are not applicable and an EMS application can, for example, disable graphical user interface (GUI) menus that are not applicable.

If the attributes of a user, such as user group membership and, consequently, task permissions, are modified, those modified attributes are not reflected in the user's current active session; they take effect in the user's next session.

#### **Password Types**

In configuring a user and that user's group membership, you can specify two types of passwords: encrypted or clear text.

The router supports both two-way and one-way (secret) encrypted user passwords. Secret passwords are ideal for user login accounts because the original unencrypted password string cannot be deduced on the basis of the encrypted secret. Some applications (PPP, for example) require only two-way passwords because they must decrypt the stored password for their own function, such as sending the password in a packet. For a login user, both types of passwords may be configured, but a warning message is displayed if one type of password is configured while the other is already present.

If both secret and password are configured for a user, the secret takes precedence for all operations that do not require a password that can be decrypted, such as login. For applications such as PPP, the two-way encrypted password is used even if a secret is present.

#### **Task-based Authorization**

AAA employs "task permissions" for any control, configure, or monitor operation through CLI or API. The Cisco IOS software concept of privilege levels has been replaced in software by a task-based authorization system.

#### Task IDs

The operational tasks that enable users to control, configure, and monitor Cisco software are represented by task IDs. A task ID defines the permission to run an operation for a command. Users are associated with sets of task IDs that define the breadth of their authorized access to the router.

Task IDs are assigned to users through the following means:

Each user is associated with one or more user groups. Every user group is associated with one or more *task groups*; in turn, every task group is defined by a set of task IDs. Consequently, a user's association with a particular user group links that user to a particular set of task IDs. A user that is associated with a task ID can execute any operation associated with that task ID.

#### General Usage Guidelines for Task IDs

Most router control, configuration, or monitoring operation (CLI, Netconf, Restconf, XML API) is associated with a particular set of task IDs. Typically, a given CLI command or API invocation is associated with at least one or more task IDs. Neither the **config** nor the **commit** commands require any specific task id permissions. The configuration and commit operations do not require specific task ID permissions. Aliases also don't require any task ID permissions. You cannot perform a configuration replace unless root-lr permissions are assigned. If you want to deny getting into configuration mode you can use the TACACS+ command authorization to deny the config command. These associations are hard-coded within the router and may not be modified.

Task IDs grant permission to perform certain tasks; task IDs do not deny permission to perform tasks. Task ID operations can be one, all, or a combination of classes that are listed in this table.

**Note** Restconf will be supported in a future release.

#### Table 1: Task ID Classes

Operation	Description	
Read	Specifies a designation that permits only a read operation.	
Write	Specifies a designation that permits a change operation and implicitly allows a read operation.	
Execute	Specifies a designation that permits an access operation; for example ping and Telnet.	
Debug	Specifies a designation that permits a debug operation.	

The system verifies that each CLI command and API invocation conforms with the task ID permission list for the user. If you are experiencing problems using a CLI command, contact your system administrator.

Multiple task ID operations separated by a slash (for example read/write) mean that both operations are applied to the specified task ID.

Multiple task ID operations separated by a comma (for example read/write, execute) mean that both operations are applied to the respective task IDs. For example, the **copy ipv4 access-list** command can have the read and write operations applied to the acl task ID, and the execute operation applied to the *filesystem* task ID.

If the task ID and operations columns have no value specified, the command is used without any previous association to a task ID and operation. In addition, users do not have to be associated to task IDs to use ROM monitor commands.

Users may need to be associated to additional task IDs to use a command if the command is used in a specific configuration submode. For example, to execute the **show redundancy** command, a user needs to be associated to the system (read) task ID and operations as shown in the following example:

RP/0/# show redundancy

#### Task IDs for TACACS+ and RADIUS Authenticated Users

Cisco software AAA provides the following means of assigning task permissions for users authenticated with the TACACS+ and RADIUS methods:

- Specify the text version of the task map directly in the configuration file of the external TACACS+ and RADIUS servers.
- Specify the privilege level in the configuration file of the external TACACS+ and RADIUS servers.
- Create a local user with the same username as the user authenticating with the TACACS+ and RADIUS methods.
- Specify, by configuration, a default task group whose permissions are applied to any user authenticating with the TACACS+ and RADIUS methods.

#### Privilege Level Mapping

For compatibility with TACACS+ daemons that do not support the concept of task IDs, AAA supports a mapping between privilege levels defined for the user in the external TACACS+ server configuration file and local user groups. Following TACACS+ authentication, the task map of the user group that has been mapped from the privilege level returned from the external TACACS+ server is assigned to the user. For example, if a privilege level of 5 is returned from the external TACACS server, AAA attempts to get the task map of the local user group priv5. This mapping process is similar for other privilege levels from 1 to 13. For privilege level 14 maps to the user group owner-sdr.

For example, with the Cisco freeware tac plus server, the configuration file has to specify *priv\_lvl* in its configuration file, as shown in the following example:

```
user = sampleuser1{
    member = bar
    service = exec-ext {
        priv_lvl = 5
    }
}
```

The number 5 in this example can be replaced with any privilege level that has to be assigned to the user *sampleuser*.

#### XML Schema for AAA Services

The extensible markup language (XML) interface uses requests and responses in XML document format to configure and monitor AAA. The AAA components publish the XML schema corresponding to the content and structure of the data used for configuration and monitoring. The XML tools and applications use the schema to communicate to the XML agent for performing the configuration.

The following schema are published by AAA:

- · Authentication, Authorization and Accounting configuration
- User, user group, and task group configuration
- TACACS+ server and server group configuration
- RADIUS server and server group configuration

#### Netconf and Restconf for AAA Services

Just as in XML schemas, in Netconf and Restconf, username and password is controlled by either local or triple A (AAA) services.

Note

Restconf will be supported in a future release.

#### **About RADIUS**

RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication and accounting requests to a central RADIUS server that contains all user authentication and network service access information.

RADIUS is a fully open protocol, distributed in source code format, that can be modified to work with any security system currently available on the market.

Cisco supports RADIUS under its AAA security paradigm. RADIUS can be used with other AAA security protocols, such as TACACS+, Kerberos, and local username lookup.

Note

RADIUS is supported on all Cisco platforms, but some RADIUS-supported features run only on specified platforms.

RADIUS has been implemented in a variety of network environments that require high levels of security while maintaining network access for remote users.

Use RADIUS in the following network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers
  from several vendors use a single RADIUS server-based security database. In an IP-based network with
  multiple vendors' access servers, dial-in users are authenticated through a RADIUS server that has been
  customized to work with the Kerberos security system.
- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a "smart card" access control system. In one case, RADIUS has been used with Enigma security cards to validate users and grant access to network resources.
- Networks already using RADIUS. You can add a Cisco router with RADIUS to the network. This might be the first step when you make a transition to a Terminal Access Controller Access Control System Plus (TACACS+) server.
- Networks in which a user must access only a single service. Using RADIUS, you can control user access to a single host, utility such as Telnet, or protocol such as Point-to-Point Protocol (PPP). For example, when a user logs in, RADIUS identifies this user as having authorization to run PPP using IP address 10.2.3.4 and the defined access list is started.
- Networks that require resource accounting. You can use RADIUS accounting independent of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, indicating the amount of resources (such as time, packets, bytes, and so on) used during the session. An Internet service provider (ISP) might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.
- Networks that support preauthentication. Using the RADIUS server in your network, you can configure AAA preauthentication and set up the preauthentication profiles. Preauthentication enables service providers to better manage ports using their existing RADIUS solutions and to efficiently manage the use of shared resources to offer differing service-level agreements.

#### Network Security Situations in Which RADIUS is Unsuitable

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support the following protocols:
  - NetBIOS Frame Control Protocol (NBFCP)
  - NetWare Asynchronous Services Interface (NASI)
  - X.25 PAD connections

- Router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one router to a router other than a Cisco router if that router requires RADIUS authentication.
- Networks using a variety of services. RADIUS generally binds a user to one service model.

#### **RADIUS** Operation

When a user attempts to log in and authenticate to an access server using RADIUS, the following steps occur:

- **1.** The user is prompted for and enters a username and password.
- 2. The username and encrypted password are sent over the network to the RADIUS server.
- 3. The user receives one of the following responses from the RADIUS server:
  - a. ACCEPT—The user is authenticated.
  - **a.** REJECT—The user is not authenticated and is prompted to reenter the username and password, or access is denied.
  - CHALLENGE—A challenge is issued by the RADIUS server. The challenge collects additional data from the user.
  - CHANGE PASSWORD—A request is issued by the RADIUS server, asking the user to select a new password.

The ACCEPT or REJECT response is bundled with additional data used for or network authorization. You must first complete RADIUS authentication before using RADIUS authorization. The additional data included with the ACCEPT or REJECT packets consists of the following:

- Services that the user can access, including Telnet, rlogin, or local-area transport (LAT) connections, and PPP, Serial Line Internet Protocol (SLIP), or services.
- Connection parameters, including the host or client IP address, access list, and user timeouts.

I

# CHAPTER .

# Implementing Certification Authority Interoperability

CA interoperability permits devices and CAs to communicate so that your device can obtain and use digital certificates from the CA. Although IPSec can be implemented in your network without the use of a CA, using a CA provides manageability and scalability for IPSec.

Note

IPSec will be supported in a future release.

#### Feature History for Implementing Certification Authority Interoperability

Release	Modification
Release 6.0	This feature was introduced.

• Implementing Certification Authority Interoperability, on page 43

# Implementing Certification Authority Interoperability

CA interoperability permits devices and CAs to communicate so that your device can obtain and use digital certificates from the CA. Although IPSec can be implemented in your network without the use of a CA, using a CA provides manageability and scalability for IPSec.

**Note** IPSec will be supported in a future release.

#### Feature History for Implementing Certification Authority Interoperability

Release	Modification
Release 6.0	This feature was introduced.

# **Prerequisites for Implementing Certification Authority**

The following prerequisites are required to implement CA interoperability:

- You must be in a user group associated with a task group that includes the proper task IDs. The command reference guides include the task IDs required for each command. If you suspect user group assignment is preventing you from using a command, contact your AAA administrator for assistance.
- You must install and activate the Package Installation Envelope (PIE) for the security software.

For detailed information about optional PIE installation, refer to the System Management Guide.

 You need to have a CA available to your network before you configure this interoperability feature. The CA must support Cisco Systems PKI protocol, the simple certificate enrollment protocol (SCEP) (formerly called certificate enrollment protocol [CEP]).

# **Restrictions for Implementing Certification Authority**

## **Configure Router Hostname and IP Domain Name**

This task configures a router hostname and IP domain name.

You must configure the hostname and IP domain name of the router if they have not already been configured. The hostname and IP domain name are required because the router assigns a fully qualified domain name (FQDN) to the keys and certificates used by IPSec, and the FQDN is based on the hostname and IP domain name you assign to the router. For example, a certificate named router20.example.com is based on a router hostname of router20 and a router IP domain name of example.com.

	Procedure
Step 1	configure
	Example:
	RP/0/# configure
	Enters mode.
Step 2	hostname name
	Example:
	RP/0/(config)# hostname myhost
	Configures the hostname of the router.
Step 3	domain name domain-name
	Example:
	RP/0/(config)# domain name mydomain.com
	Configures the IP domain name of the router.

**Step 4** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- **Cancel** —Remains in the configuration session, without committing the configuration changes.

# **Generate RSA Key Pair**

This task generates an RSA key pair.

RSA key pairs are used to sign and encrypt IKE key management messages and are required before you can obtain a certificate for your router.

#### Procedure

# Step 1 crypto key generate rsa [usage keys | general-keys] [keypair-label]

#### Example:

RP/0/# crypto key generate rsa general-keys

Generates RSA key pairs.

- Use the **usage keys** keyword to specify special usage keys; use the **general-keys** keyword to specify general- purpose RSA keys.
- The keypair-label argument is the RSA key pair label that names the RSA key pairs.

#### **Step 2** crypto key zeroize rsa [keypair-label]

#### Example:

RP/0/# crypto key zeroize rsa key1

(Optional) Deletes all RSAs from the router.

- Under certain circumstances, you may want to delete all RSA keys from you router. For example, if you
  believe the RSA keys were compromised in some way and should no longer be used, you should delete
  the keys.
- To remove a specific RSA key pair, use the keypair-label argument.
- **Step 3** show crypto key mypubkey rsa

#### Example:

RP/0/# show crypto key mypubkey rsa

(Optional) Displays the RSA public keys for your router.

# Import Public Key to the Router

This task imports a public key to the router.

A public key is imported to the router to authenticate the user.

# Procedure Step 1 crypto key import authentication rsa [usage keys | general-keys] [keypair-label] Example: RP/0/# crypto key import authentication rsa general-keys Generates RSA key pairs. • Use the usage keys keyword to specify special usage keys; use the general-keys keyword to specify general- purpose RSA keys. • The keypair-label argument is the RSA key pair label that names the RSA key pairs. Step 2 show crypto key mypubkey rsa Example:

 ${\rm RP}/0/\#$  show crypto key mypubkey rsa

(Optional) Displays the RSA public keys for your router.

# **Declare Certification Authority and Configure Trusted Point**

This task declares a CA and configures a trusted point.

Procedure		
configure		
Example:		
RP/0/# configure		
Enters mode.		
crypto ca trustpoint ca-na	me	
Example:		

Router(config) # crypto ca trustpoint myca

#### Declares a CA.

- Configures a trusted point with a selected name so that your router can verify certificates issued to peers.
- Enters trustpoint configuration mode.
- **Note** If you want to do certificate enrolment when the server or destination is in a VRF, use the following command after step 2 to configure the VRF:

Router(config-trustp)# vrf vrf-name

#### Step 3 enrollment url CA-URL

#### Example:

```
Router(config-trustp)# enrollment url http://ca.domain.com/certsrv/mscep/mscep.dll
```

Specifies the URL of the CA.

- The URL should include any nonstandard cgi-bin script location.
- **Note** If you want to do certificate enrolment when the destination URL is in a VRF, use the following command instead:

Router(config-trustp)# enrollment url tftp-address;vrf-name/ca-name

#### Step 4 query url LDAP-URL

#### Example:

Router(config-trustp) # query url ldap://my-ldap.domain.com

(Optional) Specifies the location of the LDAP server if your CA system supports the LDAP protocol.

#### **Step 5** enrollment retry period minutes

#### Example:

Router(config-trustp)# enrollment retry period 2

(Optional) Specifies a retry period.

- After requesting a certificate, the router waits to receive a certificate from the CA. If the router does not receive a certificate within a period of time (the retry period) the router will send another certificate request.
- Range is from 1 to 60 minutes. Default is 1 minute.

#### Step 6 enrollment retry count number

#### Example:

Router(config-trustp)# enrollment retry count 10

(Optional) Specifies how many times the router continues to send unsuccessful certificate requests before giving up.

• The range is from 1 to 100.

#### Step 7 rsakeypair keypair-label Example:

#### Router(config-trustp)# rsakeypair mykey

(Optional) Specifies a named RSA key pair generated using the **crypto key generate rsa** command for this trustpoint.

• Not setting this key pair means that the trustpoint uses the default RSA key in the current configuration.

**Step 8** Use the **commit** or **end** command.

commit ---Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

# **Authenticate CA**

This task authenticates the CA to your router.

The router must authenticate the CA by obtaining the self-signed certificate of the CA, which contains the public key of the CA. Because the certificate of the CA is self-signed (the CA signs its own certificate), manually authenticate the public key of the CA by contacting the CA administrator to compare the fingerprint of the CA certificate.

```
      Procedure

      Step 1
      crypto ca authenticate ca-name

      Example:

      RP/0/# crypto ca authenticate myca

      Authenticates the CA to your router by obtaining a CA certificate, which contains the public key for the CA.

      Step 2
      show crypto ca certificates

      Example:

      RP/0/# show crypto ca certificates

      Cytional) Displays information about the CA certificate.
```

# **Request Your Own Certificates**

This task requests certificates from the CA.

You must obtain a signed certificate from the CA for each of your router's RSA key pairs. If you generated general-purpose RSA keys, your router has only one RSA key pair and needs only one certificate. If you previously generated special usage RSA keys, your router has two RSA key pairs and needs two certificates.

#### Procedure

#### Step 1 crypto ca enroll ca-name

#### Example:

RP/0/# crypto ca enroll myca

Requests certificates for all of your RSA key pairs.

- This command causes your router to request as many certificates as there are RSA key pairs, so you need
  only perform this command once, even if you have special usage RSA key pairs.
- This command requires you to create a challenge password that is not saved with the configuration. This password is required if your certificate needs to be revoked, so you must remember this password.
- A certificate may be issued immediately or the router sends a certificate request every minute until the enrollment retry period is reached and a timeout occurs. If a timeout occurs, contact your system administrator to get your request approved, and then enter this command again.

#### Step 2 show crypto ca certificates

#### Example:

RP/0/# show crypto ca certificates

(Optional) Displays information about the CA certificate.

## **Configure Certificate Enrollment Using Cut-and-Paste**

This task declares the trustpoint certification authority (CA) that your router should use and configures that trustpoint CA for manual enrollment by using cut-and-paste.

## Step 2 crypto ca trustpoint ca-name Example: RP/0/(config)# crypto ca trustpoint myca RP/0//CPU0:router(config-trustp)# Declares the CA that your router should use and enters trustpoint configuration mode. • Use the *ca-name* argument to specify the name of the CA. Step 3 enrollment terminal Example: RP/0/(config-trustp)# enrollment terminal Specifies manual cut-and-paste certificate enrollment. Step 4 Use the **commit** or **end** command. **commit**—Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • **Cancel**—Remains in the configuration session, without committing the configuration changes. Step 5 crypto ca authenticate ca-name Example: RP/0/# crypto ca authenticate myca Authenticates the CA by obtaining the certificate of the CA. • Use the *ca-name* argument to specify the name of the CA. Use the same name that you entered in step 2. Step 6 crypto ca enroll ca-name Example: RP/0/# crypto ca enroll myca

Obtains the certificates for your router from the CA.

• Use the *ca-name* argument to specify the name of the CA. Use the same name that you entered in Step 2.

#### Step 7 crypto ca import ca- name certificate

#### Example:

RP/0/# crypto ca import myca certificate

Imports a certificate manually at the terminal.

• Use the *ca-name* argument to specify the name of the CA. Use the same name that you entered in Step 2.

**Note** You must enter the **crypto ca import** command twice if usage keys (signature and encryption keys) are used. The first time the command is entered, one of the certificates is pasted into the router; the second time the command is entered, the other certificate is pasted into the router. (It does not matter which certificate is pasted first.

**Step 8** show crypto ca certificates

#### Example:

```
RP/0/# show crypto ca certificates
```

Displays information about your certificate and the CA certificate.

The following example shows how to configure CA interoperability.

Comments are included within the configuration to explain various commands.

```
configure
hostname myrouter
domain name mydomain.com
end
Uncommitted changes found, commit them? [yes]:yes

## **Certificate Authority Trust Pool Management**

The trust pool feature is used to authenticate sessions, such as HTTPS, that occur between devices by using commonly recognized trusted agents called certificate authorities (CAs). This feature is enabled by default in

the software to create a scheme to provision, store, and manage a pool of certificates from known CAs in a way similar to the services a browser provides for securing sessions. A special trusted point called a trust pool is designated, containing multiple known CA certificates from Cisco and possibly from other vendors. The trust pool consists of both built-in and downloaded CA certificates.

*Implementing Certification Authority Interoperability* provides details on Certificate Authority and trusted point.

#### **CA Certificate Bundling in the Trust Pool**

The router uses a built-in CA certificate bundle that is packaged into the asr9k-k9sec PIE. The bundle is contained in a special certificate store called a CA trust pool, which is updated automatically by Cisco. This trust pool is known by Cisco and other vendors. A CA certificate bundle can be in the following formats:

- Privilege Management Infrastructure (PMI) certificates in Distinguished Encoding Rules (DER) binary format enveloped within a public-key cryptographic message syntax standard 7 (pkcs7).
- A file containing concatenated X.509 certificates in Privacy Enhanced Mail (PEM) format with PEM headers.

#### **Prerequisites for CA Trust Pool Management**

#### **Restrictions for CA trust pool management**

#### Updating the CA Trustpool

The CA trustpool must be updated when the following conditions occur:

- A certificate in the trustpool is due to expire or has been reissued.
- The published CA certificate bundle contains additional trusted certificates that are needed by a given application.
- The configuration has been corrupted.

The CA trustpool is considered as a single entity, As such, any update you perform will replace the entire trustpool.

**Note** A built-in certificate in the trustpool cannot be physically replaced. However, a built-in certificate is rendered inactive after an update if its X.509 subject-name attribute matches the certificate in the CA certificate bundle.

Following are the methods available for updating the certificates in the trustpool:

• Automatic update: A timer is established for the trustpool that matches the CA certificate with the earliest expiration time. If the timer is running and a bundle location is not configured and not explicitly disabled, syslog warnings should be issued at reasonable intervals to alert the admin that this trustpool policy option is not set. Automatic trustpool updates use the configured URL. When the CA trustpool expires, the policy is read, the bundle is loaded, and the PKI trustpool is replaced. If the automatic CA trustpool update encounters problems when initiating, then the following schedule is used to initiate the update until the download is successful: 20 days, 15 days, 10 days, 5 days, 4 days, 3 days, 2 days, 1 day, and then once every hour.

• Manual update: Manually Update Certificates in Trust Pool, on page 54 provides details.

#### **Manually Update Certificates in Trust Pool**

The CA trust pool feature is enabled by default and uses the built-in CA certificate bundle in the trust pool, which receives automatic updates from Cisco. Perform this task to manually update certificates in the trust pool if they are not current, are corrupt, or if certain certificates need to be updated.

#### Procedure

	Command or Action	Purpose
Step 1	crypto ca trustpool import url clean Example: RP/0/RSP0/CPU0:IMC0#crypto ca trustpool import url clean	(Optional) Manually removes all downloaded CA certificates. This command is run in the EXEC mode.
Step 2	<pre>crypto ca trustpool import url url Example: RP/0/RSP0/CPU0:IMC0#crypto ca trustpool import url http://www.cisco.com/security/pki/trs/ios.p7k</pre>	Specify the URL from which the CA trust pool certificate bundle must be downloaded. This manually imports (downloads) the CA certificate bundle into the CA trust pool to update or replace the existing CA certificate bundle.
Step 3	<pre>show crypto ca trustpool policy Example: RP/0/RSP0/CPU0:IMC0#show crypto ca trustpool Trustpool: Built-In</pre>	Displays the CA trust pool certificates of the router in a verbose format.
	CA certificate Serial Number : 5F:F8:7B:28:2B:54:DC:8D:42:A3:15:B5:68:C9:AD:FF Subject: CN=Cisco Root CA 2048,O=Cisco Systems Issued By : CN=Cisco Root CA 2048,O=Cisco Systems Validity Start : 20:17:12 UTC Fri May 14 2004 Validity End : 20:25:42 UTC Mon May 14 2029 SHA1 Fingerprint: DE990CED99E0431F60EDC3937E7CD5BF0ED9E5F7	
	Trustpool: Built-In CA certificate Serial Number : 2E:D2:0E:73:47:D3:33:83:4B:4F:DD:0D:D7:B6:96:7E Subject: CN=Cisco Root CA M1,O=Cisco Issued By :	

 Command or Action	Purpose
 CN=Cisco Root CA M1,0=Cisco Validity Start : 20:50:24 UTC Tue Nov 18 2008 Validity End : 21:59:46 UTC Fri Nov 18 2033 SHA1 Fingerprint:	
45AD6BB499011BB4E84E84316A81C27D89EE5CE7	

## **Configuring Optional Trustpool Policy Parameters**

#### Procedure

	Command or Action	Purpose
Step 1	configure	Enters mode.
	Example:	
	RP/0/# configure	
Step 2	crypto ca trustpool policy	Enters ca-trustpool configuration mode where
	Example:	commands can be accessed to configure CA trustpool policy parameters.
	RP/0/RSP0/CPU0:IMC0(config)#crypto ca	indstpoor poncy parameters.
	<pre>trustpool policy RP/0/RSP0/CPU0:IMC0(config-trustpool)#</pre>	
Step 3	cabundle url URL	Specifies the URL from which the CA trustpool
	Example:	certificate bundle is downloaded.
	RP/0/RSP0/CPU0:IMC0(config-trustpool)#cabundle	
	url http://www.cisco.com/security/pki/crl/crca2048.crl	
Step 4	crl optional	Disables revocation checking when the trustpool
	Example:	policy is being used. By default, the router enforces a check of the revocation status of the
	RP/0/RSP0/CPU0:IMC0(config-trustpool)#crl	
	optional	list (CRL).
Step 5	description LINE	
	Example:	
	RP/0/RSP0/CPU0:IMC0(config-trustpool)#description Trustpool for Test.	

### Handling of CA Certificates appearing both in Trust Pool and Trust Point

There may be cases where a CA resides in both the trust pool and a trust point; for example, a trust point is using a CA and a CA bundle is downloaded later with this same CA inside. In this scenario, the CA in the trust point and its policy is considered, before the CA in the trust pool or trust pool policy to ensure that any current behavior is not altered when the trust pool feature is implemented on the router.

The policy indicates how the security appliance obtains the CA certificate and the authentication policies for user certificates issued by the CA.

# Information About Implementing Certification Authority

#### Supported Standards for Certification Authority Interoperability

Cisco supports the following standards:

- IKE—A hybrid protocol that implements Oakley and Skeme key exchanges inside the Internet Security Association Key Management Protocol (ISAKMP) framework. Although IKE can be used with other protocols, its initial implementation is with the IPSec protocol. IKE provides authentication of the IPSec peers, negotiates IPSec keys, and negotiates IPSec security associations (SAs).
- Public-Key Cryptography Standard #7 (PKCS #7)—A standard from RSA Data Security Inc. used to encrypt and sign certificate enrollment messages.
- Public-Key Cryptography Standard #10 (PKCS #10)—A standard syntax from RSA Data Security Inc. for certificate requests.
- RSA keys—RSA is the public key cryptographic system developed by Ron Rivest, Adi Shamir, and Leonard Adelman. RSA keys come in pairs: one public key and one private key.
- SSL—Secure Socket Layer protocol.
- X.509v3 certificates—Certificate support that allows the IPSec-protected network to scale by providing the equivalent of a digital ID card to each device. When two devices want to communicate, they exchange digital certificates to prove their identity (thus removing the need to manually exchange public keys with each peer or specify a shared key at each peer). These certificates are obtained from a CA. X.509 as part of the X.500 standard of the ITU.

#### **Certification Authorities**

#### **Purpose of CAs**

CAs are responsible for managing certificate requests and issuing certificates to participating IPSec network devices. These services provide centralized key management for the participating devices.

CAs simplify the administration of IPSec network devices. You can use a CA with a network containing multiple IPSec-compliant devices, such as routers.

Digital signatures, enabled by public key cryptography, provide a means of digitally authenticating devices and individual users. In public key cryptography, such as the RSA encryption system, each user has a key pair containing both a public and a private key. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other. In simple terms, a signature is formed when data is encrypted with a user's private key. The receiver verifies the signature by decrypting the message with the sender's public key. The fact that the message could be decrypted using the sender's public key indicates that the holder of the private key, the sender, must have created the message. This process relies on the receiver's having a copy of the sender's public key and knowing with a high degree of certainty that it does belong to the sender and not to someone pretending to be the sender.

Digital certificates provide the link. A digital certificate contains information to identify a user or device, such as the name, serial number, company, department, or IP address. It also contains a copy of the entity's public

key. The certificate is itself signed by a CA, a third party that is explicitly trusted by the receiver to validate identities and to create digital certificates.

To validate the signature of the CA, the receiver must first know the CA's public key. Normally, this process is handled out-of-band or through an operation done at installation. For instance, most web browsers are configured with the public keys of several CAs by default. IKE, an essential component of IPSec, can use digital signatures to authenticate peer devices for scalability before setting up SAs.

Without digital signatures, a user must manually exchange either public keys or secrets between each pair of devices that use IPSec to protect communication between them. Without certificates, every new device added to the network requires a configuration change on every other device with which it communicates securely. With digital certificates, each device is enrolled with a CA. When two devices want to communicate, they exchange certificates and digitally sign data to authenticate each other. When a new device is added to the network, a user simply enrolls that device with a CA, and none of the other devices needs modification. When the new device attempts an IPSec connection, certificates are automatically exchanged and the device can be authenticated.

#### **CA Registration Authorities**

Some CAs have a registration authority (RA) as part of their implementation. An RA is essentially a server that acts as a proxy for the CA so that CA functions can continue when the CA is offline.

# **Implementing Keychain Management**

This module describes how to implement keychain management on. Keychain management is a common method of authentication to configure shared secrets on all entities that exchange secrets such as keys, before establishing trust with each other. Routing protocols and network management applications on Cisco IOS XR software often use authentication to enhance security while communicating with peers.

• Implementing Keychain Management, on page 59

# Implementing Keychain Management

This module describes how to implement keychain management on. Keychain management is a common method of authentication to configure shared secrets on all entities that exchange secrets such as keys, before establishing trust with each other. Routing protocols and network management applications on Cisco IOS XR software often use authentication to enhance security while communicating with peers.

# **Restrictions for Implementing Keychain Management**

You must be aware that changing the system clock impacts the validity of the keys in the existing configuration.

# **Configure Keychain**

This task configures a name for the keychain.

You can create or modify the name of the keychain.

#### Procedure

Step 1	configure
	Example:
	RP/0/# configure
	Enters mode.
Step 2	key chain key-chain-name
	Example:

RP/0/(config) # key chain isis-keys
RP/0/(config-isis-keys) #

Creates a name for the keychain.

- **Note** Configuring only the keychain name without any key identifiers is considered a nonoperation. When you exit the configuration, the router does not prompt you to commit changes until you have configured the key identifier and at least one of the mode attributes or keychain-key configuration mode attributes (for example, lifetime or key string).
- **Step 3** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

**Step 4 show key chain** *key-chain-name* 

#### Example:

RP/0/# show key chain isis-keys

(Optional) Displays the name of the keychain.

**Note** The *key-chain-name* argument is optional. If you do not specify a name for the *key-chain-name* argument, all the keychains are displayed.

#### Example

The following example shows how to configure keychain management:

```
configure
key chain isis-keys
accept-tolerance infinite
key 8
key-string mykey9labcd
cryptographic-algorithm MD5
send-lifetime 1:00:00 june 29 2006 infinite
accept-lifetime 1:00:00 june 29 2006 infinite
end
Uncommitted changes found, commit them? [yes]: yes
show key chain isis-keys
Key-chain: isis-keys/ -
accept-tolerance -- infinite
Key 8 -- text "1104000E120B520005282820"
cryptographic-algorithm -- MD5
```

Send lifetime: 01:00:00, 29 Jun 2006 - Always valid [Valid now] Accept lifetime: 01:00:00, 29 Jun 2006 - Always valid [Valid now]

# **Configure Tolerance Specification to Accept Keys**

This task configures the tolerance specification to accept keys for a keychain to facilitate a hitless key rollover for applications, such as routing and management protocols.

	configure
	Example:
	RP/0/# configure
	Enters mode.
	key chain key-chain-name
	Example:
	RP/0//CPU0:router(config)# key chain isis-keys
	Creates a name for the keychain.
	accept-tolerance value [infinite]
	Example:
	RP/0//CPU0:router(config-isis-keys)# accept-tolerance infinite
	Configures a tolerance value to accept keys for the keychain.
	• Use the <i>value</i> argument to set the tolerance range in seconds. The range is from 1 to 8640000.
	• Use the <b>infinite</b> keyword to specify that the tolerance specification is infinite.
	Use the <b>commit</b> or <b>end</b> command.
	commit —Saves the configuration changes and remains within the configuration session.
	end —Prompts user to take one of these actions:
	• Yes — Saves configuration changes and exits the configuration session.
	• No —Exits the configuration session without committing the configuration changes.
	• Cancel — Remains in the configuration session, without committing the configuration changes

# **Configure Key Identifier for Keychain**

This task configures a key identifier for the keychain.

You can create or modify the key for the keychain.

configure
Example:
RP/0/# configure
Enters mode.
key chain key-chain-name
Example:
RP/0//CPU0:router(config)# key chain isis-keys
Creates a name for the keychain.
key key-id
Example:
RP/0//CPU0:router(config-isis-keys)# key 8
Creates a key for the keychain. The key ID number is translated from decimal to hexadecimal to creat command mode subprompt.
• Use the <i>key-id</i> argument as a 48-bit integer.
Use the <b>commit</b> or <b>end</b> command.
commit —Saves the configuration changes and remains within the configuration session.
end —Prompts user to take one of these actions:
• Yes — Saves configuration changes and exits the configuration session.
• No —Exits the configuration session without committing the configuration changes.
• <b>Cancel</b> — Remains in the configuration session, without committing the configuration changes.

# **Configure Text for Key String**

This task configures the text for the key string.

Procedure

Step 1 configure

Example:

RP/0/# configure

Enters mode.

# Step 2key chain key-chain-name

#### Example:

RP/0//CPU0:router(config) # key chain isis-keys

Creates a name for the keychain.

Step 3 key key-id

Example:

```
RP/0//CPU0:router(config-isis-keys) # key 8
RP/0//CPU0:router(config-isis-keys-0x8) #
```

Creates a key for the keychain.

# Step 4 key-string [clear | password] key-string-text Example:

RP/0//CPU0:router(config-isis-keys-0x8) # key-string password 8

Specifies the text string for the key.

• Use the **clear** keyword to specify the key string in clear text form; use the **password** keyword to specify the key in encrypted form.

#### **Step 5** Use the **commit** or **end** command.

commit ---Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel Remains in the configuration session, without committing the configuration changes.

# **Determine Valid Keys**

This task determines the valid keys for local applications to authenticate the remote peers.

Proced	lure
--------	------

Step 1 configure

Example:

RP/0/# configure Enters mode. Step 2 key chain key-chain-name Example: RP/0/(config) # key chain isis-keys Creates a a name for the keychain. Step 3 key key-id Example: RP/0/(config-isis-keys) # key 8 RP/0/(config-isis-keys-0x8)# Creates a key for the keychain. Step 4 **accept-lifetime** *start-time* [**duration** *duration-value* | **infinite** | *end-time*] Example: RP/0/(config-isis-keys) # key 8 RP/0/(config-isis-keys-0x8)# accept-lifetime 1:00:00 october 24 2005 infinite (Optional) Specifies the validity of the key lifetime in terms of clock time. Step 5 Use the commit or end command. **commit**—Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: • Yes — Saves configuration changes and exits the configuration session.

- No —Exits the configuration session without committing the configuration changes.
- Cancel Remains in the configuration session, without committing the configuration changes.

# Configure Keys to Generate Authentication Digest for Outbound Application Traffic

This task configures the keys to generate authentication digest for the outbound application traffic.

	Procedure
Step 1	configure
	Example:

RP/0/# configure

Enters mode.

 Step 2
 key chain key-chain-name

 Example:

RP/0/(config) # key chain isis-keys

Creates a name for the keychain.

Step 3 key key-id

Example:

RP/0/(config-isis-keys)# key 8
RP/0/(config-isis-keys-0x8)#

Creates a key for the keychain.

#### **Step 4** send-lifetime start-time [duration duration-value | infinite | end-time]

#### **Example:**

```
RP/0/(config-isis-keys)#key 8
RP/0/(config-isis-keys-0x8)# send-lifetime 1:00:00 october 24 2005 infinite
```

(Optional) Specifies the set time period during which an authentication key on a keychain is valid to be sent. You can specify the validity of the key lifetime in terms of clock time.

In addition, you can specify a start-time value and one of the following values:

- duration keyword (seconds)
- infinite keyword
- end-time argument

If you intend to set lifetimes on keys, Network Time Protocol (NTP) or some other time synchronization method is recommended.

**Step 5** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

# Lifetime of Key

If you are using keys as the security method, you must specify the lifetime for the keys and change the keys on a regular basis when they expire. To maintain stability, each party must be able to store and use more than one key for an application at the same time. A keychain is a sequence of keys that are collectively managed for authenticating the same peer, peer group, or both.

Keychain management groups a sequence of keys together under a keychain and associates each key in the keychain with a lifetime.

Note

Any key that is configured without a lifetime is considered invalid; therefore, the key is rejected during configuration.

The lifetime of a key is defined by the following options:

- Start-time—Specifies the absolute time.
- End-time—Specifies the absolute time that is relative to the start-time or infinite time.

Each key definition within the keychain must specify a time interval for which that key is activated; for example, lifetime. Then, during a given key's lifetime, routing update packets are sent with this activated key. Keys cannot be used during time periods for which they are not activated. Therefore, we recommend that for a given keychain, key activation times overlap to avoid any period of time for which no key is activated. If a time period occurs during which no key is activated, neighbor authentication cannot occur; therefore, routing updates can fail.

Multiple keychains can be specified.

# **Implementing Management Plane Protection**

The Management Plane Protection (MPP) feature provides the capability to restrict the interfaces on which network management packets are allowed to enter a device. The MPP feature allows a network operator to designate one or more router interfaces as management interfaces.

The MPP protection feature, as well as all the management protocols under MPP, are disabled by default. When you configure an interface as inband, it automatically enables MPP. Consequently, this enablement extends to all the protocols under MPP. If MPP is disabled and a protocol is activated, all interfaces can pass traffic.

Afterwards, only the default management interfaces and those you have previously configured as MPP interfaces accept network management packets destined for the device. All other interfaces drop such packets. Logical interfaces (or any other interfaces not present on the data plane) filter packets based on the ingress physical interface.

• Implementing Management Plane Protection, on page 67

# Implementing Management Plane Protection

The Management Plane Protection (MPP) feature provides the capability to restrict the interfaces on which network management packets are allowed to enter a device. The MPP feature allows a network operator to designate one or more router interfaces as management interfaces.

The MPP protection feature, as well as all the management protocols under MPP, are disabled by default. When you configure an interface as inband, it automatically enables MPP. Consequently, this enablement extends to all the protocols under MPP. If MPP is disabled and a protocol is activated, all interfaces can pass traffic.

Afterwards, only the default management interfaces and those you have previously configured as MPP interfaces accept network management packets destined for the device. All other interfaces drop such packets. Logical interfaces (or any other interfaces not present on the data plane) filter packets based on the ingress physical interface.

## **Benefits of Management Plane Protection**

Implementing the MPP feature provides the following benefits:

- Greater access control for managing a device than allowing management protocols on all interfaces.
- Improved performance for data packets on non-management interfaces.

- Support for network scalability.
- Simplifies the task of using per-interface access control lists (ACLs) to restrict management access to the device.
- Fewer ACLs are needed to restrict access to the device.
- Prevention of packet floods on switching and routing interfaces from reaching the CPU.

## **Restrictions for Implementing Management Plane Protection**

The following restrictions are listed for implementing Management Plane Protection (MPP):

- Currently, MPP does not keep track of the denied or dropped protocol requests.
- MPP configuration does not enable the protocol services. MPP is responsible only for making the services available on different interfaces. The protocols are enabled explicitly.
- · Management requests that are received on inband interfaces are not necessarily acknowledged there.
- The changes made for the MPP configuration do not affect the active sessions that are established before the changes.
- Currently, MPP controls only the incoming management requests for protocols, such as TFTP, Telnet, Simple Network Management Protocol (SNMP), Secure Shell (SSH), XML and Netconf.
- MPP does not support MIB.

## **Configure Device for Management Plane Protection for Inband Interface**

An *inband management interface* is a physical or logical interface that processes management packets, as well as data-forwarding packets. An inband management interface is also called a *shared management interface*. Perform this task to configure a device that you have just added to your network or a device already operating in your network. This task shows how to configure MPP as an inband interface in which Telnet is allowed to access the router only through a specific interface.

Perform the following additional tasks to configure an inband MPP interface in non-default VRF.

- Configure the interface under the non-default inband VRF.
- Configure the global inband VRF.
- In the case of Telnet, configure the Telnet VRF server for the inband VRF.

#### Procedure

Step 1 configure

Example:

RP/0/# configure

Enters mode.

### Step 2 control-plane

### Example:

RP/0/(config)# control-plane
RP/0/(config-ctrl)#

Enters control plane configuration mode.

### Step 3 management-plane

Example:

```
RP/0/(config-ctrl)# management-plane
RP/0/(config-mpp)#
```

Configures management plane protection to allow and disallow protocols and enters management plane protection configuration mode.

### Step 4 inband

### Example:

```
RP/0/(config-mpp)# inband
RP/0/(config-mpp-inband)#
```

Configures an inband interface and enters management plane protection inband configuration mode.

### **Step 5** interface {type instance | all}

## Example:

```
RP/0/(config-mpp-inband)# interface HundredGigE 0/6/0/1
RP/0/(config-mpp-inband-Gi0_6_0_1)#
```

Configures a specific inband interface, or all inband interfaces. Use the **interface** command to enter management plane protection inband interface configuration mode.

• Use the **all** keyword to configure all interfaces.

### Step 6 allow {protocol | all} [peer]

### Example:

Configures an interface as an inband interface for a specified protocol or all protocols.

- Use the *protocol* argument to allow management protocols on the designated management interface.
  - SNMP (also versions)

- Secure Shell (v1 and v2)
- TFTP
- Telnet
- Netconf
- XML
- Use the **all** keyword to configure the interface to allow all the management traffic that is specified in the list of protocols.
- (Optional) Use the peer keyword to configure the peer address on the interface.

**Step 7** address ipv4 {peer-ip-address | peer ip-address/length}

### Example:

RP/0/(config-telnet-peer) # address ipv4 10.1.0.0/16

Configures the peer IPv4 address in which management traffic is allowed on the interface.

- Use the *peer-ip-address* argument to configure the peer IPv4 address in which management traffic is allowed on the interface.
- Use the peer ip-address/length argument to configure the prefix of the peer IPv4 address.

### **Step 8** Use the **commit** or **end** command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.

**Step 9 show mgmt-plane** [**inband** | ] [**interface** {*type instance*}]

#### Example:

RP/0/# show mgmt-plane inband interface HundredGigE 0/6/0/1

Displays information about the management plane, such as type of interface and protocols enabled on the interface.

- (Optional) Use the **inband** keyword to display the inband management interface configurations that are the interfaces that process management packets as well as data-forwarding packets.
- (Optional) Use the interface keyword to display the details for a specific interface.

L

# **Configure Device for Management Plane Protection for Out-of-band Interface**

*Out-of-band* refers to an interface that allows only management protocol traffic to be forwarded or processed. An *out-of-band management interface* is defined by the network operator to specifically receive network management traffic. The advantage is that forwarding (or customer) traffic cannot interfere with the management of the router, which significantly reduces the possibility of denial-of-service attacks.

Out-of-band interfaces forward traffic only between out-of-band interfaces or terminate management packets that are destined to the router. In addition, the out-of-band interfaces can participate in dynamic routing protocols. The service provider connects to the router's out-of-band interfaces and builds an independent overlay management network, with all the routing and policy tools that the router can provide.

Perform the following tasks to configure an out-of-band MPP interface.

- Configure the interface under the out-of-band VRF.
- Configure the global out-of-band VRF.
- In the case of Telnet, configure the Telnet VRF server for the out-of-band VRF.

## Procedure

Step 1	configure
	Example:
	RP/0/# configure
	Enters mode.
Step 2	control-plane
	Example:
	RP/0/(config)# control-plane RP/0/(config-ctrl)#
	Enters control plane configuration mode.
Step 3	management-plane
	Example:
	RP/0/(config-ctrl)# management-plane RP/0/(config-mpp)#
	Configures management plane protection to allow and disallow protocols and enters management plane protection configuration mode.
Step 4	out-of-band
	Example:

RP/0/(config-mpp)# out-of-band RP/0/(config-mpp-outband)#

Configures out-of-band interfaces or protocols and enters management plane protection out-of-band configuration mode.

```
Step 5 vrf vrf-name
```

Example:

RP/0/(config-mpp-outband) # vrf target

Configures a Virtual Private Network (VPN) routing and forwarding (VRF) reference of an out-of-band interface.

• Use the vrf-name argument to assign a name to a VRF.

```
Step 6 interface {type instance | all}
```

### Example:

```
RP/0/(config-mpp-outband) # interface HundredGigE 0/6/0/2
RP/0/(config-mpp-outband-if) #
```

Configures a specific out-of-band interface, or all out-of-band interfaces, as an out-of-band interface. Use the **interface** command to enter management plane protection out-of-band configuration mode.

• Use the all keyword to configure all interfaces.

## Step 7allow {protocol | all} [peer]

### Example:

```
RP/0/(config-mpp-outband-if)# allow TFTP peer
RP/0/(config-tftp-peer)#
```

Configures an interface as an out-of-band interface for a specified protocol or all protocols.

- Use the *protocol* argument to allow management protocols on the designated management interface.
  - HTTP or HTTPS
  - SNMP (also versions)
  - Secure Shell (v1 and v2)
  - TFTP
  - Telnet
  - Netconf

- Use the **all** keyword to configure the interface to allow all the management traffic that is specified in the list of protocols.
- (Optional) Use the peer keyword to configure the peer address on the interface.

 Step 8
 address ipv6 {peer-ip-address | peer ip-address/length}

 Example:

RP/0/(config-tftp-peer)# address ipv6 33::33

Configures the peer IPv6 address in which management traffic is allowed on the interface.

- Use the *peer-ip-address* argument to configure the peer IPv6 address in which management traffic is allowed on the interface.
- Use the *peer ip-address/length* argument to configure the prefix of the peer IPv6 address.
- Step 9 Use the commit or end command.

**commit**—Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- **Cancel**—Remains in the configuration session, without committing the configuration changes.

 Step 10
 show mgmt-plane [inband | out-of-band] [interface {type instance} | vrf]

 Example:

RP/0/# show mgmt-plane out-of-band interface HundredGigE 0/6/0/2

Displays information about the management plane, such as type of interface and protocols enabled on the interface.

- (Optional) Use the **inband** keyword to display the inband management interface configurations that are the interfaces that process management packets as well as data-forwarding packets.
- (Optional) Use the **out-of-band** keyword to display the out-of-band interface configurations.
- (Optional) Use the interface keyword to display the details for a specific interface.
- (Optional) Use the **vrf** keyword to display the Virtual Private Network (VPN) routing and forwarding reference of an out-of-band interface.

#### Example

The following example shows how to configure inband and out-of-band interfaces for a specific IP address under MPP:

```
configure
control-plane
 management-plane
  inband
   interface all
    allow SSH
     !
   interface HundredGigE 0/6/0/0
    allow all
    allow SSH
    allow Telnet peer
     address ipv4 10.1.0.0/16
   !
   1
   interface HundredGigE 0/6/0/1
    allow Telnet peer
     address ipv4 10.1.0.0/16
    !
   1
   !
  out-of-band
   vrf my_out_of_band
   interface HundredGigE 0/6/0/2
    allow TFTP peer
     address ipv6 33::33
    !
   1
   !
  !
 1
show mgmt-plane
Management Plane Protection
inband interfaces
 ------
interface - HundredGigE0_6_0_0
       ssh configured -
              All peers allowed
       telnet configured -
               peer v4 allowed - 10.1.0.0/16
       all configured -
              All peers allowed
interface - HundredGigE0 6 0 1
       telnet configured -
              peer v4 allowed - 10.1.0.0/16
interface - all
       all configured -
              All peers allowed
outband interfaces
------
interface - HundredGigE0 6 0 2
```

```
tftp configured -
peer v6 allowed - 33::33
show mgmt-plane out-of-band vrf
Management Plane Protection -
out-of-band VRF - my out of band
```

## Information About Implementing Management Plane Protection

Before you enable the Management Plane Protection feature, you should understand the following concepts:

## **Peer-Filtering on Interfaces**

The peer-filtering option allows management traffic from specific peers, or a range of peers, to be configured.

## **Control Plane Protection**

A *control plane* is a collection of processes that run at the process level on a route processor and collectively provide high-level control for most Cisco software functions. All traffic directly or indirectly destined to a router is handled by the control plane. Management Plane Protection operates within the Control Plane Infrastructure.

## **Management Plane**

The *management plane* is the logical path of all traffic that is related to the management of a routing platform. One of three planes in a communication architecture that is structured in layers and planes, the management plane performs management functions for a network and coordinates functions among all the planes (management, control, and data). In addition, the management plane is used to manage a device through its connection to the network.

Examples of protocols processed in the management plane are Simple Network Management Protocol (SNMP), Telnet, SSH, XML and Netconf. These management protocols are used for monitoring and for command-line interface (CLI) access. Restricting access to devices to internal sources (trusted networks) is critical.

I

# **Implementing Secure Shell**

Secure Shell (SSH) is an application and a protocol that provides a secure replacement to the Berkeley r-tools. The protocol secures sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley **rexec** and **rsh** tools.

Two versions of the SSH server are available: SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2). SSHv1 uses Rivest, Shamir, and Adelman (RSA) keys and SSHv2 uses either Digital Signature Algorithm (DSA) keys or Rivest, Shamir, and Adelman (RSA) keys. Cisco software supports both SSHv1 and SSHv2.

This module describes how to implement Secure Shell.

### **Feature History for Implementing Secure Shell**

Release	Modification
Release 6.0	This feature was introduced.

# Implementing Secure Shell

Secure Shell (SSH) is an application and a protocol that provides a secure replacement to the Berkeley r-tools. The protocol secures sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley **rexec** and **rsh** tools.

Two versions of the SSH server are available: SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2). SSHv1 uses Rivest, Shamir, and Adelman (RSA) keys and SSHv2 uses either Digital Signature Algorithm (DSA) keys or Rivest, Shamir, and Adelman (RSA) keys. Cisco software supports both SSHv1 and SSHv2.

This module describes how to implement Secure Shell.

### Feature History for Implementing Secure Shell

Release	Modification
Release 6.0	This feature was introduced.

## **Prerequisites for Implementing Secure Shell**

The following prerequisites are required to implement Secure Shell:

- Download the required image on your router. The SSH server and SSH client require you to have a a crypto package (data encryption standard [DES], 3DES and AES) from Cisco downloaded on your router.
- Configure user authentication for local or remote access. You can configure authentication with or without authentication, authorization, and accounting (AAA).
- AAA authentication and authorization must be configured correctly for Secure Shell File Transfer Protocol (SFTP) to work.

## **Restrictions for Implementing Secure Shell**

The following are some basic SSH restrictions and limitations of the SFTP feature:

- In order for an outside client to connect to the router, the router needs to have an RSA (for SSHv1 or SSHv2) or DSA (for SSHv2) key pair configured. DSA and RSA keys are not required if you are initiating an SSH client connection from the router to an outside routing device. The same is true for SFTP: DSA and RSA keys are not required because SFTP operates only in client mode.
- In order for SFTP to work properly, the remote SSH server must enable the SFTP server functionality. For example, the SSHv2 server is configured to handle the SFTP subsystem with a line such as /etc/ssh2/sshd2\_config:
- subsystem-sftp /usr/local/sbin/sftp-server
- The SFTP server is usually included as part of SSH packages from public domain and is turned on by default configuration.
- SFTP is compatible with sftp server version OpenSSH\_2.9.9p2 or higher.
- RSA-based user authentication is supported in the SSH and SFTP servers. The support however, is not
  extended to the SSH client.
- Execution shell and SFTP are the only applications supported.
- The SFTP client does not support remote filenames containing wildcards (\* ?, []). The user must issue the **sftp** command multiple times or list all of the source files from the remote host to download them on to the router. For uploading, the router SFTP client can support multiple files specified using a wildcard provided that the issues mentioned in the first through third bullets in this section are resolved.
- The cipher preference for the SSH server follows the order AES128, AES192, AES256, and, finally, 3DES. The server rejects any requests by the client for an unsupported cipher, and the SSH session does not proceed.
- Use of a terminal type other than vt100 is not supported, and the software generates a warning message in this case.
- · Password messages of "none" are unsupported on the SSH client.
- Files created on the local device lose the original permission information because the router infrastructure does not provide support for UNIX-like file permissions. For files created on the remote file system, the file permission adheres to the umask on the destination host and the modification and last access times are the time of the copy.

# **Configure SSH**

Perform this task to configure SSH.

Note	For SSHv1 configuration, Step 1 to Step 4 are required. For SSHv2 configuration, Step to Step 4 are optional.
	Procedure
Step 1	configure
	Example:
	RP/0/# configure
	Enters mode.
Step 2	hostname hostname
	Example:
	RP/0/(config)# hostname router1
	Configures a hostname for your router.
Step 3	domain name domain-name
	Example:
	RP/0/(config)# domain name cisco.com
	Defines a default domain name that the software uses to complete unqualified host names.
Step 4	Use the <b>commit</b> or <b>end</b> command.
	commit —Saves the configuration changes and remains within the configuration session.
	end —Prompts user to take one of these actions:
	• Yes — Saves configuration changes and exits the configuration session.
	• No —Exits the configuration session without committing the configuration changes.
	• Cancel — Remains in the configuration session, without committing the configuration changes.
Step 5	crypto key generate rsa [usage keys   general-keys] [keypair-label]
	Example:
	RP/0/# crypto key generate rsa general-keys
	Generates an RSA key pair. The RSA key modulus can be in the range of 512 to 4096 bits.
	• To delete the RSA key pair, use the crypto key zeroize rsa command.
	• This command is used for SSHv1 only.

### **Step 6** crypto key generate dsa

#### Example:

RP/0/# crypto key generate dsa

Enables the SSH server for local and remote authentication on the router. The supported key sizes are: 512, 768 and 1024 bits.

- The recommended minimum modulus size is 1024 bits.
- Generates a DSA key pair.

To delete the DSA key pair, use the crypto key zeroize dsa command.

• This command is used only for SSHv2.

## Step 7 configure

### Example:

RP/0/# configure

Enters mode.

Step 8ssh timeoutseconds

## Example:

RP/0/(config) # ssh timeout 60

(Optional) Configures the timeout value for user authentication to AAA.

- If the user fails to authenticate itself to AAA within the configured time, the connection is terminated.
- If no value is configured, the default value of 30 seconds is used. The range is from 5 to 120.

### **Step 9** Do one of the following:

- ssh server [vrf vrf-name]
- ssh server v2

### Example:

RP/0/(config) # ssh server v2

 (Optional) Brings up an SSH server using a specified VRF of up to 32 characters. If no VRF is specified, the default VRF is used.

To stop the SSH server from receiving any further connections for the specified VRF, use the **no** form of this command. If no VRF is specified, the default is assumed.

- **Note** The SSH server can be configured for multiple VRF usage.
  - (Optional) Forces the SSH server to accept only SSHv2 clients if you configure the SSHv2 option by using the **ssh server v2** command. If you choose the **ssh server v2** command, only the SSH v2 client connections are accepted.
- Step 10 Use the commit or end command.

	commit —Saves the configuration changes and remains within the configuration session.		
	end —Prompts user to take one of these actions:		
	• Yes — Saves configuration changes and exits the configuration session.		
	• No —Exits the configuration session without committing the configuration changes.		
	• <b>Cancel</b> —Remains in the configuration session, without committing the configuration changes.		
Step 11	show ssh		
	Example:		
	RP/0/# show ssh		
	(Optional) Displays all of the incoming and outgoing SSHv1 and SSHv2 connections to the router.		
Step 12	show ssh session details		
	Example:		
	RP/0/# show ssh session details		
	(Optional) Displays a detailed report of the SSHv2 connections to and from the router.		

# **Configure SSH Client**

Perform this task to configure an SSH client.

	Procedu	Ire
Step 1	configu	re
	Example	9:
	RP/0/#	configure
	Enters n	node.
Step 2	ssh clie	nt knownhost device :/filename
	Example	9:
	RP/0/(c	config)# ssh client knownhost slot1:/server_pubkey
	(Option	al) Enables the feature to authenticate and check the server public key (pubkey) at the client end.
	Note	The complete path of the filename is required. The colon (:) and slash mark (/) are also required.
Step 3	Use the	commit or end command.
	commit	—Saves the configuration changes and remains within the configuration session.
	end —P	Prompts user to take one of these actions:

- Yes Saves configuration changes and exits the configuration session.
- No —Exits the configuration session without committing the configuration changes.
- Cancel —Remains in the configuration session, without committing the configuration changes.
- **Step 4** ssh {*ipv4-address* | *ipv6-address* | *hostname*} [ username *user-* cipher | source-interface *type instance*]

Enables an outbound SSH connection.

- To run an SSHv2 server, you must have a VRF. This may be the default or a specific VRF. VRF changes are applicable only to the SSH v2 server.
- The SSH client tries to make an SSHv2 connection to the remote peer. If the remote peer supports only the SSHv1 server, the peer internally spawns an SSHv1 connection to the remote server.
- The **cipher des** option can be used only with an SSHv1 client.
- The SSHv1 client supports only the 3DES encryption algorithm option, which is still available by default for those SSH clients only.
- If the *hostname* argument is used and the host has both IPv4 and IPv6 addresses, the IPv6 address is used.
- If you are using SSHv1 and your SSH connection is being rejected, the reason could be that the RSA key pair might have been zeroed out or that you have not successfully generated an RSA key pair for your router. Another reason could be that the SSH server to which the user is connecting to using SSHv1 client does not accept SSHv1 connections. Make sure that you have specified a hostname and domain. Then use the **crypto key generate rsa** command to generate an RSA host-key pair, and then enable the SSH server.
- If you are using SSHv2 and your SSH connection is being rejected, the reason could be that the DSA, RSA host-key pair might have been zeroed out. Make sure you follow similar steps as mentioned above to generate the required host-key pairs, and then enable the SSH server.
- When configuring the RSA or DSA key pair, you might encounter the following error messages:
  - No hostname specified

You must configure a hostname for the router using the hostname command.

No domain specified

You must configure a host domain for the router using the **domain-name** command.

- The number of allowable SSH connections is limited to the maximum number of virtual terminal lines configured for the router. Each SSH connection uses a vty resource.
- SSH uses either local security or the security protocol that is configured through AAA on your router for user authentication. When configuring AAA, you must ensure that the console is not running under AAA by applying a keyword in the global configuration mode to disable AAA on the console.

**Note** If you are using Putty version 0.63 or higher to connect to the SSH client, set the 'Chokes on PuTTY's SSH2 winadj request' option under SSH > Bugs in your Putty configuration to 'On.' This helps avoid a possible breakdown of the session whenever some long output is sent from IOS XR to the Putty client.

#### **Configuring Secure Shell**

The following example shows how to configure SSHv2 by creating a hostname, defining a domain name, enabling the SSH server for local and remote authentication on the router by generating a DSA key pair, bringing up the SSH server, and saving the configuration commands to the running configuration file.

After SSH has been configured, the SFTP feature is available on the router.

```
configure
hostname routerl
domain name cisco.com
exit
crypto key generate rsa/dsa
configure
ssh server
end
```

## Information About Implementing Secure Shell

To implement SSH, you should understand the following concepts:

## SSH Server

The SSH server feature enables an SSH client to make a secure, encrypted connection to a Cisco router. This connection provides functionality that is similar to that of an inbound Telnet connection. Before SSH, security was limited to Telnet security. SSH allows a strong encryption to be used with the Cisco software authentication. The SSH server in Cisco software works with publicly and commercially available SSH clients.

## **SSH Client**

The SSH client feature is an application running over the SSH protocol to provide device authentication and encryption. The SSH client enables a Cisco router to make a secure, encrypted connection to another Cisco router or to any other device running the SSH server. This connection provides functionality that is similar to that of an outbound Telnet connection except that the connection is encrypted. With authentication and encryption, the SSH client allows for a secure communication over an insecure network.

The SSH client works with publicly and commercially available SSH servers. The SSH client supports the ciphers of AES, 3DES, message digest algorithm 5 (MD5), SHA1, and password authentication. User authentication is performed in the Telnet session to the router. The user authentication mechanisms supported for SSH are RADIUS, TACACS+, and the use of locally stored usernames and passwords.

The SSH client supports setting DSCP value in the outgoing packets.

ssh client dscp <value from 0 - 63>

If not configured, the default DSCP value set in packets is 16 (for both client and server).

The SSH client supports the following options:

```
• DSCP—DSCP value for SSH client sessions.
```

```
RP/0/5/CPU0:router#configure
RP/0/5/CPU0:router(config)#ssh ?
    client Provide SSH client service
    server Provide SSH server service
    timeout Set timeout value for SSH
RP/0/5/CPU0:router(config)#ssh client ?
```

- Knownhost—Enable the host pubkey check by local database.
- · Source-interface—Source interface for SSH client sessions.

## **SFTP Feature Overview**

SSH includes support for standard file transfer protocol (SFTP), a new standard file transfer protocol introduced in SSHv2. This feature provides a secure and authenticated method for copying router configuration or router image files.

The SFTP client functionality is provided as part of the SSH component and is always enabled on the router. Therefore, a user with the appropriate level can copy files to and from the router. Like the **copy** command, the **sftp** command can be used only in .

The SFTP client is VRF-aware, and you may configure the secure FTP client to use the VRF associated with a particular source interface during connections attempts. The SFTP client also supports interactive mode, where the user can log on to the server to perform specific tasks via the Unix server.

The SFTP Server is a sub-system of the SSH server. In other words, when an SSH server receives an SFTP server request, the SFTP API creates the SFTP server as a child process to the SSH server. A new SFTP server instance is created with each new request.

The SFTP requests for a new SFTP server in the following steps:

- The user runs the sftp command with the required arguments
- The SFTP API internally creates a child session that interacts with the SSH server
- The SSH server creates the SFTP server child process
- The SFTP server and client interact with each other in an encrypted format
- The SFTP transfer is subject to LPTS policer "SSH-Known". Low policer values will affect SFTP transfer speeds

Note

In IOS-XR SW release 4.3.1 onwards the default policer value for SSH-Known has been reset from 2500pps to 300pps. Slower transfers are expected due to this change. You can adjust the lpts policer value for this punt cause to higher values that will allow faster transfers

When the SSH server establishes a new connection with the SSH client, the server daemon creates a new SSH server child process. The child server process builds a secure communications channel between the SSH client and server via key exchange and user authentication processes. If the SSH server receives a request for the sub-system to be an SFTP server, the SSH server daemon creates the SFTP server child process. For each incoming SFTP server subsystem request, a new SSH server child and a SFTP server instance is created. The SFTP server authenticates the user session and initiates a connection. It sets the environment for the client and the default directory for the user.

Once the initialization occurs, the SFTP server waits for the SSH\_FXP\_INIT message from the client, which is essential to start the file communication session. This message may then be followed by any message based on the client request. Here, the protocol adopts a 'request-response' model, where the client sends a request to the server; the server processes this request and sends a response.

The SFTP server displays the following responses:

• Status Response

- Handle Response
- Data Response
- Name Response

Note

The server must be running in order to accept incoming SFTP connections.

## **RSA Based Host Authentication**

Verifying the authenticity of a server is the first step to a secure SSH connection. This process is called the host authentication, and is conducted to ensure that a client connects to a valid server.

The host authentication is performed using the public key of a server. The server, during the key-exchange phase, provides its public key to the client. The client checks its database for known hosts of this server and the corresponding public-key. If the client fails to find the server's IP address, it displays a warning message to the user, offering an option to either save the public key or discard it. If the server's IP address is found, but the public-key does not match, the client closes the connection. If the public key is valid, the server is verified and a secure SSH connection is established.

The IOS XR SSH server and client had support for DSA based host authentication. But for compatibility with other products, like IOS, RSA based host authentication support is also added.

## **RSA Based User Authentication**

One of the method for authenticating the user in SSH protocol is RSA public-key based user authentication. The possession of a private key serves as the authentication of the user. This method works by sending a signature created with a private key of the user. Each user has a RSA keypair on the client machine. The private key of the RSA keypair remains on the client machine.

The user generates an RSA public-private key pair on a unix client using a standard key generation mechanism such as ssh-keygen. The max length of the keys supported is 4096 bits, and the minimum length is 512 bits. The following example displays a typical key generation activity:

```
bash-2.05b$ ssh-keygen -b 1024 -t rsa
Generating RSA private key, 1024 bit long modulus
```

The public key must be in base64 encoded (binary) formats for it to be imported correctly into the router.

Note You can use third party tools available on the Internet to convert the key to the binary format.

Once the public key is imported to the router, the SSH client can choose to use the public key authentication method by specifying the request using the "-o" option in the SSH client. For example:

```
client$ ssh -o PreferredAuthentications=publickey 1.2.3.4
```

If a public key is not imported to a router using the RSA method, the SSH server initiates the password based authentication. If a public key is imported, the server proposes the use of both the methods. The SSH client then chooses to use either method to establish the connection. The system allows only 10 outgoing SSH client connections.

Currently, only SSH version 2 and SFTP server support the RSA based authentication.

**Note** The preferred method of authentication would be as stated in the SSH RFC. The RSA based authentication support is only for local authentication, and not for TACACS/RADIUS servers.

Authentication, Authorization, and Accounting (AAA) is a suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

## SSHv2 Client Keyboard-Interactive Authentication

An authentication method in which the authentication information is entered using a keyboard is known as keyboard-interactive authentication. This method is an interactive authentication method in the SSH protocol. This type of authentication allows the SSH client to support different methods of authentication without having to be aware of their underlying mechanisms.

Currently, the SSHv2 client supports the keyboard-interactive authentication. This type of authentication works only for interactive applications.

Note

The password authentication is the default authentication method. The keyboard-interactive authentication method is selected if the server is configured to support only the keyboard-interactive authentication.

# **Implementing Lawful Intercept**

Lawful intercept is the lawfully authorized interception and monitoring of communications of an intercept subject. Service providers worldwide are legally required to assist law enforcement agencies in conducting electronic surveillance in both circuit-switched and packet-mode networks.

Only authorized service provider personnel are permitted to process and configure lawfully authorized intercept orders. Network administrators and technicians are prohibited from obtaining knowledge of lawfully authorized intercept orders, or intercepts in progress. Error messages or program messages for intercepts installed in the router are not displayed on the console.

Lawful Intercept is not a part of the Cisco IOS XR software by default. You have to install it separately by installing and activating .

For more information about activating and deactivating the Lawful Intercept package, see the Installing Lawful Intercept (LI) Package, on page 93 section.

- Information About Lawful Intercept Implementation, on page 89
- Prerequisites for Implementing Lawful Intercept, on page 90
- Restrictions for Implementing Lawful Intercept, on page 90
- Lawful Intercept Topology, on page 91

- Additional Information on Lawful Intercept, on page 95

# Information About Lawful Intercept Implementation

Cisco lawful intercept is based on RFC3924 architecture and SNMPv3 provisioning architecture. SNMPv3 addresses the requirements to authenticate data origin and ensure that the connection from the router to the Mediation Device (MD) is secure. This ensures that unauthorized parties cannot forge an intercept target.

Lawful intercept offers these capabilities:

- SNMPv3 lawful intercept provisioning interface
- Lawful intercept MIB: CISCO-TAP2-MIB, version 2
- CISCO-IP-TAP-MIB manages the Cisco intercept feature for IP and is used along with CISCO-TAP2-MIB to intercept IP traffic

- IPv4 user datagram protocol (UDP) encapsulation to the MD
- Replication and forwarding of intercepted packets to the MD
- Supports the NCS55-36x100 and NCS55-18H18F line cards

# **Prerequisites for Implementing Lawful Intercept**

Lawful intercept implementation requires that these prerequisites are met:

- The router is used as content Intercept Access Point (IAP) router in lawful interception operation.
- Provisioned Router—The router must be already provisioned.

- **ip** For the purpose of lawful intercept taps, provisioning a loopback interface has advantages over other interface types.
- Management Plane Configured to Enable SNMPv3—Allows the management plane to accept SNMP commands, so that the commands go to the interface (preferably, a loopback interface) on the router. This allows the mediation device (MD) to communicate with a physical interface.
- VACM Views Enabled for SNMP Server—View-based access control model (VACM) views must be enabled on the router.
- Provisioned MD—For detailed information, see the vendor documentation associated with your MD.
- **QoS Peering** QoS peering must be enabled on the router for Lawful Intercept to work.

- Note The Lawful Intercept feature has no intersection with the QoS feature on the router. Enabling the QoS peering profile with **hw-module profile qos** ingress-model peering command on all the required line cards, allows QoS and Lawful intercept to allocate hardware resources.
- The MD uses the **CISCO-TAP2-MIB** to set up communications between the router acting as the content IAP, and the MD. The MD uses the **CISCO-IP-TAP-MIB** to set up the filter for the IP addresses and port numbers to be intercepted.
- The MD can be located anywhere in the network but must be reachable from the content IAP router, which is being used to intercept the target. MD should be reachable *only* from global routing table and *not* from VRF routing table.

# **Restrictions for Implementing Lawful Intercept**

The following restrictions are applicable for Lawful Intercept:

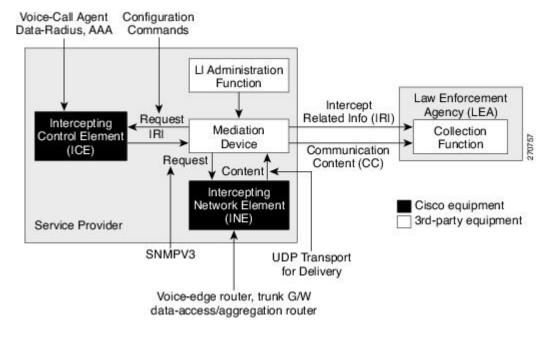

• Lawful Intercept shares a pool of 16 unique source IP addresses with tunnel-ip. The combined configuration of GRE tunnel-ips and the MDs (the cTap2MediationSrcInterface field) shall not yield

more than 16 unique source IPs. Note that when configuring the MD, if the value 0 is passed in for the cTap2MediationSrcInterface field, it will be resolved into a source IP address, which is the egress IP to the MD destination.

- Lawful intercept is supported only to match pure IP over Ethernet packets.
- Only 250 MDs and 500 Taps on IPv4 are supported.
- One Tap-to-multiple MDs is not supported.
- After the route processor reload or fail-over, the MD and Tap configuration must be re-provisioned.
- Only IPv4 MD is supported.
- The path to the MD must have the ARP resolved. Any other traffic or protocol will trigger ARP.
- MD next-hop must have ARP resolved. Any other traffic or protocol will trigger ARP.
- In Cisco IOS XR Release 6.3.x, QoS peering must be enabled for QOS to work.
- Lawful Intercept has no intersection with the GRE Tunnel feature, except that they allocate hardware resources (16 unique egress IP addresses) from the same pool. In the normal case, the egress interface for the LI packets is decided by the forwarding algorithm. No resource is needed from that unique address pool. However, if the Lawful Intercept configuration mandates that the Lawful Intercept packets have to egress through a certain interface (the cTap2MediationSrcInterface field in the MD configuration), then the forwarding module must be configured so that the packets go out through that interface. In that case a resource must be allocated from the unique address pool. If GRE uses up all resources, then LI does not work.
- Lawful Intercept Stats is not supported.
- Even though the original packets can be fragmented, the LI packets cannot be fragmented. The MTU of the egress interface to the MD must be large enough to support the size of the packets captured.
- Lawful intercept does not provide support for these features on the router:
  - IPv4/IPv6 multicast tapping
  - IPv6 MD encapsulation
  - Per interface tapping
  - Tagged packet tapping
  - Replicating a single tap to multiple MDs
  - Tapping L2 flows
  - RTP encapsulation
  - Lawful Intercept and SPAN on the same interface

# Lawful Intercept Topology

This figure shows intercept access points and interfaces in a lawful intercept topology for both voice and data interception.

#### Figure 1: Lawful Intercept Topology for Both Voice and Data Interception

```
Note
```

- The router will be used as content Intercept Access Point (IAP) router, or the Intercepting Network Element (INE) in lawful interception operation.
- The Intercepting Control Element (ICE) could be either a Cisco equipment or a third party equipment.

# **Benefits of Lawful Intercept**

Lawful intercept has the following benefits:

- Allows multiple LEAs to run a lawful intercept on the same Router without each other's knowledge.
- · Does not affect subscriber services on the router.
- Supports wiretaps in both the input and output direction.
- Supports wiretaps of Layer 3 traffic.
- Cannot be detected by the target.
- Uses Simple Network Management Protocol Version 3 (SNMPv3) and security features such as the View-based Access Control Model (SNMP-VACM-MIB) and User-based Security Model (SNMP-USM-MIB) to restrict access to lawful intercept information and components.
- Hides information about lawful intercepts from all but the most privileged users. An administrator must set up access rights to enable privileged users to access lawful intercept information.

# Installing Lawful Intercept (LI) Package

As LI is not a part of the Cisco IOS XR image by default, you need to install it separately.

## Installing and Activating the LI Package

Use the show install committed command in EXEC mode to verify the committed software packages.

To install the Lawful Intercept (LI) package, you must install and activate the .

### Configuration

```
Router# install add source tftp://223.255.254.252/auto/tftp-sjc-users/username/
Router# install activate
Router# install commit
```

#### Verification

```
Router# show install active
Node 0/RP0/CPU0 [RP]
Boot Partition: xr_lv0
Active Packages: 2
```

```
Node 0/0/CPU0 [LC]
Boot Partition: xr_lcp_lv0
Active Packages: 2
```

## **Deactivating the LI RPM**

To uninstall the Lawful Intercept package, deactivate as shown in the following steps:

## Configuration

```
Router# install deactivate
Router# install commit
Router# install remove
Router# show install committed
```

# How to Configure SNMPv3 Access for Lawful Intercept

Perform these procedures to configure SNMPv3 for the purpose of Lawful Intercept enablement:

## **Disabling SNMP-based Lawful Intercept**

Lawful Intercept is enabled by default on the router after installing and activating the .

• To disable Lawful Intercept, enter the lawful-intercept disable command in global configuration mode.

• To re-enable it, use the **no** form of this command.

#### **Disabling SNMP-based Lawful Intercept: Example**

```
Router# configure
Router(config)# lawful-intercept disable
```

Note The lawful-intercept disable command is available on the router, only after installing and activating the .

All SNMP-based taps are dropped when lawful intercept is disabled.

## **Configuring the Inband Management Plane Protection Feature**

If MPP was not earlier configured to work with another protocol, then ensure that the MPP feature is also not configured to enable the SNMP server to communicate with the mediation device for lawful interception. In such cases, MPP must be configured specifically as an inband interface to allow SNMP commands to be accepted by the router, using a specified interface or all interfaces.

Note

Ensure this task is performed, even if you have recently migrated to Cisco IOS XR Software from Cisco IOS, and you had MPP configured for a given protocol.

For lawful intercept, a loopback interface is often the choice for SNMP messages. If you choose this interface type, you must include it in your inband management configuration.

#### **Example: Configuring the Inband Management Plane Protection Feature**

This example illustrates how to enable the MPP feature, which is disabled by default, for the purpose of lawful intercept.

You must specifically enable management activities, either globally or on a per-inband-port basis, using this procedure. To globally enable inbound MPP, use the keyword **all** with the **interface** command, rather than use a particular interface type and instance ID with it.

```
router# configure
router(config)# control-plane
router(config-ctrl)# management-plane
router(config-mpp)# inband
router(config-mpp-inband)# interface loopback0
router(config-mpp-inband-Loopback0)# allow snmp
router(config-mpp-inband-Loopback0)# commit
router(config-mpp-inband-Loopback0)# exit
router(config-mpp-inband) # exit
router(config-mpp) # exit
router(config-ctr) # exit
router(config) # exit
router# show mgmt-plane inband interface loopback0
Management Plane Protection - inband interface
interface - Loopback0
        snmp configured -
```

All peers allowed router(config) # commit

# **Enabling the Lawful Intercept SNMP Server Configuration**

The following SNMP server configuration tasks enable the Cisco LI feature on a router running Cisco IOS XR Software by allowing the MD to intercept data sessions.

### Configuration

```
router(config)# snmp-server engineID local 00:00:00:00:00:00:a1:61:6c:20:56
router(config)# snmp-server host 1.75.55.1 traps version 3 priv user-name udp-port 4444
router(config)# snmp-server user user-name li-group v3 auth md5 clear lab priv des56 clear
lab
router(config)# snmp-server view li-view ciscoTap2MIB included
router(config)# snmp-server view li-view ciscoIpTapMIB included
router(config)# snmp-server view li-view snmp included
router(config)# snmp-server view li-view ifMIB included
router(config)# snmp-server view li-view ifMIB included
router(config)# snmp-server view li-view 1.3.6.1.6.3.1.1.4.1 included
router(config)# snmp-server group li-group v3 auth read li-view write li-view notify li-view
```

SNMP configuration must be removed while deactivating the LI RPM.

# Additional Information on Lawful Intercept

## Interception Mode

The lawful intercept operates in the Global LI mode.

In this mode, the taps are installed on all the line cards in the ingress direction. The lawful intercept is available on line cards where QoS peering is enabled. With the global tap, the traffic for the target can be intercepted regardless of ingress point. Only the tap that has wild cards in the interface field is supported.

## **Data Interception**

Data are intercepted in this manner:

- The MD initiates communication content intercept requests to the content IAP router using SNMPv3.
- The content IAP router intercepts the communication content, replicates it, and sends it to the MD in IPv4 UDP format.
- Intercepted data sessions are sent from the MD to the collection function of the law enforcement agency, using a supported delivery standard for lawful intercept.

#### Information About the MD

The MD performs these tasks:

- Activates the intercept at the authorized time and removes it when the authorized time period elapses.
- Periodically audits the elements in the network to ensure that:
  - only authorized intercepts are in place.
  - all authorized intercepts are in place.

## **Scale or Performance Values**

The router support the following scalability and performance values for lawful intercept:

- IPv4, or IPv6, or a combination of IPv4 and IPv6, lawful intercept tap limit is up to a maximum of 500 taps.
- The scale decreases, if port ranges are used in the taps.
- The IPv6 entries consume double the memory of the IPv4 entries. Hence, the IPv6 scale will reduce to half of the IPv4 scale.
- A maximum of 250 IPv4 MDs are supported.
- Interception rate is 1 Gbps best effort per Linecard NPU.

## Intercepting IPv4 and IPv6 Packets

This section provides details for intercepting IPv4 and IPv6 packets supported on the router.

## Lawful Intercept Filters

The following filters are supported for classifying a tap:

- IP address type
- Destination address
- · Destination mask
- · Source address
- Source mask
- ToS (Type of Service) and ToS mask
- L4 Protocol
- · Destination port with range
- · Source port with range
- VRF (VPN Routing and Forwarding)

Note Flow-id and inteface filters are not supported.

## **Encapsulation Type Supported for Intercepted Packets**

Intercepted packets mapping the tap are replicated, encapsulated, and then sent to the MD. IPv4 and IPv6 packets are encapsulated using IPv4 UDP encapsulation. The replicated packets are forwarded to MD using UDP as the content delivery protocol.

The intercepted packet gets a new UDP header and IPv4 header. Information for IPv4 header is derived from MD configuration. Apart from the IP and UDP headers, a 4-byte channel identifier (CCCID) is also inserted after the UDP header in the packet. The router does not support forwarding the same replicated packets to multiple MDs.

Note

Encapsulation types, such as RTP and RTP-NOR, are not supported.

## High Availability for Lawful Intercept

High availability for lawful intercept provides operational continuity of the TAP flows and provisioned MD tables to reduce loss of information due to route processor fail over (RPFO).

To achieve continuous interception of a stream, when RP fail over is detected; MDs are required to re-provision all the rows relating to CISCO-TAP2-MIB and CISCO-IP-TAP-MIB to synchronize database view across RP and MD.

## Preserving TAP and MD Tables during RP Fail Over

At any point in time, MD has the responsibility to detect the loss of the taps via SNMP configuration process.

After RPFO is completed, MD should re-provision all the entries in the stream tables, MD tables, and IP taps with the same values they had before fail over. As long as an entry is re-provisioned in time, existing taps will continue to flow without any loss.

The following restrictions are listed for re-provisioning MD and tap tables with respect to behavior of SNMP operation on citapStreamEntry, cTap2StreamEntry, cTap2MediationEntry MIB objects:

- After RPFO, table rows that are not re-provisioned, shall return NO\_SUCH\_INSTANCE value as result of SNMP Get operation.
- Entire row in the table must be created in a single configuration step, with exactly same values as before RPFO, and with the rowStatus as CreateAndGo. Only exception is the cTap2MediationTimeout object, that should reflect valid future time.

## **Replay Timer**

The replay timer is an internal timeout that provides enough time for MD to re-provision tap entries while maintaining existing tap flows. It resets and starts on the active RP when RPFO takes place. The replay timer is a factor of number of LI entries in router with a minimum value of 10 minutes.

After replay timeout, interception stops on taps that are not re-provisioned.

Note

In case high availability is not required, MD waits for entries to age out after fail over. MD cannot change an entry before replay timer expiry. It can either reinstall taps as is, and then modify; or wait for it to age out.
