

## Logging Connections in Network Traffic

---

As devices monitor traffic generated by the hosts on your network, they can generate logs of the connections they detect. Various settings in access control and SSL policies give you granular control over which connections you log, when you log them, and where you store the data. An access control rule's specific logging configuration also determines whether you log file and malware events associated with the connection.

In most cases, you can log a connection at its beginning and its end. When you log a connection, the system generates a *connection event*. You can also log a special kind of connection event, called a *Security Intelligence event*, whenever a connection is blacklisted (blocked) by the reputation-based Security Intelligence feature.

Connection events contain data about the detected sessions.

You should log connections according to the security and compliance needs of your organization.

For more information on logging connection data, see:

- [Deciding Which Connections To Log, page 36-1](#)
- [Logging Security Intelligence \(Blacklisting\) Decisions, page 36-8](#)
- [Logging Connections Based on Access Control Handling, page 36-9](#)
- [Logging URLs Detected in Connections, page 36-13](#)
- [Logging Encrypted Connections, page 36-14](#)

## Deciding Which Connections To Log

**License:** Any

Using various settings in access control and SSL policies, you can log any connection that your ASA FirePOWER module monitors. In most cases, you can log a connection at its beginning and its end. However, because blocked traffic is immediately denied without further inspection, the system can log only beginning-of-connection events for blocked or blacklisted traffic; there is no unique end of connection to log.

When you log a connection event, you can view it in the event viewer. You can also send connection data to an external syslog or SNMP trap server.

**Tip**

---

To perform detailed analysis of connection data using the ASA FirePOWER module, Cisco recommends you log the ends of critical connections.

---

For more information, see:

- [Logging Critical Connections, page 36-2](#)
- [Logging the Beginning and End of Connections, page 36-3](#)
- [Logging Connections to the ASA FirePOWER Module or External Server, page 36-4](#)
- [Understanding How Access Control and SSL Rule Actions Affect Logging, page 36-4](#)
- [License Requirements for Connection Logging, page 36-7](#)

## Logging Critical Connections

**License:** Any

You should log connections according to the security and compliance needs of your organization. If your goal is to limit the number of events you generate and improve performance, only enable logging for the connections critical to your analysis. However, if you want a broad view of your network traffic for profiling purposes, you can enable logging for additional connections. Various settings in access control and SSL policies give you granular control over which connections you log, when you log them, and where you store the data.

### Caution

---

Logging blocked TCP connections during a Denial of Service (DoS) attack can overwhelm the system with multiple similar events. Before you enable logging for an Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

---

In addition to the logging that you configure, the system automatically logs most connections where the system detects a prohibited file, malware, or intrusion attempt. The system saves these end-of-connection events for further analysis. All connection events reflect why they were automatically logged using the Action and Reason fields.

### Security Intelligence Blacklisting Decisions (Optional)

You can log a connection whenever it is blacklisted (blocked) by the reputation-based Security Intelligence feature. Optionally, and recommended in passive deployments, you can use a monitor-only setting for Security Intelligence filtering. This allows the system to further analyze connections that would have been blacklisted, but still log the match to the blacklist.

When you enable Security Intelligence logging, blacklist matches generate Security Intelligence events as well as connection events. A Security Intelligence event is a special kind of connection event that you can view and analyze separately, and that is also stored and pruned separately. For more information, see [Logging Security Intelligence \(Blacklisting\) Decisions, page 36-8](#).

### Access Control Handling (Optional)

You can log a connection when it is handled by an access control rule or the access control default action. You configure this logging on a per-access control rule basis so that you only log critical connections. For more information, see [Logging Connections Based on Access Control Handling, page 36-9](#).

### Connections Associated with Intrusions (Automatic)

When an intrusion policy invoked by an access control rule (see [Tuning Traffic Flow Using Access Control Rules, page 6-1](#)) detects an intrusion and generates an intrusion event, the system automatically logs the end of the connection where the intrusion occurred, regardless of the logging configuration of the rule.

However, when an intrusion policy associated with the access control default action (see [Setting Default Handling and Inspection for Network Traffic, page 4-4](#)) generates an intrusion event, the system does **not** automatically log the end of the associated connection. Instead, you must explicitly enable default action connection logging. This is useful for intrusion prevention-only deployments where you do not want to log any connection data.

For connections where an intrusion was blocked, the action for the connection in the connection log is `Block`, with a reason of `Intrusion Block`, even though to perform intrusion inspection you must use an `Allow` rule.

#### Connections Associated with File and Malware Events (Automatic)

When a file policy invoked by an access control rule detects a prohibited file (including malware) and generates a file or malware event, the system automatically logs the end of the connection where the file was detected, regardless of the logging configuration of the access control rule. You **cannot** disable this logging.

#### Note

---

File events generated by inspecting NetBIOS-ssn (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.

---

For connections where a file was blocked, the action for the connection in the connection log is `Block` even though to perform file and malware inspection you must use an `Allow` rule. The connection's reason is either `File Monitor` (a file type or malware was detected), or `Malware Block` or `File Block` (a file was blocked).

## Logging the Beginning and End of Connections

#### License: Any

When the system detects a connection, in most cases you can log it at its beginning and its end.

However, because blocked traffic is immediately denied without further inspection, in most cases you can log only beginning-of-connection events for blocked or blacklisted traffic; there is no unique end of connection to log.

#### Note

---

For a single non-blocked connection, the end-of-connection event contains all of the information in the beginning-of-connection event, as well as information gathered over the duration of the session.

---

Note that monitoring a connection for any reason forces end-of-connection logging; see [Understanding Logging for Monitored Connections, page 36-5](#).

The following table details the differences between beginning and end-of-connection events, including the advantages to logging each.

**Table 36-1 Comparing Beginning and End-of-Connection Events**

	Beginning-of-Connection Events	End-of-Connection Events
Can be generated...	when the system detects the beginning of a connection (or, after the first few packets if event generation depends on application or URL identification)	when the system: <ul style="list-style-type: none"> <li>• detects the close of a connection</li> <li>• does not detect the end of a connection after a period of time</li> <li>• can no longer track the session due to memory constraints</li> </ul>
Can be logged for...	all connections evaluated by Security Intelligence or access control rules	all connections are configurable, though the system cannot log the end of blocked or blacklisted connections
Contain...	only information that can be determined in the first packet (or the first few packets, if event generation depends on application or URL identification)	all information in the beginning-of-connection event, plus information determined by examining traffic over the duration of the session, for example, the total amount of data transmitted or the timestamp of the last packet in the connection
Are useful...	if you want to log: <ul style="list-style-type: none"> <li>• blocked connections, including Security Intelligence blacklisting decisions</li> </ul>	if you want to: <ul style="list-style-type: none"> <li>• perform any kind of detailed analysis on information collected over the duration of the session</li> <li>• view connection data in graphical format</li> </ul>

## Logging Connections to the ASA FirePOWER Module or External Server

**License:** Any

You can log connection events to the ASA FirePOWER module, as well as to an external syslog or SNMP trap server. Before you can log connection data to an external server, you must configure a connection to that server called an *alert response*; see [Working with Alert Responses](#), page 38-2.

## Understanding How Access Control and SSL Rule Actions Affect Logging

**License:** feature dependent

Every access control and SSL rule has an *action* that determines not only how the system inspects and handles the traffic that matches the rule, but also when and how you can log details about matching traffic.

For more information, see:

- [Using Rule Actions to Determine Traffic Handling and Inspection](#), page 6-6
- [Understanding Logging for Monitored Connections](#), page 36-5
- [Understanding Logging for Trusted Connections](#), page 36-5
- [Understanding Logging for Blocked and Interactively Blocked Connections](#), page 36-5
- [Understanding Logging for Allowed Connections](#), page 36-6

- [Disabling File and Malware Event Logging for Allowed Connections, page 36-7](#)

## Understanding Logging for Monitored Connections

**License:** feature dependent

The system always logs the ends of the following connections to the ASA FirePOWER module, regardless of the logging configuration of the rule or default action that later handles the connection:

- connections matching a Security Intelligence blacklist set to monitor
- connections matching an access control Monitor rule

In other words, if a packet matches a Monitor rule or Security Intelligence monitored blacklist, the connection is always logged, even if the packet matches no other rules and you do not enable logging on the default action. Whenever the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately; see [Logging Security Intelligence \(Blacklisting\) Decisions, page 36-8](#).

Because monitored traffic is always later handled by another rule or by the default action, the action associated with a connection logged due to a monitor rule is never `Monitor`. Rather, it reflects the action of the rule or default action that later handles the connection.

The system does **not** generate a separate event each time a single connection matches an SSL or access control Monitor rule. Because a single connection can match multiple Monitor rules, each connection event logged to the ASA FirePOWER module can include and display information on the first eight Monitor access control rules that the connection matches, as well as the first matching Monitor SSL rule.

Similarly, if you send connection events to an external syslog or SNMP trap server, the system does not send a separate alert each time a single connection matches a Monitor rule. Rather, the alert that the system sends at the end of the connection contains information on the Monitor rules the connection matched.

## Understanding Logging for Trusted Connections

**License:** feature dependent

A trusted connection is one that is handled by a Trust access control rule or the default action in an access control policy. You can log the beginnings and ends of these connections; however, keep in mind that trusted connections, regardless of whether they are encrypted, are not inspected for intrusions, or prohibited files and malware. Therefore, connection events for trusted connections contain limited information.

## Understanding Logging for Blocked and Interactively Blocked Connections

**License:** feature dependent

For access control rules and access control policy default actions that block traffic (including interactive blocking rules), the system logs **beginning**-of-connection events. Matching traffic is denied without further inspection.

Connection events for sessions blocked by an access control or SSL rule have an action of `Block` or `Block with reset`. Blocked encrypted connections have a reason of `SSL Block`.

Interactive blocking access control rules, which cause the system to display a warning page when a user browses to a prohibited website, log ends of connections. This is because if the user clicks through the warning page, the connection is considered a new, allowed connection which the system can monitor and

log; see [Understanding Logging for Allowed Connections, page 36-6](#).

Therefore, for packets that match an Interactive Block or Interactive Block with reset rule, the system can generate the following connection events:

- a beginning-of-connection event when a user's request is initially blocked and the warning page is displayed; this event has an associated action of `Interactive Block Or Interactive Block with reset`
- multiple beginning- or end-of-connection events if the user clicks through the warning page and loads the originally requested page; these events have an associated action of `Allow` and a reason of `User Bypass`

Note that only devices deployed inline can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

#### Caution

Logging blocked TCP connections during a Denial of Service (DoS) attack can overwhelm the system with multiple similar events. Before you enable logging for an Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

## Understanding Logging for Allowed Connections

**License:** feature dependent

Decrypt SSL rules, Do not decrypt SSL rules, and Allow access control rules permit matching traffic to pass to the next phase of inspection and traffic handling.

When you allow traffic with an access control rule, you can use an associated intrusion or file policy (or both) to further inspect traffic and block intrusions, prohibited files, and malware before the traffic can reach its final destination.

Connections for traffic matching an Allow access control rule are logged as follows:

- When an intrusion policy invoked by an access control rule detects an intrusion and generates an intrusion event, the system automatically logs the end of the connection where the intrusion occurred to the ASA FirePOWER module, regardless of the logging configuration of the rule.
- When a file policy invoked by an access control rule detects a prohibited file (including malware) and generates a file or malware event, the system automatically logs the end of the connection where the file was detected to the ASA FirePOWER module, regardless of the logging configuration of the access control rule.
- Optionally, you can enable beginning- and end-of-connection logging for any allowed traffic, including traffic that the system deems safe or that you do not inspect with an intrusion or file policy.

For all of the resulting connection events, the Action and Reason fields reflect why the events were logged. Note that:

- An action of `Allow` represents explicitly allowed and user-bypassed interactively blocked connections that reached their final destination.
- An action of `Block` represents a connection that was at first allowed by an access control rule, but where an intrusion, prohibited file, or malware was detected.

## Disabling File and Malware Event Logging for Allowed Connections

**License:** Protection or Malware

When you allow unencrypted or decrypted traffic with an access control rule, you can use an associated file policy to inspect transmitted files, and block prohibited files and malware before it can reach its destination; see [Tuning Intrusion Prevention Performance, page 11-6](#).

When the system detects a prohibited file, it automatically logs one of the following types of event to the ASA FirePOWER module:

- *file events*, which represent detected or blocked files, including malware files
- *malware events*, which represent detected or blocked malware files only
- *retrospective malware events*, which are generated when the malware disposition for a previously detected file changes

If you do not want to log file or malware events, you can disable this logging on a per-access-control-rule basis by clearing the **Log Files** check box on the Logging tab of the access control rule editor.

**Note**

Cisco recommends you leave file and malware event logging enabled.

Regardless of whether you save file and malware events, when network traffic violates a file policy, the system automatically logs the end of the associated connection to the ASA FirePOWER module, regardless of the logging configuration of the invoking access control rule; see [Connections Associated with File and Malware Events \(Automatic\), page 36-3](#).

## License Requirements for Connection Logging

**License:** feature dependent

Because you configure connection logging in access control and SSL policies, you can log any connection that those policies can successfully handle.

Although you can create access control and SSL policies regardless of the licenses on your ASA FirePOWER module, certain aspects of access control require that you enable specific licensed capabilities before you can apply the policy.

The following table explains the licenses you must have to successfully configure access control, and therefore to log connections handled by an access control policy.

**Table 36-2 License Requirements for Connection Logging in Access Control Policies**

To log connections...	License
for traffic handled using, network, port, or literal URL criteria	Any
for traffic handled using geolocation data	Any
associated with: <ul style="list-style-type: none"> <li>• IP addresses with a poor reputation (Security Intelligence filtering)</li> <li>• intrusions or prohibited files in unencrypted or decrypted traffic</li> </ul>	Protection
associated with malware detected in unencrypted or decrypted traffic	Malware

**Table 36-2 License Requirements for Connection Logging in Access Control Policies (continued)**

To log connections...	License
for traffic handled by user control or application control	Control
for traffic that the system filters using URL category and reputation data, and to display URL category and URL reputation information for URLs requested by monitored hosts	URL Filtering

## Logging Security Intelligence (Blacklisting) Decisions

### License: Protection

As a first line of defense against malicious Internet content, the ASA FirePOWER module includes the Security Intelligence feature, which allows you to immediately blacklist (block) connections based on the latest reputation intelligence, removing the need for a more resource-intensive, in-depth analysis. This traffic filtering takes place **before** any other policy-based inspection, analysis, or traffic handling.

Optionally, and recommended in passive deployments, you can use a monitor-only setting for Security Intelligence filtering. This allows the system to further analyze connections that would have been blacklisted, but still log the match to the blacklist.

Enabling Security Intelligence logging logs all blocked and monitored connections handled by an access control policy. However, the system does not log whitelist matches; logging of whitelisted connections depends on their eventual disposition.

When the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately. Both types of events use the **Action** and **Reason** fields to reflect the blacklist match. Additionally, so that you can identify the blacklisted IP address in the connection, host icons next to blacklisted and monitored IP addresses look slightly different in the event viewer.

### Logging Blocked Blacklisted Connections

For a blocked connection, the system logs beginning-of-connection Security Intelligence and connection events. Because blacklisted traffic is immediately denied without further inspection, there is no unique end of connection to log. For these events, the action is `Block` and the reason is `IP Block`.

`IP Block` connection events have a threshold of 15 seconds per unique initiator-responder pair. That is, once the system generates an event when it blocks a connection, it does not generate another connection event for additional blocked connections between those two hosts for the next 15 seconds, regardless of port or protocol.

### Logging Monitored Blacklisted Connections

For connections monitored—rather than blocked—by Security Intelligence, the system logs end-of-connection Security Intelligence and connection events to the ASA FirePOWER module. This logging occurs regardless of how the connection is later handled by an SSL policy, access control rule, or the access control default action.

For these connection events, the action depends on the connection's eventual disposition. The **Reason** field contains `IP Monitor`, as well as any other reason why the connection may have been logged.

Note that the system may also generate beginning-of-connection events for monitored connections, depending on the logging settings in the access control rule or default action that later handles the connection.

**To log blacklisted connections:**

- 
- Step 1** Select **Configuration > ASA FirePOWER Configuration > Policies > Access Control Policy**.  
The Access Control Policy page appears.
- Step 2** Click the edit icon (✎) next to the access control policy you want to configure.  
The access control policy editor appears.
- Step 3** Select the Security Intelligence tab.  
Security Intelligence settings for the access control policy appear.
- Step 4** Click the logging icon (📄).  
The Blacklist Options pop-up window appears.
- Step 5** Select the **Log Connections** check box.
- Step 6** Specify where to send connection and Security Intelligence events. You have the following choices:
- To send events to the ASA FirePOWER module, select **Event Viewer**.
  - To send events to an external syslog server, select **Syslog**, then select a syslog alert response from the drop-down list. Optionally, you can add a syslog alert response by clicking the add icon (+); see [Creating a Syslog Alert Response, page 38-3](#).
  - To send connection events to an SNMP trap server, select **SNMP Trap**, then select an SNMP alert response from the drop-down list. Optionally, you can add an SNMP alert response by clicking the add icon (+); see [Creating an SNMP Alert Response, page 38-2](#).
- You **must** send events to the **Event Viewer** if you want to set blacklisted objects to monitor-only, or perform any other ASA FirePOWER module-based analysis on connection events generated by Security Intelligence filtering. For more information, see [Logging Connections to the ASA FirePOWER Module or External Server, page 36-4](#).
- Step 7** Click **OK** to set your logging options.  
The Security Intelligence tab appears again.
- Step 8** Click **Store ASA FirePOWER Changes**.  
You must apply the access control policy for your changes to take effect; see [Deploying Configuration Changes, page 4-12](#).
- 

## Logging Connections Based on Access Control Handling

**License:** Any

Within an access control policy, access control rules provide a granular method of handling network traffic. So that you can log only critical connections, you enable connection logging on a per-access-control-rule basis—if you enable connection logging for a rule, the system logs all connections handled by that rule.

You can also log connections for the traffic handled by the default action of your access control policy. The default action determines how the system handles traffic that matches none of the access control rules in the policy (except Monitor rules, which match and log—but do not handle or inspect—traffic).

Note that even if you disable logging for all access control rules and the default action, end-of-connection events may still be logged to the ASA FirePOWER module if the connection matches an access control rule and contains an intrusion attempt, prohibited file, or malware, or if it was decrypted by the system and you enabled logging for the connection in the SSL policy.

Depending on the rule or default policy action and the associated inspection options that you configure, your logging options differ. For more information, see:

- [Logging Connections Matching an Access Control Rule, page 36-10](#)
- [Logging Connections Handled by the Access Control Default Action, page 36-11](#)

## Logging Connections Matching an Access Control Rule

**License:** Any

To log only critical connections, you enable connection logging on a per-access-control-rule basis. If you enable logging for a rule, the system logs all connections handled by that rule.

Depending on the rule action and intrusion and file inspection configuration of the rule, your logging options differ; see [Understanding How Access Control and SSL Rule Actions Affect Logging, page 36-4](#). Also, note that even if you disable logging for an access control rule, end-of-connection events for connections matching that rule may still be logged to the ASA FirePOWER module if the connection:

- contains an intrusion attempt, prohibited file, or malware
- previously matched at least one access control Monitor rule

**To configure an access control rule to log connection, file, and malware information:**

- 
- Step 1** Select **Configuration > ASA FirePOWER Configuration > Policies > Access Control Policy**.  
The Access Control Policy page appears.
- Step 2** Click the edit icon (✎) next to the access control policy you want to modify.  
The access control policy editor appears, focused on the Rules tab.
- Step 3** Click the edit icon (✎) next to the rule where you want to configure logging.  
The access control rule editor appears.
- Step 4** Select the Logging tab.  
The Logging tab appears.
- Step 5** Specify whether you want to **Log at Beginning and End of Connection**, **Log at End of Connection**, or you want **No Logging at Connection**.  
For a single non-blocked connection, the end-of-connection event contains all of the information in the beginning-of-connection event, as well as information gathered over the duration of the session. Because blocked traffic is immediately denied without further inspection, the system logs only beginning-of-connection events for Block rules. For this reason, when you set the rule action to **Block** or **Block with reset** you are prompted **Log at Beginning of Connection**.
- Step 6** Use the **Log Files** check box to specify whether the system should log any file and malware events associated with the connection.  
The system automatically enables this option when you associate a file policy with the rule to perform either file control or AMP. Cisco recommends you leave this option enabled; see [Disabling File and Malware Event Logging for Allowed Connections, page 36-7](#).

**Step 7** Specify where to send connection events. You have the following choices:

- To send connection events to the ASA FirePOWER module, select **Event Viewer**. You cannot disable this option for Monitor rules.
- To send events to an external syslog server, select **Syslog**, then select a syslog alert response from the drop-down list. Optionally, you can add a syslog alert response by clicking the add icon (+); see [Creating a Syslog Alert Response, page 38-3](#).
- To send events to an SNMP trap server, select **SNMP Trap**, then select an SNMP alert response from the drop-down list. Optionally, you can add an SNMP alert response by clicking the add icon (+); see [Creating an SNMP Alert Response, page 38-2](#).

You **must** send events to the event viewer if you want to perform ASA FirePOWER module-based analysis on connection events. For more information, see [Logging Connections to the ASA FirePOWER Module or External Server, page 36-4](#).

**Step 8** Click **Store ASA FirePOWER Changes** to save the rule.

Your rule is saved. You must apply the access control policy for your changes to take effect; see [Deploying Configuration Changes, page 4-12](#).

## Logging Connections Handled by the Access Control Default Action

**License:** Any

You can log connections for the traffic handled by the default action of your access control policy. The default action determines how the system handles traffic that matches none of the access control rules in the policy (except Monitor rules, which match and log—but do not handle or inspect—traffic); see [Setting Default Handling and Inspection for Network Traffic, page 4-4](#).

The mechanisms and options for logging connections handled by the policy default action largely parallel the options for logging connections handled by individual access control rules, as described in the following table. That is, except for blocked traffic, the system logs the beginning and end of connections, and you can send connection events to the ASA FirePOWER module, or to an external syslog or SNMP trap server.

**Table 36-3** Access Control Default Action Logging Options

Default Action	Compare To	See...
Access Control: Block All Traffic	Block rules	<a href="#">Understanding Logging for Blocked and Interactively Blocked Connections, page 36-5</a>
Access Control: Trust All Traffic	Trust rules	<a href="#">Understanding Logging for Trusted Connections, page 36-5</a>
Intrusion Prevention	Allow rules with associated intrusion policies	<a href="#">Understanding Logging for Allowed Connections, page 36-6</a>

However, there are some differences between logging connections handled by access control rules versus the default action:

- The default action has no file logging options. You cannot perform file control or AMP using the default action.
- When an intrusion policy associated with the access control default action generates an intrusion event, the system does **not** automatically log the end of the associated connection. This is useful for intrusion detection and prevention-only deployments, where you do not want to log any connection data.

An exception to this rule occurs if you enable beginning- and end-of-connection logging for the default action. In that case, the system **does** log the end of the connection when an associated intrusion policy triggers, in addition to logging the beginning of the connection.

Note that even if you disable logging for the default action, end-of-connection events for connections matching that rule may still be logged to the ASA FirePOWER module if the connection previously matched at least one access control Monitor rule, or was inspected and logged by an SSL policy.

#### To log connections in traffic handled by the access control default action:

---

**Step 1** Select **Configuration > ASA FirePOWER Configuration > Policies > Access Control Policy**.

The Access Control Policy page appears.

**Step 2** Click the edit icon (✎) next to the access control policy you want to modify.

The access control policy editor appears, focused on the Rules tab.

**Step 3** Click the logging icon (📄) next to the **Default Action** drop-down list.

The Logging pop-up window appears.

**Step 4** Specify whether you want to **Log at Beginning and End of Connection**, **Log at End of Connection**, or you want **No Logging at Connection**.

For a single non-blocked connection, the end-of-connection event contains all of the information in the beginning-of-connection event, as well as information gathered over the duration of the session. Because blocked traffic is immediately denied without further inspection, the system logs only beginning-of-connection events for the Block All Traffic default action. For this reason, when you set the default action to **Access Control: Block All Traffic** you are prompted **Log at Beginning of Connection**.

**Step 5** Specify where to send connection events. You have the following choices:

- To send connection events to the ASA FirePOWER module, select **Event Viewer**. You cannot disable this option for Monitor rules.
- To send events to an external syslog server, select **Syslog**, then select a syslog alert response from the drop-down list. Optionally, you can add a syslog alert response by clicking the add icon (+); see [Creating a Syslog Alert Response, page 38-3](#).
- To send events to an SNMP trap server, select **SNMP Trap**, then select an SNMP alert response from the drop-down list. Optionally, you can add an SNMP alert response by clicking the add icon (+); see [Creating an SNMP Alert Response, page 38-2](#).

You **must** send events to the event viewer if you want to perform ASA FirePOWER module-based analysis on connection events. For more information, see [Logging Connections to the ASA FirePOWER Module or External Server, page 36-4](#).

- Step 6** Click **Store ASA FirePOWER Changes** to save the policy.
- Your policy is saved. You must apply the access control policy for your changes to take effect; see [Deploying Configuration Changes, page 4-12](#).
- 

## Logging URLs Detected in Connections

**License:** Any

When you log an end-of-connection event to the ASA FirePOWER module for HTTP traffic, the system records the URL requested by the monitored host during the session.

By default, the system stores the first 1024 characters of the URL in the connection log. However, you can configure the system to store up to 4096 characters per URL to make sure you capture the full URLs requested by monitored hosts. Or, if you are uninterested in the individual URLs visited, you can disable URL storage entirely by storing zero characters. Depending on your network traffic, disabling or limiting the number of stored URL characters may improve system performance.

Note that disabling URL logging does not affect URL filtering. Access control rules properly filter traffic based on requested URLs, their categories, and reputations, even though the system does not record the individual URLs requested in the traffic handled by those rules. For more information, see [Blocking URLs, page 8-7](#).

**To customize the number of URL characters you store:**

---

- Step 1** Select **Configuration > ASA FirePOWER Configuration > Policies > Access Control Policy**.
- The Access Control Policy page appears.
- Step 2** Click the edit icon (✎) next to the access control policy you want to configure.
- The access control policy editor appears.
- Step 3** Select the Advanced tab.
- Advanced settings for the access control policy appear.
- Step 4** Click the edit icon (✎) next to General Settings.
- The General Settings pop-up window appears.
- Step 5** Type the **Maximum URL characters to store in connection events**.
- You can specify any number from zero to 4096. Storing zero characters disables URL storage without disabling URL filtering.
- Step 6** Click **OK**.
- Advanced settings for the access control policy appear.
- Step 7** Click **Store ASA FirePOWER Changes** to save the policy.
- Your policy is saved. You must apply the access control policy for your changes to take effect; see [Deploying Configuration Changes, page 4-12](#).
-

# Logging Encrypted Connections

**License:** Any

As part of access control, the *SSL inspection* feature allows you to use an SSL policy to decrypt encrypted traffic for further evaluation by access control rules. You can force the system to log these decrypted connections, regardless of how the system later handles or inspects the traffic. You can also log connections when you block encrypted traffic, or when you allow it to pass to access control rules without decryption.

Connection logs for encrypted sessions contain details about the encryption, such as the certificate used to encrypt that session. You configure connection logging for encrypted sessions in the SSL policy on a per-SSL rule basis so that you only log critical connections.

For more information, see the following sections:

- [Logging Decryptable Connections with SSL Rules, page 36-14](#)
- [Setting Default Logging for Encrypted and Undecryptable Connections, page 36-15](#)

## Logging Decryptable Connections with SSL Rules

**License:** Any

Within an SSL policy, *SSL rules* provide a granular method of handling encrypted traffic across multiple managed devices. So that you can log only critical connections, you enable connection logging on a per-SSL-rule basis—if you enable connection logging for a rule, the system logs all connections handled by that rule.

For encrypted connections inspected by an SSL policy, you can log connection events to an external syslog or SNMP trap server. You can log only end-of-connection events, however:

- for blocked connections (Block, Block with reset), the system immediately ends the session and generates an event
- for monitored connections (Monitor) and connections that you pass to access control rules (Decrypt, Do not decrypt), the system generates an event when the session ends, regardless of the logging configuration of the access control rule or default action that later handles it

For more information, see [Understanding How Access Control and SSL Rule Actions Affect Logging, page 36-4](#).

**To log decryptable connections:**

- 
- Step 1** Select **Configuration > ASA FirePOWER Configuration > Policies > SSL**.  
The SSL Policy page appears.
  - Step 2** Click the edit icon (✎) next to the rule where you want to configure logging.  
The SSL rule editor appears.
  - Step 3** Select the Logging tab.  
The Logging tab appears.
  - Step 4** Select **Log at End of Connection**.
  - Step 5** Specify where to send connection events. You have the following choices:

- To send events to an external syslog, select **Syslog**, then select a syslog alert response from the drop-down list. Optionally, you can add a syslog alert response by clicking the add icon (  ); see [Creating a Syslog Alert Response, page 38-3](#).
- To send events to an SNMP trap server, select **SNMP Trap**, then select an SNMP alert response from the drop-down list. Optionally, you can add an SNMP alert response by clicking the add icon (  ); see [Creating an SNMP Alert Response, page 38-2](#).

**Step 6** Click **Add** to save your changes.

You must apply the access control policy the SSL policy is associated with for your changes to take effect; see [Deploying Configuration Changes, page 4-12](#).

## Setting Default Logging for Encrypted and Undecryptable Connections

### License: SSL

You can log connections for the traffic handled by the default action of your SSL policy. These logging settings also govern how the system logs undecryptable sessions.

The SSL policy default action determines how the system handles encrypted traffic that matches none of the SSL rules in the policy (except Monitor rules, which match and log—but do not handle or inspect—traffic). If your SSL policy does not contain any SSL rules, the default action determines how all encrypted sessions on your network are logged. For more information, see [Setting Default Handling and Inspection for Encrypted Traffic, page 15-3](#).

You can configure the SSL policy default action to log connection events to an external syslog or SNMP trap server. You can log only end-of-connection events, however:

- for blocked connections (Block, Block with reset), the system immediately ends the sessions and generates an event
- for connections that you allow to pass unencrypted to access control rules (Do not decrypt), the system generates an event when the session ends

Note that even if you disable logging for the SSL policy default action, end-of-connection events may still be logged if the connection previously matched at least one SSL Monitor rule, or later matches an access control rule or the access control policy default action.

### To set the default handling for encrypted and undecryptable traffic:

**Access:** Admin/Access Admin/Network Admin/Security Approver

---

**Step 1** Select **Configuration > ASA FirePOWER Configuration > Policies > SSL**.

The SSL Policy page appears.

**Step 2** Click the logging icon (  ) next to the **Default Action** drop-down list.

The Logging pop-up window appears.

**Step 3** Select **Log at End of Connection** to enable logging connection events.

**Step 4** Specify where to send connection events. You have the following choices:

- To send events to an external syslog server, select **Syslog**, then select a syslog alert response from the drop-down list. Optionally, you can configure a syslog alert response by clicking the add icon (  ); see [Creating a Syslog Alert Response, page 38-3](#).

- To send events to an SNMP trap server, select **SNMP Trap**, then select an SNMP alert response from the drop-down list. Optionally, you can configure an SNMP alert response by clicking the add icon (+); see [Creating an SNMP Alert Response, page 38-2](#).

**Step 5** Click **OK** to save your changes.

You must apply the access control policy the SSL policy is associated with for your changes to take effect; see [Deploying Configuration Changes, page 4-12](#).
