Advanced Configuration

Some device features are configured using ASA configuration commands. Although the FDM can configure many command-based features, it does not support all of them. If you need to use some of these ASA features that are not otherwise supported in the FDM, you can use Smart CLI or FlexConfig to manually configure the features.

The following topics explain this type of advanced configuration in more detail.

About Smart CLI and FlexConfig

FTD uses ASA configuration commands to implement some features, but not all features. There is no unique set of the FTD configuration commands.

You can configure features using the CLI using the following methods:

- **Smart CLI**—(Preferred method.) A Smart CLI template is a pre-defined template for a particular feature. All of the commands needed for the feature are provided, and you simply need to select values for variables. The system validates your selection, so that you are more likely to configure a feature correctly. If a Smart CLI template exists for the feature you want, you must use this method.

- **FlexConfig**—The FlexConfig policy is a collection of FlexConfig objects. The FlexConfig objects are more free-form than Smart CLI templates, and the system does no CLI, variable, or data validation. You must know ASA configuration commands and follow the ASA configuration guides to create a valid sequence of commands.

The point of Smart CLI and FlexConfig is to allow you to configure features that are not directly supported through FDM policies and settings.

⚠️

Caution Cisco strongly recommends using Smart CLI and FlexConfig only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through Smart CLI and FlexConfig may cause unintended results with other configured features.

You may contact the Cisco Technical Assistance Center for support concerning Smart CLI and FlexConfig objects that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other FTD features. Smart CLI and FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for the FDM support. When in doubt, do not use Smart CLI or FlexConfig.

The following topics explain these features in more detail.

Recommended Usage for Smart CLI and FlexConfig

There are two main recommended uses for FlexConfig:

- You are migrating from ASA to FTD, and there are compatible features you are using (and need to continue using) that the FDM does not directly support. In this case, use the **show running-config** command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Verify by comparing **show running-config** output on the two devices.

- You are using the FTD but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

Before trying to recreate an ASA configuration, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control, which the ASA implements using separate features. Because many features are not configured using CLI commands, you will not see every policy represented within the output of **show running-config**.

✎

Note At all times, keep in mind that there is not a one-to-one overlap between ASA and FTD. Do not attempt to completely recreate an ASA configuration on the FTD device. You must carefully test any feature that you configure using FlexConfig.

CLI Commands in Smart CLI and FlexConfig Objects

The FTD uses ASA configuration commands to configure some features. Although not all ASA features are compatible with FTD, there are some features that can work on the FTD but that you cannot configure in the FDM policies. You can use Smart CLI and FlexConfig objects to specify the CLI required to configure these features.

If you decide to use Smart CLI or FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig does not validate CLI command

syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

- ASA CLI configuration guides explain how to configure a feature. Find the guides at http://www.cisco.com/c/en/us/support/security/asa-5500-series-next-generation-firewalls/products-installation-and-configuration-guides-list.html

- ASA command references provide additional information sorted by command name. Find the references at http://www.cisco.com/c/en/us/support/security/asa-5500-series-next-generation-firewalls/products-command-reference-list.html

The following topics explain more about configuration commands.

Determine the ASA Software Version and Current CLI Configuration

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the FTD device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from the FTD configuration. Many FTD policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and FTD configuration.

To view this information, either open the CLI Console in the FDM or make an SSH connection to the device's management interface and issue the following commands:

- **show version system** and look for the Cisco Adaptive Security Appliance Software Version number.

- **show running-config** to view the current CLI configuration.

- **show running-config all** to include all the default commands in the current CLI configuration.

Prohibited CLI Commands

The purpose of Smart CLI and FlexConfig is to configure features that are available on ASA devices that you cannot configure on the FTD devices using the FDM.

Thus, you are prevented from configuring ASA features that have equivalents in the FDM. The following table lists some of these prohibited command areas. This list contains many parent commands that enter configuration modes. The prohibition of the parent includes the prohibition of the children commands. It also includes the **no** version of the commands and their associated **clear** commands.

The FlexConfig object editor prevents you from including these commands in the object. This list does not apply to Smart CLI templates, as they include only those commands you can validly configure.

Prohibited CLI Command	Comments
aaa	Use **Objects** > **Identity Realm**.
aaa-server	Use **Objects** > **Identity Realm**.
access-group	Use **Policies** > **Access Control** to configure access rules.

Prohibited CLI Command	Comments
access-list	Partially blocked. • You can create **extended** and **standard** access lists and use them matching criteria in commands others than **access-group**. For example, you could use extended access lists for match criteria in service policy rules. • You can create **ethertype** access lists. • You cannot create **advanced** access lists, which the system uses with the **access-group** command. Instead, use **Policies** > **Access Control** to configure access rules. • You cannot create **webtype** access lists.
anyconnect-custom-data	Use **Device** > **Remote Access VPN** to configure AnyConnect Client.
asdm	This feature does not apply to a FTD system.
attribute	—
auth-prompt	This feature does not apply to a FTD system.
boot	—
call-home	—
captive-portal	Use **Policies** > **Identity** to configure the captive portal used for active authentication.
clear	—
client-update	—
clock	Use **Device** > **System Settings** > **NTP** to configure system time.
cluster	—
command-alias	—
compression	—
configure	—
crypto	On the **Objects** page, use **Certificates**, **IKE Policies**, and **IPSec Proposals**.
dhcp-client	—
dhcpd	Use **Device** > **System Settings** > **DHCP Server**.
dns	—
domain-name	—

Prohibited CLI Command	Comments
dynamic-access-policy-config dynamic-access-policy-record	—
enable	—
event	—
failover	—
fips	—
firewall	FDM supports routed firewall mode only.
hostname	Use **Device** > **System Settings** > **Hostname**.
hpm	This feature does not apply to a FTD system.
http	Use the **Data Interfaces** tab on **Device** > **System Settings** > **Management Access**.
inline-set	—

interface for BVI, Management, Ethernet, GigabitEthernet, and subinterfaces.	Partially blocked.
	
	Configure physical interfaces, subinterfaces, and Bridge Virtual Interfaces on the **Device** > **Interfaces** page. You can then configure additional options using FlexConfig.
	
	However, the following **interface** mode commands are prohibited for these types of interface.
	
	    cts
	    ip address
	    ip address dhcp
	    ipv6 address
	    ipv6 enable
	    ipv6 nd dad
	    ipv6 nd suppress-ra
	    mode
	    nameif
	    security-level
	    shutdown
	    zone-member

interface for **vni**, **redundant**, **tunnel**, **portchannel**	Configure interfaces on the **Device** > **Interfaces** page. FDM does not support these types of interface.
ip audit	This feature does not apply to a FTD system. Instead, apply intrusion policies using access control rules.

Prohibited CLI Command	Comments
ip-client	To configure the system to use data interfaces as the management gateway, use **Device** > **System Settings** > **Management Interface**.
ip local pool	Use **Device** > **Remote Access VPN** to configure address pools.
ipsec	—
ipv6	—
ipv6-vpn-addr-assign	Use **Device** > **Remote Access VPN** to configure address pools.
isakmp	Use **Device** > **Site-to-Site VPN**.
jumbo-frame	The system automatically enables jumbo frame support if you increase the MTU of any interface over the default 1500.
ldap	—
license-server	Use **Device** > **Smart License**.
logging	Use **Objects** > **Syslog Servers** and **Device** > **System Settings** > **Logging Settings**.
management-access	—
migrate	Use **Device** > **Remote Access VPN** and **Device** > **Site-to-Site VPN** to enable IKEv2 support.
mode	FDM supports single context mode only.
mount	—
mtu	Configure MTU per interface on **Device** > **Interfaces**.
nat	Use **Policies** > **NAT**.
ngips	—
ntp	Use **Device** > **System Settings** > **NTP**
object-group network object network	Use **Objects** > **Network**. You cannot create network objects or groups in FlexConfig, but you can use network objects and groups defined in the object manager inside the template as variables.
object service |natorigsvc object service |natmappedsvc	The **object service** command is allowed in general, but you cannot edit the internal objects named |natorigsvc or |natmappedsvc. In these names, the vertical bar is intentional and it is the first character of the restricted object names.
passwd password	—

Prohibited CLI Command	Comments
password-policy	—
policy-map sub-commands	You cannot configure the following commands in a policy map. **priority** **police** **match tunnel-group**
priority-queue	—
privilege	—
reload	You cannot schedule reloads. The system does not use the **reload** command to restart the system, it uses the **reboot** command.
rest-api	This feature does not apply to a FTD system. The REST API is always installed and enabled.
route	Use **Device** > **Routing** to configure static routes.
router ospf	Use the Smart CLI templates for OSPF.
scansafe	This feature does not apply to a FTD system. Instead, configure URL filtering in access control rules.
setup	This feature does not apply to a FTD system.
sla	—
ssh	Use the **Data Interfaces** tab on **Device** > **System Settings** > **Management Access**.
ssl	—
telnet	FTD does not support Telnet connections. Use SSH instead of Telnet to access the device CLI.
time-range	—
tunnel-group	Use **Device** > **Remote Access VPN** and **Device** > **Site-to-Site VPN**.
tunnel-group-map	Use **Device** > **Remote Access VPN** and **Device** > **Site-to-Site VPN**.
user-identity	Use **Policies** > **Identity**.
username	To create CLI users, open an SSH or console session to the device and use the **configure user** commands.
vpdn	—
vpn	—
vpn-addr-assign	—

Prohibited CLI Command	Comments
vpnclient	—
vpn-sessiondb	—
vpnsetup	—
webvpn	—
zone	—
zonelabs-integrity	This feature does not apply to a FTD system.

Smart CLI Templates

The following table explains the Smart CLI templates based on the feature.

Feature	Templates	Description
Routing: OSPFv2	OSPF Interface	Use the OSPF template to configure the routing process, and the Interface template to configure per-interface OSPF behavior. **Tips:** • If you intend to redistribute routes from other routing processes, you should first configure those processes. For example, before configuring OSPF to redistribute EIGRP routes, first create and deploy the FlexConfig object that configures EIGRP. • You can configure up to 2 OSPF processes.

Guidelines and Limitations for Smart CLI and FlexConfig

Please keep the following in mind when configuring features through Smart CLI or FlexConfig.

• The commands defined in FlexConfig objects are deployed after all commands for features defined through FDM, including Smart CLI. Thus, you can depend on objects, interfaces, and so forth being configured before these commands are issued to the device. If you need to use a FlexConfig-deployed item in a Smart CLI template, create and deploy the FlexConfig before creating and deploying the Smart CLI template. For example, if you want to use the OSPF Smart CLI template to redistribute EIGRP routes, first use FlexConfig to configure EIGRP, then create the OSPF Smart CLI template.

• If you want to remove a feature or part of a feature that you configured through FlexConfig, but a Smart CLI template refers to that feature, you must first remove the commands in the Smart CLI template that use the feature. Then, deploy the configuration so that the Smart-CLI configured feature no longer refers to it. You can then remove the feature from FlexConfig and redeploy the configuration to finally eliminate it altogether.

Configuring Smart CLI Objects

Smart CLI objects define features that cannot be configured elsewhere in the FDM. Smart CLI objects provide a level of guidance in configuring a feature. For a given feature (template), all possible commands are pre-loaded, and the variables you enter are validated. Thus, although you still use CLI commands to configure a feature, Smart CLI objects are not as free-form as FlexConfig objects.

Although Smart CLI templates do provide a level of guidance, you must still read the ASA configuration guides and command references to understand the command usage so that you pick values that work correctly for your network. Ideally, you already have an ASA configuration to work from, and you merely need to build the same sequence of commands in the Smart CLI object.

Smart CLI objects are grouped according to feature area.

Note   All Smart CLI objects that you define are deployed. Unlike FlexConfig, you cannot create several Smart CLI objects and then select which of them to deploy. Create Smart CLI objects only for those features you want to configure.

Procedure

Step 1   Click **View Configuration** in **Device** > **Advanced Configuration**.

Step 2   Click the appropriate feature area under **Smart CLI** in the Advanced Configuration table of contents.

Step 3   Do one of the following:

- To create an object, click the + button.

- To edit an object, click the edit icon ( ) for the object.

To delete an object, click the trash can icon ( ) for the object.

Step 4   Enter a Name for the object and optionally, a description.

Step 5   Select the **CLI Template** for the feature you are configuring.

The system loads the command template into the **Template** window. Initially, only the required commands are shown. These represent the minimum configuration required for the template.

Note   Some features require more than one template. For example, to configure OSPFv2, you need to create two Smart CLI objects, using the **OSPF** and the **Interface** templates. Note that you cannot use the OSPF template to configure OSPFv3.

Step 6   Fill in the variables and add commands as needed in the template.

Ideally, you are working with an existing configuration from an ASA or FTD device (one that is managed by the FMC). With a configuration in hand, you simply need to make the template conform to it, changing variables such as IP addresses and interface names as appropriate for the location of this specific device in your network.

Following are some tips for filling in the template:

- To select a value for a variable, click the variable and either type in the appropriate value, or select it from a list (in the case of enumerated values). Mousing over variables that require typing shows the valid values for the option, such as a range of numbers. In some cases, the recommended value is mentioned.

  For example, in the OSPF template, the required command **router ospf** *process-id* shows "Process ID (1-65535)" on mouse-over, and when you click *process-id*, the field is highlighted. Simply type in the number you want.

- When you select an option for a variable, if there are additional possible commands to configure the option, these are automatically exposed and disabled or enabled as appropriate. Watch for these additional commands.

- Use the **Show**/**Hide Disabled** link above the template to control your view. Disabled commands will not be configured, but you must display them to configure them. To see the full template, click the **Show Disabled** link above the template. To see only those commands that will be configured, click the **Hide Disabled** link above the table.

- To clear all of your edits since you last saved the object, click the **Reset** link above the template.

- To enable an optional command, click the + button to the left of the line number.

- To disable an optional command, click the **-** button to the left of the line number. If you edited the line, your edits are not deleted.

- To duplicate a command, click the Options **...** button and select **Duplicate**. You are allowed to duplicate commands only if it is valid to enter the command more than once.

- To delete a duplicated command, click the Options **...** button and select **Delete**. You cannot delete the commands that are a part of the base template.

Step 7 Click **OK**.

Configuring the FlexConfig Policy

The FlexConfig Policy is simply a list of the FlexConfig objects that you want to deploy to the device configuration. Only those objects included in the policy are deployed, all others are simply defined and unused.

The commands defined in FlexConfig objects are deployed after all commands for features defined through FDM, including Smart CLI. Thus, you can depend on objects, interfaces, and so forth being configured before these commands are issued to the device. If you need to use a FlexConfig-deployed item in a Smart CLI template, create and deploy the FlexConfig before creating and deploying the Smart CLI template. For example, if you want to use the OSPF Smart CLI template to redistribute EIGRP routes, first use FlexConfig to configure EIGRP, then create the OSPF Smart CLI template.

Note If there is a Smart CLI template for a feature, you cannot configure it using FlexConfig. You must use the Smart CLI object.

Before you begin

Create the FlexConfig objects. See the following topics:

Procedure

Step 1   Click **View Configuration** in **Device** > **Advanced Configuration**.

Step 2   Click **FlexConfig** > **FlexConfig Policy** in the Advanced Configuration table of contents.

Step 3   Manage the list of objects in the **Group List**.

- To add an object, click the + button. If the object does not yet exist, click **Create New FlexConfig Object** to define it.

- To delete an object, click the **X** button at the right of the object entry.

Note   We recommend that each object be completely self-contained and not depend on the configuration defined in any other FlexConfig object. This ensures that you can add or remove objects without affecting other objects. Although you can reposition the objects in the list, the order is not saved and it does not change the order in which the objects are deployed.

Step 4   Evaluate the proposed commands in the **Preview** pane.

You can click the **Expand** button (and subsequently, **Collapse**) to widen the screen so you can see long commands more clearly.

The preview evaluates variables and produces the exact commands that will be issued. Ensure that these commands are correct and valid. You are responsible for ensuring the commands will not result in errors or poor configurations that make the device unusable.

Caution   The system does not validate the commands. It is possible for you to deploy invalid and even potentially destructive commands. Examine the preview very carefully before deploying changes.

Step 5   Click **Save**.

What to do next

After editing the FlexConfig policy, carefully examine the results of the next deployment. If there are errors, correct the CLI in the object. See .

Configuring FlexConfig Objects

A FlexConfig object contains the ASA commands required to configure a particular feature that you cannot otherwise configure using the FDM. You are responsible for ensuring that you enter the right sequence of commands, without typos. The system does not validate the content of FlexConfig objects.

We recommend that you create separate objects for each general feature you intend to configure. For example, if you want to define banners and also configure the RIP routing protocol, use 2 separate objects. Isolating

features in separate objects makes it easier for you to pick and choose which to objects to deploy, and also makes troubleshooting more straight-forward.

Note   Do not include the **enable** and **configure terminal** commands. The system enters the right mode for configuration commands automatically.

Procedure

Step 1   Click **View Configuration** in **Device** > **Advanced Configuration**.

Step 2   Click **FlexConfig** > **FlexConfig Objects** in the Advanced Configuration table of contents.

Step 3   Do one of the following:

- To create an object, click the + button.

- To edit an object, click the edit icon ( ) for the object.

To delete an unreferenced object, click the trash can icon ( ) for the object.

Step 4   Enter a Name for the object and optionally, a description.

Step 5   In the **Variables** section, create any variables that you want to use in the object body.

The only variables that you must create are those that point to objects defined within the FDM, specifically, the Network, Port, and Secret Key variable types, or the Interface variable, which points to a named interface. For other variable types, you can simply type in the values into the object body.

For detailed information on creating and using variables, see .

Step 6   In the **Template** section, type in the ASA commands required to configure the feature.

You must enter commands in the right order for configuring the feature. Use the ASA CLI configuration guides to learn how to enter the commands. Ideally, you should have a pre-tested configuration file from an ASA or another FTD device that you can use as a reference.

You can also use Mustache notation to refer to and process variables. For detailed information, see .

Following are some tips for creating the object body:

- To add lines, put the cursor at the end of a line and press Enter.

- To use a variable, type the variable name between double-braces: {{*variable_name*}}. For variables that refer to objects, you must include the attribute whose value you are retrieving: {{*variable_name.attribute*}}. The available attributes differ based on object type. For complete information, see .

- Click the **Expand/Collapse** link above the template body to make the body larger or smaller.

- Click the **Reset** link to erase any changes you made since you last saved the object.

Step 7 In the **Negate Template** section, enter the commands needed to remove or reverse the commands configured in the object body.

The Negate section is very important and serves two purposes:

- It simplifies deployment. Before re-deploying the commands in the body, the system uses these commands to first erase or undo the configuration. This ensures a clean deployment.

- If you decide to remove the feature by removing the object from the FlexConfig Policy, the system uses these commands to remove the commands from the device.

If you do not supply the commands needed to negate or reverse the CLI in the object body, the deployment might need to clear the entire device configuration and redeploy all policies, not just the commands within the object. This will make deployment take longer and also disrupt traffic. Ensure that you have all, and only, those commands needed to undo the configuration defined in the object body. Although negate commands are typically the **no** or **clear** form of the commands in the template, if you are actually turning off a feature that was already enabled, the "negate" command is actually the positive form of the command, the one that enables the feature.

Use the ASA configuration guides and command reference to determine the appropriate commands. Sometimes, you can undo a configuration with a single command. For example, in an object that configures RIP, a simple **no router rip** command removes the entire **router rip** configuration, including subcommands.

Likewise, if you entered several **banner login** commands to create a multi-line banner, a single **no banner login** command negates the entire login banner.

If your template creates several nested objects, the negate template needs to remove the objects in reverse order, to first remove references to the objects before deleting the objects. For example, if you first create an ACL, then refer to it in a traffic class, then refer to the traffic class in a policy map, and finally enable the policy map using a service policy, the negate template must undo the configuration by first removing the service policy, then the policy map, then the traffic class, and finally the ACL.

Step 8 Click **OK**.

What to do next

Simply creating a FlexConfig object is not enough to get it deployed. You must add the object to the FlexConfig Policy. Only those objects in the FlexConfig policy get deployed. This makes it possible for you to refine your FlexConfig objects, and have some ready for special uses, without having all of them automatically deployed. See .

Creating Variables in a FlexConfig Object

The variables you use inside a FlexConfig object are defined within the object itself. There is no separate list of variables. Thus, you cannot define a variable and then use it within separate FlexConfig objects.

Variables provide these main benefits:

- They make it possible to point to objects defined using the FDM. This includes network, port, and secret key objects.

- They isolate values that might change from the object body. Thus, if you need to change a value, you simply edit the variable and you do not need to edit the object body. This can be especially helpful if you need to refer to the object in several command lines.

This procedure explains the process of adding variables to a FlexConfig object.

Procedure

Step 1   Edit or create a FlexConfig object from the **Device** > **Advanced Configuration** page.

See Configuring FlexConfig Objects, on page 11.

Step 2   Do one of the following in the **Variables** section:

- To add a variable, click the + button (or click **Add Variable** if there are none yet defined).

- To edit a variable, click the edit icon ( ) for the variable.

To delete a variable, click the trash can ( ) icon for the variable. Make sure you remove any references to it from the template body.

Step 3   Enter a Name for the variable and optionally, a description.

Step 4   Select a data **Type** for the variable, then enter or select the value.

You can create the following types of variable. Choose a type that fits the data requirements of the commands in which you will use the variable.

- **String**—A text string. For example, hostnames, usernames, and so forth.

- **Numeric**—An integer number. Do not include commas, decimals, signs (such as negative), or hexadecimal notation. For non-integer numbers, use a string variable.

- **Boolean**—A logical true/false. Select either True or False.

- **Network**—A network object or group defined on the Objects page. Select the network object or group.

- **Port**—A TCP or UDP port object defined on the Objects page. Select the port object. You cannot select groups or objects for other protocols.

- **Interface**—A named interface defined on the Device > Interfaces page. Select the interface. You cannot select interfaces that have no names.

- **IP**—A single IPv4 or IPv6 IP address without netmask or prefix length.

- **Secret**—A secret key object defined for FlexConfig. Select the object. For information on creating secret key objects, see Configuring Secret Key Objects, on page 19.

Step 5   Click **Add** or **Save** in the Variable dialog box.

You can now use the variable within the body of the FlexConfig object. The way you refer to the variable differs based on variable type. For details on how to use these variables, see the following topics:

- Variable References: {{variable}} , on page 15

- Sections {{#key}} {{/key}} and Inverse Sections {{^key}} {{/key}}, on page 17

Step 6   Click **OK** in the FlexConfig Object dialog box.

Referring to FlexConfig Variables and Retrieving Values

FlexConfig uses Mustache as the template language, but support is limited to the features explained in the following sections. Use these features to refer to variables, retrieve their values, and process them.

Variable References: {{variable}}

To refer to a variable, which you define within a FlexConfig object, you use the following notation:

{{*variable_name*}}

This is sufficient for simple variables that are single values, which includes variables of the following types: **Numeric**, **String**, **Boolean**, and **IP**.

However, for variables that point to elements that are modeled as objects in the configuration database, you must use dot notation and include the name of the object attribute you want to retrieve. You can find these attribute names by examining the models in the API Explorer for the related object type. You must use the following notation to use variables of the following types: **Secret**, **Network**, **Port**, and **Interface**.

{{*variable_name.attribute*}}

For example, to retrieve the address from a network variable named net-object1 (which points to a network object, not a network group), you would use:

{{net-object1.value}}

If you are trying to retrieve an attribute value from an object within an object, you need to use a series of dotted attributes to drill down to the desired value. For example, the IP addresses for an interface are modeled as sub-objects, named ipv4 and ipv6, to the interface object. Thus, to retrieve the IPv4 address and subnet mask for an interface variable named int-inside (which points to the inside interface), you would use:

{{int-inside.ipv4.ipAddress.ipAddress}} {{int-inside.ipv4.ipAddress.netmask}}

Note   To open API Explorer, change the last part of the URL in the browser to /#/api-explorer.

The following table lists the variable types, how to refer to them, and for objects, the name of the API model and the most likely references that you might use.

Variable Type	Reference Models	Description

Boolean
 	
(simple variable)
	Variable:
	
	{{*variable_name*}}
	
	Section:
	
	`{{#variable_name}}`
	`commands`
	`{{/variable_name}}`
	
	Inverse Section:
	
	`{{^variable_name}}`
	`commands`
	`{{/variable_name}}`
		A logical true/false. The main purpose for Boolean variables is for sections or inverse sections. You can edit the value of a Boolean variable to turn a section of commands on or off, for example, if you need to enable a feature periodically or under special circumstances only.
		
		Some objects also have Boolean attributes in their models, which you can use to provide optional processing of a section.

Interface
 	
(object variable: API model is Interface)
	Variable:
	
	{{*variable_name.attribute*}}
	
	Section:
	
	`{{#variable_name.attribute}}`
	`commands`
	`{{/variable_name.attribute}}`
	
	Inverse Section:
	
	`{{^variable_name.attribute}}`
	`commands`
	`{{/variable_name.attribute}}`
		A named interface defined on the Device > Interfaces page. You cannot point to unnamed interfaces.
		
		There is a wide variety of attributes available in the interface model. Also, the interface model includes sub-objects, for example, for IP addresses.
		
		Following are some of the main attributes that you might find useful:
		
		• *variable_name*.**name** returns the logical name of the interface.
		
		• *variable_name*.**hardwareName** returns the interface port name, such as GigabitEthernet1/8.
		
		• *variable_name*.**managementOnly** is a Boolean value. TRUE means that the interface is defined as management only. FALSE means the interface is for through-the-device traffic. You could use this option as a section key.
		
		• *variable_name*.**ipv4.ipAddress.ipAddress** returns the IPv4 address for the interface.
		
		• *variable_name*.**ipv4.ipAddress.netmask** returns the subnet mask for the IPv4 address for the interface.

IP (simple variable)	**Variable:** {{*variable_name*}}	A single IPv4 or IPv6 IP address without netmask or prefix length.

Variable Type	Reference Models	Description

Network
 	
(object variable: API model is NetworkObject)
	Variable (Network Objects):
	
	{{*variable_name.attribute*}}
	
	Section (Group Objects):
	
	{{#*variable_name*.**networkObjects**}}
	commands referring to one of
	  {{**value**}}
	  {{**name**}}
	{{/*variable_name*.**networkObjects**}}
		A network object or group defined on the Objects page. You can use sections to process network groups.
		
		Following are the main attributes that you might find useful:
		
		• {{*variable_name*.**name**}} returns the name of the network object or group.
		
		• {{*variable_name*.**value**}} returns the IP address contents of a network object (but not a network group). Ensure that you use a network object that has the right type of contents for a given command, for example, a host address rather than a subnet address.
		
		• {{*variable_name*.**groups**}} returns the list of network objects contained within a network group. Use this only with variables that point to network groups, and use it on a section tag to iteratively process the contents of the group. Use either {{**value**}} or {{**name**}} to retrieve the contents of each network object in turn.

Numeric (simple variable)	**Variable:** {{*variable_name*}}	An integer number. Do not include commas, decimals, signs (such as negative), or hexadecimal notation. For non-integer numbers, use a string variable.
Port (object variable: API model is PortObject, tcpports or udpports)	**Variable:** {{*variable_name.attribute*}}	A TCP or UDP port object defined on the Objects page. This must be a port object, not a port group. Following are the main attributes that you might find useful: • {{*variable_name*.**port**}} returns the port number. The protocol is not included. • {{*variable_name*.**name**}} returns the name of the port object.
Secret (object variable: API model is Secret)	**Variable:** {{*variable_name*.**password**}}	A secret key object defined for FlexConfig. The only reference you should make is to the **password** attribute, which returns the encrypted string.
String (simple variable)	**Variable:** {{*variable_name*}}	A text string. For example, hostnames, usernames, and so forth.

Sections {{#key}} {{/key}} and Inverse Sections {{^key}} {{/key}}

A section or an inverse section is a block of commands between the section start and end tags, which use a key as the processing criteria. How the section is processed depends on whether it is a regular or an inverse section:

• A regular section (or simply, a section) is processed if the key is TRUE or has non-empty contents. If the key is FALSE or the object has no content, the commands in the section are not configured. The section is bypassed.

The following is the syntax for a regular section.

```
{{#key}}
one or more commands
{{/key}}
```

- An inverse section is the opposite of a section. It is processed if the key is FALSE or the object has no contents. If the key is TRUE or the object has contents, the inverse section is bypassed.

  The following is the syntax for an inverse section. The only difference is that a caret replaces the hash tag.

```
{{^key}}
one or more commands
{{/key}}
```

The following topics explain the main uses for sections and inverse sections.

How to Process Multiple-Value Variables

The primary example of processing a multiple-value variable is a network variable that points to a network group. Because the group contains multiple objects (under the **objects** attribute), you can iteratively go through the values in the network group to configure the same command multiple times with different values.

Although an object group defines the contained network objects within the objects attribute, those objects do not include the contents of the contained objects. Instead, you use the **networkObjects** attribute to get at the contents of the contained objects.

For example, if you have a network group named net-group with the hosts 192.168.10.0, 192.168.20.0, and 192.168.30.0, you can use the following technique to configure a network command for each address for RIP routing. Note that you use the network object's **value** attribute alone, because the use of **net-group.networkObjects** in the section start implies that the value attribute will be taken from the member objects. (You do not create a separate variable for the "value" attribute within the FlexConfig object.)

```
router rip
{{#net-group.networkObjects}}
 network {{value}}
{{/net-group.networkObjects}}
```

The system translates the section structure as:

```
router rip
   network 192.168.10.0
   network 192.168.20.0
   network 192.168.30.0
```

How to Perform Optional Processing Based on a Boolean Value or an Empty Object

If the content of the variable in the section start tag is TRUE, or an object is not empty, the section is processed. If a Boolean value is FALSE or empty (such as an empty object), the section is bypassed.

The main use here is for Boolean values. For example, you could create a Boolean variable, and put commands within a section covered by the variable. Then, if you need to enable or disable a section of the commands in

the FlexConfig object, you merely need to change the value of the Boolean variable, you do not need to delete those lines from the code. This makes it easy to turn features on or off.

For example, you might want to be able to turn off SNMP traps if you use FlexConfig to enable SNMP. You could create a Boolean variable named enable-traps, and initially set it to TRUE. Then, if you need to turn off traps, you simply edit the variable, change it to FALSE, save the object and then redeploy the configuration. The command sequence could look like the following:

```
snmp-server enable
snmp-server host inside 192.168.1.5
snmp-server community clearTextString
{{#enable-traps}}
snmp-server enable traps all
{{/enable-traps}}
```

You can also do this type of processing based on Boolean values within an object. For example, you could check whether an interface is management-only before configuring some characteristic on it. In the following example, int-inside is an interface variable that points to the interface named inside. The FlexConfig configures the EIGRP-related interface options on the interface only if the interface is not set to management only. You would use an inverse section so that the commands are configured only if the Boolean value is FALSE.

```
router eigrp 2
 network 192.168.1.0 255.255.255.0
{{^int-inside.managementOnly}}
interface {{int-inside.hardwareName}}
 hello interval eigrp 2 60
 delay 200
{{/int-inside.managementOnly}}
```

Configuring Secret Key Objects

The point of a secret key object is to obscure passwords or sensitive strings. If you do not want to risk someone seeing a string used in a FlexConfig object or Smart CLI template, create a secret key object for the string.

Procedure

Step 1   Select **Objects**, then select **Secret Keys** from the table of contents.

Step 2   Do one of the following:

- To create an object, click the + button.

- To edit an object, click the edit icon (●) for the object.

To delete an unreferenced object, click the trash can icon (●) for the object.

Step 3   Enter a Name for the object and optionally, a description.

Step 4   Enter the password or other secret string in both the **Password** and **Confirm Password** fields.

The system obscures the text as you type.

Step 5   Click **OK**.

What to do next

• If this is a new object, to use it in FlexConfig, edit a FlexConfig object, create a variable of the secret key type, and select the object. Then, refer to the variable within the object body. For more information, see Creating Variables in a FlexConfig Object, on page 13.

• If you are editing an existing object that is used in a FlexConfig object that is part of the FlexConfig policy, you need to deploy the configuration to update the device with the new string.

• In Smart CLI templates, if a command requires a secret key, you will see a list of these objects when editing the relevant property. Select the right key for the purpose.

Troubleshooting the FlexConfig Policy

After editing the FlexConfig policy, carefully examine the results of the next deployment. If you get a "Deployment has failed" message, look at the Status column in the Deployment Summary dialog box. The status for the failed job should include a **See Details** link.

If the deployment fails because of a FlexConfig problem, the details will mention the FlexConfig object with the bad command, and show the command that failed. Use this information to correct the object and try deployment again. The object name is a link, click it to open the edit dialog for the object.

For example, you might want to configure the maximum TCP segment size (TCP MSS). You can control this setting with the **sysopt connection tcpmss** command. When configured by FDM, the FTD default for this option is 0, compared to the ASA default of 1380.

The ASA default is designed for optimal processing when running an IPv4 VPN on interfaces that use the default MTU of 1500. The system needs 120 bytes for the VPN headers. For IPv6, the system needs 140 bytes. The FTD default of 0 simply allows the endpoints to negotiate the MSS, which is the ideal setting for normal traffic, especially if you use different MTUs across the interfaces on the device, including MTUs over 1500. Because TCP MSS is a global setting and not per-interface, you would change it only if a significant percentage of your traffic is over VPN and you are getting excessive fragmentation. In that case, you might set TCP MSS to MTU minus 120 (for IPv4) or 140 (for IPv6), and use the same MTU for all interfaces.

For purposes of illustration, suppose you want to set TCP MSS to 3 bytes. The command takes 48 bytes as the minimum value, so you will get a deployment error similar to the following:

• "Template" field of sysopt-connection-tcpmss caused an error. ERROR: [3] is smaller than minimum allowed MSS of 48 by RFC 791 Usage: [no] sysopt connection { permit-vpn | reclassify-vpn | preserve-vpn-flows | timewait | {tcpmss [minimum] [bytes]} [no] sysopt noproxyarp [if-name] [no] sysopt nodnsalias { inbound | outbound } [no] sysopt radius ignore-secret [no] sysopt traffic detailed-statistics [no] sysopt uauth allow-http-cache [DEPRECATED] show running-config [all] sysopt clear configure sysopt

```
1    sysopt connection tcpmss 3
```

The error is composed of these elements:

1. The deployment error message, which includes the name of the FlexConfig object that caused the error. The object name is linked to the edit dialog box so you can quickly open the object and correct the error. This is the first sentence of the message.

2. The text starting with "ERROR:" is the message returned from the device. This is exactly how an ASA would respond if you typed in the errant command, without the formatting of an SSH client. In this example, the error message is "ERROR: [3] is smaller than the minimum allowed MSS of 48 by RFC 791." The information following "Usage:" is additional information that is meant to help a user who is actually in the CLI, which you can ignore. If you were on an ASA using SSH, the interaction would look like the following:

```
asa3(config)# sysopt connection tcpmss 3
ERROR: <3> is smaller than minimum allowed MSS of 48 by RFC 791
Usage:
    [no] sysopt connection { permit-vpn | reclassify-vpn | preserve-vpn-flows |
              timewait | {tcpmss [minimum] <bytes>}
    [no] sysopt noproxyarp <if-name>
    [no] sysopt nodnsalias { inbound | outbound }
    [no] sysopt radius ignore-secret
    [no] sysopt traffic detailed-statistics
    [no] sysopt uauth allow-http-cache [DEPRECATED]
    show running-config [all] sysopt
    clear configure sysopt
```

3. The text in black is the actual line from the FlexConfig object that caused the error. You must fix this line. In this example, if you are trying to accommodate IPv4 VPN traffic on MTU 1500 interfaces (the common situation), you would change 3 to 1380.

In fixing this example, you can keep the CLI Console open and use **show running-config all sysopt** to see all of the **sysopt** command settings. Most of the **sysopt** commands have default settings appropriate for most uses, so they do not appear in the running configuration. The **all** keyword includes these default settings in the output.

Examples for FlexConfig

The following topics provide some examples for using FlexConfig to configure features.

How to Enable and Disable Global Default Inspections

Some protocols embed IP addressing information in the user data packet or open secondary channels on dynamically assigned ports. These protocols require the system to do a deep packet inspection so that NAT can be applied and secondary channels can be allowed. Several common inspection engines are enabled on the system by default, but you might need to enable others, or disable default inspections, depending on your network.

To see the list of currently enabled inspections, use the **show running-config policy-map** command, either in CLI Console or an SSH session. Following is what you would see on a system where no changes have been made to the inspection configuration. In this output, the list of **inspect** commands at the end of the output shows which protocol inspections are enabled. The preceding commands enable these inspections on the inspection_default traffic class (which is the normal protocols and, if applicable, port numbers, for the inspected protocol). This class is part of the global_policy policy map, which applies these inspections on all interfaces using a service-policy command that is not shown in the output. For example, ICMP inspection is done on all ICMP traffic that passes through the device.

```
> show running-config policy-map
```

```
!
policy-map type inspect dns preset_dns_map
 parameters
  message-length maximum client auto
  message-length maximum 512
  no tcp-inspection
policy-map global_policy
 class inspection_default
  inspect dns preset_dns_map
  inspect ftp
  inspect h323 h225
  inspect h323 ras
  inspect rsh
  inspect rtsp
  inspect sqlnet
  inspect skinny
  inspect sunrpc
  inspect xdmcp
  inspect sip
  inspect netbios
  inspect tftp
  inspect ip-options
  inspect icmp
  inspect icmp error
!
```

Note   For a detailed discussion of each inspection, see the *Cisco ASA Series Firewall Configuration Guide* available from https://www.cisco.com/c/en/us/support/security/asa-firepower-services/products-installation-and-configuration-guides-list.html.

The following procedure shows you how to enable, or disable, inspections in this globally-applied default inspection class. For purposes of illustration, the example:

- Enables PPTP (Point-to-Point Tunneling Protocol). This protocol is used for tunneling a point-to-point connection between to endpoints.

- Disables SIP (Session Initiation Protocol). You would typically disable SIP only if the inspection is causing problems in the network. However, if you disable SIP, you must ensure that your access control policies allow the SIP traffic (UDP/TCP 5060) and any dynamically allocated ports, and that you do not need NAT support for SIP connections. Adjust the access control and NAT policies accordingly through the standard pages, not through FlexConfig.

Before you begin

Good planning will help you use FlexConfig efficiently. In this example, we are changing two different and unrelated inspections, although we are making the changes in the same traffic class. But it is highly likely that if you need to alter these policies, you will do so independently.

Therefore, we recommend creating separate FlexConfig objects for each inspection in this example. That way, you can easily change your setting for one inspection without changing the other, and without needing to edit the FlexConfig object.

Procedure

Step 1 Click **View Configuration** in **Device** > **Advanced Configuration**.

Step 2 Click **FlexConfig** > **FlexConfig Objects** in the Advanced Configuration table of contents.

Step 3 Create the object to enable PPTP inspection.

a) Click the + button to create a new object.

b) Enter a name for the object. For example, **Enable_PPTP_Global_Inspection**.

c) In the **Template** editor, enter the following lines, including indentations.

```
policy-map global_policy
 class inspection_default
  inspect pptp
```

d) In the **Negate Template** editor, enter the lines required to undo this configuration.

Just as you need to include the parent commands to enter the correct sub-mode for a command to enable it, you also need to include those commands in the negate template.

The negate template will be applied if you remove this object from the FlexConfig policy (after having deployed it successfully), and also during an unsuccessful deployment (to reset the configuration to its previous condition).

Thus, for this example, the negate template would be the following:

```
policy-map global_policy
 class inspection_default
  no inspect pptp
```

The object should look like the following:

Name

Enable_PPTP_Global_Inspection

Description

Variables

There are no variables yet.
Start with adding a new variable.

+ ADD VARIABLE

Template

```
1   policy-map global_policy
2     class inspection_default
3       inspect pptp
```

Negate Template ⬤

```
1   policy-map global_policy
2     class inspection_default
3       no inspect pptp
```

> **Note**   Because the inspection_default class has other inspection commands enabled, you do not want to negate the entire class. Similarly, the global_policy policy map includes these other inspections, and you do not want to negate the policy map either.

e) Click **OK** to save the object.

Step 4   Create the object to disable SIP inspection.

a) Click the + button to create a new object.

b) Enter a name for the object. For example, **Disable_SIP_Global_Inspection**.

c) In the **Template** editor, enter the following lines, including indentations.

```
policy-map global_policy
 class inspection_default
  no inspect sip
```

d) In the **Negate Template** editor, enter the lines required to undo this configuration.

The "negate" command for a disabling "no" command is the command that enables the feature. Thus, the "negate" template is not just the commands to disable a feature, it is the commands to reverse whatever you do in the "positive" template. The point of the negate template is to undo your changes.

Thus, for this example, the negate template would be the following:

```
policy-map global_policy
 class inspection_default
```

```
inspect sip
```

The object should look like the following:

Name

Disable_SIP_Global_Inspection

Description

Variables

There are no variables yet.
Start with adding a new variable.

+ ADD VARIABLE

Template

```
1    policy-map global_policy
2       class inspection_default
3          no inspect sip
```

Negate Template 🔶

```
1    policy-map global_policy
2       class inspection_default
3          inspect sip
```
    e) Click **OK** to save the object.
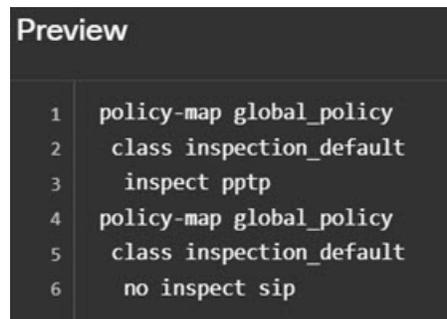

Step 5   Add the objects to the FlexConfig policy.

Creating an object isn't enough. Objects are deployed only if you add them to the FlexConfig policy (and save your changes). This allows you to experiment with objects (and leave them partially complete) without risking deployment failures on unfinished work. You can then easily turn features on or off simply by adding and removing objects: there is no need to recreate the object each time.

    a) Click **FlexConfig Policy** in the table of contents.
    b) Click + in the Group List.
    c) Select the Enable_PPTP_Global_Inspection and Disable_SIP_Global_Inspection objects and click **OK**.

The group list should look like the following:

FlexConfig Policy

Group List

+

>_ 1. Enable_PPTP_Global_Inspection

>_ 2. Disable_SIP_Global_Inspection

The preview should update with the commands in the template. Verify you are seeing the expected commands.

Preview

```
1    policy-map global_policy
2      class inspection_default
3        inspect pptp
4    policy-map global_policy
5      class inspection_default
6        no inspect sip
```

d) Click **Save**.

You can now deploy the policy.

Step 6   Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

Step 7   In CLI Console or an SSH session, use the **show running-config policy-map** command and verify that the running configuration has the correct changes.

In the following output, note that **inspect pptp** is added to the bottom of the inspection_default class, and that **inspect sip** is no longer in the class. This confirms that the changes defined in the FlexConfig object were successfully deployed.

```
> show running-config policy-map
!
policy-map type inspect dns preset_dns_map
 parameters
  message-length maximum client auto
  message-length maximum 512
  no tcp-inspection
```

```
policy-map global_policy
 class inspection_default
  inspect dns preset_dns_map
  inspect ftp
  inspect h323 h225
  inspect h323 ras
  inspect rsh
  inspect rtsp
  inspect sqlnet
  inspect skinny
  inspect sunrpc
  inspect xdmcp
  inspect netbios
  inspect tftp
  inspect ip-options
  inspect icmp
  inspect icmp error
  inspect pptp
!
```

How to Undo Your FlexConfig Changes

If you enter a correct negate template in a FlexConfig object, removing the changes made using that object is trivial. You simply delete the object from the FlexConfig policy, and upon the next deployment, the system uses your negate template to undo your changes.

You do not need to create a new object to undo your changes.

The following example shows how to re-enable global SIP inspection. The example reverts the change explained in , which disabled SIP inspection.

Before you begin

Verify that the FlexConfig object has the correct negate template. If it does not, edit the object to correct the negate template.

Procedure

Step 1 Click **View Configuration** in **Device** > **Advanced Configuration**.

Step 2 Click **FlexConfig** > **FlexConfig Policy** in the Advanced Configuration table of contents.

Step 3 Click the **X** on the right side of the **Disable_SIP_Global_Inspection** object's entry in the FlexConfig policy to delete it from the policy.
The commands from the object are removed from the preview. The negate commands are not added to the preview, these will be executed behind the scenes.

Step 4 Click **Save**.

Step 5 Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

Step 6 In CLI Console or an SSH session, use the **show running-config policy-map** command and verify that the running configuration has the correct changes.

In the following output, note that **inspect sip** is added to the bottom of the inspection_default class. This confirms that the changes defined in the FlexConfig object were successfully deployed. (Order is not important in this class, so it does not matter that **inspect sip** is at the end and not in its original location.)

```
> show running-config policy-map
!
policy-map type inspect dns preset_dns_map
 parameters
  message-length maximum client auto
  message-length maximum 512
  no tcp-inspection
policy-map global_policy
 class inspection_default
  inspect dns preset_dns_map
  inspect ftp
  inspect h323 h225
  inspect h323 ras
  inspect rsh
  inspect rtsp
  inspect sqlnet
  inspect skinny
  inspect sunrpc
  inspect xdmcp
  inspect netbios
  inspect tftp
  inspect ip-options
  inspect icmp
  inspect icmp error
  inspect pptp
  inspect sip
!
```

How to Enable Inspections for Unique Traffic Classes

In this example, we will enable PPTP inspection for traffic between two endpoints on a specific interface. This targets the inspection to just those endpoints that have a point-to-point tunnel configured between them.

The CLI required to enable PPTP inspection between 2 endpoints involves the following:

1. An ACL with the source and destination set to the IP addresses of the endpoint hosts.

2. A traffic class that refers to this ACL.

3. A policy map that includes the traffic class, and that enables PPTP inspection on the traffic class.

4. A service policy that applies the policy map to the desired interface. This is the step that actually activates the policy and enables the inspection.

✎

Note For a detailed discussion of service policies related to inspections, see the *Cisco ASA Series Firewall Configuration Guide* available from https://www.cisco.com/c/en/us/support/security/asa-firepower-services/products-installation-and-configuration-guides-list.html.

Procedure

Step 1 Click **View Configuration** in **Device** > **Advanced Configuration**.

Step 2 Click **FlexConfig** > **FlexConfig Objects** in the Advanced Configuration table of contents.

Step 3 Click the + button to create a new object.

Step 4 Enter a name for the object. For example, **Enable_PPTP_Inspection_on_Interface**.

Step 5 Add a variable for the inside interface.

  a) Click + above the Variables list.
  b) Enter a name for the variable, for example, **pptp-if**.
  c) For **Type**, select **Interface**.
  d) For **Value**, select the **inside** interface.

  The dialog box should look like the following:

  e) Click **Add**.

Step 6 In the **Template** editor, enter the following lines, including indentations.

```
access-list MATCH_ACL permit ip host 192.168.1.55 host 198.51.100.1
class-map MATCH_CMAP
 match access-list MATCH_ACL
policy-map PPTP_POLICY
 class MATCH_CMAP
```

```
  inspect pptp
service-policy PPTP_POLICY interface {{pptp-if.name}}
```

Note that to use the variable, you type the variable name between double braces. You also need to use dot notation to pick out the attribute you want to retrieve, because the object that defines an interface has many attributes. Because the interface name is held in the "name" attribute, entering **{{pptp-if.name}}** retrieves the value of the name attribute for the interface assigned to the variable. If you need to change the interface for PPTP inspection, you simply need to select a different interface in the variable definition.

Step 7 In the **Negate Template** editor, enter the lines required to undo this configuration.

For this example, we will assume that the class map, policy map, and service policy exist for the sole purpose of applying PPTP inspection. Thus, in the negate template, we want to remove all of these.

If, however, you are actually adding PPTP inspection to an existing service policy on an interface, you would not negate the policy map or service policy. You would either negate the class from the policy map, or simply turn off inspection within the class within the policy map. You need to have a clear understanding of what you are implementing in other FlexConfig objects to ensure that your negate template does not have unintended consequences.

When deleting nested items, you need to do it in the reverse order in which you created them. Thus, you start by deleting the service policy, and end by deleting the access list. Otherwise, you would be trying to delete objects that are in use, and the system will return errors and not let you do that.

```
no service-policy PPTP_POLICY interface {{pptp-if.name}}
no policy-map PPTP_POLICY
no class-map MATCH_CMAP
no access-list MATCH_ACL permit ip host 192.168.1.55 host 198.51.100.1
```

The object should look like the following:

Name

Enable_PPTP_Inspection_on_Interface

Description

Variables

NAME	TYPE	VALUE	DESCRIPTION	ACTIONS
pptp-if	Interface	inside		

Template   ⇕ Expand   ○ Reset

```
1    access-list MATCH_ACL permit ip host 192.168.1.55 host 198.51.100.1
2    class-map MATCH_CMAP
3     match access-list MATCH_ACL
4    policy-map PPTP_POLICY
5     class MATCH_CMAP
6       inspect pptp
7    service-policy PPTP_POLICY interface {{pptp-if.name}}
```

Negate Template ⚠   ⇕ Expand   ○ Reset

```
1    no service-policy PPTP_POLICY interface {{pptp-if.name}}
2    no policy-map PPTP_POLICY
3    no class-map MATCH_CMAP
4    no access-list MATCH_ACL permit ip host 192.168.1.55 host 198.51.100.1
```

Step 8   Click **OK** to save the object.

Step 9   Add the objects to the FlexConfig policy.

a) Click **FlexConfig Policy** in the table of contents.

b) Click + in the Group List.

c) Select the **Enable_PPTP_Inspection_on_Interface** object and click **OK**.

The group list should look like the following:

FlexConfig Policy

Group List

+   Drag and drop to reorder

>_ 1. Enable_PPTP_Inspection_on_Interface

The preview should update with the commands in the template. Verify you are seeing the expected commands, as shown in the following graphic. Notice that the interface variable resolves to the name "inside" in the preview. Pay special attention to variables: if they do not resolve correctly in the preview, they will not deploy correctly. Edit the FlexConfig object until you get the correct variable translation in the preview.

```
Preview                                    ‹ › Expand

1    access-list MATCH_ACL permit ip host 192.168.1.55 host
     198.51.100.1
2    class-map MATCH_CMAP
3     match access-list MATCH_ACL
4    policy-map PPTP_POLICY
5     class MATCH_CMAP
6       inspect pptp
7    service-policy PPTP_POLICY interface inside
8
```

d) Click **Save**.

You can now deploy the policy.

Step 10   Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

Step 11   In CLI Console or an SSH session, use variations of the **show running-config** command and verify that the running configuration has the correct changes.

You can enter **show running-config** and examine the entire CLI configuration, or you can use the following commands to verify each part of this configuration:

- **show running-config access-list MATCH_ACL** to verify the ACL.

- **show running-config class** to verify the class map. This command will show all of the class maps.

- **show running-config policy-map PPTP_POLICY** to verify the class and policy map configuration.

- **show running-config service-policy** to verify that the policy map was applied to the interface. This will show all service policies.

The following output shows this sequence of commands, and you can see that configuration is correctly applied.

```
> show running-config access-list MATCH_ACL
```

```
access-list MATCH_ACL extended permit ip host 192.168.1.55 host 198.51.100.1

> show running-config class
!
class-map MATCH_CMAP
 match access-list MATCH_ACL
class-map inspection_default
 match default-inspection-traffic
!

> show running-config policy-map PPTP_POLICY
!
policy-map PPTP_POLICY
 class MATCH_CMAP
   inspect pptp
!
> show running-config service-policy
service-policy global_policy global
service-policy PPTP_POLICY interface inside
```
