PREFACE

Preface **xcvii**

Document Conventions **xcvii**

Related Documentation **xcix**

Obtaining Documentation and Submitting a Service Request **xcix**

CHAPTER 1

Using the Command-Line Interface **1**

Information About Using the Command-Line Interface **1**

Command Modes **1**

Understanding Abbreviated Commands **3**

No and Default Forms of Commands **4**

CLI Error Messages **4**

Configuration Logging **4**

Using the Help System **5**

How to Use the CLI to Configure Features **6**

Configuring the Command History **6**

Changing the Command History Buffer Size **6**

Recalling Commands **6**

Disabling the Command History Feature **7**

Enabling and Disabling Editing Features **7**

Editing Commands Through Keystrokes **8**

Editing Command Lines That Wrap **9**

Searching and Filtering Output of show and more Commands **10**

Accessing the CLI **10**

Accessing the CLI Through a Console Connection or Through Telnet **11**

CHAPTER 2

Using the Web Graphical User Interface **13**

Prerequisites for Using the Web GUI 13

Information About Using The Web GUI 14

 Web GUI Features 14

Connecting the Console Port of the Device 15

Logging On to the GUI 15

Enabling Web and Secure Web Modes 16

Configuring the Device Web GUI 16

PART I

CleanAir 21

CHAPTER 3

Configuring Cisco CleanAir 23

Finding Feature Information 23

Prerequisites for CleanAir 23

Restrictions for CleanAir 24

Information About CleanAir 25

 Cisco CleanAir Components 25

 Terms Used in Cisco CleanAir 27

 Interference Types that Cisco CleanAir can Detect 27

 Interference Device Merging 28

 Persistent Devices 29

 Persistent Devices Detection 29

 Persistent Device Avoidance 29

 EDRRM and AQR Update Mode 29

 CleanAir High Availability 29

How to Configure CleanAir 30

 Enabling CleanAir for 2.4-GHz Band 30

 Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices 30

 Configuring Interference Reporting for 2.4-GHz Devices 32

 Enabling CleanAir for 5-GHz Band 33

 Configuring a CleanAir Alarm for 5-GHz Air-Quality and Devices 34

 Configuring Interference Reporting for 5-GHz devices 35

 Configuring EDRRM for CleanAir-Events 37

 Configuring Persistent Device Avoidance 37

Configuring Cisco CleanAir using the Controller GUI 38

Configuring Cisco CleanAir on the Cisco Wireless LAN Controller (GUI)	38
Configuring Cisco CleanAir on an Access Point (GUI)	40
Configuring Cisco Spectrum Expert	40
Configuring Spectrum Expert (GUI)	40
Configuring Spectrum Expert (CLI)	42
Monitoring CleanAir Parameters	43
Monitoring the Interference Devices	46
Monitoring the Interference Devices (GUI)	46
Monitoring the Worst Air Quality of Radio Bands (GUI)	47
Configuration Examples for Configuring CleanAir	47
CleanAir FAQs	48
Additional References	50

PART II
Interface and Hardware Component 51

CHAPTER 4
Configuring Interface Characteristics 53

Finding Feature Information	53
Information About Configuring Interface Characteristics	53
Interface Types	53
Port-Based VLANs	54
Switch Ports	54
Routed Ports	55
Switch Virtual Interfaces	56
EtherChannel Port Groups	57
10-Gigabit Ethernet Interfaces	57
Power over Ethernet Ports	57
Using the Switch USB Ports	57
USB Mini-Type B Console Port	57
USB Type A Port	58
Interface Connections	59
Interface Configuration Mode	59
Default Ethernet Interface Configuration	61
Interface Speed and Duplex Mode	62
Speed and Duplex Configuration Guidelines	62

IEEE 802.3x Flow Control	63
Layer 3 Interfaces	63
How to Configure Interface Characteristics	64
Configuring Interfaces	64
Adding a Description for an Interface	65
Configuring a Range of Interfaces	67
Configuring and Using Interface Range Macros	68
Configuring Ethernet Interfaces	70
Setting the Interface Speed and Duplex Parameters	70
Configuring IEEE 802.3x Flow Control	71
Configuring Layer 3 Interfaces	72
Configuring Logical Layer 3 GRE Tunnel Interfaces	74
Configuring SVI Autostate Exclude	75
Shutting Down and Restarting the Interface	76
Configuring the Console Media Type	78
Configuring the USB Inactivity Timeout	79
Monitoring Interface Characteristics	80
Monitoring Interface Status	80
Clearing and Resetting Interfaces and Counters	81
Configuration Examples for Interface Characteristics	81
Adding a Description to an Interface: Example	81
Configuring a Range of Interfaces: Examples	82
Configuring and Using Interface Range Macros: Examples	82
Setting Interface Speed and Duplex Mode: Example	83
Configuring Layer 3 Interfaces: Example	83
Configuring the Console Media Type: Example	83
Configuring the USB Inactivity Timeout: Example	84
Additional References for the Interface Characteristics Feature	84
Feature History and Information for Configuring Interface Characteristics	85

CHAPTER 5
Configuring Auto-MDIX 87

Prerequisites for Auto-MDIX	87
Restrictions for Auto-MDIX	87
Information about Configuring Auto-MDIX	88

Auto-MDIX on an Interface	88
How to Configure Auto-MDIX	88
Configuring Auto-MDIX on an Interface	88
Example for Configuring Auto-MDIX	89
Additional References	90
Feature History and Information for Auto-MDIX	90

CHAPTER 6**Configuring Ethernet Management Port 91**

Finding Feature Information	91
Prerequisites for Ethernet Management Ports	91
Information about the Ethernet Management Port	91
Ethernet Management Port Direct Connection to a Device	92
Ethernet Management Port Connection to Stack Devices using a Hub	92
Ethernet Management Port and Routing	92
Supported Features on the Ethernet Management Port	93
How to Configure the Ethernet Management Port	94
Disabling and Enabling the Ethernet Management Port	94
Additional References	95
Feature Information for Ethernet Management Ports	96

CHAPTER 7**Configuring LLDP, LLDP-MED, and Wired Location Service 97**

Finding Feature Information	97
LLDP, LLDP-MED, and Wired Location Service Overview	97
LLDP	97
LLDP Supported TLVs	98
LLDP and Cisco Device Stacks	98
LLDP and Cisco Medianet	98
LLDP-MED	98
LLDP-MED Supported TLVs	98
Wired Location Service	100
Default LLDP Configuration	101
Restrictions for LLDP	101
How to Configure LLDP, LLDP-MED, and Wired Location Service	101
Enabling LLDP	101

- Configuring LLDP Characteristics 103
- Configuring LLDP-MED TLVs 105
- Configuring Network-Policy TLV 106
- Configuring Location TLV and Wired Location Service 109
 - Enabling Wired Location Service on the Device 111
- Configuration Examples for LLDP, LLDP-MED, and Wired Location Service 113
 - Configuring Network-Policy TLV: Examples 113
- Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service 113
- Additional References for LLDP, LLDP-MED, and Wired Location Service 114
- Feature Information for LLDP, LLDP-MED, and Wired Location Service 115

CHAPTER 8

Configuring System MTU 117

- Configuring System MTU 117
 - Finding Feature Information 117
 - Information about the MTU 117
 - Restrictions for System MTU 117
 - System MTU Value Application 117
 - Configuring the System MTU 118
 - Configuring the System MTU 118
 - Configuring Protocol-Specific MTU 119
 - Configuration Examples for System MTU 120
 - Example: Configuring the System MTU 120
 - Example: Configuring Protocol-Specific MTU 120
 - Additional References for System MTU 120
 - Feature Information for System MTU 121

CHAPTER 9

Configuring Internal Power Supplies 123

- Information About Internal Power Supplies 123
- How to Configure Internal Power Supplies 123
 - Configuring Internal Power Supply 123
- Monitoring Internal Power Supplies 124
- Configuration Examples for Internal Power Supplies 124
- Additional References 125
- Feature History and Information for Internal Power Supplies 126

CHAPTER 10	Configuring Stack Power	127
	Finding Feature Information	127
	Prerequisites for StackPower	127
	Restrictions for StackPower	128
	Information About StackPower	128
	Power Supplies for the Stacking Switch	128
	StackPower Modes	128
	Power Priority	129
	Load Shedding	130
	How to Configure StackPower	130
	Configuring PowerStack Parameters	130
	Configuring PowerStack Switch Power Parameters	132
	Configuring PoE Port Priority	133
	Configuration Examples for Stack Power	134
	Immediate Load Shedding: Examples	134
	Configuring PowerStack Parameters: Example	136
	Configuring PowerStack Switch Power Parameters: Example	136
	Configuring PoE Port Priority: Example	137
	Where to Go Next	137
	Additional References for StackPower	137
	Feature History and Information for StackPower	138
CHAPTER 11	Configuring the Cisco eXpandable Power System (XPS) 2200	139
	Restrictions for Configuring the XPS 2200	139
	Information About Configuring the XPS 2200	139
	Cisco eXpandable Power System (XPS) 2200 Overview	139
	XPS 2200 Power Supply Modes	140
	RPS Mode	140
	Stack Power Mode	141
	Mixed Modes	142
	XPS 2200 System Defaults	142
	How to Configure the XPS 2200	143
	Configuring System Names	143

- Configuring XPS Ports 144
- Configuring XPS Power Supplies 145
- Monitoring and Maintaining the XPS 2200 146
- Additional References 146
 - Feature History and Information for XPS 2200 147
 - Related Documents 147
 - Standards 147
 - MIBs 147
 - RFCs 147
 - Technical Assistance 148

CHAPTER 12

Configuring PoE 149

- Finding Feature Information 149
- Information about PoE 149
 - Power over Ethernet Ports 149
 - Supported Protocols and Standards 149
 - Powered-Device Detection and Initial Power Allocation 150
 - Power Management Modes 151
 - Cisco Universal Power Over Ethernet 154
- How to Configure PoE 154
 - Configuring a Power Management Mode on a PoE Port 154
 - Enabling Power on Signal/Spare Pairs 156
 - Configuring Power Policing 157
- Monitoring Power Status 159
- Additional References 160
- Feature Information for PoE 160

CHAPTER 13

Configuring EEE 161

- Finding Feature Information 161
- Information About EEE 161
 - EEE Overview 161
 - Default EEE Configuration 162
- Restrictions for EEE 162
- How to Configure EEE 162

Enabling or Disabling EEE	162
Monitoring EEE	163
Configuration Examples for Configuring EEE	163
Additional References	164
Feature History and Information for Configuring EEE	164

PART III
IPv6 165

CHAPTER 14
Configuring MLD Snooping 167

Finding Feature Information	167
Information About Configuring IPv6 MLD Snooping	167
Understanding MLD Snooping	168
MLD Messages	169
MLD Queries	169
Multicast Client Aging Robustness	170
Multicast Router Discovery	170
MLD Reports	170
MLD Done Messages and Immediate-Leave	170
Topology Change Notification Processing	171
MLD Snooping in Switch Stacks	171
How to Configure IPv6 MLD Snooping	172
Default MLD Snooping Configuration	172
MLD Snooping Configuration Guidelines	172
Enabling or Disabling MLD Snooping on the Switch (CLI)	173
Enabling or Disabling MLD Snooping on a VLAN (CLI)	174
Configuring a Static Multicast Group (CLI)	174
Configuring a Multicast Router Port (CLI)	175
Enabling MLD Immediate Leave (CLI)	176
Configuring MLD Snooping Queries (CLI)	177
Disabling MLD Listener Message Suppression (CLI)	178
Displaying MLD Snooping Information	179
Configuration Examples for Configuring MLD Snooping	180
Configuring a Static Multicast Group: Example	180
Configuring a Multicast Router Port: Example	180

Enabling MLD Immediate Leave: Example	180
Configuring MLD Snooping Queries: Example	181

CHAPTER 15

Configuring IPv6 Unicast Routing	183
Finding Feature Information	183
Information About Configuring IPv6 Unicast Routing	183
Understanding IPv6	183
IPv6 Addresses	184
Supported IPv6 Unicast Routing Features	184
Unsupported IPv6 Unicast Routing Features	189
IPv6 Feature Limitations	189
IPv6 and Switch Stacks	190
Default IPv6 Configuration	191
Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI)	191
Configuring IPv4 and IPv6 Protocol Stacks (CLI)	194
Configuring Default Router Preference (CLI)	196
Configuring IPv6 ICMP Rate Limiting (CLI)	197
Configuring CEF and dCEF for IPv6	198
Configuring Static Routing for IPv6 (CLI)	199
Configuring RIP for IPv6 (CLI)	200
Configuring OSPF for IPv6 (CLI)	202
Configuring EIGRP for IPv6	204
Configuring IPv6 Unicast Reverse Path Forwarding	205
Displaying IPv6	205
Configuring DHCP for IPv6 Address Assignment	206
Default DHCPv6 Address Assignment Configuration	206
DHCPv6 Address Assignment Configuration Guidelines	206
Enabling DHCPv6 Server Function (CLI)	207
Enabling DHCPv6 Client Function (CLI)	209
Configuration Examples for IPv6 Unicast Routing	210
Configuring IPv6 Addressing and Enabling IPv6 Routing: Example	210
Configuring Default Router Preference: Example	211
Configuring IPv4 and IPv6 Protocol Stacks: Example	211
Enabling DHCPv6 Server Function: Example	211

Enabling DHCPv6 Client Function: Example	212
Configuring IPv6 ICMP Rate Limiting: Example	212
Configuring Static Routing for IPv6: Example	212
Configuring RIP for IPv6: Example	212
Displaying IPv6: Example	212

CHAPTER 16
Implementing IPv6 Multicast 215

Finding Feature Information	215
Information About Implementing IPv6 Multicast Routing	215
IPv6 Multicast Overview	215
IPv6 Multicast Routing Implementation	216
IPv6 Multicast Listener Discovery Protocol	216
Multicast Queriers and Hosts	216
MLD Access Group	217
Explicit Tracking of Receivers	217
Protocol Independent Multicast	217
PIM-Sparse Mode	217
IPv6 BSR: Configure RP Mapping	218
PIM-Source Specific Multicast	218
Routable Address Hello Option	219
PIM IPv6 Stub Routing	219
Static Mroutes	220
MRIB	220
MFIB	220
MFIB	221
IPv6 Multicast Process Switching and Fast Switching	221
Multiprotocol BGP for the IPv6 Multicast Address Family	222
Implementing IPv6 Multicast	222
Enabling IPv6 Multicast Routing	222
Customizing and Verifying the MLD Protocol	223
Customizing and Verifying MLD on an Interface	223
Implementing MLD Group Limits	224
Configuring Explicit Tracking of Receivers to Track Host Behavior	226
Resetting the MLD Traffic Counters	226

Clearing the MLD Interface Counters	227
Configuring PIM	227
Configuring PIM-SM and Displaying PIM-SM Information for a Group Range	227
Configuring PIM Options	228
Resetting the PIM Traffic Counters	230
Clearing the PIM Topology Table to Reset the MRIB Connection	230
Configuring PIM IPv6 Stub Routing	231
PIM IPv6 Stub Routing Configuration Guidelines	232
Default IPv6 PIM Routing Configuration	232
Enabling IPv6 PIM Stub Routing	232
Monitoring IPv6 PIM Stub Routing	234
Configuring a BSR	234
Configuring a BSR and Verifying BSR Information	235
Sending PIM RP Advertisements to the BSR	235
Configuring BSR for Use Within Scoped Zones	236
Configuring BSR Switches to Announce Scope-to-RP Mappings	237
Configuring SSM Mapping	237
Configuring Static Mroutes	238
Using MFIB in IPv6 Multicast	239
Verifying MFIB Operation in IPv6 Multicast	239
Resetting MFIB Traffic Counters	240

CHAPTER 17

Configuring IPv6 Client IP Address Learning	241
Prerequisites for IPv6 Client Address Learning	241
Information About IPv6 Client Address Learning	241
SLAAC Address Assignment	242
Stateful DHCPv6 Address Assignment	243
Static IP Address Assignment	244
Router Solicitation	244
Router Advertisement	244
Neighbor Discovery	245
Neighbor Discovery Suppression	245
RA Guard	245
RA Throttling	246

Configuring IPv6 Unicast (CLI)	246
Configuring RA Guard Policy (CLI)	247
Applying RA Guard Policy (CLI)	248
Configuring RA Throttle Policy (CLI)	249
Applying RA Throttle Policy on VLAN (CLI)	250
Configuring IPv6 Snooping (CLI)	251
Configuring IPv6 ND Suppress Policy (CLI)	252
Configuring IPv6 Snooping on VLAN/PortChannel	253
Configuring IPv6 on Switch (CLI)	254
Configuring DHCP Pool (CLI)	254
Configuring Stateless Auto Address Configuration Without DHCP (CLI)	255
Configuring Stateless Auto Address Configuration With DHCP (CLI)	257
Configuring Stateful DHCP Locally (CLI)	258
Configuring Stateful DHCP Externally (CLI)	260
Monitoring IPv6 Clients (GUI)	262
Verifying IPv6 Address Learning Configuration	262
Additional References	263
Feature Information for IPv6 Client Address Learning	264

CHAPTER 18

Configuring IPv6 WLAN Security	265
Prerequisites for IPv6 WLAN Security	265
Restrictions for IPv6 WLAN Security	265
Information About IPv6 WLAN Security	265
How to Configure IPv6 WLAN Security	268
Configuring Local Authentication	268
Creating a Local User	268
Creating an Client VLAN and Interface	268
Configuring a EAP Profile	270
Creating a Local Authentication Model	272
Creating a Client WLAN	274
Configuring Local Authentication with WPA2+AES	275
Configuring External RADIUS Server	279
Configuring RADIUS Authentication Server Host	279
Configuring RADIUS Authentication Server Group	280

Creating a Client VLAN	282
Creating 802.1x WLAN Using an External RADIUS Server	283
Additional References	284
Feature Information for IPv6 WLAN Security	285

CHAPTER 19

Configuring IPv6 ACL	287
Prerequisites for IPv6 ACL	287
Restrictions for IPv6 ACL	287
Information About IPv6 ACL	288
Understanding IPv6 ACLs	288
Types of ACL	289
Per User IPv6 ACL	289
Filter ID IPv6 ACL	289
Downloadable IPv6 ACL	289
IPv6 ACLs and Switch Stacks	290
Configuring IPv6 ACLs	290
Default IPv6 ACL Configuration	291
Interaction with Other Features and Switches	291
How To Configure an IPv6 ACL	291
Creating IPv6 ACL	291
Applying an IPv6 to an Interface	295
Creating WLAN IPv6 ACL	296
Verifying IPv6 ACL	297
Displaying IPv6 ACLs	297
Configuration Examples for IPv6 ACL	297
Example: Creating IPv6 ACL	297
Example: Applying IPv6 ACLs	298
Example: Displaying IPv6 ACLs	298
Example: Configuring RA Throttling and NS Suppression	298
Example: Configuring RA Guard Policy	300
Example: Configuring IPv6 Neighbor Binding	301
Additional References	302
Feature Information for IPv6 ACLs	302

CHAPTER 20	Configuring IPv6 Web Authentication	305
	Prerequisites for IPv6 Web Authentication	305
	Restrictions for IPv6 Web Authentication	305
	Information About IPv6 Web Authentication	306
	Web Authentication Process	306
	How to Configure IPv6 Web Authentication	307
	Disabling WPA	307
	Enabling Security on the WLAN	308
	Enabling a Parameter Map on the WLAN	309
	Enabling Authentication List on WLAN	309
	Configuring a Global WebAuth WLAN Parameter Map	309
	Configuring the WLAN	310
	Enabling IPv6 in Global Configuration Mode	312
	Verifying IPv6 Web Authentication	312
	Verifying the Parameter Map	312
	Verifying Authentication List	313
	Additional References	314
	Feature Information for IPv6 Web Authentication	315

CHAPTER 21	Configuring IPv6 Client Mobility	317
	Prerequisites for IPv6 Client Mobility	317
	Restrictions For IPv6 Client Mobility	317
	Information About IPv6 Client Mobility	318
	Using Router Advertisement	318
	RA Throttling and NS suppression	319
	IPv6 Address Learning	320
	Handling Multiple IP Addresses	320
	IPv6 Configuration	320
	High Availability	321
	Verifying IPv6 Client Mobility	321
	Monitoring IPv6 Client Mobility	321
	Additional References	322
	Feature Information For IPv6 Client Mobility	323

CHAPTER 22	Configuring IPv6 Mobility	325
	Pre-requisites for IPv6 Mobility	325
	Information About IPv6 Mobility	325
	Inter Controller Roaming	325
	Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming	326
	How to Configure IPv6 Mobility	326
	Monitoring IPv6 Mobility	326
	Additional References	328
	Feature Information for IPv6 Mobility	329

PART IV	IP	331
----------------	-----------	------------

CHAPTER 23	Configuring HSRP	333
	Configuring HSRP	333
	Finding Feature Information	333
	Information About Configuring HSRP	333
	HSRP Overview	333
	HSRP Versions	335
	Multiple HSRP	336
	SSO HSRP	336
	HSRP and Switch Stacks	337
	Configuring HSRP for IPv6	337
	How to Configure HSRP	337
	Default HSRP Configuration	337
	HSRP Configuration Guidelines	338
	Enabling HSRP	338
	Configuring HSRP Priority	340
	Configuring MHSRP	342
	Configuring HSRP Authentication and Timers	348
	Enabling HSRP Support for ICMP Redirect Messages	350
	Configuring HSRP Groups and Clustering	350
	Verifying HSRP	350
	Verifying HSRP Configurations	350

Configuration Examples for Configuring HSRP	351
Enabling HSRP: Example	351
Configuring HSRP Priority: Example	351
Configuring MHSRP: Example	351
Configuring HSRP Authentication and Timer: Example	352
Configuring HSRP Groups and Clustering: Example	352
Additional References for Configuring HSRP	353
Feature Information for Configuring HSRP	354

PART V**Layer 2/3 355****CHAPTER 24****Configuring Spanning Tree Protocol 357**

Finding Feature Information	357
Restrictions for STP	357
Information About Spanning Tree Protocol	358
Spanning Tree Protocol	358
Spanning-Tree Topology and BPDUs	359
Bridge ID, Device Priority, and Extended System ID	360
Port Priority Versus Path Cost	361
Spanning-Tree Interface States	362
How a Device or Port Becomes the Root Device or Root Port	365
Spanning Tree and Redundant Connectivity	365
Spanning-Tree Address Management	366
Accelerated Aging to Retain Connectivity	366
Spanning-Tree Modes and Protocols	366
Supported Spanning-Tree Instances	367
Spanning-Tree Interoperability and Backward Compatibility	367
STP and IEEE 802.1Q Trunks	368
Spanning Tree and Device Stacks	368
Default Spanning-Tree Configuration	369
How to Configure Spanning-Tree Features	370
Changing the Spanning-Tree Mode (CLI)	370
Disabling Spanning Tree (CLI)	371
Configuring the Root Device (CLI)	372

Configuring a Secondary Root Device (CLI)	373
Configuring Port Priority (CLI)	375
Configuring Path Cost (CLI)	376
Configuring the Device Priority of a VLAN (CLI)	377
Configuring the Hello Time (CLI)	378
Configuring the Forwarding-Delay Time for a VLAN (CLI)	379
Configuring the Maximum-Aging Time for a VLAN (CLI)	380
Configuring the Transmit Hold-Count (CLI)	381
Monitoring Spanning-Tree Status	382
Additional References for Spanning-Tree Protocol	383
Feature Information for STP	384

CHAPTER 25
Configuring Multiple Spanning-Tree Protocol 385

Finding Feature Information	385
Prerequisites for MSTP	385
Restrictions for MSTP	386
Information About MSTP	387
MSTP Configuration	387
MSTP Configuration Guidelines	387
Root Switch	388
Multiple Spanning-Tree Regions	389
IST, CIST, and CST	389
Operations Within an MST Region	390
Operations Between MST Regions	390
IEEE 802.1s Terminology	391
Illustration of MST Regions	391
Hop Count	392
Boundary Ports	393
IEEE 802.1s Implementation	393
Port Role Naming Change	393
Interoperation Between Legacy and Standard Devices	394
Detecting Unidirectional Link Failure	394
MSTP and Device Stacks	395
Interoperability with IEEE 802.1D STP	395

RSTP Overview	396
Port Roles and the Active Topology	396
Rapid Convergence	397
Synchronization of Port Roles	398
Bridge Protocol Data Unit Format and Processing	399
Topology Changes	400
Protocol Migration Process	401
Default MSTP Configuration	401
How to Configure MSTP Features	402
Specifying the MST Region Configuration and Enabling MSTP (CLI)	402
Configuring the Root Device (CLI)	405
Configuring a Secondary Root Device (CLI)	406
Configuring Port Priority (CLI)	407
Configuring Path Cost (CLI)	409
Configuring the Device Priority (CLI)	410
Configuring the Hello Time (CLI)	411
Configuring the Forwarding-Delay Time (CLI)	412
Configuring the Maximum-Aging Time (CLI)	413
Configuring the Maximum-Hop Count (CLI)	414
Specifying the Link Type to Ensure Rapid Transitions (CLI)	415
Designating the Neighbor Type (CLI)	416
Restarting the Protocol Migration Process (CLI)	418
Additional References for MSTP	419
Feature Information for MSTP	420

CHAPTER 26

Configuring Optional Spanning-Tree Features	421
Finding Feature Information	421
Restriction for Optional Spanning-Tree Features	421
Information About Optional Spanning-Tree Features	422
PortFast	422
BPDU Guard	422
BPDU Filtering	423
UplinkFast	423
Cross-Stack UplinkFast	425

How Cross-Stack UplinkFast Works	426
Events That Cause Fast Convergence	427
BackboneFast	428
EtherChannel Guard	430
Root Guard	430
Loop Guard	431
How to Configure Optional Spanning-Tree Features	432
Enabling PortFast (CLI)	432
Enabling BPDU Guard (CLI)	433
Enabling BPDU Filtering (CLI)	435
Enabling UplinkFast for Use with Redundant Links (CLI)	436
Disabling UplinkFast (CLI)	438
Enabling BackboneFast (CLI)	439
Enabling EtherChannel Guard (CLI)	440
Enabling Root Guard (CLI)	441
Enabling Loop Guard (CLI)	442
Monitoring the Spanning-Tree Status	443
Additional References for Optional Spanning Tree Features	444
Feature Information for Optional Spanning-Tree Features	445

CHAPTER 27

Configuring EtherChannels	447
Finding Feature Information	447
Restrictions for EtherChannels	447
Information About EtherChannels	448
EtherChannel Overview	448
EtherChannel Modes	449
EtherChannel on Devices	449
EtherChannel Link Failover	451
Channel Groups and Port-Channel Interfaces	451
Port Aggregation Protocol	452
PAgP Modes	452
PAgP Learn Method and Priority	453
PAgP Interaction with Other Features	454
Link Aggregation Control Protocol	454

LACP Modes	455
LACP and Link Redundancy	455
LACP Interaction with Other Features	456
EtherChannel On Mode	456
Load-Balancing and Forwarding Methods	456
MAC Address Forwarding	457
IP Address Forwarding	457
Load-Balancing Advantages	458
EtherChannel and Device Stacks	459
Device Stack and PAgP	459
Device Stacks and LACP	460
Default EtherChannel Configuration	460
EtherChannel Configuration Guidelines	461
Layer 2 EtherChannel Configuration Guidelines	462
Layer 3 EtherChannel Configuration Guidelines	463
Auto-LAG	463
Auto-LAG Configuration Guidelines	464
How to Configure EtherChannels	465
Configuring Layer 2 EtherChannels (CLI)	465
Configuring Layer 3 EtherChannels (CLI)	467
Configuring EtherChannel Load-Balancing (CLI)	469
Configuring EtherChannel Extended Load-Balancing (CLI)	471
Configuring the PAgP Learn Method and Priority (CLI)	472
Configuring LACP Hot-Standby Ports	473
Configuring the LACP Max Bundle Feature (CLI)	474
Configuring LACP Port-Channel Standalone Disable	475
Configuring the LACP Port Channel Min-Links Feature (CLI)	476
Configuring the LACP System Priority (CLI)	477
Configuring the LACP Port Priority (CLI)	478
Configuring Auto-LAG Globally	479
Configuring Auto-LAG on a Port Interface	480
Configuring Persistence with Auto-LAG	481
Monitoring EtherChannel, PAgP, and LACP Status	482
Configuration Examples for Configuring EtherChannels	483

Configuring Layer 2 EtherChannels: Examples	483
Configuring Layer 3 EtherChannels: Examples	484
Configuring LACP Hot-Standby Ports: Example	485
Configuring Auto LAG: Examples	485
Additional References for EtherChannels	486
Feature Information for EtherChannels	487

CHAPTER 28**Configuring UniDirectional Link Detection 489**

Finding Feature Information	489
Restrictions for Configuring UDLD	489
Information About UDLD	490
Modes of Operation	490
Normal Mode	490
Aggressive Mode	490
Methods to Detect Unidirectional Links	491
Neighbor Database Maintenance	491
Event-Driven Detection and Echoing	492
UDLD Reset Options	492
Default UDLD Configuration	492
How to Configure UDLD	493
Enabling UDLD Globally (CLI)	493
Enabling UDLD on an Interface (CLI)	494
Monitoring and Maintaining UDLD	495
Additional References for UDLD	495
Feature Information for UDLD	496

PART VI**Lightweight Access Point 497****CHAPTER 29****Configuring the Device for Access Point Discovery 499**

Finding Feature Information	499
Prerequisites for Configuring the Device for Access Point Discovery	499
Restrictions for Configuring the Device for Access Point Discovery	500
Information About Configuring the Device for Access Point Discovery	500
Access Point Communication Protocols	501

Viewing Access Point Join Information	501
Troubleshooting the Access Point Join Process	501
How to Configure Access Point Discovery	502
Configuring the Syslog Server for Access Points (GUI)	502
Configuring the Syslog Server for Access Points (CLI)	502
Monitoring Access Point Join Information (CLI)	503
Searching for Access Point Radios (GUI)	504
Monitoring the Interface Details (GUI)	504
Configuration Examples for Configuring the Device for Access Point Discovery	505
Displaying the MAC Addresses of all Access Points: Example	505
DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example	506
Configuring AP Pass Through	506
Information About AP Pass Through	506
Configuring AP Pass Through	506

CHAPTER 30**Configuring Data Encryption 509**

Finding Feature Information	509
Prerequisites for Configuring Data Encryption	509
Restrictions for Configuring Data Encryption	509
Information About Data Encryption	510
How to Configure Data Encryption	510
Configuring Data Encryption (CLI)	510
Configuring Data Encryption (GUI)	511
Configuration Examples for Configuring Data Encryption	511
Displaying Data Encryption States for all Access Points: Examples	511

CHAPTER 31**Configuring Retransmission Interval and Retry Count 513**

Finding Feature Information	513
Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count	513
Information About Retransmission Interval and Retry Count	514
How to Configure Access Point Retransmission Interval and Retry Count	514
Configuring the Access Point Retransmission Interval and Retry Count (CLI)	514
Configuring the Access Point Retransmission Interval and Retry Count (GUI)	515
Viewing CAPWAP Maximum Transmission Unit Information (CLI)	516

Viewing CAPWAP Maximum Transmission Unit Information (GUI)	517
Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count	517
Viewing the CAPWAP Retransmission Details: Example	517
Viewing Maximum Transmission Unit Information: Example	517

CHAPTER 32**Configuring Adaptive Wireless Intrusion Prevention System 519**

Finding Feature Information	519
Prerequisites for Configuring wIPS	519
How to Configure wIPS on Access Points	519
Configuring wIPS on an Access Point (CLI)	519
Configuring wIPS on an Access Point (GUI)	521
Monitoring wIPS Information	521
Configuration Examples for Configuring wIPS on Access Points	522
Displaying the Monitor Configuration Channel Set: Example	522
Displaying wIPS Information: Examples	523

CHAPTER 33**Configuring Authentication for Access Points 525**

Finding Feature Information	525
Prerequisites for Configuring Authentication for Access Points	525
Restrictions for Configuring Authentication for Access Points	526
Information about Configuring Authentication for Access Points	526
How to Configure Authentication for Access Points	526
Configuring Global Credentials for Access Points (CLI)	526
Configuring Global Credentials for Access Points (GUI)	528
Configuring Authentication for Access Points (CLI)	529
Configuring Authentication for Access Points (GUI)	531
Configuring the Switch for Authentication (CLI)	532
Configuration Examples for Configuring Authentication for Access Points	534
Displaying the Authentication Settings for Access Points: Examples	534

CHAPTER 34**Converting Autonomous Access Points to Lightweight Mode 535**

Finding Feature Information	535
Prerequisites for Converting Autonomous Access Points to Lightweight Mode	535
Information About Autonomous Access Points Converted to Lightweight Mode	536

Reverting from Lightweight Mode to Autonomous Mode	536
Using DHCP Option 43 and DHCP Option 60	536
How Converted Access Points Send Crash Information to the Device	537
Uploading Memory Core Dumps from Converted Access Points	537
Displaying MAC Addresses for Converted Access Points	537
Configuring a Static IP Address for a Lightweight Access Point	537
How to Convert a Lightweight Access Point Back to an Autonomous Access Point	538
Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)	538
Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)	538
Authorizing Access Points (CLI)	539
Authorizing Access Points (GUI)	540
Disabling the Reset Button on Converted Access Points (CLI)	541
Monitoring the AP Crash Log Information	542
How to Configure a Static IP Address on an Access Point	542
Configuring a Static IP Address on an Access Point (CLI)	542
Configuring a Static IP Address on an Access Point (GUI)	544
Recovering the Access Point Using the TFTP Recovery Procedure	545
Configuration Examples for Converting Autonomous Access Points to Lightweight Mode	545
Displaying the IP Address Configuration for Access Points: Example	545
Displaying Access Point Crash File Information: Example	545

CHAPTER 35

Using Cisco Workgroup Bridges	547
Finding Feature Information	547
Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges	547
Monitoring the Status of Workgroup Bridges	548
Debugging WGB Issues (CLI)	548
Configuration Examples for Configuring Workgroup Bridges	550
WGB Configuration: Example	550

CHAPTER 36

Configuring Probe Request Forwarding	551
Finding Feature Information	551
Information About Configuring Probe Request Forwarding	551
How to Configure Probe Request Forwarding (CLI)	551

CHAPTER 37**Optimizing RFID Tracking 553**

- Finding Feature Information 553
- Optimizing RFID Tracking on Access Points 553
- How to Optimize RFID Tracking on Access Points 553
 - Optimizing RFID Tracking on Access Points (CLI) 553
- Configuration Examples for Optimizing RFID Tracking 555
 - Displaying all the Access Points in Monitor Mode: Example 555

CHAPTER 38**Configuring Country Codes 557**

- Finding Feature Information 557
- Prerequisites for Configuring Country Codes 557
- Information About Configuring Country Codes 558
- How to Configure Country Codes (CLI) 558
- Configuration Examples for Configuring Country Codes 561
 - Displaying Channel List for Country Codes: Example 561

CHAPTER 39**Configuring Link Latency 563**

- Finding Feature Information 563
- Prerequisites for Configuring Link Latency 563
- Restrictions for Configuring Link Latency 563
- Information About Configuring Link Latency 564
 - TCP MSS 564
 - Link Tests 564
- How to Configure Link Latency 565
 - Configuring Link Latency (CLI) 565
 - Configuring Link Latency (GUI) 567
- How to Configure TCP MSS 568
 - Configuring TCP MSS (CLI) 568
 - Configuring TCP MSS (GUI) 568
- Performing a Link Test (CLI) 569
- Configuration Examples for Configuring Link Latency 570
 - Running a Link Test: Example 570
 - Displaying Link Latency Information: Example 570

Displaying TCP MSS Settings: Example 571

CHAPTER 40

Configuring Power over Ethernet 573

Finding Feature Information 573

Information About Configuring Power over Ethernet 573

How to Configure Power over Ethernet 573

Configuring Power over Ethernet (CLI) 573

Configuring Power over Ethernet (GUI) 574

Configuration Examples for Configuring Power over Ethernet 576

Displaying Power over Ethernet Information: Example 576

PART VII

Mobility 577

CHAPTER 41

Information About Mobility 579

Overview 579

Wired and Wireless Mobility 580

Features of Mobility 580

Sticky Anchoring for Low Latency Roaming 582

Bridge Domain ID and L2/L3 Roaming 582

Link Down Behavior 582

Platform Specific Scale Requirement for the Mobility Controller 583

CHAPTER 42

Mobility Network Elements 585

Mobility Agent 585

Mobility Controller 586

Mobility Oracle 587

Guest Controller 587

CHAPTER 43

Mobility Control Protocols 589

About Mobility Control Protocols 589

Initial Association and Roaming 589

Initial Association 590

Intra Switch Handoff 591

Intra Switch Peer Group Handoff 591

Inter Switch Peer Group Handoff 592

Inter Sub Domain Handoff 593

Inter Mobility Group Handoff 595

CHAPTER 44

Configuring Mobility 597

Configuring Mobility Controller 597

Configuring Converged Access Controllers 597

Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI) 597

Creating Peer Groups, Peer Group Member, and Bridge Domain ID (GUI) 599

Configuring Local Mobility Group (CLI) 599

Configuring Local Mobility Group (GUI) 600

Adding a Peer Mobility Group (CLI) 601

Adding a Peer Mobility Group (GUI) 601

Configuring Optional Parameters for Roaming Behavior 602

Pointing the Mobility Controller to a Mobility Oracle (CLI) 602

Pointing the Mobility Controller to a Mobility Oracle (GUI) 603

Configuring Guest Controller 603

Configuring Guest Anchor 604

Configuring Mobility Agent 605

Configuring Mobility Agent by Pointing to Mobility Controller (CLI) 605

Configuring Mobility Agent by Pointing to Mobility Controller (GUI) 606

Configuring the Mobility Controller for the Mobility Agent (CLI) 607

Adding a Mobility Controller Role to the Mobility Agent 607

Configuring Optional Parameters on a Mobility Agent (CLI) 608

PART VIII

Network Management 609

CHAPTER 45

Configuring Cisco IOS Configuration Engine 611

Finding Feature Information 611

Prerequisites for Configuring the Configuration Engine 611

Restrictions for Configuring the Configuration Engine 612

Information About Configuring the Configuration Engine 612

Cisco Configuration Engine Software 612

Configuration Service 613

Event Service	613
NameSpace Mapper	614
Cisco Networking Services IDs and Device Hostnames	614
ConfigID	614
DeviceID	614
Hostname and DeviceID	615
Hostname, DeviceID, and ConfigID	615
Cisco IOS CNS Agents	615
Initial Configuration	615
Incremental (Partial) Configuration	616
Synchronized Configuration	617
Automated CNS Configuration	617
How to Configure the Configuration Engine	618
Enabling the CNS Event Agent	618
Enabling the Cisco IOS CNS Agent	619
Enabling an Initial Configuration for Cisco IOS CNS Agent	621
Refreshing DeviceIDs	626
Enabling a Partial Configuration for Cisco IOS CNS Agent	628
Monitoring CNS Configurations	629
Additional References	630
Feature History and Information for the Configuration Engine	631

CHAPTER 46
Configuring the Cisco Discovery Protocol 633

Finding Feature Information	633
Information About CDP	633
CDP Overview	633
CDP and Stacks	634
Default CDP Configuration	634
How to Configure CDP	634
Configuring CDP Characteristics	634
Disabling CDP	636
Enabling CDP	637
Disabling CDP on an Interface	639
Enabling CDP on an Interface	640

Monitoring and Maintaining CDP	642
Additional References	643
Feature History and Information for Cisco Discovery Protocol	644

CHAPTER 47**Configuring Simple Network Management Protocol 645**

Finding Feature Information	645
Prerequisites for SNMP	645
Restrictions for SNMP	647
Information About SNMP	648
SNMP Overview	648
SNMP Manager Functions	648
SNMP Agent Functions	648
SNMP Community Strings	649
SNMP MIB Variables Access	649
SNMP Notifications	650
SNMP ifIndex MIB Object Values	650
Default SNMP Configuration	650
SNMP Configuration Guidelines	651
How to Configure SNMP	651
Disabling the SNMP Agent	651
Configuring Community Strings	653
Configuring SNMP Groups and Users	655
Configuring SNMP Notifications	658
Setting the Agent Contact and Location Information	663
Limiting TFTP Servers Used Through SNMP	664
Configuring Trap Flags for SNMP	666
Enabling SNMP Wireless Trap Notification	668
Monitoring SNMP Status	669
SNMP Examples	669
Additional References	670
Feature History and Information for Simple Network Management Protocol	671

CHAPTER 48**Configuring Service Level Agreements 673**

Finding Feature Information	673
-----------------------------	-----

Restrictions on SLAs	673
Information About SLAs	674
Cisco IOS IP Service Level Agreements (SLAs)	674
Network Performance Measurement with Cisco IOS IP SLAs	675
IP SLA Responder and IP SLA Control Protocol	676
Response Time Computation for IP SLAs	676
IP SLAs Operation Scheduling	677
IP SLA Operation Threshold Monitoring	677
UDP Jitter	678
How to Configure IP SLAs Operations	679
Default Configuration	679
Configuration Guidelines	679
Configuring the IP SLA Responder	680
Implementing IP SLA Network Performance Measurement	681
Analyzing IP Service Levels by Using the UDP Jitter Operation	685
Analyzing IP Service Levels by Using the ICMP Echo Operation	689
Monitoring IP SLA Operations	692
Monitoring IP SLA Operation Examples	693
Additional References	694
Feature History and Information for Service Level Agreements	695

CHAPTER 49

Configuring Local Policies	697
Finding Feature Information	697
Restrictions for Configuring Local Policies	697
Information About Configuring Local Policies	698
How to Configure Local Policies	699
Configuring Local Policies (CLI)	699
Creating a Service Template (CLI)	700
Creating an Interface Template (CLI)	701
Creating a Parameter Map (CLI)	701
Creating a Class Map (CLI)	702
Creating a Policy Map (CLI)	703
Applying a Local Policy for a Device on a WLAN (CLI)	704
Configuring Local Policies (GUI)	705

Creating a Service Template (GUI)	706
Creating a Policy Map (GUI)	706
Applying Local Policies to WLAN (GUI)	707
Monitoring Local Policies	708
Examples: Local Policies Configuration	709
Additional References for Configuring Local Policies	710
Feature History for Performing Local Policies Configuration	711

CHAPTER 50**Configuring SPAN and RSPAN 713**

Finding Feature Information	713
Prerequisites for SPAN and RSPAN	713
Restrictions for SPAN and RSPAN	714
Information About SPAN and RSPAN	715
SPAN and RSPAN	715
Local SPAN	716
Remote SPAN	717
SPAN and RSPAN Concepts and Terminology	717
SPAN and RSPAN Interaction with Other Features	723
SPAN and RSPAN and Device Stacks	724
Flow-Based SPAN	724
Default SPAN and RSPAN Configuration	725
Configuration Guidelines	725
SPAN Configuration Guidelines	725
RSPAN Configuration Guidelines	726
FSPAN and FRSPAN Configuration Guidelines	726
How to Configure SPAN and RSPAN	726
Creating a Local SPAN Session	726
Creating a Local SPAN Session and Configuring Incoming Traffic	729
Specifying VLANs to Filter	731
Configuring a VLAN as an RSPAN VLAN	733
Creating an RSPAN Source Session	735
Specifying VLANs to Filter	737
Creating an RSPAN Destination Session	739
Creating an RSPAN Destination Session and Configuring Incoming Traffic	741

Configuring an FSPAN Session	743
Configuring an FRSPAN Session	746
Monitoring SPAN and RSPAN Operations	749
SPAN and RSPAN Configuration Examples	749
Example: Configuring Local SPAN	749
Examples: Creating an RSPAN VLAN	751
Additional References	752
Feature History and Information for SPAN and RSPAN	753

CHAPTER 51**Configuring Wireshark 755**

Finding Feature Information	755
Prerequisites for Wireshark	755
Restrictions for Wireshark	755
Information About Wireshark	757
Wireshark Overview	757
Capture Points	757
Attachment Points	758
Filters	759
Actions	759
Storage of Captured Packets to Buffer in Memory	760
Storage of Captured Packets to a .pcap File	760
Packet Decoding and Display	761
Packet Storage and Display	761
Wireshark Capture Point Activation and Deactivation	762
Wireshark Features	762
Guidelines for Wireshark	764
Default Wireshark Configuration	766
How to Configure Wireshark	767
Defining a Capture Point	767
Adding or Modifying Capture Point Parameters	772
Deleting Capture Point Parameters	774
Deleting a Capture Point	776
Activating and Deactivating a Capture Point	777
Clearing the Capture Point Buffer	781

Monitoring Wireshark **783**

Configuration Examples for Wireshark **783**

 Example: Displaying a Brief Output from a .pcap File **783**

 Example: Displaying Detailed Output from a .pcap File **784**

 Example: Simple Capture and Display **785**

 Example: Simple Capture and Store **787**

 Example: Using Buffer Capture **789**

 Example: Capture Sessions **796**

 Example: Capture and Store in Lock-step Mode **797**

 Example: Simple Capture and Store of Packets in Egress Direction **798**

Additional References **800**

Feature History and Information for WireShark **801**

Embedded Packet Capture **801**

 Finding Feature Information **801**

 Prerequisites for Embedded Packet Capture **801**

 Restrictions for Embedded Packet Capture **802**

 Information About Embedded Packet Capture **802**

 Embedded Packet Capture Overview **802**

 Benefits of Embedded Packet Capture **802**

 Packet Data Capture **803**

 How to Implement Embedded Packet Capture **803**

 Managing Packet Data Capture **803**

 Monitoring and Maintaining Captured Data **805**

 Configuration Examples for Embedded Packet Capture **806**

 Example: Managing Packet Data Capture **806**

 Example: Monitoring and Maintaining Captured Data **806**

 Additional References **809**

PART IX

Network Powered Lighting 811

CHAPTER 52

Configuring COAP Proxy Server 813

 Finding Feature Information **813**

 Information about COAP Proxy Server **813**

 Supported Hardware for COAP Proxy Server **814**

Configuring COAP Proxy Server	816
Configuring COAP Proxy	816
Configuring COAP Endpoints	819
Monitoring COAP Proxy Server	820
Examples: COAP Proxy Server	821

CHAPTER 53

Configuring Auto SmartPorts	825
Finding Feature Information	825
Information about Auto SmartPorts	825
Auto SmartPort Macros	826
Commands executed by CISCO_LIGHT_AUTO_SMARTPORT	826
Enabling Auto SmartPort	827
Configuring Mapping Between Event Triggers and Built-in Macros	828
Example: Enabling Auto SmartPorts	830
Example: Configuring Mapping Between Event Triggers and Built-in Macros	830

CHAPTER 54

Configuring 2-event Classification	831
Finding Feature Information	831
Information about 2-event Classification	831
Configuring 2-event Classification	831
Example: Configuring 2-Event Classification	832

CHAPTER 55

Configuring Perpetual and Fast POE	835
Restrictions for Perpetual and Fast PoE	835
Perpetual POE	835
Fast POE	835
Supported Hardware for Perpetual POE and Fast POE	836
Configuring Perpetual and Fast POE	838
Example: Configuring Perpetual and Fast POE	839

CHAPTER 56

Frequently Asked Questions	841
Finding Feature Information	841
Frequently Asked Questions	841

PART X**QoS 845**

CHAPTER 57**Configuring QoS 847**

- Finding Feature Information 847
- Prerequisites for QoS 847
- QoS Components 848
- QoS Terminology 848
- Information About QoS 849
 - QoS Overview 849
 - Modular QoS Command-Line Interface 849
 - Wireless QoS Overview 849
 - QoS and IPv6 for Wireless 850
 - Supported QoS Features for Wired Access 851
 - Wired and Wireless Access Supported Features 851
 - Supported QoS Features on Wireless Targets 853
 - Port Policies 855
 - Radio Policies 857
 - SSID Policies 858
 - Client Policies 858
 - Hierarchical QoS 859
 - Hierarchical Wireless QoS 860
- QoS Implementation 861
 - Layer 2 Frame Prioritization Bits 862
 - Layer 3 Packet Prioritization Bits 863
 - End-to-End QoS Solution Using Classification 863
 - Packet Classification 863
- QoS Wired Model 865
 - Ingress Port Activity 866
 - Egress Port Activity 866
- Classification 866
 - Access Control Lists 867
 - Class Maps 867
 - Policy Maps 868

Policing	870
Token-Bucket Algorithm	871
Marking	871
Packet Header Marking	871
Switch Specific Information Marking	872
Table Map Marking	872
Traffic Conditioning	873
Policing	874
Shaping	875
Queueing and Scheduling	876
Bandwidth	876
Weighted Tail Drop	877
Priority Queues	879
Queue Buffer	879
Queueing in Wireless	880
Trust Behavior	881
Trust Behavior for Wired Ports	881
Trust Behavior for Wired and Wireless Ports	882
Port Security on a Trusted Boundary for Cisco IP Phones	883
Wireless QoS Mobility	883
Inter-Device Roaming	884
Intra-Device Roaming	884
Precious Metal Policies for Wireless QoS	884
Standard QoS Default Settings	885
Default Wired QoS Configuration	885
Default Wireless QoS Configuration	887
Configuring Auto QoS for Wireless	887
Information About Auto QoS for Wireless	887
Configuring Auto QoS for Wireless (GUI)	889
Configuring Auto QoS for Wireless (CLI)	889
Guidelines for QoS Policies	889
Restrictions for QoS on Wired Targets	889
Restrictions for QoS on Wireless Targets	892
How to Configure QoS	895

Configuring Class, Policy, and Table Maps	895
Creating a Traffic Class (CLI)	895
Creating a Traffic Policy (CLI)	898
Configuring Client Policies (GUI)	903
Configuring Client Policies	905
Configuring Class-Based Packet Marking (CLI)	906
Configuring Class Maps for Voice and Video (CLI)	911
Attaching a Traffic Policy to an Interface (CLI)	912
Configuring SSID Policies (GUI)	913
Applying an SSID or Client Policy on a WLAN (CLI)	915
Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps (CLI)	916
Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps (CLI)	919
Configuring Table Maps (CLI)	923
Configuring Trust	925
Configuring Trust Behavior for the Device Type	925
Configuring Trust Behavior for Wireless Traffic (CLI)	927
Configuring QoS Features and Functionality	928
Configuring Call Admission Control (CLI)	928
Configuring Bandwidth (CLI)	935
Configuring NetFlow Sampler	937
Configuring Police (CLI)	939
Configuring Priority (CLI)	941
Configuring Queues and Shaping	944
Configuring Egress Queue Characteristics	944
Configuring Queue Buffers (CLI)	944
Configuring Queue Limits (CLI)	946
Configuring Shaping (CLI)	949
Configuring Precious Metal Policies (CLI)	951
Configuring QoS Policies for Multicast Traffic (CLI)	952
Configuring Port Policies (GUI)	953
Applying or Changing Port Policies (GUI)	953
Applying a QoS Policy on a WLAN (GUI)	954
Monitoring QoS	955
Monitoring SSID and Client Policies Statistics (GUI)	958

Configuration Examples for QoS	959
Examples: Classification by Access Control Lists	959
Examples: Class of Service Layer 2 Classification	959
Examples: Class of Service DSCP Classification	960
Examples: VLAN ID Layer 2 Classification	960
Examples: Classification by DSCP or Precedence Values	960
Examples: Hierarchical Classification	961
Examples: Hierarchical Policy Configuration	961
Examples: Classification for Voice and Video	962
Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic	963
Examples: Configuring Downstream SSID Policy	964
Examples: Ingress SSID Policies	965
Examples: Client Policies	966
Examples: Average Rate Shaping Configuration	968
Examples: Queue-limit Configuration	969
Examples: Queue Buffers Configuration	970
Examples: Policing Action Configuration	970
Examples: Policer VLAN Configuration	971
Examples: Policing Units	971
Examples: Single-Rate Two-Color Policing Configuration	972
Examples: Dual-Rate Three-Color Policing Configuration	972
Examples: Table Map Marking Configuration	973
Example: Table Map Configuration to Retain CoS Markings	974
Where to Go Next	974
Additional References for QoS	974
Feature History and Information for QoS	976

CHAPTER 58
Configuring Auto-QoS 979

Finding Feature Information	979
Prerequisites for Auto-QoS	979
Restrictions for Auto-QoS	979
Information About Configuring Auto-QoS	981
Auto-QoS Overview	981
Auto-QoS Compact Overview	981

Auto-QoS Global Configuration Templates	981
Auto-QoS Policy and Class Maps	981
Effects of Auto-QoS on Running Configuration	982
Effects of Auto-QoS Compact on Running Configuration	982
How to Configure Auto-QoS	983
Configuring Auto-QoS (CLI)	983
Upgrading Auto-QoS (CLI)	985
Enabling Auto-QoS Compact	987
Monitoring Auto-QoS	989
Troubleshooting Auto-QoS	989
Configuration Examples for Auto-QoS	989
Example: auto qos trust cos	989
Example: auto qos trust cos	991
Example: auto qos trust dscp	994
Example: auto qos trust dscp	996
Example: auto qos video cts	999
Example: auto qos video cts	1001
Example: auto qos video ip-camera	1004
Example: auto qos video ip-camera	1006
Example: auto qos video media-player	1009
Example: auto qos video media-player	1011
Example: auto qos voip trust	1014
Example: auto qos voip trust	1016
Example: auto qos voip cisco-phone	1019
Example: auto qos voip cisco-phone	1022
Example: auto qos voip cisco-softphone	1025
Example: auto qos voip cisco-softphone	1029
auto qos classify police	1034
auto qos classify police	1038
auto qos global compact	1042
Where to Go Next for Auto-QoS	1042
Additional References for Auto-QoS	1043
Feature History and Information for Auto-QoS	1044

PART XI**Radio Resource Management 1045****CHAPTER 59****Configuring Radio Resource Management 1047**

Finding Feature Information 1047

Prerequisites for Configuring Radio Resource Management 1047

Restrictions for Radio Resource Management 1048

Information About Radio Resource Management 1048

Radio Resource Monitoring 1049

Information About RF Groups 1049

RF Group Leader 1050

RF Group Name 1051

Mobility Controller 1051

Mobility Agent 1052

Information About Rogue Access Point Detection in RF Groups 1052

Transmit Power Control 1053

Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings 1053

Dynamic Channel Assignment 1053

Coverage Hole Detection and Correction 1055

How to Configure RRM 1056

Configuring Advanced RRM CCX Parameters (CLI) 1056

Configuring Neighbor Discovery Type (CLI) 1056

Configuring RRM Profile Thresholds, Monitoring Channels, and Monitoring Intervals (GUI) 1057

Configuring RF Groups 1058

Configuring the RF Group Mode (GUI) 1058

Configuring RF Group Selection Mode (CLI) 1059

Configuring an RF Group Name (CLI) 1060

Configuring an RF Group Name (GUI) 1060

Configuring Members in a 802.11 Static RF Group (CLI) 1061

Configuring Transmit Power Control 1061

Configuring the Tx-Power Control Threshold (CLI) 1061

Configuring the Tx-Power Level (CLI) 1062

Configuring Transmit Power Control (GUI) 1063

Configuring 802.11 RRM Parameters 1064

- Configuring Advanced 802.11 Channel Assignment Parameters (CLI) 1064
- Configuring Dynamic Channel Assignment (GUI) 1066
- Configuring 802.11 Coverage Hole Detection (CLI) 1069
- Configuring Coverage Hole Detection (GUI) 1070
- Configuring 802.11 Event Logging (CLI) 1071
- Configuring 802.11 Statistics Monitoring (CLI) 1072
- Configuring the 802.11 Performance Profile (CLI) 1074
- Configuring Rogue Access Point Detection in RF Groups 1075
 - Configuring Rogue Access Point Detection in RF Groups (CLI) 1075
 - Enabling Rogue Access Point Detection in RF Groups (GUI) 1076
- Monitoring RRM Parameters and RF Group Status 1077
 - Monitoring RRM Parameters 1077
 - Monitoring RF Group Status (CLI) 1078
 - Monitoring RF Group Status (GUI) 1078
- Examples: RF Group Configuration 1079
- Information About ED-RRM 1079
 - Configuring ED-RRM on the Cisco Wireless LAN Controller (CLI) 1079
 - Configuring ED-RRM (GUI) 1080
- Additional References for Radio Resource Management 1080
- Feature History and Information For Performing Radio Resource Management Configuration 1081

PART XII

Routing 1083

CHAPTER 60

Configuring MSDP 1085

- Finding Feature Information 1085
- Information About Configuring MSDP 1085
 - MSDP Overview 1086
 - MSDP Operation 1086
 - MSDP Benefits 1087
- How to Configure MSDP 1088
 - Default MSDP Configuration 1088
 - Configuring a Default MSDP Peer 1088
 - Caching Source-Active State 1090
 - Controlling Source Information that Your Switch Originates 1091

Redistributing Sources	1091
Filtering Source-Active Request Messages	1093
Controlling Source Information that Your Switch Forwards	1095
Using a Filter	1095
Using TTL to Limit the Multicast Data Sent in SA Messages	1097
Controlling Source Information that Your Switch Receives	1098
Configuring an MSDP Mesh Group	1100
Shutting Down an MSDP Peer	1101
Including a Bordering PIM Dense-Mode Region in MSDP	1102
Configuring an Originating Address other than the RP Address	1104
Monitoring and Maintaining MSDP	1105
Configuration Examples for Configuring MSDP	1106
Configuring a Default MSDP Peer: Example	1106
Caching Source-Active State: Example	1106
Controlling Source Information that Your Switch Originates: Example	1107
Controlling Source Information that Your Switch Forwards: Example	1107
Controlling Source Information that Your Switch Receives: Example	1107

CHAPTER 61

Configuring IP Unicast Routing	1109
Finding Feature Information	1110
Information About Configuring IP Unicast Routing	1110
Information About IP Routing	1110
Types of Routing	1111
IP Routing and Switch Stacks	1112
Classless Routing	1113
Address Resolution	1114
Proxy ARP	1115
ICMP Router Discovery Protocol	1115
UDP Broadcast Packets and Protocols	1116
Broadcast Packet Handling	1116
IP Broadcast Flooding	1116
How to Configure IP Routing	1117
How to Configure IP Addressing	1118
Default IP Addressing Configuration	1118

Assigning IP Addresses to Network Interfaces	1120
Using Subnet Zero	1121
Disabling Classless Routing	1122
Configuring Address Resolution Methods	1123
Defining a Static ARP Cache	1123
Setting ARP Encapsulation	1125
Enabling Proxy ARP	1126
Routing Assistance When IP Routing is Disabled	1127
Proxy ARP	1127
Default Gateway	1127
ICMP Router Discovery Protocol (IRDP)	1128
Configuring Broadcast Packet Handling	1130
Enabling Directed Broadcast-to-Physical Broadcast Translation	1130
Forwarding UDP Broadcast Packets and Protocols	1132
Establishing an IP Broadcast Address	1133
Flooding IP Broadcasts	1134
Monitoring and Maintaining IP Addressing	1136
How to Configure IP Unicast Routing	1137
Enabling IP Unicast Routing	1137
Example of Enabling IP Routing	1138
What to Do Next	1138
Information About RIP	1138
Summary Addresses and Split Horizon	1139
How to Configure RIP	1139
Default RIP Configuration	1139
Configuring Basic RIP Parameters	1140
Configuring RIP Authentication	1142
Configuring Summary Addresses and Split Horizon	1143
Configuring Split Horizon	1145
Configuration Example for Summary Addresses and Split Horizon	1146
Information About OSPF	1146
OSPF Nonstop Forwarding	1147
OSPF NSF Awareness	1147
OSPF NSF Capability	1147

OSPF Area Parameters	1148
Other OSPF Parameters	1148
LSA Group Pacing	1149
Loopback Interfaces	1149
How to Configure OSPF	1150
Default OSPF Configuration	1150
Configuring Basic OSPF Parameters	1151
Configuring OSPF Interfaces	1153
Configuring OSPF Area Parameters	1155
Configuring Other OSPF Parameters	1157
Changing LSA Group Pacing	1159
Configuring a Loopback Interface	1159
Monitoring OSPF	1160
Configuration Examples for OSPF	1161
Example: Configuring Basic OSPF Parameters	1161
Information About EIGRP	1161
EIGRP Features	1162
EIGRP Components	1162
EIGRP Nonstop Forwarding	1163
EIGRP NSF Awareness	1163
EIGRP NSF Capability	1163
EIGRP Stub Routing	1164
How to Configure EIGRP	1165
Default EIGRP Configuration	1165
Configuring Basic EIGRP Parameters	1167
Configuring EIGRP Interfaces	1168
Configuring EIGRP Route Authentication	1170
Monitoring and Maintaining EIGRP	1172
Information About BGP	1172
BGP Network Topology	1172
Nonstop Forwarding Awareness	1174
Information About BGP Routing	1174
Routing Policy Changes	1174
BGP Decision Attributes	1175

Route Maps	1176
BGP Filtering	1176
Prefix List for BGP Filtering	1177
BGP Community Filtering	1177
BGP Neighbors and Peer Groups	1178
Aggregate Routes	1178
Routing Domain Confederations	1178
BGP Route Reflectors	1178
Route Dampening	1179
More BGP Information	1179
How to Configure BGP	1179
Default BGP Configuration	1179
Enabling BGP Routing	1183
Managing Routing Policy Changes	1185
Configuring BGP Decision Attributes	1186
Configuring BGP Filtering with Route Maps	1188
Configuring BGP Filtering by Neighbor	1189
Configuring BGP Filtering by Access Lists and Neighbors	1190
Configuring Prefix Lists for BGP Filtering	1191
Configuring BGP Community Filtering	1192
Configuring BGP Neighbors and Peer Groups	1194
Configuring Aggregate Addresses in a Routing Table	1196
Configuring Routing Domain Confederations	1197
Configuring BGP Route Reflectors	1199
Configuring Route Dampening	1200
Monitoring and Maintaining BGP	1201
Configuration Examples for BGP	1202
Example: Configuring BGP on Routers	1202
Information About ISO CLNS Routing	1204
Connectionless Routing	1204
IS-IS Dynamic Routing	1204
Nonstop Forwarding Awareness	1205
IS-IS Global Parameters	1205
IS-IS Interface Parameters	1206

How to Configure ISO CLNS Routing	1207
Default IS-IS Configuration	1207
Enabling IS-IS Routing	1208
Configuring IS-IS Global Parameters	1210
Configuring IS-IS Interface Parameters	1213
Monitoring and Maintaining ISO IGRP and IS-IS	1215
Configuration Examples for ISO CLNS Routing	1217
Example: Configuring IS-IS Routing	1217
Information About Multi-VRF CE	1218
Understanding Multi-VRF CE	1218
Network Topology	1219
Packet-Forwarding Process	1219
Network Components	1220
VRF-Aware Services	1220
How to Configure Multi-VRF CE	1220
Default Multi-VRF CE Configuration	1220
Multi-VRF CE Configuration Guidelines	1221
Configuring VRFs	1221
Configuring VRF-Aware Services	1223
Configuring VRF-Aware Services for ARP	1223
Configuring VRF-Aware Services for Ping	1224
Configuring VRF-Aware Services for SNMP	1224
Configuring VRF-Aware Services for uRPF	1225
Configuring VRF-Aware RADIUS	1226
Configuring VRF-Aware Services for Syslog	1226
Configuring VRF-Aware Services for Traceroute	1227
Configuring VRF-Aware Services for FTP and TFTP	1228
Configuring Multicast VRFs	1229
Configuring a VPN Routing Session	1230
Configuring BGP PE to CE Routing Sessions	1232
Monitoring Multi-VRF CE	1233
Configuration Examples for Multi-VRF CE	1233
Multi-VRF CE Configuration Example	1233
Configuring Unicast Reverse Path Forwarding	1237

Protocol-Independent Features	1237
Distributed Cisco Express Forwarding	1238
Information About Cisco Express Forwarding	1238
How to Configure Cisco Express Forwarding	1238
Load-Balancing Scheme for CEF Traffic	1240
Restrictions for Configuring a Load-Balancing Scheme for CEF Traffic	1240
Prerequisites for Configuring a Load-Balancing Scheme for CEF Traffic	1240
CEF Load-Balancing Overview	1240
Per-Destination Load Balancing for CEF Traffic	1240
Per-Packet Load Balancing for CEF Traffic	1241
Load-Balancing Algorithms for CEF Traffic	1241
How to Configure a Load-Balancing for CEF Traffic	1241
Configuration Examples for CEF Traffic Load-Balancing	1244
Number of Equal-Cost Routing Paths	1245
Information About Equal-Cost Routing Paths	1245
How to Configure Equal-Cost Routing Paths	1245
Static Unicast Routes	1246
Information About Static Unicast Routes	1246
Configuring Static Unicast Routes	1247
Default Routes and Networks	1248
Information About Default Routes and Networks	1248
How to Configure Default Routes and Networks	1248
Route Maps to Redistribute Routing Information	1249
Information About Route Maps	1249
How to Configure a Route Map	1250
How to Control Route Distribution	1253
Policy-Based Routing	1255
Information About Policy-Based Routing	1255
How to Configure PBR	1256
Filtering Routing Information	1259
Setting Passive Interfaces	1259
Controlling Advertising and Processing in Routing Updates	1260
Filtering Sources of Routing Information	1261
Managing Authentication Keys	1262

Prerequisites	1262
How to Configure Authentication Keys	1262
Monitoring and Maintaining the IP Network	1264

PART XIII Security 1265

CHAPTER 62 Preventing Unauthorized Access	1267
Finding Feature Information	1267
Preventing Unauthorized Access	1267

CHAPTER 63 Controlling Switch Access with Passwords and Privilege Levels	1269
Finding Feature Information	1269
Restrictions for Controlling Switch Access with Passwords and Privileges	1269
Information About Passwords and Privilege Levels	1270
Default Password and Privilege Level Configuration	1270
Additional Password Security	1270
Password Recovery	1270
Terminal Line Telnet Configuration	1271
Username and Password Pairs	1271
Privilege Levels	1271
How to Control Switch Access with Passwords and Privilege Levels	1272
Setting or Changing a Static Enable Password	1272
Protecting Enable and Enable Secret Passwords with Encryption	1274
Disabling Password Recovery	1275
Setting a Telnet Password for a Terminal Line	1277
Configuring Username and Password Pairs	1278
Setting the Privilege Level for a Command	1280
Changing the Default Privilege Level for Lines	1282
Logging into and Exiting a Privilege Level	1283
Monitoring Switch Access	1284
Configuration Examples for Setting Passwords and Privilege Levels	1284
Example: Setting or Changing a Static Enable Password	1284
Example: Protecting Enable and Enable Secret Passwords with Encryption	1284
Example: Setting a Telnet Password for a Terminal Line	1284

Example: Setting the Privilege Level for a Command 1285
 Additional References 1285

CHAPTER 64
Configuring TACACS+ 1287

Finding Feature Information 1287
 Prerequisites for TACACS+ 1287
 Information About TACACS+ 1289
 TACACS+ and Switch Access 1289
 TACACS+ Overview 1289
 TACACS+ Operation 1290
 Method List 1291
 TACACS+ Configuration Options 1291
 TACACS+ Login Authentication 1291
 TACACS+ Authorization for Privileged EXEC Access and Network Services 1292
 TACACS+ Accounting 1292
 Default TACACS+ Configuration 1292
 How to Configure TACACS+ 1292
 Identifying the TACACS+ Server Host and Setting the Authentication Key 1293
 Configuring TACACS+ Login Authentication 1294
 Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services 1297
 Starting TACACS+ Accounting 1299
 Establishing a Session with a Router if the AAA Server is Unreachable 1300
 Monitoring TACACS+ 1300
 Additional References 1301

CHAPTER 65
Configuring RADIUS 1303

Finding Feature Information 1303
 Prerequisites for Configuring RADIUS 1303
 Restrictions for Configuring RADIUS 1304
 Information about RADIUS 1305
 RADIUS and Switch Access 1305
 RADIUS Overview 1305
 RADIUS Operation 1306
 RADIUS Change of Authorization 1307

Change-of-Authorization Requests	1308
CoA Request Response Code	1310
CoA Request Commands	1311
Stacking Guidelines for Session Termination	1313
Default RADIUS Configuration	1314
RADIUS Server Host	1314
RADIUS Login Authentication	1315
AAA Server Groups	1316
AAA Authorization	1316
RADIUS Accounting	1316
Vendor-Specific RADIUS Attributes	1316
Vendor-Proprietary RADIUS Server Communication	1328
How to Configure RADIUS	1328
Identifying the RADIUS Server Host	1328
Configuring RADIUS Login Authentication	1331
Defining AAA Server Groups	1333
Configuring RADIUS Authorization for User Privileged Access and Network Services	1335
Starting RADIUS Accounting	1337
Configuring Settings for All RADIUS Servers	1338
Configuring the Device to Use Vendor-Specific RADIUS Attributes	1340
Configuring the Device for Vendor-Proprietary RADIUS Server Communication	1341
Configuring CoA on the Device	1343
Monitoring CoA Functionality	1345
Configuration Examples for Controlling Switch Access with RADIUS	1346
Examples: Identifying the RADIUS Server Host	1346
Example: Using Two Different RADIUS Group Servers	1346
Examples: Configuring the Switch to Use Vendor-Specific RADIUS Attributes	1347
Example: Configuring the Switch for Vendor-Proprietary RADIUS Server Communication	1347
Additional References	1348

CHAPTER 66
Configuring Kerberos 1351

Finding Feature Information	1351
Prerequisites for Controlling Switch Access with Kerberos	1351
Information about Kerberos	1352

Kerberos and Switch Access	1352
Kerberos Overview	1352
Kerberos Operation	1354
Authenticating to a Boundary Switch	1354
Obtaining a TGT from a KDC	1355
Authenticating to Network Services	1355
How to Configure Kerberos	1355
Monitoring the Kerberos Configuration	1355
Additional References	1355

CHAPTER 67	Configuring Local Authentication and Authorization	1357
	Finding Feature Information	1357
	How to Configure Local Authentication and Authorization	1357
	Configuring the Switch for Local Authentication and Authorization	1357
	Monitoring Local Authentication and Authorization	1360
	Additional References	1360

CHAPTER 68	Configuring Secure Shell (SSH)	1361
	Finding Feature Information	1361
	Prerequisites for Configuring Secure Shell	1361
	Restrictions for Configuring Secure Shell	1362
	Information about SSH	1362
	SSH and Switch Access	1362
	SSH Servers, Integrated Clients, and Supported Versions	1363
	SSH Configuration Guidelines	1363
	Secure Copy Protocol Overview	1364
	Secure Copy Protocol	1364
	How to Configure SSH	1365
	Setting Up the Device to Run SSH	1365
	Configuring the SSH Server	1366
	Monitoring the SSH Configuration and Status	1368
	Additional References	1369

CHAPTER 69	Configuring Secure Socket Layer HTTP	1371
-------------------	---	-------------

Finding Feature Information	1371
Information about Secure Sockets Layer (SSL) HTTP	1371
Secure HTTP Servers and Clients Overview	1371
Certificate Authority Trustpoints	1372
CipherSuites	1373
Default SSL Configuration	1374
SSL Configuration Guidelines	1374
How to Configure Secure HTTP Servers and Clients	1375
Configuring a CA Trustpoint	1375
Configuring the Secure HTTP Server	1377
Configuring the Secure HTTP Client	1380
Monitoring Secure HTTP Server and Client Status	1381
Additional References	1381

CHAPTER 70
Configuring IPv4 ACLs 1383

Finding Feature Information	1383
Restrictions for Configuring IPv4 Access Control Lists	1383
Information about Network Security with ACLs	1384
Cisco TrustSec and ACLs	1385
ACL Overview	1385
Access Control Entries	1385
ACL Supported Types	1385
Supported ACLs	1385
ACL Precedence	1386
Port ACLs	1386
Router ACLs	1387
VLAN Maps	1388
ACEs and Fragmented and Unfragmented Traffic	1388
ACEs and Fragmented and Unfragmented Traffic Examples	1388
ACLs and Switch Stacks	1389
Active Switch and ACL Functions	1389
Stack Member and ACL Functions	1390
Active Switch Failure and ACLs	1390
Standard and Extended IPv4 ACLs	1390

IPv4 ACL Switch Unsupported Features	1390
Access List Numbers	1390
Numbered Standard IPv4 ACLs	1391
Numbered Extended IPv4 ACLs	1392
Named IPv4 ACLs	1392
ACL Logging	1393
Hardware and Software Treatment of IP ACLs	1393
VLAN Map Configuration Guidelines	1394
VLAN Maps with Router ACLs	1395
VLAN Maps and Router ACL Configuration Guidelines	1395
VACL Logging	1395
Time Ranges for ACLs	1396
IPv4 ACL Interface Considerations	1396
How to Configure ACLs	1397
Configuring IPv4 ACLs	1397
Creating a Numbered Standard ACL	1397
Creating a Numbered Extended ACL	1399
Creating Named Standard ACLs	1402
Creating Extended Named ACLs	1404
Configuring Time Ranges for ACLs	1405
Applying an IPv4 ACL to a Terminal Line	1407
Applying an IPv4 ACL to an Interface	1409
Creating Named MAC Extended ACLs	1410
Applying a MAC ACL to a Layer 2 Interface	1411
Configuring VLAN Maps	1413
Creating a VLAN Map	1415
Applying a VLAN Map to a VLAN	1416
Configuring VACL Logging	1417
Monitoring IPv4 ACLs	1419
Configuration Examples for ACLs	1419
Examples: Using Time Ranges with ACLs	1419
Examples: Including Comments in ACLs	1420
Examples: Troubleshooting ACLs	1421
IPv4 ACL Configuration Examples	1422

ACLs in a Small Networked Office	1422
Examples: ACLs in a Small Networked Office	1422
Example: Numbered ACLs	1423
Examples: Extended ACLs	1423
Examples: Named ACLs	1424
Examples: Time Range Applied to an IP ACL	1425
Examples: Configuring Commented IP ACL Entries	1425
Examples: ACL Logging	1426
Configuration Examples for ACLs and VLAN Maps	1427
Example: Creating an ACL and a VLAN Map to Deny a Packet	1427
Example: Creating an ACL and a VLAN Map to Permit a Packet	1427
Example: Default Action of Dropping IP Packets and Forwarding MAC Packets	1428
Example: Default Action of Dropping MAC Packets and Forwarding IP Packets	1428
Example: Default Action of Dropping All Packets	1429
Configuration Examples for Using VLAN Maps in Your Network	1429
Example: Wiring Closet Configuration	1429
Example: Restricting Access to a Server on Another VLAN	1431
Example: Denying Access to a Server on Another VLAN	1431
Configuration Examples of Router ACLs and VLAN Maps Applied to VLANs	1432
Example: ACLs and Switched Packets	1432
Example: ACLs and Bridged Packets	1432
Example: ACLs and Routed Packets	1433
Example: ACLs and Multicast Packets	1434
Additional References	1434
Feature Information for IPv4 Access Control Lists	1435

CHAPTER 71

Configuring IPv6 ACLs	1437
Finding Feature Information	1437
IPv6 ACLs Overview	1437
Switch Stacks and IPv6 ACLs	1438
Interactions with Other Features and Switches	1438
Restrictions for IPv6 ACLs	1438
Default Configuration for IPv6 ACLs	1439
Configuring IPv6 ACLs	1439

Attaching an IPv6 ACL to an Interface	1443
Monitoring IPv6 ACLs	1445
Additional References	1445

CHAPTER 72
Configuring DHCP 1447

Finding Feature Information	1447
Information About DHCP	1447
DHCP Server	1447
DHCP Relay Agent	1447
DHCP Snooping	1448
Option-82 Data Insertion	1449
Cisco IOS DHCP Server Database	1452
DHCP Snooping Binding Database	1452
DHCP Snooping and Switch Stacks	1453
How to Configure DHCP Features	1454
Default DHCP Snooping Configuration	1454
DHCP Snooping Configuration Guidelines	1455
Configuring the DHCP Server	1455
DHCP Server and Switch Stacks	1455
Configuring the DHCP Relay Agent	1455
Specifying the Packet Forwarding Address	1457
Prerequisites for Configuring DHCP Snooping and Option 82	1459
Enabling DHCP Snooping and Option 82	1460
Enabling the Cisco IOS DHCP Server Database	1463
Monitoring DHCP Snooping Information	1463
Configuring DHCP Server Port-Based Address Allocation	1464
Information About Configuring DHCP Server Port-Based Address Allocation	1464
Default Port-Based Address Allocation Configuration	1464
Port-Based Address Allocation Configuration Guidelines	1464
Enabling the DHCP Snooping Binding Database Agent	1464
Enabling DHCP Server Port-Based Address Allocation	1466
Monitoring DHCP Server Port-Based Address Allocation	1468
Additional References	1469

CHAPTER 73	Configuring IP Source Guard	1471
	Finding Feature Information	1471
	Information About IP Source Guard	1471
	IP Source Guard	1471
	IP Source Guard for Static Hosts	1472
	IP Source Guard Configuration Guidelines	1473
	How to Configure IP Source Guard	1473
	Enabling IP Source Guard	1473
	Configuring IP Source Guard for Static Hosts on a Layer 2 Access Port	1475
	Monitoring IP Source Guard	1477
	Additional References	1477

CHAPTER 74	Configuring Dynamic ARP Inspection	1479
	Finding Feature Information	1479
	Restrictions for Dynamic ARP Inspection	1479
	Understanding Dynamic ARP Inspection	1481
	Interface Trust States and Network Security	1482
	Rate Limiting of ARP Packets	1483
	Relative Priority of ARP ACLs and DHCP Snooping Entries	1484
	Logging of Dropped Packets	1484
	Default Dynamic ARP Inspection Configuration	1484
	Relative Priority of ARP ACLs and DHCP Snooping Entries	1485
	Configuring ARP ACLs for Non-DHCP Environments	1485
	Configuring Dynamic ARP Inspection in DHCP Environments	1488
	Limiting the Rate of Incoming ARP Packets	1490
	Performing Dynamic ARP Inspection Validation Checks	1492
	Monitoring DAI	1494
	Verifying the DAI Configuration	1494
	Additional References	1495

CHAPTER 75	Configuring IEEE 802.1x Port-Based Authentication	1497
	Finding Feature Information	1497
	Information About 802.1x Port-Based Authentication	1497

Port-Based Authentication Process	1498
Port-Based Authentication Initiation and Message Exchange	1500
Authentication Manager for Port-Based Authentication	1501
Port-Based Authentication Methods	1501
Per-User ACLs and Filter-Ids	1502
Port-Based Authentication Manager CLI Commands	1503
Ports in Authorized and Unauthorized States	1504
Port-Based Authentication and Switch Stacks	1505
802.1x Host Mode	1506
802.1x Multiple Authentication Mode	1506
Multi-auth Per User VLAN assignment	1507
MAC Move	1508
MAC Replace	1509
802.1x Accounting	1509
802.1x Accounting Attribute-Value Pairs	1510
802.1x Readiness Check	1511
Switch-to-RADIUS-Server Communication	1511
802.1x Authentication with VLAN Assignment	1511
802.1x Authentication with Per-User ACLs	1513
802.1x Authentication with Downloadable ACLs and Redirect URLs	1514
Cisco Secure ACS and Attribute-Value Pairs for the Redirect URL	1516
Cisco Secure ACS and Attribute-Value Pairs for Downloadable ACLs	1516
VLAN ID-based MAC Authentication	1516
802.1x Authentication with Guest VLAN	1517
802.1x Authentication with Restricted VLAN	1518
802.1x Authentication with Inaccessible Authentication Bypass	1519
Inaccessible Authentication Bypass Support on Multiple-Authentication Ports	1519
Inaccessible Authentication Bypass Authentication Results	1519
Inaccessible Authentication Bypass Feature Interactions	1520
802.1x Critical Voice VLAN	1521
802.1x User Distribution	1521
802.1x User Distribution Configuration Guidelines	1522
IEEE 802.1x Authentication with Voice VLAN Ports	1522
IEEE 802.1x Authentication with Port Security	1523

IEEE 802.1x Authentication with Wake-on-LAN	1523
IEEE 802.1x Authentication with MAC Authentication Bypass	1523
Network Admission Control Layer 2 IEEE 802.1x Validation	1524
Flexible Authentication Ordering	1525
Open1x Authentication	1525
Multidomain Authentication	1526
Limiting Login for Users	1527
802.1x Supplicant and Authenticator Switches with Network Edge Access Topology (NEAT)	1528
Voice Aware 802.1x Security	1529
Common Session ID	1530
How to Configure 802.1x Port-Based Authentication	1530
Default 802.1x Authentication Configuration	1530
802.1x Authentication Configuration Guidelines	1532
802.1x Authentication	1532
VLAN Assignment, Guest VLAN, Restricted VLAN, and Inaccessible Authentication Bypass	1533
MAC Authentication Bypass	1533
Maximum Number of Allowed Devices Per Port	1534
Configuring 802.1x Readiness Check	1534
Configuring Voice Aware 802.1x Security	1536
Configuring 802.1x Violation Modes	1538
Configuring 802.1x Authentication	1539
Configuring 802.1x Port-Based Authentication	1540
Configuring Switch-to-RADIUS-Server Communication	1543
Configuring the Host Mode	1544
Configuring Periodic Re-Authentication	1546
Changing the Quiet Period	1547
Changing the Switch-to-Client Retransmission Time	1548
Setting the Switch-to-Client Frame-Retransmission Number	1549
Setting the Re-Authentication Number	1550
Enabling MAC Move	1552
Enabling MAC Replace	1553
Configuring 802.1x Accounting	1554
Configuring a Guest VLAN	1556

Configuring a Restricted VLAN	1557
Configuring Number of Authentication Attempts on a Restricted VLAN	1558
Configuring 802.1x Inaccessible Authentication Bypass with Critical Voice VLAN	1560
Example of Configuring Inaccessible Authentication Bypass	1563
Configuring 802.1x Authentication with WoL	1563
Configuring MAC Authentication Bypass	1564
Configuring 802.1x User Distribution	1565
Example of Configuring VLAN Groups	1566
Configuring NAC Layer 2 802.1x Validation	1567
Configuring Limiting Login for Users	1569
Configuring an Authenticator Switch with NEAT	1570
Configuring a Supplicant Switch with NEAT	1572
Configuring 802.1x Authentication with Downloadable ACLs and Redirect URLs	1575
Configuring Downloadable ACLs	1575
Configuring a Downloadable Policy	1576
Configuring VLAN ID-based MAC Authentication	1579
Configuring Flexible Authentication Ordering	1580
Configuring Open1x	1581
Disabling 802.1x Authentication on the Port	1583
Resetting the 802.1x Authentication Configuration to the Default Values	1584
Monitoring 802.1x Statistics and Status	1585
Additional References	1586

CHAPTER 76

Configuring Device Sensor	1589
About Device Sensor	1589
MSP-IOS Sensor Device Classifier Interaction	1590
Configuring Device Sensor	1591
Enabling MSP	1591
Enabling Accounting Augmentation	1592
Creating a Cisco Discovery Protocol Filter	1592
Creating an LLDP Filter	1593
Creating a DHCP Filter	1593
Applying a Protocol Filter to the Device Sensor Output	1594
Tracking TLV Changes	1595

Verifying the Device Sensor Configuration	1595
Troubleshooting Commands	1596
Restrictions for Device Sensor	1596
Configuration Examples for the Device Sensor Feature	1596

CHAPTER 77

Configuring MACsec Encryption	1599
Finding Feature Information	1599
Restriction for MACSec Encryption	1599
Information About MACsec Encryption	1599
Media Access Control Security and MACsec Key Agreement	1600
MKA Policies	1601
Virtual Ports	1601
MACsec and Stacking	1601
MACsec, MKA and 802.1x Host Modes	1602
Configuring MKA and MACsec	1603
Default MACsec MKA Configuration	1603
Configuring an MKA Policy	1603
Configuring MACsec on an Interface	1604
Information About Cisco TrustSec	1607
Configuring Cisco TrustSec MACsec	1609
Configuring Cisco TrustSec Credentials on the Switch	1609
Configuring Cisco TrustSec Switch-to-Switch Link Security in 802.1x Mode	1610
Configuring Cisco TrustSec Switch-to-Switch Link Security in Manual Mode	1612
Configuration Examples	1615
Example: Configuring MACsec on an Interface	1615
Cisco TrustSec Switch-to-Switch Link Security Configuration Example	1618

CHAPTER 78

Configuring Web-Based Authentication	1621
Finding Feature Information	1621
Web-Based Authentication Overview	1621
Device Roles	1622
Host Detection	1623
Session Creation	1623
Authentication Process	1623

Local Web Authentication Banner	1624
Web Authentication Customizable Web Pages	1627
Guidelines	1627
Authentication Proxy Web Page Guidelines	1628
Redirection URL for Successful Login Guidelines	1629
Custom Web Authentication Guidelines	1629
Web-based Authentication Interactions with Other Features	1629
Port Security	1629
LAN Port IP	1629
Gateway IP	1630
ACLs	1630
Context-Based Access Control	1630
EtherChannel	1630
How to Configure Web-Based Authentication	1630
Default Web-Based Authentication Configuration	1630
Web-Based Authentication Configuration Guidelines and Restrictions	1631
Configuring the Authentication Rule and Interfaces	1632
Configuring AAA Authentication	1634
Configuring Switch-to-RADIUS-Server Communication	1636
Configuring the HTTP Server	1638
Customizing the Authentication Proxy Web Pages	1639
Specifying a Redirection URL for Successful Login	1641
Configuring the Web-Based Authentication Parameters	1642
Configuring a Web-Based Authentication Local Banner	1643
Configuring Web-Based Authentication without SVI	1644
Configuring Web-Based Authentication with VRF Aware	1645
Removing Web-Based Authentication Cache Entries	1646
Downloading Web Authentication Tar Bundle (CLI)	1647
Downloading Web Authentication Tar Bundle (GUI)	1648
Integrating Customized Web Authentication Pages into a Parameter Map (CLI)	1648
Linking Image in Custom Pages	1650
Sample Web Authentication Login HTML	1651
Configuring a Parameter Map for Local Web Authentication (CLI)	1652
Monitoring Web-Based Authentication Status	1655

CHAPTER 79

Configuring Port-Based Traffic Control	1657
Overview of Port-Based Traffic Control	1657
Finding Feature Information	1658
Information About Storm Control	1658
Storm Control	1658
How Traffic Activity is Measured	1658
Traffic Patterns	1659
How to Configure Storm Control	1660
Configuring Storm Control and Threshold Levels	1660
Information About Protected Ports	1662
Protected Ports	1662
Default Protected Port Configuration	1663
Protected Ports Guidelines	1663
How to Configure Protected Ports	1663
Configuring a Protected Port	1663
Monitoring Protected Ports	1665
Where to Go Next	1665
Information About Port Blocking	1665
Port Blocking	1665
How to Configure Port Blocking	1665
Blocking Flooded Traffic on an Interface	1665
Monitoring Port Blocking	1667
Prerequisites for Port Security	1667
Restrictions for Port Security	1667
Information About Port Security	1668
Port Security	1668
Types of Secure MAC Addresses	1668
Sticky Secure MAC Addresses	1668
Security Violations	1669
Port Security Aging	1670
Port Security and Switch Stacks	1670
Default Port Security Configuration	1670
Port Security Configuration Guidelines	1671

Overview of Port-Based Traffic Control	1672
How to Configure Port Security	1673
Enabling and Configuring Port Security	1673
Enabling and Configuring Port Security Aging	1678
Configuration Examples for Port Security	1680

CHAPTER 80
Configuring IPv6 First Hop Security 1683

Finding Feature Information	1683
Prerequisites for First Hop Security in IPv6	1683
Restrictions for First Hop Security in IPv6	1684
Information about First Hop Security in IPv6	1684
How to Configure an IPv6 Snooping Policy	1687
How to Attach an IPv6 Snooping Policy to an Interface	1688
How to Attach an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface	1690
How to Attach an IPv6 Snooping Policy to VLANs Globally	1691
How to Configure the IPv6 Binding Table Content	1692
How to Configure an IPv6 Neighbor Discovery Inspection Policy	1693
How to Attach an IPv6 Neighbor Discovery Inspection Policy to an Interface	1695
How to Attach an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface	1696
How to Attach an IPv6 Neighbor Discovery Inspection Policy to VLANs Globally	1697
How to Configure an IPv6 Router Advertisement Guard Policy	1698
How to Attach an IPv6 Router Advertisement Guard Policy to an Interface	1700
How to Attach an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface	1701
How to Attach an IPv6 Router Advertisement Guard Policy to VLANs Globally	1703
How to Configure an IPv6 DHCP Guard Policy	1703
How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface	1706
How to Attach an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface	1707
How to Attach an IPv6 DHCP Guard Policy to VLANs Globally	1708
How to Configure IPv6 Source Guard	1709
How to Attach an IPv6 Source Guard Policy to an Interface	1710
How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface	1711
How to Configure IPv6 Prefix Guard	1712

How to Attach an IPv6 Prefix Guard Policy to an Interface	1713
How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface	1714
Configuration Examples for IPv6 First Hop Security	1715
Examples: How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface	1715
Examples: How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface	1716
Additional References	1716

CHAPTER 81	Configuring Cisco TrustSec	1719
	Information about Cisco TrustSec	1719
	Finding Feature Information	1719
	Feature Information for Cisco TrustSec	1720

CHAPTER 82	Configuring Wireless Guest Access	1721
	Finding Feature Information	1721
	Prerequisites for Guest Access	1721
	Restrictions for Guest Access	1722
	Information about Wireless Guest Access	1722
	Fast Secure Roaming	1722
	How to Configure Guest Access	1723
	Creating a Lobby Administrator Account	1723
	Configuring Guest User Accounts	1724
	Configuring Mobility Agent (MA)	1725
	Configuring Mobility Controller	1726
	Obtaining a Web Authentication Certificate	1728
	Displaying a Web Authentication Certificate	1728
	Choosing the Default Web Authentication Login Page	1729
	Choosing a Customized Web Authentication Login Page from an External Web Server	1730
	Assigning Login, Login Failure, and Logout Pages per WLAN	1732
	Configuring AAA-Override	1733
	Configuring Client Load Balancing	1734
	Configuring Preauthentication ACL	1735
	Configuring IOS ACL Definition	1736
	Configuring Webpassthrough	1737
	Configuration Examples for Guest Access	1738

Example: Creating a Lobby Ambassador Account	1738
Example: Obtaining Web Authentication Certificate	1738
Example: Displaying a Web Authentication Certificate	1740
Example: Configuring Guest User Accounts	1740
Example: Configuring Mobility Controller	1741
Example: Choosing the Default Web Authentication Login Page	1741
Example: Choosing a Customized Web Authentication Login Page from an External Web Server	1742
Example: Assigning Login, Login Failure, and Logout Pages per WLAN	1742
Example: Configuring AAA-Override	1743
Example: Configuring Client Load Balancing	1743
Example: Configuring Preauthentication ACL	1743
Example: Configuring IOS ACL Definition	1744
Example: Configuring Webpassthrough	1744
Additional References for Guest Access	1744
Feature History and Information for Guest Access	1745

CHAPTER 83**Managing Rogue Devices 1747**

Finding Feature Information	1747
Information About Rogue Devices	1747
Validating Rogue Devices Using MSE	1752
How to Configure Rogue Detection	1752
Configuring Rogue Detection (CLI)	1752
Configuring Rogue Detection (GUI)	1754
Monitoring Rogue Detection	1755
Examples: Rogue Detection Configuration	1755
Additional References for Rogue Detection	1756
Feature History and Information For Performing Rogue Detection Configuration	1757

CHAPTER 84**Classifying Rogue Access Points 1759**

Finding Feature Information	1759
Information About Classifying Rogue Access Points	1759
Restrictions on Classifying Rogue Access Points	1762
How to Classify Rogue Access Points	1763

Configuring Rogue Classification Rules (CLI)	1763
Configuring Rogue Classification Rules (GUI)	1766
Viewing and Classifying Rogue Devices (GUI)	1768
Examples: Classifying Rogue Access Points	1770
Additional References for Classifying Rogue Access Points	1770
Feature History and Information For Classifying Rogue Access Points	1771

CHAPTER 85**Configuring wIPS 1773**

Finding Feature Information	1773
Information About wIPS	1773
How to Configure wIPS on an Access Point	1779
Configuring wIPS on an Access Point (CLI)	1779
Configuring wIPS on an Access Point (GUI)	1780
Monitoring wIPS Information	1780
Examples: wIPS Configuration	1780
Additional References for Configuring wIPS	1781
Feature History for Performing wIPS Configuration	1781

CHAPTER 86**Configuring Intrusion Detection System 1783**

Finding Feature Information	1783
Information About Intrusion Detection System	1783
How to Configure Intrusion Detection System	1784
Configuring IDS Sensors	1784
Monitoring Intrusion Detection System	1785

PART XIV**Stack Manager and High Availability 1787**

CHAPTER 87**Managing Switch Stacks 1789**

Finding Feature Information	1789
Prerequisites for Switch Stacks	1789
Restrictions for Switch Stacks	1789
Information About Switch Stacks	1790
Switch Stack Overview	1790
Supported Features in a Switch Stack	1790

Switch Stack Membership	1791
Changes to Switch Stack Membership	1791
Stack Member Numbers	1792
Stack Member Priority Values	1794
Switch Stack Bridge ID and MAC Address	1794
Persistent MAC Address on the Switch Stack	1794
Active and Standby Switch Election and Reelection	1794
Switch Stack Configuration Files	1796
Offline Configuration to Provision a Stack Member	1797
Effects of Adding a Provisioned Switch to a Switch Stack	1797
Effects of Replacing a Provisioned Switch in a Switch Stack	1799
Effects of Removing a Provisioned Switch from a Switch Stack	1799
Upgrading a Switch Running Incompatible Software	1799
Auto-Upgrade	1799
Auto-Advise	1800
SDM Template Mismatch in Switch Stacks	1801
Switch Stack Management Connectivity	1801
Connectivity to Specific Stack Members	1801
Connectivity to the Switch Stack Through an IP Address	1802
Connectivity to the Switch Stack Through Console Ports or Ethernet Management Ports	1802
How to Configure a Switch Stack	1803
Enabling the Persistent MAC Address Feature	1803
Assigning a Stack Member Number	1804
Setting the Stack Member Priority Value	1805
Provisioning a New Member for a Switch Stack	1806
Removing Provisioned Switch Information	1807
Displaying Incompatible Switches in the Switch Stack	1808
Upgrading an Incompatible Switch in the Switch Stack	1809
Troubleshooting the Switch Stack	1809
Accessing the Diagnostic Console of a Stack Member	1809
Temporarily Disabling a Stack Port	1810
Reenabling a Stack Port While Another Member Starts	1811
Monitoring the Device Stack	1812
Configuration Examples for Switch Stacks	1812

Switch Stack Configuration Scenarios	1812
Enabling the Persistent MAC Address Feature: Example	1814
Provisioning a New Member for a Switch Stack: Example	1814
show switch stack-ports summary Command Output: Example	1815
Software Loopback: Examples	1816
Software Loopback with Connected Stack Cables: Examples	1817
Software Loopback with no Connected Stack Cable: Example	1818
Finding a Disconnected Stack Cable: Example	1818
Fixing a Bad Connection Between Stack Ports: Example	1819
Additional References for Switch Stacks	1819

CHAPTER 88

Configuring Cisco NSF with SSO	1821
Finding Feature Information	1821
Prerequisites for NSF with SSO	1821
Restrictions for NSF with SSO	1822
Information About NSF with SSO	1822
Overview of NSF with SSO	1822
SSO Operation	1823
Cisco Express Forwarding	1824
How to Configure Cisco NSF with SSO	1825
Configuring SSO	1825
Configuring SSO Example	1826
Verifying CEF NSF	1826

CHAPTER 89

Configuring Wireless High Availability	1829
Finding Feature Information	1829
Information about High Availability	1829
Information About Redundancy	1830
Configuring Redundancy in Access Points	1830
Configuring Heartbeat Messages	1831
Information about Access Point Stateful Switch Over	1832
Initiating Graceful Switchover	1832
Configuring EtherChannels for High Availability	1832
Configuring LACP	1833

Troubleshooting High Availability	1834
Access the Standby Console	1834
Before a Switchover	1835
After a Switchover	1836
Viewing Redundancy Switchover History (GUI)	1837
Viewing Switchover States (GUI)	1837
Monitoring the Device Stack	1838
LACP Configuration: Example	1839
Flex Link Configuration: Example	1841

PART XV
System Management 1845

CHAPTER 90
Administering the System 1847

Finding Feature Information	1847
Information About Administering the Device	1847
System Time and Date Management	1847
System Clock	1848
Network Time Protocol	1848
NTP Stratum	1849
NTP Associations	1850
NTP Security	1850
NTP Implementation	1850
NTP Version 4	1851
System Name and Prompt	1851
Stack System Name and Prompt	1851
Default System Name and Prompt Configuration	1851
DNS	1852
Default DNS Settings	1852
Login Banners	1852
Default Banner Configuration	1852
MAC Address Table	1852
MAC Address Table Creation	1853
MAC Addresses and VLANs	1853
MAC Addresses and Device Stacks	1853

Default MAC Address Table Settings	1854
ARP Table Management	1854
How to Administer the Device	1854
Configuring the Time and Date Manually	1854
Setting the System Clock	1855
Configuring the Time Zone	1855
Configuring Summer Time (Daylight Saving Time)	1856
Configuring a System Name	1860
Setting Up DNS	1861
Configuring a Message-of-the-Day Login Banner	1862
Configuring a Login Banner	1864
Managing the MAC Address Table	1865
Changing the Address Aging Time	1865
Configuring MAC Address Change Notification Traps	1866
Configuring MAC Address Move Notification Traps	1868
Configuring MAC Threshold Notification Traps	1870
Adding and Removing Static Address Entries	1872
Configuring Unicast MAC Address Filtering	1873
Monitoring and Maintaining Administration of the Device	1875
Configuration Examples for Device Administration	1876
Example: Setting the System Clock	1876
Examples: Configuring Summer Time	1876
Example: Configuring a MOTD Banner	1876
Example: Configuring a Login Banner	1877
Example: Configuring MAC Address Change Notification Traps	1877
Example: Configuring MAC Threshold Notification Traps	1877
Example: Adding the Static Address to the MAC Address Table	1877
Example: Configuring Unicast MAC Address Filtering	1878
Additional References for Device Administration	1878
Feature History and Information for Device Administration	1879
CHAPTER 91	Performing Device Setup Configuration 1881
Finding Feature Information	1881
Information About Performing Device Setup Configuration	1881

Device Boot Process	1881
Software Installer Features	1882
Software Boot Modes	1883
Installed Boot Mode	1883
Bundle Boot Mode	1883
Boot Mode for a Switch Stack	1884
Devices Information Assignment	1884
Default Switch Information	1885
DHCP-Based Autoconfiguration Overview	1885
DHCP Client Request Process	1886
DHCP-based Autoconfiguration and Image Update	1887
Restrictions for DHCP-based Autoconfiguration	1887
DHCP Autoconfiguration	1887
DHCP Auto-Image Update	1887
DHCP Server Configuration Guidelines	1888
Purpose of the TFTP Server	1888
Purpose of the DNS Server	1889
How to Obtain Configuration Files	1889
How to Control Environment Variables	1890
Common Environment Variables	1891
Environment Variables for TFTP	1892
Scheduled Reload of the Software Image	1893
How to Perform Device Setup Configuration	1893
Configuring DHCP Autoconfiguration (Only Configuration File)	1893
Configuring DHCP Auto-Image Update (Configuration File and Image)	1895
Configuring the Client to Download Files from DHCP Server	1899
Manually Assigning IP Information to Multiple SVIs	1900
Modifying the Device Startup Configuration	1902
Specifying the Filename to Read and Write the System Configuration	1902
Manually Booting the Switch	1903
Booting the Device in Installed Mode	1904
Booting the Device in Bundle Mode	1905
Booting a Specific Software Image On a Switch Stack	1906
Configuring a Scheduled Software Image Reload	1907

Monitoring Device Setup Configuration	1909
Example: Verifying the Device Running Configuration	1909
Examples: Displaying Software Bootup in Install Mode	1910
Example: Emergency Installation	1912
Configuration Examples for Performing Device Setup	1913
Example: Configuring a Device as a DHCP Server	1913
Example: Configuring DHCP Auto-Image Update	1913
Example: Configuring a Device to Download Configurations from a DHCP Server	1914
Examples: Scheduling Software Image Reload	1914
Additional References For Performing Device Setup	1915
Feature History and Information For Performing Device Setup Configuration	1916

CHAPTER 92

Configuring Right-To-Use Licenses	1917
Finding Feature Information	1917
Restrictions for Configuring RTU Licenses	1917
Information About Configuring RTU Licenses	1918
Right-To-Use Licensing	1918
Right-To-Use Image Based Licenses	1918
Right-To-Use License States	1918
License Activation for Switch Stacks	1919
Mobility Controller Mode	1919
Right-To-Use AP-Count Licensing	1920
Right-to-Use AP-Count Evaluation Licenses	1920
Right-To-Use Adder AP-Count Rehosting Licenses	1921
How to Configure RTU Licenses	1921
Activating an Imaged Based License	1921
Activating an AP-Count License	1922
Obtaining an Upgrade or Capacity Adder License	1923
Rehosting a License	1924
Changing Mobility Mode	1925
Monitoring and Maintaining RTU Licenses	1926
Configuration Examples for RTU Licensing	1927
Examples: Activating RTU Image Based Licenses	1927
Examples: Displaying RTU Licensing Information	1927

Example: Displaying RTU License Details 1929

Example: Displaying RTU License Mismatch 1930

Example: Displaying RTU Licensing Usage 1931

Additional References for RTU Licensing 1932

Feature History and Information for RTU Licensing 1933

CHAPTER 93

Configuring Administrator Usernames and Passwords 1935

Finding Feature Information 1935

Information About Configuring Administrator Usernames and Passwords 1935

Configuring Administrator Usernames and Passwords 1936

Examples: Administrator Usernames and Passwords Configuration 1938

Additional References for Administrator Usernames and Passwords 1939

Feature History and Information For Performing Administrator Usernames and Passwords Configuration 1939

CHAPTER 94

Configuring 802.11 parameters and Band Selection 1941

Finding Feature Information 1941

Restrictions on Band Selection, 802.11 Bands, and Parameters 1941

Information About Configuring Band Selection, 802.11 Bands, and Parameters 1942

Band Selection 1942

802.11 Bands 1943

802.11n Parameter 1943

802.11h Parameter 1943

How to Configure 802.11 Bands and Parameters 1943

Configuring Band Selection (CLI) 1943

Configuring the 802.11 Bands (CLI) 1945

Configuring the 802.11 Bands (GUI) 1947

Configuring 802.11n Parameters (CLI) 1948

Configuring the 802.11n Parameters (GUI) 1951

Configuring 802.11h Parameters (CLI) 1952

Configuring the 802.11h Parameters (GUI) 1953

Monitoring Configuration Settings for Band Selection, 802.11 Bands, and Parameters 1954

Monitoring Configuration Settings Using Band Selection and 802.11 Bands Commands 1954

Example: Viewing the Configuration Settings for 5-GHz Band 1954

Example: Viewing the Configuration Settings for 24-GHz Band	1956
Example: Viewing the status of 802.11h Parameters	1957
Example: Verifying the Band Selection Settings	1958
Configuration Examples for Band Selection, 802.11 Bands, and Parameters	1958
Examples: Band Selection Configuration	1958
Examples: 802.11 Bands Configuration	1959
Examples: 802.11n Configuration	1959
Examples: 802.11h Configuration	1960
Additional References for 802.11 Parameters and Band Selection	1960
Feature History and Information For Performing 802.11 parameters and Band Selection Configuration	1961

CHAPTER 95**Configuring Aggressive Load Balancing 1963**

Finding Feature Information	1963
Restrictions for Aggressive Load Balancing	1963
Information for Configuring Aggressive Load Balancing Parameters	1964
Aggressive Load Balancing	1964
How to Configure Aggressive Load Balancing	1965
Configuring Aggressive Load Balancing	1965
Monitoring Aggressive Load Balancing	1966
Examples: Aggressive Load Balancing Configuration	1966
Additional References for Aggressive Load Balancing	1967
Feature History and Information For Performing Aggressive Load Balancing Configuration	1968

CHAPTER 96**Configuring Client Roaming 1969**

Finding Feature Information	1969
Restrictions for Configuring Client Roaming	1969
Information About Client Roaming	1969
Inter-Subnet Roaming	1971
Voice-over-IP Telephone Roaming	1971
CCX Layer 2 Client Roaming	1971
How to Configure Layer 2 or Layer 3 Roaming	1972
Configuring Layer 2 or Layer 3 Roaming	1972
Configuring CCX Client Roaming Parameters (CLI)	1973

Configuring Mobility Oracle 1975
 Configuring Mobility Controller 1975
 Configuring Mobility Agent 1978
 Monitoring Client Roaming Parameters 1979
 Monitoring Mobility Configurations 1979
 Additional References for Configuring Client Roaming 1980
 Feature History and Information For Performing Client Roaming Configuration 1981

CHAPTER 97

Configuring Application Visibility and Control 1983

Finding Feature Information 1983
 Information About Application Visibility and Control 1983
 Supported AVC Class Map and Policy Map Formats 1984
 Prerequisites for Application Visibility and Control 1986
 Guidelines for Inter-Device Roaming with Application Visibility and Control 1987
 Restrictions for Application Visibility and Control 1987
 How to Configure Application Visibility and Control 1988
 Configuring Application Visibility and Control (CLI) 1988
 Creating a Flow Record 1988
 Creating a Flow Exporter (Optional) 1991
 Creating a Flow Monitor 1992
 Creating AVC QoS Policy 1993
 Configuring WLAN to Apply Flow Monitor in IPV4 Input/Output Direction 2004
 Configuring Application Visibility and Control (GUI) 2005
 Configuring Application Visibility (GUI) 2005
 Configuring Application Visibility and Control (GUI) 2006
 Monitoring Application Visibility and Control 2007
 Monitoring Application Visibility and Control (CLI) 2007
 Monitoring Application Visibility and Control (GUI) 2008
 Monitoring SSID and Client Policies Statistics (GUI) 2009
 Examples: Application Visibility and Control 2010
 Examples: Application Visibility Configuration 2010
 Examples: Application Visibility and Control QoS Configuration 2010
 Example: Configuring QoS Attribute for Local Profiling Policy 2012
 Additional References for Application Visibility and Control 2013

Feature History and Information For Application Visibility and Control 2014

CHAPTER 98

Configuring Voice and Video Parameters 2015

Finding Feature Information 2015

Prerequisites for Voice and Video Parameters 2015

Restrictions for Voice and Video Parameters 2015

Information About Configuring Voice and Video Parameters 2016

Call Admission Control 2016

Static-Based CAC 2017

Load-Based CAC 2017

IOSd Call Admission Control 2017

Expedited Bandwidth Requests 2018

U-APSD 2019

Traffic Stream Metrics 2019

Information About Configuring Voice Prioritization Using Preferred Call Numbers 2020

Information About EDCA Parameters 2020

How to Configure Voice and Video Parameters 2021

Configuring Voice Parameters (CLI) 2021

Configuring Video Parameters (CLI) 2024

Configuring SIP-Based CAC (CLI) 2027

Configuring a Preferred Call Number (CLI) 2028

Configuring EDCA Parameters (CLI) 2030

Configuring EDCA Parameters (GUI) 2031

Monitoring Voice and Video Parameters 2032

Configuration Examples for Voice and Video Parameters 2034

Example: Configuring Voice and Video 2034

Additional References for Voice and Video Parameters 2035

Feature History and Information For Performing Voice and Video Parameters Configuration 2036

CHAPTER 99

Configuring RFID Tag Tracking 2037

Finding Feature Information 2037

Information About Configuring RFID Tag Tracking 2037

How to Configure RFID Tag Tracking 2037

Configuring RFID Tag Tracking (CLI) 2037

Monitoring RFID Tag Tracking Information	2038
Additional References RFID Tag Tracking	2039
Feature History and Information For Performing RFID Tag Tracking Configuration	2040

CHAPTER 100**Configuring Location Settings 2041**

Finding Feature Information	2041
Information About Configuring Location Settings	2041
How to Configure Location Settings	2042
Configuring Location Settings (CLI)	2042
Modifying the NMSP Notification Interval for Clients, RFID Tags, and Rogues (CLI)	2044
Modifying the NMSP Notification threshold for Clients, RFID Tags, and Rogues (CLI)	2045
Monitoring Location Settings and NMSP Settings	2046
Monitoring Location Settings (CLI)	2046
Monitoring NMSP Settings (CLI)	2046
Examples: Location Settings Configuration	2047
Examples: NMSP Settings Configuration	2047
Additional References for Location Settings	2048
Feature History and Information For Performing Location Settings Configuration	2049

CHAPTER 101**Monitoring Flow Control 2051**

Finding Feature Information	2051
Information About Flow Control	2051
Monitoring Flow Control	2051
Examples: Monitoring Flow Control	2052
Additional References for Monitoring Flow Control	2053
Feature History and Information For Monitoring Flow Control	2053

CHAPTER 102**Configuring SDM Templates 2055**

Finding Feature Information	2055
Information About Configuring SDM Templates	2055
SDM Templates	2055
SDM Templates and Switch Stacks	2057
How to Configure SDM Templates	2057
Configuring SDM Templates	2057

Configuring the Switch SDM Template	2057
Monitoring and Maintaining SDM Templates	2058
Configuration Examples for SDM Templates	2059
Examples: Configuring SDM Templates	2059
Examples: Displaying SDM Templates	2059
Additional References for SDM Templates	2060
Feature History and Information for Configuring SDM Templates	2061

CHAPTER 103**Configuring System Message Logs 2063**

Finding Feature Information	2063
Restrictions for Configuring System Message Logs	2063
Information About Configuring System Message Logs	2064
System Message Logging	2064
System Log Message Format	2064
Default System Message Logging Settings	2065
Syslog Message Limits	2066
Enabling Syslog Trap Messages	2066
How to Configure System Message Logs	2066
Setting the Message Display Destination Device	2066
Synchronizing Log Messages	2068
Disabling Message Logging	2070
Enabling and Disabling Time Stamps on Log Messages	2070
Enabling and Disabling Sequence Numbers in Log Messages	2071
Defining the Message Severity Level	2072
Limiting Syslog Messages Sent to the History Table and to SNMP	2073
Logging Messages to a UNIX Syslog Daemon	2074
Monitoring and Maintaining System Message Logs	2075
Monitoring Configuration Archive Logs	2075
Configuration Examples for System Message Logs	2075
Example: Stacking System Message	2075
Example: Switch System Message	2076
Additional References for System Message Logs	2076
Feature History and Information For System Message Logs	2077

CHAPTER 104	Configuring Online Diagnostics	2079
	Finding Feature Information	2079
	Information About Configuring Online Diagnostics	2079
	Online Diagnostics	2079
	How to Configure Online Diagnostics	2080
	Starting Online Diagnostic Tests	2080
	Configuring Online Diagnostics	2081
	Scheduling Online Diagnostics	2081
	Configuring Health-Monitoring Diagnostics	2082
	Monitoring and Maintaining Online Diagnostics	2085
	Displaying Online Diagnostic Tests and Test Results	2085
	Configuration Examples for Online Diagnostic Tests	2085
	Examples: Start Diagnostic Tests	2085
	Example: Configure a Health Monitoring Test	2086
	Examples: Schedule Diagnostic Test	2086
	Examples: Displaying Online Diagnostics	2086
	Additional References for Online Diagnostics	2087
	Feature History and Information for Configuring Online Diagnostics	2088

CHAPTER 105	Managing Configuration Files	2089
	Prerequisites for Managing Configuration Files	2089
	Restrictions for Managing Configuration Files	2089
	Information About Managing Configuration Files	2089
	Types of Configuration Files	2089
	Configuration Mode and Selecting a Configuration Source	2090
	Configuration File Changes Using the CLI	2090
	Location of Configuration Files	2090
	Copy Configuration Files from a Network Server to the Device	2091
	Copying a Configuration File from the Device to a TFTP Server	2091
	Copying a Configuration File from the Device to an RCP Server	2091
	Copying a Configuration File from the Device to an FTP Server	2093
	Copy Configuration Files from a Switch to Another Switch	2094
	Configuration Files Larger than NVRAM	2094

Compressing the Configuration File	2094
Storing the Configuration in Flash Memory on Class A Flash File Systems	2095
Loading the Configuration Commands from the Network	2095
Configuring the Device to Download Configuration Files	2095
Network Versus Host Configuration Files	2095
How to Manage Configuration File Information	2096
Displaying Configuration File Information (CLI)	2096
Modifying the Configuration File (CLI)	2097
Copying a Configuration File from the Device to a TFTP Server (CLI)	2098
What to Do Next	2099
Copying a Configuration File from the Device to an RCP Server (CLI)	2099
Examples	2101
What to Do Next	2101
Copying a Configuration File from the Device to the FTP Server (CLI)	2101
Examples	2102
What to Do Next	2103
Copying a Configuration File from a TFTP Server to the Device (CLI)	2103
What to Do Next	2104
Copying a Configuration File from the rcp Server to the Device (CLI)	2104
Examples	2105
What to Do Next	2106
Copying a Configuration File from an FTP Server to the Device (CLI)	2106
Examples	2107
What to Do Next	2108
Maintaining Configuration Files Larger than NVRAM	2108
Compressing the Configuration File (CLI)	2108
Storing the Configuration in Flash Memory on Class A Flash File Systems (CLI)	2110
Loading the Configuration Commands from the Network (CLI)	2111
Copying Configuration Files from Flash Memory to the Startup or Running Configuration (CLI)	2112
Copying Configuration Files Between Flash Memory File Systems (CLI)	2113
Copying a Configuration File from an FTP Server to Flash Memory Devices (CLI)	2115
What to Do Next	2116
Copying a Configuration File from an RCP Server to Flash Memory Devices (CLI)	2116

- Copying a Configuration File from a TFTP Server to Flash Memory Devices (CLI) **2117**
- Re-executing the Configuration Commands in the Startup Configuration File (CLI) **2118**
- Clearing the Startup Configuration (CLI) **2118**
- Deleting a Specified Configuration File (CLI) **2119**
- Specifying the CONFIG_FILE Environment Variable on Class A Flash File Systems (CLI) **2120**
 - What to Do Next **2121**
- Configuring the Device to Download Configuration Files **2122**
 - Configuring the Device to Download the Network Configuration File (CLI) **2122**
 - Configuring the Device to Download the Host Configuration File (CLI) **2123**
- Additional References **2125**

CHAPTER 106

Configuration Replace and Configuration Rollback 2127

- Prerequisites for Configuration Replace and Configuration Rollback **2127**
- Restrictions for Configuration Replace and Configuration Rollback **2128**
- Information About Configuration Replace and Configuration Rollback **2128**
 - Configuration Archive **2128**
 - Configuration Replace **2129**
 - Configuration Rollback **2130**
 - Configuration Rollback Confirmed Change **2130**
 - Benefits of Configuration Replace and Configuration Rollback **2130**
- How to Use Configuration Replace and Configuration Rollback **2131**
 - Creating a Configuration Archive (CLI) **2131**
 - Performing a Configuration Replace or Configuration Rollback Operation (CLI) **2133**
 - Monitoring and Troubleshooting the Feature (CLI) **2135**
- Configuration Examples for Configuration Replace and Configuration Rollback **2137**
 - Creating a Configuration Archive **2137**
 - Replacing the Current Running Configuration with a Saved Cisco IOS Configuration File **2137**
 - Reverting to the Startup Configuration File **2138**
 - Performing a Configuration Replace Operation with the configure confirm Command **2138**
 - Performing a Configuration Rollback Operation **2138**
- Additional References **2139**

CHAPTER 107

Working with the Flash File System 2143

- Information About the Flash File System **2143**

Displaying Available File Systems	2143
Setting the Default File System	2146
Displaying Information About Files on a File System	2146
Changing Directories and Displaying the Working Directory (CLI)	2147
Creating Directories (CLI)	2148
Removing Directories	2149
Copying Files	2149
Copying Files from One Device in a Stack to Another Device in the Same Stack	2150
Deleting Files	2151
Creating, Displaying and Extracting Files (CLI)	2151
Additional References	2153

CHAPTER 108

Working with Cisco IOS XE Software Bundles	2155
About Software Bundles and Packages	2155
Bundle and Package File Location on the Device	2155
Upgrading Cisco IOS XE Software	2156
Upgrading Cisco IOS XE Software: Install Mode	2156
Upgrading Cisco IOS XE Software Install Mode Example	2156
Upgrading Cisco IOS XE Software: Bundle Mode	2157
Upgrading Cisco IOS XE Software Bundle Mode Example	2157
Converting from the Bundle Running Mode to the Install Running Mode	2158
Converting from the Bundle Running Mode to the Install Running Mode Example	2158
Copying IOS XE Package and Bundle Files from One Stack Member to Another	2159
Copying IOS XE Package and Bundle Files from One Stack Member to Another Example	2159
Upgrading a Device Running Incompatible Software	2161
Upgrading a Device Running Incompatible Software Example	2161
Upgrading a Device Running in Incompatible Running Mode	2162
Upgrading a Device Running in Incompatible Running Mode Example	2162
Additional References	2164

CHAPTER 109

Troubleshooting the Software Configuration	2167
Finding Feature Information	2167
Information About Troubleshooting the Software Configuration	2167
Software Failure on a Switch	2167

Lost or Forgotten Password on a Device	2168
Power over Ethernet Ports	2168
Disabled Port Caused by Power Loss	2168
Disabled Port Caused by False Link-Up	2169
Ping	2169
Layer 2 Traceroute	2169
Layer 2 Traceroute Guidelines	2169
IP Traceroute	2170
Time Domain Reflector Guidelines	2171
Debug Commands	2172
Crashinfo Files	2172
System Reports	2173
Onboard Failure Logging on the Switch	2174
Fan Failures	2174
Possible Symptoms of High CPU Utilization	2175
How to Troubleshoot the Software Configuration	2175
Recovering from a Software Failure	2175
Recovering from a Lost or Forgotten Password	2177
Procedure with Password Recovery Enabled	2178
Procedure with Password Recovery Disabled	2180
Preventing Switch Stack Problems	2182
Preventing Autonegotiation Mismatches	2183
Troubleshooting SFP Module Security and Identification	2183
Monitoring SFP Module Status	2184
Executing Ping	2184
Monitoring Temperature	2184
Monitoring the Physical Path	2184
Executing IP Traceroute	2185
Running TDR and Displaying the Results	2185
Redirecting Debug and Error Message Output	2185
Using the show platform forward Command	2186
Using the show debug command	2186
Configuring OBFL	2186
Verifying Troubleshooting of the Software Configuration	2187

Displaying OBFL Information	2187
Example: Verifying the Problem and Cause for High CPU Utilization	2188
Scenarios for Troubleshooting the Software Configuration	2189
Scenarios to Troubleshoot Power over Ethernet (PoE)	2189
Configuration Examples for Troubleshooting Software	2191
Example: Pinging an IP Host	2191
Example: Performing a Traceroute to an IP Host	2192
Example: Enabling All System Diagnostics	2193
Additional References for Troubleshooting Software Configuration	2194
Feature History and Information for Troubleshooting Software Configuration	2195

PART XVI
VideoStream 2197

CHAPTER 110
Configuring VideoStream 2199

Finding Feature Information	2199
Prerequisites for VideoStream	2199
Restrictions for Configuring VideoStream	2199
Information about VideoStream	2200
How to Configure VideoStream	2200
Configuring Multicast-Direct Globally for Media-Stream	2200
Configuring Media-Stream for 802.11 bands	2201
Configuring WLAN to Stream Video	2203
Deleting a Media-Stream	2204
Monitoring Media Streams	2205

CHAPTER 111
Configuring VideoStream GUI 2207

Configuring VideoStream (GUI)	2207
-------------------------------	------

PART XVII
VLAN 2211

CHAPTER 112
Configuring VTP 2213

Finding Feature Information	2213
Prerequisites for VTP	2213
Restrictions for VTP	2214

Information About VTP	2214
VTP	2214
VTP Domain	2215
VTP Modes	2216
VTP Advertisements	2217
VTP Version 2	2218
VTP Version 3	2218
VTP Pruning	2219
VTP and Device Stacks	2220
VTP Configuration Guidelines	2221
VTP Configuration Requirements	2221
VTP Settings	2221
Domain Names for Configuring VTP	2221
Passwords for the VTP Domain	2222
VTP Version	2222
How to Configure VTP	2223
Configuring VTP Mode (CLI)	2223
Configuring a VTP Version 3 Password (CLI)	2225
Configuring a VTP Version 3 Primary Server (CLI)	2226
Enabling the VTP Version (CLI)	2227
Enabling VTP Pruning (CLI)	2229
Configuring VTP on a Per-Port Basis (CLI)	2230
Adding a VTP Client to a VTP Domain (CLI)	2231
Monitoring VTP	2233
Configuration Examples for VTP	2234
Example: Configuring a Switch as the Primary Server	2234
Where to Go Next	2235
Additional References	2235
Feature History and Information for VTP	2236

CHAPTER 113
Configuring VLANs 2237

Finding Feature Information	2237
Prerequisites for VLANs	2237
Restrictions for VLANs	2238

Information About VLANs	2238
Logical Networks	2238
Supported VLANs	2239
VLAN Port Membership Modes	2239
VLAN Configuration Files	2240
Normal-Range VLAN Configuration Guidelines	2241
Extended-Range VLAN Configuration Guidelines	2242
How to Configure VLANs	2242
How to Configure Normal-Range VLANs	2242
Creating or Modifying an Ethernet VLAN (CLI)	2243
Deleting a VLAN (CLI)	2246
Assigning Static-Access Ports to a VLAN (CLI)	2247
How to Configure Extended-Range VLANs	2249
Creating an Extended-Range VLAN (CLI)	2249
How to Configure VLANs (GUI)	2251
Creating Layer2 VLAN (GUI)	2251
Creating Layer3 Interface (GUI)	2252
Viewing Layer2 VLAN (GUI)	2252
Viewing Layer3 Interface (GUI)	2252
Removing Layer2 VLAN (GUI)	2253
Removing Layer3 Interface (GUI)	2253
Monitoring VLANs	2254
Where to Go Next	2255
Additional References	2256
Feature History and Information for VLANs	2257

CHAPTER 114

Configuring VLAN Groups	2259
Finding Feature Information	2259
Prerequisites for VLAN Groups	2259
Restrictions for VLAN Groups	2259
Information About VLAN Groups	2260
How to Configure VLAN Groups	2260
Creating VLAN Groups (CLI)	2260
Removing VLAN Group (CLI)	2261

Creating VLAN Groups (GUI)	2262
Adding a VLAN Group to WLAN (CLI)	2262
Adding a VLAN Group to WLAN (GUI)	2263
Removing VLAN Groups (GUI)	2263
Viewing VLANs in VLAN Groups (CLI)	2263
Viewing VLAN Groups (GUI)	2264
Where to Go Next	2264
Additional References	2264
Feature History and Information for VLAN Groups	2266

CHAPTER 115**Configuring VLAN Trunks 2267**

Finding Feature Information	2267
Prerequisites for VLAN Trunks	2267
Restrictions for VLAN Trunks	2268
Information About VLAN Trunks	2269
Trunking Overview	2269
Trunking Modes	2269
Layer 2 Interface Modes	2269
Allowed VLANs on a Trunk	2270
Load Sharing on Trunk Ports	2270
Network Load Sharing Using STP Priorities	2270
Network Load Sharing Using STP Path Cost	2271
Feature Interactions	2271
How to Configure VLAN Trunks	2271
Configuring an Ethernet Interface as a Trunk Port	2272
Configuring a Trunk Port (CLI)	2272
Defining the Allowed VLANs on a Trunk (CLI)	2274
Changing the Pruning-Eligible List (CLI)	2276
Configuring the Native VLAN for Untagged Traffic (CLI)	2277
Configuring Trunk Ports for Load Sharing	2278
Configuring Load Sharing Using STP Port Priorities (CLI)	2278
Configuring Load Sharing Using STP Path Cost (CLI)	2282
Where to Go Next	2285
Additional References	2285

Feature History and Information for VLAN Trunks 2286

CHAPTER 116

Configuring Voice VLANs 2287

Finding Feature Information 2287

Prerequisites for Voice VLANs 2287

Restrictions for Voice VLANs 2288

Information About Voice VLAN 2288

Voice VLANs 2288

Cisco IP Phone Voice Traffic 2288

Cisco IP Phone Data Traffic 2289

Voice VLAN Configuration Guidelines 2289

How to Configure Voice VLAN 2290

Configuring Cisco IP Phone Voice Traffic (CLI) 2290

Configuring the Priority of Incoming Data Frames (CLI) 2292

Monitoring Voice VLAN 2294

Where to Go Next 2294

Additional References 2294

Feature History and Information for Voice VLAN 2295

CHAPTER 117

Configuring Private VLANs 2297

Finding Feature Information 2297

Prerequisites for Private VLANs 2297

Restrictions for Private VLANs 2297

Information About Private VLANs 2298

Private VLAN Domains 2298

Secondary VLANs 2299

Private VLANs Ports 2299

Private VLANs in Networks 2300

IP Addressing Scheme with Private VLANs 2301

Private VLANs Across Multiple Devices 2301

Private-VLAN Interaction with Other Features 2302

Private VLANs and Unicast, Broadcast, and Multicast Traffic 2302

Private VLANs and SVIs 2302

Private VLANs and Device Stacks 2303

Private VLAN with Dynamic Mac Address	2303
Private VLAN with Static Mac Address	2303
Private VLAN Interaction with VACL/QOS	2303
Private VLANs and HA Support	2304
Private-VLAN Configuration Guidelines	2304
Default Private-VLAN Configurations	2304
Secondary and Primary VLAN Configuration	2304
Private VLAN Port Configuration	2306
How to Configure Private VLANs	2307
Configuring Private VLANs	2307
Configuring and Associating VLANs in a Private VLAN	2308
Configuring a Layer 2 Interface as a Private VLAN Host Port	2311
Configuring a Layer 2 Interface as a Private VLAN Promiscuous Port	2313
Mapping Secondary VLANs to a Primary VLAN Layer 3 VLAN Interface	2315
Monitoring Private VLANs	2317
Configuration Examples for Private VLANs	2317
Example: Configuring and Associating VLANs in a Private VLAN	2317
Example: Configuring an Interface as a Host Port	2318
Example: Configuring an Interface as a Private VLAN Promiscuous Port	2318
Example: Mapping Secondary VLANs to a Primary VLAN Interface	2319
Example: Monitoring Private VLANs	2319
Where to Go Next	2319
Additional References	2320

PART XVIII
WLAN 2323

CHAPTER 118
Configuring WLANs 2325

Finding Feature Information	2325
Prerequisites for WLANs	2325
Restrictions for WLANs	2326
Information About WLANs	2327
Band Selection	2327
Off-Channel Scanning Defer	2328
DTIM Period	2328

Session Timeouts	2329
Cisco Client Extensions	2329
Peer-to-Peer Blocking	2329
Diagnostic Channel	2330
Per-WLAN Radius Source Support	2330
How to Configure WLANs	2331
Creating WLANs (CLI)	2331
Creating WLANs (GUI)	2331
Deleting WLANs (CLI)	2332
Deleting WLANs (GUI)	2333
Searching WLANs (CLI)	2333
Searching WLANs (GUI)	2334
Enabling WLANs (CLI)	2334
Disabling WLANs (CLI)	2335
Configuring General WLAN Properties (CLI)	2336
Configuring General WLAN Properties (GUI)	2338
Configuring Advanced WLAN Properties (CLI)	2339
Configuring Advanced WLAN Properties (GUI)	2342
Applying a QoS Policy on a WLAN (GUI)	2345
Monitoring WLAN Properties (CLI)	2346
Viewing WLAN Properties (GUI)	2347
Where to Go Next	2347
Additional References	2347
Feature Information for WLANs	2348

CHAPTER 119

Configuring DHCP for WLANs	2349
Finding Feature Information	2349
Prerequisites for Configuring DHCP for WLANs	2349
Restrictions for Configuring DHCP for WLANs	2351
Information About the Dynamic Host Configuration Protocol	2351
Internal DHCP Servers	2351
External DHCP Servers	2352
DHCP Assignments	2352
Information About DHCP Option 82	2353

Configuring DHCP Scopes	2354
Information About DHCP Scopes	2354
How to Configure DHCP for WLANs	2354
Configuring DHCP for WLANs (CLI)	2354
Configuring DHCP Scopes (CLI)	2356
Additional References	2357
Feature Information for DHCP for WLANs	2358

CHAPTER 120**Configuring WLAN Security 2359**

Finding Feature Information	2359
Prerequisites for Layer 2 Security	2359
Information About AAA Override	2360
How to Configure WLAN Security	2360
Configuring Static WEP + 802.1X Layer 2 Security Parameters (CLI)	2360
Configuring Static WEP Layer 2 Security Parameters (CLI)	2361
Configuring WPA + WPA2 Layer 2 Security Parameters (CLI)	2362
Configuring 802.1X Layer 2 Security Parameters (CLI)	2364
Configuring Layer 2 Parameters (GUI)	2365
Additional References	2368
Feature Information about WLAN Layer 2 Security	2369

CHAPTER 121**Setting Client Count Per WLAN 2371**

Finding Feature Information	2371
Restrictions for Setting Client Count for WLANs	2371
Information About Setting the Client Count per WLAN	2372
How to Configure Client Count Per WLAN	2372
Configuring Client Count per WLAN (CLI)	2372
Configuring Client Count Per AP Per WLAN (CLI)	2373
Configuring Client Count per AP Radio per WLAN (CLI)	2374
Monitoring Client Connections (CLI)	2374
Additional References for Client Connections	2375
Feature Information about Client Connections Per WLAN	2376

CHAPTER 122**Configuring 802.11w 2377**

Finding Feature Information	2377
Prerequisites for 802.11w	2377
Restrictions for 802.11w	2378
Information About 802.11w	2378
How to Configure 802.11w	2379
Configuring 802.11w (CLI)	2379
Disabling 802.11w (CLI)	2380
Monitoring 802.11w (CLI)	2382
Additional References for 802.11w	2383
Feature Information for 802.11w	2384

CHAPTER 123**Configuring Wi-Fi Direct Client Policy 2385**

Finding Feature Information	2385
Restrictions for the Wi-Fi Direct Client Policy	2385
Information About the Wi-Fi Direct Client Policy	2385
How to Configure Wi-Fi Direct Client Policy	2386
Configuring the Wi-Fi Direct Client Policy (CLI)	2386
Disabling Wi-Fi Direct Client Policy (CLI)	2387
Monitoring Wi-Fi Direct Client Policy (CLI)	2388
Additional References for Wi-Fi Direct Client Policy	2388
Feature Information about Wi-Fi Direct Client Policy	2389

CHAPTER 124**Configuring 802.11r BSS Fast Transition 2391**

Finding Feature Information	2391
Restrictions for 802.11r Fast Transition	2391
Information About 802.11r Fast Transition	2392
How to Configure 802.11r Fast Transition	2394
Configuring 802.11r Fast Transition in an Open WLAN (CLI)	2394
Configuring 802.11r BSS Fast Transition on a Dot1x Security Enabled WLAN (CLI)	2396
Configuring 802.11r Fast Transition on a PSK Security Enabled WLAN (CLI)	2397
Configuring 802.11 Fast Transition (GUI)	2398
Disabling 802.11r Fast Transition (CLI)	2399
Monitoring 802.11r Fast Transition (GUI)	2400
Monitoring 802.11r Fast Transition (CLI)	2400

Additional References for 802.11r Fast Transition	2402
Feature Information for 802.11r Fast Transition	2403

CHAPTER 125

Configuring Assisted Roaming	2405
Finding Feature Information	2405
Restrictions for Assisted Roaming	2405
Information About Assisted Roaming	2406
How to Configure Assisted Roaming	2407
Configuring Assisted Roaming (CLI)	2407
Monitoring Assisted Roaming	2408
Configuration Examples for Assisted Roaming	2409
Additional References for Assisted Roaming	2409
Feature History and Information For Performing Assisted Roaming Configuration	2410

CHAPTER 126

Configuring Access Point Groups	2411
Finding Feature Information	2411
Prerequisites for Configuring AP Groups	2411
Restrictions for Configuring Access Point Groups	2412
Information About Access Point Groups	2412
How to Configure Access Point Groups	2413
Creating Access Point Groups	2413
Assigning an Access Point to an AP Group	2414
Viewing Access Point Group	2414

Preface

- [Document Conventions, on page xcvi](#)
- [Related Documentation, on page xcix](#)
- [Obtaining Documentation and Submitting a Service Request, on page xcix](#)

Document Conventions

This document uses the following conventions:

Convention	Description
^ or Ctrl	Both the ^ symbol and Ctrl represent the Control (Ctrl) key on a keyboard. For example, the key combination ^D or Ctrl-D means that you hold down the Control key while you press the D key. (Keys are indicated in capital letters but are not case sensitive.)
bold font	Commands and keywords and user-entered text appear in bold font .
<i>Italic font</i>	Document titles, new or emphasized terms, and arguments for which you supply values are in <i>italic font</i> .
Courier font	Terminal sessions and information the system displays appear in <code>courier font</code> .
Bold Courier font	Bold Courier font indicates text that the user must enter.
[x]	Elements in square brackets are optional.
...	An ellipsis (three consecutive nonbolded periods without spaces) after a syntax element indicates that the element can be repeated.
	A vertical line, called a pipe, indicates a choice within a set of keywords or arguments.
[x y]	Optional alternative keywords are grouped in brackets and separated by vertical bars.
{x y}	Required alternative keywords are grouped in braces and separated by vertical bars.

Convention	Description
[x {y z}]	Nested set of square brackets or braces indicate optional or required choices within optional or required elements. Braces and a vertical bar within square brackets indicate a required choice within an optional element.
string	A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks.
< >	Nonprinting characters such as passwords are in angle brackets.
[]	Default responses to system prompts are in square brackets.
!, #	An exclamation point (!) or a pound sign (#) at the beginning of a line of code indicates a comment line.

Reader Alert Conventions

This document may use the following conventions for reader alerts:

Note Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

Tip Means *the following information will help you solve a problem*.

Caution Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

Timesaver Means *the described action saves time*. You can save time by performing the action described in the paragraph.

Warning IMPORTANT SAFETY INSTRUCTIONS

This warning symbol means danger. You are in a situation that could cause bodily injury. Before you work on any equipment, be aware of the hazards involved with electrical circuitry and be familiar with standard practices for preventing accidents. Use the statement number provided at the end of each warning to locate its translation in the translated safety warnings that accompanied this device. Statement 1071

SAVE THESE INSTRUCTIONS

Related Documentation

Note Before installing or upgrading the device, refer to the device release notes.

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/c/en/us/td/docs/general/whatsnew/whatsnew.html>

Subscribe to the *What's New in Cisco Product Documentation* as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS version 2.0.

CHAPTER

1

Using the Command-Line Interface

- [Information About Using the Command-Line Interface, on page 1](#)
- [How to Use the CLI to Configure Features, on page 6](#)

Information About Using the Command-Line Interface

Command Modes

The Cisco IOS user interface is divided into many different modes. The commands available to you depend on which mode you are currently in. Enter a question mark (?) at the system prompt to obtain a list of commands available for each command mode.

You can start a CLI session through a console connection, through Telnet, an SSH, or by using the browser.

When you start a session, you begin in user mode, often called user EXEC mode. Only a limited subset of the commands are available in user EXEC mode. For example, most of the user EXEC commands are one-time commands, such as **show** commands, which show the current configuration status, and **clear** commands, which clear counters or interfaces. The user EXEC commands are not saved when the device reboots.

To have access to all commands, you must enter privileged EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. From this mode, you can enter any privileged EXEC command or enter global configuration mode.

Using the configuration modes (global, interface, and line), you can make changes to the running configuration. If you save the configuration, these commands are stored and used when the device reboots. To access the various configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and line configuration mode .

This table describes the main command modes, how to access each one, the prompt you see in that mode, and how to exit the mode.

Table 1: Command Mode Summary

Mode	Access Method	Prompt	Exit Method	About This Mode
User EXEC	Begin a session using Telnet, SSH, or console.	Device>	Enter logout or quit .	Use this mode to <ul style="list-style-type: none"> • Change terminal settings. • Perform basic tests. • Display system information.
Privileged EXEC	While in user EXEC mode, enter the enable command.	Device#	Enter disable to exit.	Use this mode to verify commands that you have entered. Use a password to protect access to this mode. Use this mode to execute privilege EXEC commands for access points. These commands are not part of the running config of the controller, they are sent to the IOS config of the access point.
Global configuration	While in privileged EXEC mode, enter the configure command.	Device(config)#	To exit to privileged EXEC mode, enter exit or end , or press Ctrl-Z .	Use this mode to configure parameters that apply to the entire device. Use this mode to configure access point commands that are part of the running config of the controller.

Mode	Access Method	Prompt	Exit Method	About This Mode
VLAN configuration	While in global configuration mode, enter the vlan <i>vlan-id</i> command.	Device (config-vlan) #	To exit to global configuration mode, enter the exit command. To return to privileged EXEC mode, press Ctrl-Z or enter end .	Use this mode to configure VLAN parameters. When VTP mode is transparent, you can create extended-range VLANs (VLAN IDs greater than 1005) and save configurations in the device startup configuration file.
Interface configuration	While in global configuration mode, enter the interface command (with a specific interface).	Device (config-if) #	To exit to global configuration mode, enter exit . To return to privileged EXEC mode, press Ctrl-Z or enter end .	Use this mode to configure parameters for the Ethernet ports.
Line configuration	While in global configuration mode, specify a line with the line vty or line console command.	Device (config-line) #	To exit to global configuration mode, enter exit . To return to privileged EXEC mode, press Ctrl-Z or enter end .	Use this mode to configure parameters for the terminal line.

Understanding Abbreviated Commands

You need to enter only enough characters for the device to recognize the command as unique.

This example shows how to enter the **show configuration** privileged EXEC command in an abbreviated form:

```
Device# show conf
```

No and Default Forms of Commands

Almost every configuration command also has a **no** form. In general, use the **no** form to disable a feature or function or reverse the action of a command. For example, the **no shutdown** interface configuration command reverses the shutdown of an interface. Use the command without the keyword **no** to reenable a disabled feature or to enable a feature that is disabled by default.

Configuration commands can also have a **default** form. The **default** form of a command returns the command setting to its default. Most commands are disabled by default, so the **default** form is the same as the **no** form. However, some commands are enabled by default and have variables set to certain default values. In these cases, the **default** command enables the command and sets variables to their default values.

CLI Error Messages

This table lists some error messages that you might encounter while using the CLI to configure your device.

Table 2: Common CLI Error Messages

Error Message	Meaning	How to Get Help
% Ambiguous command: "show con"	You did not enter enough characters for your device to recognize the command.	Reenter the command followed by a question mark (?) without any space between the command and the question mark. The possible keywords that you can enter with the command appear.
% Incomplete command.	You did not enter all of the keywords or values required by this command.	Reenter the command followed by a question mark (?) with a space between the command and the question mark. The possible keywords that you can enter with the command appear.
% Invalid input detected at '^' marker.	You entered the command incorrectly. The caret (^) marks the point of the error.	Enter a question mark (?) to display all of the commands that are available in this command mode. The possible keywords that you can enter with the command appear.

Configuration Logging

You can log and view changes to the device configuration. You can use the Configuration Change Logging and Notification feature to track changes on a per-session and per-user basis. The logger tracks each configuration command that is applied, the user who entered the command, the time that the command was entered, and the parser return code for the command. This feature includes a mechanism for asynchronous notification to registered applications whenever the configuration changes. You can choose to have the notifications sent to the syslog.

Note Only CLI or HTTP changes are logged.

Using the Help System

You can enter a question mark (?) at the system prompt to display a list of commands available for each command mode. You can also obtain a list of associated keywords and arguments for any command.

SUMMARY STEPS

1. **help**
2. *abbreviated-command-entry ?*
3. *abbreviated-command-entry <Tab>*
4. **?**
5. *command ?*
6. *command keyword ?*

DETAILED STEPS

	Command or Action	Purpose
Step 1	help Example: Device# help	Obtains a brief description of the help system in any command mode.
Step 2	<i>abbreviated-command-entry ?</i> Example: Device# di? dir disable disconnect	Obtains a list of commands that begin with a particular character string.
Step 3	<i>abbreviated-command-entry <Tab></i> Example: Device# sh conf<tab> Device# show configuration	Completes a partial command name.
Step 4	? Example: Device> ?	Lists all commands available for a particular command mode.
Step 5	<i>command ?</i> Example: Device> show ?	Lists the associated keywords for a command.
Step 6	<i>command keyword ?</i> Example: Device(config)# cdp holdtime ? <10-255> Length of time (in sec) that receiver must keep this packet	Lists the associated arguments for a keyword.

How to Use the CLI to Configure Features

Configuring the Command History

The software provides a history or record of commands that you have entered. The command history feature is particularly useful for recalling long or complex commands or entries, including access lists. You can customize this feature to suit your needs.

Changing the Command History Buffer Size

By default, the device records ten command lines in its history buffer. You can alter this number for a current terminal session or for all sessions on a particular line. This procedure is optional.

SUMMARY STEPS

1. `terminal history [size number-of-lines]`

DETAILED STEPS

	Command or Action	Purpose
Step 1	terminal history [size <i>number-of-lines</i>] Example: Device# <code>terminal history size 200</code>	Changes the number of command lines that the device records during the current terminal session in privileged EXEC mode. You can configure the size from 0 to 256.

Recalling Commands

To recall commands from the history buffer, perform one of the actions listed in this table. These actions are optional.

Note The arrow keys function only on ANSI-compatible terminals such as VT100s.

SUMMARY STEPS

1. **Ctrl-P** or use the **up arrow** key
2. **Ctrl-N** or use the **down arrow** key
3. **show history**

DETAILED STEPS

	Command or Action	Purpose
Step 1	Ctrl-P or use the up arrow key	Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall successively older commands.

	Command or Action	Purpose
Step 2	Ctrl-N or use the down arrow key	Returns to more recent commands in the history buffer after recalling commands with Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands.
Step 3	show history Example: Device# <code>show history</code>	Lists the last several commands that you just entered in privileged EXEC mode. The number of commands that appear is controlled by the setting of the terminal history global configuration command and the history line configuration command.

Disabling the Command History Feature

The command history feature is automatically enabled. You can disable it for the current terminal session or for the command line. This procedure is optional.

SUMMARY STEPS

1. `terminal no history`

DETAILED STEPS

	Command or Action	Purpose
Step 1	terminal no history Example: Device# <code>terminal no history</code>	Disables the feature during the current terminal session in privileged EXEC mode.

Enabling and Disabling Editing Features

Although enhanced editing mode is automatically enabled, you can disable it and reenble it.

SUMMARY STEPS

1. `terminal editing`
2. `terminal no editing`

DETAILED STEPS

	Command or Action	Purpose
Step 1	terminal editing Example: Device# <code>terminal editing</code>	Reenables the enhanced editing mode for the current terminal session in privileged EXEC mode.
Step 2	terminal no editing Example:	Disables the enhanced editing mode for the current terminal session in privileged EXEC mode.

Command or Action	Purpose
Device# <code>terminal no editing</code>	

Editing Commands Through Keystrokes

The keystrokes help you to edit the command lines. These keystrokes are optional.

Note The arrow keys function only on ANSI-compatible terminals such as VT100s.

Table 3: Editing Commands

Editing Commands	Description
Ctrl-B or use the left arrow key	Moves the cursor back one character.
Ctrl-F or use the right arrow key	Moves the cursor forward one character.
Ctrl-A	Moves the cursor to the beginning of the command line.
Ctrl-E	Moves the cursor to the end of the command line.
Esc B	Moves the cursor back one word.
Esc F	Moves the cursor forward one word.
Ctrl-T	Transposes the character to the left of the cursor with the character located at the cursor.
Delete or Backspace key	Erases the character to the left of the cursor.
Ctrl-D	Deletes the character at the cursor.
Ctrl-K	Deletes all characters from the cursor to the end of the command line.
Ctrl-U or Ctrl-X	Deletes all characters from the cursor to the beginning of the command line.
Ctrl-W	Deletes the word to the left of the cursor.
Esc D	Deletes from the cursor to the end of the word.
Esc C	Capitalizes at the cursor.
Esc L	Changes the word at the cursor to lowercase.
Esc U	Capitalizes letters from the cursor to the end of the word.
Ctrl-V or Esc Q	Designates a particular keystroke as an executable command, perhaps as a shortcut.

Return key	Scrolls down a line or screen on displays that are longer than the terminal screen can display. Note The More prompt is used for any output that has more lines than can be displayed on the terminal screen, including show command output. You can use the Return and Space bar keystrokes whenever you see the More prompt.
Space bar	Scrolls down one screen.
Ctrl-L or Ctrl-R	Redisplays the current command line if the device suddenly sends a message to your screen.

Editing Command Lines That Wrap

You can use a wraparound feature for commands that extend beyond a single line on the screen. When the cursor reaches the right margin, the command line shifts ten spaces to the left. You cannot see the first ten characters of the line, but you can scroll back and check the syntax at the beginning of the command. The keystroke actions are optional.

To scroll back to the beginning of the command entry, press **Ctrl-B** or the left arrow key repeatedly. You can also press **Ctrl-A** to immediately move to the beginning of the line.

Note The arrow keys function only on ANSI-compatible terminals such as VT100s.

The following example shows how to wrap a command line that extends beyond a single line on the screen.

SUMMARY STEPS

1. **access-list**
2. **Ctrl-A**
3. **Return key**

DETAILED STEPS

	Command or Action	Purpose
Step 1	access-list Example: <pre>Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 Device(config)# \$ 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.25 Device(config)# \$t tcp 10.15.22.25 255.255.255.0 131.108.1.20 255.255.255.0 eq Device(config)# \$15.22.25 255.255.255.0 10.15.22.35 255.255.255.0 eq 45</pre>	Displays the global configuration command entry that extends beyond one line. When the cursor first reaches the end of the line, the line is shifted ten spaces to the left and redisplayed. The dollar sign (\$) shows that the line has been scrolled to the left. Each time the cursor reaches the end of the line, the line is again shifted ten spaces to the left.
Step 2	Ctrl-A	Checks the complete syntax.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.25</pre>	The dollar sign (\$) appears at the end of the line to show that the line has been scrolled to the right.
Step 3	Return key	<p>Execute the commands.</p> <p>The software assumes that you have a terminal screen that is 80 columns wide. If you have a different width, use the terminal width privileged EXEC command to set the width of your terminal.</p> <p>Use line wrapping with the command history feature to recall and modify previous complex command entries.</p>

Searching and Filtering Output of show and more Commands

You can search and filter the output for **show** and **more** commands. This is useful when you need to sort through large amounts of output or if you want to exclude output that you do not need to see. Using these commands is optional.

SUMMARY STEPS

1. `{show | more} command | {begin | include | exclude} regular-expression`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>{show more} command {begin include exclude} regular-expression</code></p> <p>Example:</p> <pre>Device# show interfaces include protocol Vlan1 is up, line protocol is up Vlan10 is up, line protocol is down GigabitEthernet1/0/1 is up, line protocol is down GigabitEthernet1/0/2 is up, line protocol is up</pre>	<p>Searches and filters the output.</p> <p>Expressions are case sensitive. For example, if you enter <code> exclude output</code>, the lines that contain output are not displayed, but the lines that contain output appear.</p>

Accessing the CLI

You can access the CLI through a console connection, through Telnet, a SSH, or by using the browser.

You manage the switch stack and the stack member interfaces through the active switch. You cannot manage stack members on an individual switch basis. You can connect to the active switch through the console port or the Ethernet management port of one or more stack members. Be careful with using multiple CLI sessions on the active switch. Commands that you enter in one session are not displayed in the other sessions. Therefore, it is possible to lose track of the session from which you entered commands.

Note We recommend using one CLI session when managing the switch stack.

If you want to configure a specific stack member port, you must include the stack member number in the CLI command interface notation.

To debug the standby switch, use the **session standby ios** privileged EXEC command from the active switch to access the IOS console of the standby switch. To debug a specific stack member, use the **session switch stack-member-number** privileged EXEC command from the active switch to access the diagnostic shell of the stack member. For more information about these commands, see the switch command reference.

To debug a specific stack member, you can start a CLI session from the stack master by using the **session stack-member-number** privileged EXEC command. The stack member number is appended to the system prompt. For example, *Switch-2#* is the prompt for stack member 2 where the system prompt for the stack master is *Switch*. Only the **show** and **debug** commands are available in a CLI session to a specific stack member. You can also use the **remote command stack-member-number LINE** privileged EXEC command on the stack master to enable debugging on a member switch without first starting a session.

Accessing the CLI Through a Console Connection or Through Telnet

Before you can access the CLI, you must connect a terminal or a PC to the device console or connect a PC to the Ethernet management port and then power on the device, as described in the hardware installation guide that shipped with your device.

If your device is already configured, you can access the CLI through a local console connection or through a remote Telnet session, but your device must first be configured for this type of access.

You can use one of these methods to establish a connection with the device:

Procedure

- Connect the device console port to a management station or dial-up modem, or connect the Ethernet management port to a PC. For information about connecting to the console or Ethernet management port, see the device hardware installation guide.
- Use any Telnet TCP/IP or encrypted Secure Shell (SSH) package from a remote management station. The device must have network connectivity with the Telnet or SSH client, and the device must have an enable secret password configured.
 - The device supports up to 16 simultaneous Telnet sessions. Changes made by one Telnet user are reflected in all other Telnet sessions.
 - The device supports up to five simultaneous secure SSH sessions.

After you connect through the console port, through the Ethernet management port, through a Telnet session or through an SSH session, the user EXEC prompt appears on the management station.

CHAPTER 2

Using the Web Graphical User Interface

- Prerequisites for Using the Web GUI, on page 13
- Information About Using The Web GUI, on page 14
- Connecting the Console Port of the Device , on page 15
- Logging On to the GUI, on page 15
- Enabling Web and Secure Web Modes , on page 16
- Configuring the Device Web GUI, on page 16

Prerequisites for Using the Web GUI

Wired Web UI (Device Manager) System Requirements

Hardware Requirements

Table 4: Minimum Hardware Requirements

Processor Speed	DRAM	Number of Colors	Resolution	Font Size
233 MHz minimum 1	512 MB 2	256	1024 x 768	Small

¹ We recommend 1 GHz.

² We recommend 1 GB DRAM.

Software Requirements

- – Windows 7, Windows Vista, Windows XP, Windows 2003, or Windows 2000
- – Microsoft Internet Explorer 6.0 and 7.0, and Mozilla Firefox up to version 26.0, with JavaScript enabled.

Wireless Web UI Software Requirements

- Operating Systems
 - Windows 7
 - Windows 8

- Mac OS X 10.8
- Browsers:
 - Google Chrome, version 35
 - Microsoft Internet Explorer, versions 10 or 11
 - Mozilla Firefox, version 30 or later
 - Safari, version 6.1

Information About Using The Web GUI

A web browser, or graphical user interface (GUI), is built into each device.

You can use either the service port interface or the management interface to access the GUI. We recommend that you use the service-port interface. Click Help at the top of any page in the GUI to display online help. You might need to disable your browser's pop-up blocker to view the online help.

Web GUI Features

The device web GUI supports the following:

The Configuration Wizard—After initial configuration of the IP address and the local username/password or auth via the authentication server (privilege 15 needed), the wizard provides a method to complete the initial wireless configuration. Start the wizard through Configuration -> Wizard and follow the nine-step process to configure the following:

- Admin Users
- SNMP System Summary
- Management Port
- Wireless Management
- RF Mobility and Country code
- Mobility configuration
- WLANs
- 802.11 Configuration
- Set Time

The Monitor tab:

- Displays summary details of device, clients, and access points.
- Displays all radio and AP join statistics.
- Displays air quality on access points.
- Displays list of all Cisco Discovery Protocol (CDP) neighbors on all interfaces and the CDP traffic information.
- Displays all rogue access points based on their classification—friendly, malicious, ad hoc, classified, and unclassified.

The Configuration tab:

- Enables you to configure the device for all initial operation using the web Configuration Wizard. The wizard allows you to configure user details, management interface, and so on.
- Enables you to configure the system, internal DHCP server, management, and mobility management parameters.
- Enables you to configure the device, WLAN, and radios.
- Enables you to configure and set security policies on your device.
- Enables you to access the device operating system software management commands.

The Administration tab enables you to configure system logs.

Connecting the Console Port of the Device

Before you begin

Before you can configure the device for basic operations, you need to connect it to a PC that uses a VT-100 terminal emulation program (such as HyperTerminal, ProComm, Minicom, or Tip).

-
- Step 1** Connect one end of a null-modem serial cable to the device's RJ-45 console port and the other end to your PC's serial port.
- Step 2** Plug the AC power cord into the device and a grounded 100 to 240 VAC, 50/60-Hz electrical outlet. Turn on the power supply. The bootup script displays operating system software initialization (code download and power-on self-test verification) and basic configuration. If the device passes the power-on self-test, the bootup script runs the configuration wizard, which prompts you for basic configuration input.
- Step 3** Enter **yes**. Proceed with basic initial setup configuration parameters in the CLI setup wizard. Specify the IP address for the service port which is the gigabitethernet 0/0 interface.

After entering the configuration parameters in the configuration wizard, you can access the Web GUI. Now, the device is configured with the IP address for service port.

Logging On to the GUI

Note Do not configure TACACS authentication when the controller is set to use local authentication.

- Step 1** Enter the device IP address in your browser's address bar. For a secure connection, enter **https://ip-address**. For a less secure connection, enter **http://ip-address**.
- Step 2** When prompted, enter a valid username and password and click **OK**.

Note The administrative username and password that you created in the configuration wizard are case sensitive. The default username is admin, and the default password is cisco.

The Accessing page appears.

Enabling Web and Secure Web Modes

- Step 1** Choose **Configuration > Controller > Switch > Management > Protocol Management > HTTP-HTTPS**.
The **HTTP-HTTPS Configuration** page appears.
- Step 2** To enable web mode, which allows users to access the device GUI using “http://ip-address,” choose Enabled from the HTTP Access drop-down list. Otherwise, choose Disabled. Web mode (HTTP) is not a secure connection.
- Step 3** To enable secure web mode, which allows users to access the device GUI using “https://ip-address,” choose Enabled from the HTTPS Access drop-down list. Otherwise, choose Disabled. Secure web mode (HTTPS) is a secure connection.
- Step 4** Choose to track the device in the IP Device Tracking check box.
- Step 5** Choose to enable the trust point in the Enable check box.
- Step 6** Choose the trustpoints from the Trustpoints drop-down list.
- Step 7** Enter the amount of time, in seconds, before the web session times out due to inactivity in the HTTP Timeout-policy (1 to 600 sec) text box.
The valid range is from 1 to 600 seconds.
- Step 8** Enter the server life time in the Server Life Time (1 to 86400 sec) text box.
The valid range is from 1 to 86400 seconds.
- Step 9** Enter the maximum number of connection requests that the server can accept in the Maximum number of Requests (1 to 86400) text box.
The valid range is from 1 to 86400 connections.
- Step 10** Click **Apply**.
- Step 11** Click **Save Configuration**.
-

Configuring the Device Web GUI

The configuration wizard enables you to configure basic settings on the device. You can run the wizard after you receive the device from the factory or after the device has been reset to factory defaults. The configuration wizard is available in both GUI and CLI formats.

-
- Step 1** Connect your PC to the service port and configure an IPv4 address to use the same subnet as the device. The device is loaded with IOS XE image and the service port interface is configured as gigabitethernet 0/0.
- Step 2** Start Internet Explorer 10 (or later), Firefox 2.0.0.11 (or later), or Google Chrome on your PC and enter the management interface IP address on the browser window. The management interface IP address is same as the gigabitethernet 0/0

(also known as service port interface). When you log in for the first time, you need to enter HTTP username and password. By default, the username is **admin** and the password is **cisco**.

You can use both HTTP and HTTPS when using the service port interface. HTTPS is enabled by default and HTTP can also be enabled.

When you log in for the first time, the **Accessing Cisco Switch Accessing Cisco Controller <Model Number> <Hostname>** page appears.

Step 3 On the **Accessing Cisco Switch Accessing Cisco Controller** page, click the **Wireless Web GUI** link to access device web GUI **Home** page.

Step 4 Choose **Configuration > Wizard** to perform all steps that you need to configure the device initially.

The **Admin Users** page appears.

Step 5 On the **Admin Users** page, enter the administrative username to be assigned to this device in the User Name text box and the administrative password to be assigned to this device in the Password and Confirm Password text boxes. Click **Next**.

The default username is **admin** and the default password is **cisco**. You can also create a new administrator user for the device. You can enter up to 24 ASCII characters for username and password.

The **SNMP System Summary** page appears.

Step 6 On the **SNMP System Summary** page, enter the following SNMP system parameters for the device, and click **Next**:

- Customer-definable device location in the Location text box.
- Customer-definable contact details such as phone number with names in the Contact text box.
- Choose **enabled** to send SNMP notifications for various SNMP traps or **disabled** not to send SNMP notifications for various SNMP traps from the SNMP Global Trap drop-down list.
- Choose **enabled** to send system log messages or **disabled** not to send system log messages from the SNMP Logging drop-down list.

Note The SNMP trap server, must be reachable through the distribution ports (and not through the gigabitethernet0/0 service or management interface).

The **Management Port** page appears.

Step 7 In the **Management Port** page, enter the following parameters for the management port interface (gigabitethernet 0/0) and click **Next**.

- Interface IP address that you assigned for the service port in the IP Address text box.
- Network mask address of the management port interface in the Netmask text box.
- The IPv4 Dynamic Host Configuration Protocol (DHCP) address for the selected port in the IPv4 DHCP Server text box.

The **Wireless Management** page appears.

Step 8 In the **Wireless Management** page, enter the following wireless interface management details, and click **Next**.

- Choose the interface—VLAN, or Ten Gigabit Ethernet from the Select Interface drop-down list.
- VLAN tag identifier, or 0 for no VLAN tag in the VLAN id text box.

- IP address of wireless management interface where access points are connected in the IP Address text box.
- Network mask address of the wireless management interface in the Netmask text box.
- DHCP IPv4 IP address in the IPv4 DHCP Server text box.

When selecting VLAN as interface, you can specify the ports as –Trunk or Access ports from the selected list displayed in the Switch Port Configuration text box.

The **RF Mobility and Country Code** page appears.

Step 9

In the **RF Mobility and Country Code** page, enter the RF mobility domain name in the RF Mobility text box, choose current country code from the Country Code drop-down list, and click **Next**. From the GUI, you can select only one country code.

Note Before configuring RF grouping parameters and mobility configuration, ensure that you refer to the relevant conceptual content and then proceed with the configuration.

The **Mobility Configuration** page with mobility global configuration settings appears.

Step 10

In the **Mobility Configuration** page, view and enter the following mobility global configuration settings, and click **Next**.

- Displays Mobility Controller in the Mobility Role text box.
- Displays mobility protocol port number in the Mobility Protocol Port text box.
- Displays the mobility group name in the Mobility Group Name text box.
- Displays whether DTLS is enabled in the DTLS Mode text box.
DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS.
- Displays mobility domain identifier for 802.11 radios in the Mobility Domain ID for 802.11 radios text box.
- Displays the number of members configured on the device in the Mobility Domain Member Count text box.
- To enable the controller as a Mobility Oracle, select the Mobility Oracle Enabled check box.

Note Only the controller can be configured as Mobility Oracle. You cannot configure the switch as Mobility Oracle.

The Mobility Oracle is optional, it maintains the client database under one complete mobility domain.

- The amount of time (in seconds) between each ping request sent to an peer device in the Mobility Keepalive Interval (1-30)sec text box.

Valid range is from 1 to 30 seconds, and the default value is 10 seconds.

- Number of times a ping request is sent to an peer device before the peer is considered to be unreachable in the Mobility Keepalive Count (3-20) text box.

The valid range is from 3 to 20, and the default value is 3.

- The DSCP value that you can set for the mobility device in the Mobility Control Message DSCP Value (0-63) text box.

The valid range is 0 to 63, and the default value is 0.

The **WLANS** page appears.

Step 11 In the **Mobility Configuration** page, view and enter the following mobility global configuration settings, and click **Next**.

- Choose **Mobility Controller** or **Mobility Agent** from the Mobility Role drop-down list:
 - If Mobility Agent is chosen, enter the mobility controller IP address in the Mobility Controller IP Address text box and mobility controller IP address in the Mobility Controller Public IP Address text box.
 - If Mobility Controller is chosen, then the mobility controller IP address and mobility controller public IP address are displayed in the respective text boxes.
- Displays mobility protocol port number in the Mobility Protocol Port text box.
- Displays the mobility switch peer group name in the Mobility Switch Peer Group Name text box.
- Displays whether DTLS is enabled in the DTLS Mode text box.

DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS.
- Displays mobility domain identifier for 802.11 radios in the Mobility Domain ID for 802.11 radios text box.
- The amount of time (in seconds) between each ping request sent to a peer device in the Mobility Keepalive Interval (1-30)sec text box.

Valid range is from 1 to 30 seconds, and the default value is 10 seconds.
- Number of times a ping request is sent to a peer device before the peer is considered to be unreachable in the Mobility Keepalive Count (3-20) text box.

The valid range is from 3 to 20, and the default value is 3.
- The DSCP value that you can set for the mobility device in the Mobility Control Message DSCP Value (0-63) text box.

The valid range is 0 to 63, and the default value is 0.
- Displays the number of mobility switch peer group member configured in the Switch Peer Group Members Configured text box.

The **WLANs** page appears.

Step 12 In the **WLANs** page, enter the following WLAN configuration parameters, and click **Next**.

- WLAN identifier in the WLAN ID text box.
- SSID of the WLAN that the client is associated with in the SSID text box.
- Name of the WLAN used by the client in the Profile Name text box.

The **802.11 Configuration** page appears.

Step 13 In the **802.11 Configuration** page, check either one or both 802.11a/n/ac and 802.11b/g/n check boxes to enable the 802.11 radios, and click **Next**.

The **Set Time** page appears.

Step 14 In the **Set Time** page, you can configure the time and date on the device based on the following parameters, and click **Next**.

- Displays current timestamp on the device in the Current Time text box.

- Choose either Manual or NTP from the Mode drop-down list.

On using the NTP server, all access points connected to the device, synchronizes its time based on the NTP server settings available.

- Choose date on the device from the Year, Month, and Day drop-down list.
- Choose time from the Hours, Minutes, and Seconds drop-down list.
- Enter the time zone in the Zone text box and select the off setting required when compared to the current time configured on the device from the Offset drop-down list.

The **Save Wizard** page appears.

Step 15

In the **Save Wizard** page, you can review the configuration settings performed on the device using these steps, and if you wish to change any configuration value, click **Previous** and navigate to that page.

You can save the device configuration created using the wizard only if a success message is displayed for all the wizards. If the **Save Wizard** page displays errors, you must recreate the wizard for initial configuration of the device.

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for CleanAir

You can configure Cisco CleanAir only on CleanAir-enabled access points.

Only Cisco CleanAir-enabled access points using the following access point modes can perform Cisco CleanAir spectrum monitoring:

- **Local**—In this mode, each Cisco CleanAir-enabled access point radio provides air quality and interference detection reports for the current operating channel only.
- **Monitor**—When Cisco CleanAir is enabled in monitor mode, the access point provides air quality and interference detection reports for all monitored channels.

The following options are available:

- All— All channels
- DCA—Channel selection governed by the DCA list
- Country—All channel legal within a regulatory domain

Note The access point does not participate in AQ HeatMap in Prime Infrastructure.

- SE-Connect—This mode enables a user to connect a Spectrum Expert application running on an external Microsoft Windows XP or Vista PC to a Cisco CleanAir-enabled access point in order to display and analyze detailed spectrum data. The Spectrum Expert application connects directly to the access point, bypassing the device. An access point in SE-Connect mode does not provide any Wi-Fi, RF, or spectrum data to the device. All CleanAir system functionality is suspended while the AP is in this mode, and no clients are served. This mode is intended for remote troubleshooting only. Up to three active Spectrum Expert connections are possible.
- Only Cisco Catalyst 3850 and Switches can function as a Mobility Agent.
- Cisco Catalyst 3850 Switches and Cisco 5760 Wireless LAN Controllers can function as Mobility Controllers.

Restrictions for CleanAir

- Access points in monitor mode do not transmit Wi-Fi traffic or 802.11 packets. They are excluded from radio resource management (RRM) planning and are not included in the neighbor access point list. IDR clustering depends on the device's ability to detect neighboring in-network access points. Correlating interference device detections from multiple access points is limited between monitor-mode access points.
- SE-connect is an access point mode similar to local mode or monitor mode. The access point provides spectrum information to Spectrum Expert only for the current channel(s). The spectrum data is available for the current active channel(s) and the common monitored channel list is available. The access point continues to send AQ (Air Quality) and IDR (Interference Device Reports) reports to the device and perform normal activities according to the current mode. Sniffer and rogue detections access point modes are incompatible with all types of CleanAir spectrum monitoring.
- Local Mode access point—Serves WLAN clients with the time slicing off-channel scanning and listens for 50 ms on each channel, and scans configurable feature scanning for all/country/DCA channels.
- Monitor Mode access point—Does not serve WLAN clients and are dedicated to scanning only. These access points listen for 1.2 s on each channel, and scans all channels.

- Cisco recommends a ratio of 1 monitor mode access point for every 5 local mode access points, this may also vary based on the network design and expert guidance for best coverage.
- Spectrum Expert (Windows XP laptop client) and AP should be pingable, otherwise; it will not work.

Information About CleanAir

Cisco CleanAir is a spectrum intelligence solution designed to proactively manage the challenges of a shared wireless spectrum. All of the users of the shared spectrum can be seen (both native devices and foreign interferers). It also enables the network to act upon this information. For example, the interfering device can be manually removed or the system can automatically change the channel away from the interference.

A Cisco CleanAir system consists of CleanAir-enabled access points, wireless controller modules, mobility controllers, mobility anchors and next generation switches. The access points join the mobility controller directly or through the mobility anchor. They collect information about all devices that operate in the industrial, scientific, and medical (ISM) bands, identify and evaluate the information as a potential interference source, and forward it to the device. The device controls the access points, collects spectrum data, and forwards information to Cisco Prime Infrastructure (PI) or a Cisco Mobility Services Engine (MSE) upon request.

Any networking configurations can be performed only on the mobility controller, configurations cannot be performed in the MA mode. However, any radio level CleanAir configurations can be done using mobility anchor.

For every device operating in the unlicensed band, Cisco CleanAir tells what it is, where it is, how it is impacting the wireless network, and what actions should be taken. It simplifies RF.

Wireless LAN systems operate in unlicensed 2.4-GHz and 5-GHz ISM bands. Many devices like microwave ovens, cordless phones, and Bluetooth devices also operate in these bands and can negatively affect the Wi-Fi operations.

Some of the most advanced WLAN services, such as voice over wireless and IEEE 802.11n radio communications, could be significantly impaired by the interference caused by other legal users of the ISM bands. The integration of Cisco CleanAir functionality addresses this problem of radio frequency (RF) interference.

Cisco CleanAir Components

The basic Cisco CleanAir architecture consists of Cisco CleanAir-enabled APs and device. Cisco Prime Infrastructure (PI), Mobility Services Engine (MSE) and Cisco Spectrum Expert are optional system components. Cisco PI and MSE provide user interfaces for advanced spectrum capabilities such as historic charts, tracking interference devices, location services and impact analysis.

Figure 1: Cisco CleanAir Solution

An access point equipped with Cisco CleanAir technology collects information about non-Wi-Fi interference sources, processes it, and forwards it to the MA. The access point sends AQR and IDR reports to the controller.

The mobility controller (MC) controls and configures CleanAir-capable access points, collects and processes spectrum data, and provides it to the PI and/or the MSE. The MC provides local user interfaces (GUI and CLI) to configure basic CleanAir features and services and display current spectrum information. The MC also does detection, merging and mitigation of interference devices using RRM TPC and DCM. For details on Interference Device Merging, see [Interference Device Merging, on page 28](#).

Cisco PI provides advanced user interfaces for CleanAir that include feature enabling and configuration, consolidated display information, historic AQ records and reporting engines. PI also shows charts of interference devices, AQ trends, and alerts.

Cisco MSE is required for location and historic tracking of interference devices, and provides coordination and consolidation of interference reports across multiple controllers. MSE also provides adaptive Wireless Intrusion Prevention System (WIPS) service that provides comprehensive over-the-air threat detection, location and mitigation. MSE also merges all the interference data.

To obtain detailed spectrum data that can be used to generate RF analysis plots similar to those provided by a spectrum analyzer, you can configure a Cisco CleanAir-enabled access point to connect directly to a Microsoft Windows XP or Vista PC running the Cisco Spectrum Expert application.

The device performs the following tasks in a Cisco CleanAir system:

- Configures Cisco CleanAir capabilities on the access point.
- Provides interfaces (GUI, CLI, and SNMP) for configuring Cisco CleanAir features and retrieving data.
- Displays spectrum data.
- Collects and processes AQRs from the access point and stores them in the air quality database. AQRs contains information about the total interference from all identified sources represented by Air Quality Index (AQI) and summary for the most severe interference categories. The CleanAir system can also

include unclassified interference information under per interference type reports which enable you to take action in cases where the interference due to unclassified interfering devices is frequent.

- Collects and processes Interference Device Reports (IDRs) from the access point and stores them in the interference device database.
- Forwards spectrum data to Prime Infrastructure and the MSE.

Terms Used in Cisco CleanAir

Table 5: CleanAir-related Terms

Term	Description
AQI	Air Quality Index. The AQI is an indicator of air quality, based on the air pollutants. An AQI of 0 is bad and an AQI > 85 is good.
AQR	Air Quality Report. AQRs contain information about the total interference from all identified sources represented by AQI and summary of the most severe interference categories. AQRs are sent every 15 minutes to the Mobility Controller and every 30 seconds in the Rapid mode.
DC	Duty Cycle. Percentage of time that the channel is utilized by a device.
EDRRM	EDRRM Event Driven RRM. EDRRM allows an access point in distress to bypass normal RRM intervals and immediately change channels.
IDR	Interference Device Reports that the access point sends to the controller.
ISI	Interference Severity Index. The ISI is an indicator of the severity of the interference.
MA	Mobility Agent. An MA is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. An MA is the wireless component that maintains client mobility state machine for a mobile client that is connected to an access point to the device that the MA is running on.
MC	Mobility Controller. An MC provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members.
RSSI	Received Signal Strength Indicator. RSSI is a measurement of the power present in a received radio signal. It is the power at which an access point sees the interferer device.

Interference Types that Cisco CleanAir can Detect

Cisco CleanAir can detect interference, report on the location and severity of the interference, and recommend different mitigation strategies. Two such mitigation strategies are persistent device avoidance and spectrum event-driven RRM. New

Wi-Fi chip-based RF management systems share these characteristics:

- Any RF energy that cannot be identified as a Wi-Fi signal is reported as noise.
- Noise measurements that are used to assign a channel plan tend to be averaged over a period of time to avoid instability or rapid changes that can be disruptive to certain client devices.
- Averaging measurements reduces the resolution of the measurement. As such, a signal that disrupts clients might not look like it needs to be mitigated after averaging.

- All RF management systems available today are reactive in nature.

Cisco CleanAir is different and can positively identify not only the source of the noise but also its location and potential impact to a WLAN. Having this information allows you to consider the noise within the context of the network and make intelligent and, where possible, proactive decisions. For CleanAir, two types of interference events are common:

- Persistent interference
- Spontaneous interference

Persistent interference events are created by devices that are stationary in nature and have intermittent but largely repeatable patterns of interference. For example, consider the case of a microwave oven located in a break room. Such a device might be active for only 1 or 2 minutes at a time. When operating, however, it can be disruptive to the performance of the wireless network and associated clients. Using Cisco CleanAir, you can positively identify the device as a microwave oven rather than indiscriminate noise. You can also determine exactly which part of the band is affected by the device, and because you can locate it, you can understand which access points are most severely affected. You can then use this information to direct RRM in selecting a channel plan that avoids this source of interference for the access points within its range. Because this interference is not active for a large portion of the day, existing RF management applications might attempt to again change the channels of the affected access points. Persistent device avoidance is unique, however, in that it remains in effect as long as the source of interference is periodically detected to refresh the persistent status. The Cisco CleanAir system knows that the microwave oven exists and includes it in all future planning. If you move either the microwave oven or the surrounding access points, the algorithm updates RRM automatically.

Note Spectrum event-driven RRM can be triggered only by Cisco CleanAir-enabled access points in local mode.

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a threshold for air quality (AQ) that, if exceeded, triggers an immediate channel change for the affected access point. Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an access point detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active. Cisco CleanAir also identifies and locates the source of interference so that more permanent mitigation of the device can be performed at a later time.

In the case of Bluetooth devices, Cisco CleanAir-enabled access points can detect and report interference only if the devices are actively transmitting. Bluetooth devices have extensive power save modes. For example, interference can be detected when data or voice is being streamed between the connected devices.

Interference Device Merging

The Interference Devices (ID) messages are processed on a Mobility Controller (MC). The Mobility Anchor (MA) forwards the ID messages from APs and hence they are processed on the MC. The MC has visibility of the neighbor information across APs connected to different MAs.

ID merging logic requires AP neighbor information. Neighbor information is obtained from the RRM module. This api only gives neighbor information to the APs directly connected to MC.

Currently the AP neighbor list on MA is synced to MC once every 3 minutes; hence the AP neighbor list obtained by this api could be at most 3 mins old. This delay results in delay in merging of Devices as they

are discovered. The subsequent periodic merge will pick up the updated neighbor information and merge is performed

Persistent Devices

Some interference devices such as outdoor bridges and Microwave Ovens only transmit when needed. These devices can cause significant interference to the local WLAN due to short duration and periodic operation remain largely undetected by normal RF management metrics. With CleanAir the RRM DCA algorithm can detect, measure, register and remember the impact and adjust the DCA algorithm. This minimizes the use of channels affected by the persistent devices in the channel plan local to the interference source. Cisco CleanAir detects and stores the persistent device information in the device and this information is used to mitigate interfering channels.

Persistent Devices Detection

CleanAir-capable Monitor Mode access point collects information about persistent devices on all configured channels and store the information in controller. Local/Bridge mode AP detects interference devices on the serving channels only.

Persistent Device Avoidance

When a Persistent Device (PD) is detected in the CleanAir module, it is reported to the RRM module on the MA. This information is used in the channel selection by the subsequent EDRRM Event Driven RRM (ED-RRM) signal sent to the RRM module.

EDRRM and AQR Update Mode

EDRRM is a feature that allows an access point that is in distress to bypass normal RRM intervals and immediately change channels. A CleanAir access point always monitors AQ and reports the AQ every 15 minutes. AQ only reports classified interference devices. The key benefit of EDRRM is very fast action time. If an interfering device is operating on an active channel and causes enough AQ degradation to trigger an EDRRM, then no clients will be able to use that channel or the access point. You must remove the access point from the channel. EDRRM is not enabled by default, you must first enable CleanAir and then enable EDRRM.

AQRs are only available on the MC. The mode configuration and timers are held in Radio Control Block (RCB) on MA (for APs connected to MA). There is no change to the current API available for EMS/NMS. No change is required for directly connected APs as RCB (spectrum config and timers) is available locally. For remote APs (APs connected to MA), three new control messages are added. These three messages are for enable, restart timer and disable rapid update mode for a given AP MAC address and slot.

Related Topics

[Configuring EDRRM for CleanAir-Events](#), on page 37

CleanAir High Availability

CleanAir configuration (network and radio) is stateful during the switchover. On the MC, Embedded Instrumentation Core (EICORE) provides the sync on network configurations across active and standby nodes. The radio configurations are synced using the HA Infrastructure. The CleanAir configurations on MA are pulled from the MC upon joining. The network configuration is not stored in the EICORE on MA, hence it is synced using HA Infrastructure.

CleanAir Data (AQ and IDR) reports are not stateful, that is, the standby and active nodes are not synced. On switchover, the APs send the reports to the current active slot. The RRM Client (HA Infra Client) is used for CleanAir HA sync.

How to Configure CleanAir

Enabling CleanAir for 2.4-GHz Band

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz cleanair`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 24ghz cleanair Example: Device(config)# <code>ap dot11 24ghz cleanair</code> Device(config)# <code>no ap dot11 24ghz cleanair</code>	Enables the CleanAir feature on 802.11b network. Add no in the command to disable CleanAir on the 802.11b network.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 5ghz cleanair alarm air-quality threshold <i>threshold_value</i> Example: Device(config)# <code>ap dot11 5ghz cleanair alarm air-quality threshold 50</code>	Configures the alarm for the threshold value for air-quality for all the 5-GHz devices. Add the No form of the command to disable the alarm.

	Command or Action	Purpose
Step 3	<p>ap dot11 5ghz cleanair alarm device{canopy cont-tx dect-like inv jammer nonstd radar report superag tdd-tx video wimax-fixed wimax-mobile}</p> <p>Example:</p> <pre>Device(config)#ap dot11 5ghz cleanair alarm device</pre>	<p>Configures the alarm for the 5-GHz devices. Add the no form of the command to disable the alarm.</p> <ul style="list-style-type: none"> • canopy—Canopy devices. • cont-tx—Continuous Transmitter. • dect-like—Digital Enhanced Cordless Communication (DECT) like phone. • fh—802.11 frequency hopping devices. • inv—Devices using spectrally inverted WiFi signals. • jammer—Jammer. • nonstd—Devices using non-standard WiFi channels. • radar—Radars. • report—Interference device reporting. • superag—802.11 SuperAG devices. • tdd-tx—TDD Transmitter. • video—Video cameras. • wimax-fixed—WiMax Fixed. • wimax-mobile—WiMax Mobile.
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</p>

Configuring Interference Reporting for 5-GHz devices

SUMMARY STEPS

1. **configure terminal**
2. **ap dot11 5ghz cleanair device**{canopy | cont-tx | dect-like | inv | jammer | nonstd | radar | report | superag | tdd-tx | video | wimax-fixed | wimax-mobile}
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 5ghz cleanair device {canopy cont-tx dect-like inv jammer nonstd radar report superag tdd-tx video wimax-fixed wimax-mobile} Example: Device (config) # ap dot11 5ghz cleanair device canopy Device (config) # ap dot11 5ghz cleanair device cont-tx Device (config) # ap dot11 5ghz cleanair device dect-like Device (config) # ap dot11 5ghz cleanair device inv Device (config) # ap dot11 5ghz cleanair device jammer Device (config) # ap dot11 5ghz cleanair device nonstd Device (config) # ap dot11 5ghz cleanair device radar Device (config) # ap dot11 5ghz cleanair device report Device (config) # ap dot11 5ghz cleanair device superag Device (config) # ap dot11 5ghz cleanair device tdd-tx Device (config) # ap dot11 5ghz cleanair device video Device (config) # ap dot11 5ghz cleanair device wimax-fixed Device (config) # ap dot11 5ghz cleanair device wimax-mobile	Configures the 5-GHz interference devices to report to the device. Add the no form of the command to disable interference device reporting. <ul style="list-style-type: none"> • canopy—Canopy devices • cont-tx—Continuous Transmitter • dect-like—Digital Enhanced Cordless Communication (DECT) like phone • fh—802.11 frequency hopping devices • inv—Devices using spectrally inverted WiFi signals • jammer—Jammer • nonstd—Devices using non-standard WiFi channels • radar—Radars • report—Interference device reporting • superag—802.11 SuperAG devices • tdd-tx—TDD Transmitter • video—Video cameras • wimax-fixed—WiMax Fixed • wimax-mobile—WiMax Mobile
Step 3	end Example: Device (config) # end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring EDRRM for CleanAir-Events

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 {24ghz | 5ghz} rrm channel cleanair-event`
3. `ap dot11 {24ghz | 5ghz} rrm channel cleanair-event [sensitivity {high | low | medium}]`
4. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rrm channel cleanair-event Example: Device(config)# <code>ap dot11 24ghz rrm channel cleanair-event</code> Device(config)# <code>no ap dot11 24ghz rrm channel cleanair-event</code>	Enables EDRRM cleanair-event. Add the no form of the command to disable EDRRM.
Step 3	ap dot11 {24ghz 5ghz} rrm channel cleanair-event [sensitivity {high low medium}] Example: Device(config)# <code>ap dot11 24ghz rrm channel cleanair-event sensitivity high</code>	Configures the EDRRM sensitivity of cleanair-event. <ul style="list-style-type: none"> • High—Specifies the most sensitivity to non Wi-Fi interference as indicated by the air quality (AQ) value. • Low—Specifies the least sensitivity to non Wi-Fi interference as indicated by the AQ value. • Medium—Specifies medium sensitivity to non Wi-Fi interference as indicated by the AQ value.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Persistent Device Avoidance

SUMMARY STEPS

1. `configure terminal`

2. `ap dot11 {24ghz | 5ghz} rrm channel device`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rrm channel device Example: Device(config)# <code>ap dot11 24ghz rrm channel device</code>	Enables the persistent non Wi-Fi device avoidance in the 802.11 channel assignment. Add the no form of the command to disable the persistent device avoidance.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Cisco CleanAir using the Controller GUI

Configuring Cisco CleanAir on the Cisco Wireless LAN Controller (GUI)

- Step 1** Choose **Configuration > Wireless > 802.11a/n or 802.11b/g/n > CleanAir** to open the **802.11a (or 802.11b) > CleanAir** page.
- Step 2** Select the **CleanAir** check box to enable Cisco CleanAir functionality on the 802.11a/n or 802.11b/g/n network, or unselect it to prevent the device from detecting spectrum interference. By default, the Cisco CleanAir is disabled.
- Step 3** Select the **Report Interferers** check box to enable the Cisco CleanAir system to report any detected sources of interference, or unselect it to prevent the device from reporting interferers. The default value is selected.
- Note** Device Security alarms, Event Driven RRM, and the Persistence Device Avoidance algorithm do not work if Report Interferers are disabled.
- Step 4** Select the **Persistent Device Propagation** check box to enable propagation of information about persistent devices that can be detected by CleanAir. Persistent device propagation enables you to propagate information about persistent devices to the neighboring access points connected to the same device. Persistent interferers are present at the location and interfere with the WLAN operations even if they are not detectable at all times.
- Step 5** Ensure that any sources of interference that need to be detected and reported by the Cisco CleanAir system appear in the Interferences to Detect box and any that do not need to be detected appear in the Interferences to Ignore box. Use the > and < buttons to move interference sources between these two boxes. By default, all interference sources are detected. The sources of interference that you can choose depend on the type of radio, 802.11a/n/ac or 802.11b/g/n, and are as follows:
- **802.11 FH**—A 802.11 FH device

- **802.15.4**—A 802.15.4 or ZigBee device
- **Continuous Transmitter**—A continuous transmitter
- **Bluetooth Discovery**—A Bluetooth device
- **DECT-like Phone**—A digital enhanced cordless communication (DECT)-compatible phone
- **Microsoft**—A Microsoft device
- **SuperAG**—A 802.11a/g SuperAG device
- **Microwave Phone**—A microwave phone
- **Jammer**—A jamming device
- **Canopy**—A canopy bridge device
- **TDD Transmitter**—A time division duplex (TDD) transmitter device
- **Video Camera**—An analog video camera
- **WiFi Invalid Channel**—A WiFi invalid channel
- **WiFi Inverted**—A device using spectrally inverted Wi-Fi signals (I and Q signals of the RF signal are inverted)
- **WiMAX Fixed**—A WiMAX fixed device (802.11a/n only)
- **WiMAX Mobile**—A WiMAX mobile device (802.11a/n only)

Note Access points that are associated to the device send interference reports only for the interferers that appear in the Interferences to Detect box. This functionality allows you to filter out interferers that you do not want as well as any that may be flooding the network and causing performance problems for the device or Prime Infrastructure. Filtering allows the system to resume normal performance levels.

Step 6 Configure Cisco CleanAir alarms as follows:

- a) Select the **Enable AQI (Air Quality Index) Trap** check box to enable the triggering of air quality alarms, or unselect the box to disable this feature. The default value is selected.
- b) If you selected the **Enable AQI Trap** check box in *Step a*, enter a value between 1 and 100 (inclusive) in the AQI Alarm Threshold text box to specify the threshold at which you want the air quality alarm to be triggered. When the air quality falls below the threshold level, the alarm is triggered. A value of 1 represents the worst air quality, and 100 represents the best. The default value is 35.
- c) Enter the AQI threshold in the **AQI Alarm Threshold** text box. An alarm is generated when the air quality reaches a threshold value. The default is 35. The range is from 1 and 100.
- d) Select the **Enable Interference For Security Alarm** check box to trigger interferer alarms when the device detects specified device types, or unselect it to disable this feature. The default value is selected
- e) Make sure that any sources of interference that need to trigger interferer alarms appear in the **Trap on These Types** box and any that do not need to trigger interferer alarms appear in the **Do Not Trap on These Types** box. Use the > and < buttons to move interference sources between these two boxes. By default, all interference sources trigger interferer alarms.

For example, if you want the device to send an alarm when it detects a jamming device, select the **Enable Interference For Security Alarm** check box and move the jamming device to the **Trap on These Types** box.

Step 7 Click **Apply**.

Step 8 Trigger spectrum event-driven radio resource management (RRM) to run when a Cisco CleanAir-enabled access point detects a significant level of interference as follows:

- a) Look at the **EDRRM** field to see the current status of spectrum event-driven RRM and, if enabled, the Sensitivity Threshold field to see the threshold level at which event-driven RRM is invoked.
- b) If you want to change the current status of event-driven RRM or the sensitivity level, go to the **802.11a (or 802.11b) > RRM > Dynamic Channel Assignment (DCA)** page.
- c) Select the **EDRRM** check box to trigger RRM to run when an access point detects a certain level of interference, or unselect it to disable this feature. The default value is selected.

- d) If you selected the **EDRRM** check box in *Step c*, choose **Low**, **Medium**, **High**, or **Custom** from the Sensitivity Threshold drop-down list to specify the threshold at which you want RRM to be triggered. When the interference for the access point rises above the threshold level, RRM initiates a local dynamic channel assignment (DCA) run and changes the channel of the affected access point radio if possible to improve network performance. EDRRM prevents the access point from returning to the original channel for three hours after the event.

High—Represents an increased sensitivity to changes in the environment.

Custom—Allows you to set a threshold value in the Custom Sensitivity Threshold field. The default sensitivity is 35.

Low—Represents a decreased sensitivity to changes in the environment.

The EDRRM AQ threshold value for low sensitivity is 35, medium sensitivity is 50, and high sensitivity is 60.

- e) Click **Apply**.

Step 9 Click **Save Configuration**.

Configuring Cisco CleanAir on an Access Point (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > Radios > 802.11a/n or 802.11b/g/n** to open the 802.11a/n (or 802.11b/g/n) Radios page.

Step 2 Select the check box adjacent to the desired access point and click **Configure**. The 802.11a/n (or 802.11b/g/n) Radios page appears.

The **CleanAir Capable** field shows whether this access point can support CleanAir functionality. If it can, go to the next step to enable or disable CleanAir for this access point. If the access point cannot support CleanAir functionality, you cannot enable CleanAir for this access point.

Note By default, the Cisco CleanAir functionality is enabled on the radios.

Step 3 Enable Cisco CleanAir functionality for this access point by choosing **Enable** from the CleanAir Admin Status drop-down list. To disable CleanAir functionality for this access point, choose **Disable**. The default value is Enable. This setting overrides the global CleanAir configuration for this access point.

Step 4 Click **Apply**.

Step 5 Click **Save Configuration**.

Configuring Cisco Spectrum Expert

Configuring Spectrum Expert (GUI)

Before you begin

- Spectrum Expert (Windows XP laptop client) and access point should be pingable, otherwise; it will not work.

- Prior to establishing a connection between the Spectrum Expert console and the access point, make sure that IP address routing is properly configured and the network spectrum interface (NSI) ports are open in any intervening firewalls.
- The access point must be a TCP server listening on ports 37540 for 2.4 GHz and 37550 for 5 GHz frequencies. These ports must be opened for the spectrum expert application to connect to the access point using the NSI protocol.
- You can view the NSI key from the device CLI by using the **show ap name *ap_name* config dot11 {24ghz | 5ghz}** command.

Step 1 Ensure that Cisco CleanAir functionality is enabled for the access point that will be connected to the Spectrum Expert console.

Note The SE-Connect mode is set for the entire access point, not just a single radio. However, the Spectrum Expert console connects to a single radio at a time.

Step 2 Choose **Configuration > Wireless > Access Points > All APs** to open the All APs page.

Step 3 Click the name of the desired access point to open the All APs > Details page.

Step 4 Choose **SE-Connect** from the AP Mode drop-down list. This mode is available only for access points that are capable of supporting Cisco CleanAir functionality. For the SE-Connect mode to appear as an available option, the access point must have at least one spectrum-capable radio in the Enable state.

Step 5 Click **Apply** to commit your changes.

Step 6 Click **OK** when prompted to reboot the access point.

Step 7 On the Windows PC, access the Cisco Software Center from this URL:

<http://www.cisco.com/cisco/software/navigator.html>

Step 8 Click **Product > Wireless > Cisco Spectrum Intelligence > Cisco Spectrum Expert > Cisco Spectrum Expert Wi-Fi**, and then download the Spectrum Expert 4.1.11 executable (*.exe) file.

Step 9 Run the Spectrum Expert application on the PC.

Step 10 When the Connect to Sensor dialog box appears, enter the IP address of the access point, choose the access point radio, and enter the 16-byte network spectrum interface (NSI) key to authenticate. The Spectrum Expert application opens a TCP/IP connection directly to the access point using the NSI protocol.

When an access point in SE-Connect mode joins a device, it sends a Spectrum Capabilities notification message, and the device responds with a Spectrum Configuration Request. The request contains the 16-byte random NSI key generated by the device for NSI authentication. The device generates one key per access point, which the access point stores until it is rebooted.

Note You can establish up to three Spectrum Expert console connections per access point radio.

Step 11 Verify that the Spectrum Expert console is connected to the access point by selecting the Slave Remote Sensor text box in the bottom right corner of the Spectrum Expert application. If the two devices are connected, the IP address of the access point appears in this text box.

Step 12 Use the Spectrum Expert application to view and analyze spectrum data from the access point.

Configuring Spectrum Expert (CLI)

Before you begin

- Spectrum Expert (Windows XP laptop client) and access point should be pingable, otherwise; it will not work.
- Prior to establishing a connection between the Spectrum Expert console and the access point, make sure that IP address routing is properly configured and the network spectrum interface (NSI) ports are open in any intervening firewalls.
- The access point must be a TCP server listening on ports 37540 for 2.4-GHz and 37550 for 5-GHz frequencies. These ports must be opened for the spectrum expert application to connect to the access point using the NSI protocol.
- You can view the NSI key from the device CLI by using the **show ap name *ap_name* config dot11 {24ghz | 5ghz}** command.

Step 1 To configure the access point for SE-Connect mode, enter this command:

```
ap name ap_name mode se-connect
```

Example:

```
Device#ap name Cisco_AP3500 mode se-connect
```

Step 2 When prompted to reboot the access point, enter **Y**.

Step 3 To view the NSI key for the access point, enter this command:

```
show ap name ap_name config dot11 {24ghz | 5ghz}
```

Example:

```
Device#show ap name Cisco_AP3500 config dot11 24ghz
```

```
<snippet>
CleanAir Management Information
CleanAir Capable                : Yes
CleanAir Management Admin State : Enabled
CleanAir Management Operation State : Up
CleanAir NSI Key                 : 274F1F9B1A5206683FAF57D87BFFBC9B
CleanAir Sensor State           : Configured
```

```
<snippet>
```

What to do next

On the Windows PC, download Cisco Spectrum Expert:

- Access the Cisco Software Center from this URL: <http://www.cisco.com/cisco/software/navigator.html>
- Click **Product > Wireless > Cisco Spectrum Intelligence > Cisco Spectrum Expert > Cisco Spectrum Expert Wi-Fi**, and then download the Spectrum Expert 4.1.11 executable (*.exe) file.
- Run the Spectrum Expert application on the PC.

- When the Connect to Sensor dialog box appears, enter the IP address of the access point, choose the access point radio, and enter the 16-byte network spectrum interface (NSI) key to authenticate. The Spectrum Expert application opens a TCP/IP connection directly to the access point using the NSI protocol.

When an access point in SE-Connect mode joins a device, it sends a Spectrum Capabilities notification message, and the device responds with a Spectrum Configuration Request. The request contains the 16-byte random NSI key generated by the device for use in NSI authentication. The device generates one key per access point, which the access point stores until it is rebooted.

Note You can establish up to three Spectrum Expert console connections per access point radio.

- Verify that the Spectrum Expert console is connected to the access point by selecting the Slave Remote Sensor text box in the bottom right corner of the Spectrum Expert application. If the two devices are connected, the IP address of the access point appears in this text box.
- Use the Spectrum Expert application to view and analyze spectrum data from the access point.

Monitoring CleanAir Parameters

You can monitor CleanAir parameters using the following commands:

Table 6: Commands for Monitoring CleanAir

Commands	Description
show ap dot11 24ghz cleanair air-quality summary	Displays CleanAir Air Quality (AQ) data for 2.4-GHz band
show ap dot11 24ghz cleanair air-quality worst	Displays CleanAir Air Quality (AQ) worst data for 2.4-GHz band
show ap dot11 24ghz cleanair config	Displays CleanAir Configuration for 2.4-GHz band
show ap dot11 24ghz cleanair device type all	Displays all CleanAir Interferers for 2.4-GHz band
show ap dot11 24ghz cleanair device type bt-discovery	Displays CleanAir Interferers of type BT Discovery for 2.4-GHz band
show ap dot11 24ghz cleanair device type bt-link	Displays CleanAir Interferers of type BT Link for 2.4-GHz band
show ap dot11 24ghz cleanair device type canopy	Displays CleanAir Interferers of type Canopy for 2.4-GHz band
show ap dot11 24ghz cleanair device type cont-tx	Displays CleanAir Interferers of type Continuous transmitter for 2.4-GHz band
show ap dot11 24ghz cleanair device type dect-like	Displays CleanAir Interferers of type DECT Like for 2.4-GHz band

Commands	Description
show ap dot11 24ghz cleanair device type fh	Displays CleanAir Interferers of type 802.11FH for 2.4-GHz band
show ap dot11 24ghz cleanair device type inv	Displays CleanAir Interferers of type WiFi Inverted for 2.4-GHz band
show ap dot11 24ghz cleanair device type jammer	Displays CleanAir Interferers of type Jammer for 2.4-GHz band
show ap dot11 24ghz cleanair device type mw-oven	Displays CleanAir Interferers of type MW Oven for 2.4-GHz band
show ap dot11 24ghz cleanair device type nonstd	Displays CleanAir Interferers of type WiFi Inv. Ch for 2.4-GHz band
show ap dot11 24ghz cleanair device type persistent	Displays CleanAir Interferers of type Persistent for 2.4-GHz band
show ap dot11 24ghz cleanair device type superag	Displays CleanAir Interferers of type SuperAG for 2.4-GHz band
show ap dot11 24ghz cleanair device type tdd-tx	Displays CleanAir Interferers of type TDD Transmit for 2.4-GHz band
show ap dot11 24ghz cleanair device type video	Displays CleanAir Interferers of type Video Camera for 2.4-GHz band
show ap dot11 24ghz cleanair device type wimax-fixed	Displays CleanAir Interferers of type WiMax Fixed for 2.4-GHz band
show ap dot11 24ghz cleanair device type wimax-mobile	Displays CleanAir Interferers of type WiMax Mobile for 2.4-GHz band
show ap dot11 24ghz cleanair device type xbox	Displays CleanAir Interferers of type Xbox for 2.4-GHz band
show ap dot11 24ghz cleanair device type zigbee	Displays CleanAir Interferers of type zigbee for 2.4-GHz band
show ap dot11 5ghz cleanair air-quality summary	Displays CleanAir Air Quality (AQ) data for 5-GHz band
show ap dot11 5ghz cleanair air-quality worst	Displays CleanAir Air Quality (AQ) worst data for 5-GHz band
show ap dot11 5ghz cleanair config	Displays CleanAir Configuration for 5-GHz band
show ap dot11 5ghz cleanair device type all	Displays all CleanAir Interferers for 5-GHz band
show ap dot11 5ghz cleanair device type canopy	Displays CleanAir Interferers of type Canopy for 5-GHz band
show ap dot11 5ghz cleanair device type cont-tx	Displays CleanAir Interferers of type Continuous TX for 5-GHz band

Commands	Description
show ap dot11 5ghz cleanair device type dect-like	Displays CleanAir Interferers of type DECT Like for 5-GHz band
show ap dot11 5ghz cleanair device type inv	Displays CleanAir Interferers of type WiFi Inverted for 5-GHz band
show ap dot11 5ghz cleanair device type jammer	Displays CleanAir Interferers of type Jammer for 5-GHz band
show ap dot11 5ghz cleanair device type nonstd	Displays CleanAir Interferers of type WiFi Inv. Ch for 5-GHz band
show ap dot11 5ghz cleanair device type persistent	Displays CleanAir Interferers of type Persistent for 5-GHz band
show ap dot11 5ghz cleanair device type superag	Displays CleanAir Interferers of type SuperAG for 5-GHz band
show ap dot11 5ghz cleanair device type tdd-tx	Displays CleanAir Interferers of type TDD Transmit for 5-GHz band
show ap dot11 5ghz cleanair device type video	Displays CleanAir Interferers of type Video Camera for 5-GHz band
show ap dot11 5ghz cleanair device type wimax-fixed	Displays CleanAir Interferers of type WiMax Fixed for 5-GHz band
show ap dot11 5ghz cleanair device type wimax-mobile	Displays CleanAir Interferers of type WiMax Mobile for 5-GHz band

You can also check the CleanAir status of the access points using the device GUI:

Choose **Monitor > Wireless > Access Points > 802.11 a/n/ac or 802.11 b/g/n**.

The **Radios** page is displayed showing a list of access points that are associated with the device. You can see the CleanAir Admin and CleanAir Status.

The Cisco CleanAir status is one of the following:

- **UP**—The spectrum sensor for the access point radio is currently operational (error code 0).
 - **DOWN**—The spectrum sensor for the access point radio is currently not operational because an error has occurred. The most likely reason for the error is that the access point radio is disabled (error code 8). To correct this error, enable the radio.
 - **ERROR**—The spectrum sensor for the access point radio has crashed (error code 128), making CleanAir monitoring nonoperational for this radio. If this error occurs, reboot the access point. If the error continues to appear, you might want to disable Cisco CleanAir functionality on the radio.
 - **N/A**—This access point radio is not capable of supporting Cisco CleanAir functionality.
-

Monitoring the Interference Devices

When a CleanAir-enabled access point detects interference devices, detections of the same device from multiple sensors are merged together to create clusters. Each cluster is given a unique ID. Some devices conserve power by limiting the transmit time until actually needed which results in the spectrum sensor to temporarily stop detecting the device. This device is then correctly marked as down. A down device is correctly removed from the spectrum database. In cases when all the interferer detections for a specific devices are reported, the cluster ID is kept alive for an extended period of time to prevent possible device detection bouncing. If the same device is detected again, it is merged with the original cluster ID and the device detection history is preserved.

For example, some bluetooth headsets operate on battery power. These devices employ methods to reduce power consumption, such as turning off the transmitter when not actually needed. Such devices can appear to come and go from the classification. To manage these devices, CleanAir keeps the cluster IDs longer and they are remerged into a single record upon detection. This process smoothens the user records and accurately represents the device history.

Monitoring the Interference Devices (GUI)

Before you begin

You can configure Cisco CleanAir only on CleanAir-enabled access points.

Step 1 Choose **Monitor > Interferers > Cisco CleanAir > 802.11a/n or 802.11b/g/n > Interference Devices** to open the Cisco APs > Interference Devices page.

This page shows the following information:

- **AP Name**—The name of the access point where the interference device is detected.
- **Interferer Type**—Type of the interferer.
- **Affected Channel**—Channel that the device affects.
- **Severity**—Severity index of the interfering device.
- **Duty Cycle (%)**—Proportion of time during which the interfering device was active.
- **RSSI**—Receive signal strength indicator (RSSI) of the access point.
- **DevID**—Device identification number that uniquely identified the interfering device.
- **ClusterID**—Cluster identification number that uniquely identifies the type of the devices.

Step 2 Click the **Filter** icon or choose the **Quick Filter** option from the Show drop-down list to display the information about interference devices based on a particular criteria.

Related Topics

[Configuring Interference Reporting for 2.4-GHz Devices](#), on page 32

[Configuring Interference Reporting for 5-GHz devices](#), on page 35

Monitoring the Worst Air Quality of Radio Bands (GUI)

Choose **Monitor > Cisco CleanAir > Worst Air-Quality** to open the Air Quality Report page.

This page shows the air quality of both the 802.11a/n and 802.11b/g/n radio bands. This page displays the following information:

- **AP Name**—Name of the access point that reported the worst air quality for the 802.11 radio band.
- **Channel Number**—Radio channel with the worst reported air quality.
- **Minimum Air Quality Index**—Minimum air quality for this radio channel. The range is from 1 to 100. An air quality index (AQI) value of 100 is the best, and 1 is the worst.
- **Average Air Quality Index**—Average air quality for this radio channel. The range is from 1 to 100. An air quality index (AQI) value of 100 is the best, and 1 is the worst.
- **Interference Device Count**—Number of interferers detected by the radios on the 802.11 radio band.

Configuration Examples for Configuring CleanAir

Enabling CleanAir on 2.4-GHz Band and an Access Point: Example

This example shows how to enable CleanAir on the 2.4-GHz band and an access point operating in the channel:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair
Device(config)#exit
Device#ap name TAP1 dot11 24ghz cleanair
Device#end
```

Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices: Example

This example shows how to configure a CleanAir Alarm for 2.4-GHz Air-Quality threshold of 50 dBm and an Xbox device:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair alarm air-quality threshold 50
Device(config)#ap dot11 24ghz cleanair alarm device xbox
Device(config)#end
```

Configuring Interference Reporting for 5-GHz Devices: Example

This example shows how to configure interference reporting for 5-GHz devices:

```
Device#configure terminal
Device(config)#ap dot11 5ghz cleanair alarm device xbox
Device(config)#end
```

Configuring EDRRM for CleanAir-Events: Example

This example shows how to enable an EDRRM cleanair-event in the 2.4-GHz band and configure high sensitivity to non Wi-Fi interference:

```
Device#configure terminal
Device(config)#ap dot11 24ghz rrm channel cleanair-event
Device(config)#ap dot11 24ghz rrm channel cleanair-event sensitivity high
Device(config)#end
```

Configuring Persistent Device Avoidance: Example

This example shows how to enable persistent non Wi-Fi device avoidance in the 2.4-GHz band:

```
Device#configure terminal
Device(config)#ap dot11 24ghz rrm channel device
Device(config)#end
```

Configuring an Access Point for SE-Connect Mode: Example

This example shows how to configure an access point in the SE-Connect mode:

```
Device#ap name Cisco_AP3500 mode se-connect
```

CleanAir FAQs

Q. How do I check if my MC is up?

A. To check if the MC is up, use the command: **show wireless mobility summary**.

This example shows how to display the mobility summary:

```
Device#show wireless mobility summary

Mobility Controller Summary:
Mobility Role                : Mobility Controller
Mobility Protocol Port       : 16666
Mobility Group Name          : MG-AK
Mobility Oracle              : Disabled
Mobility Oracle IP Address   : 0.0.0.0
DTLS Mode                    : Enabled
Mobility Domain ID for 802.11r : 0x39b2
Mobility Keepalive Interval  : 10
Mobility Keepalive Count     : 3
Mobility Control Message DSCP Value : 48
Mobility Domain Member Count : 2
Link Status is Control Link Status : Data Link Status
Controllers configured in the Mobility Domain:
IP          Public IP      Group Name      Multicast IP      Link Status
-----
9.6.136.10  -                       MG-AK           0.0.0.0           UP      : UP
```

Q. Multiple access points detect the same interference device, however, the device shows them as separate clusters or different suspected devices clustered together. Why does this happen?

A. Access points must be RF neighbors for the device to consider the merging of devices that are detected by these access points. The access point takes time to establish neighbor relationships. A few minutes

after the device reboots or a change in the RF group and similar events, clustering will not be very accurate.

Q. Can I merge two monitor mode access points using a device?

A. No, you cannot merge two monitor mode access points using a device. You can merge the monitor mode access points only using MSE.

Q. How do I view neighbor access points?

A. To view neighbor access points, use the command: **show ap ap_name auto-rf dot11 {24ghz | 5ghz}**

This example shows how to display the neighbor access points:

```
Device#show ap name AS-5508-5-AP3 auto-rf dot11 24ghz
```

```
<snippet>

```

Q. What are the debug commands available for CleanAir?

A. The debug commands for CleanAir are:

```
debug cleanair {all | error | event | internal-event | nmsp | packet}
```

```
debug rrm {all | channel | detail | error | group | ha | manager | message | packet
| power | prealarm | profile | radar | rf-change | scale | spectrum}
```

Q. Why are CleanAir Alarms not generated for interferer devices?

A. Verify that the access points are CleanAir-capable and CleanAir is enabled both on the access point and the device.

Q. Can the Cisco Catalyst 3850 Series Switches function as a Mobility Agent (MA)?

A. Yes, the Cisco Catalyst 3850 Series Switches can function as an MA.

Q. Are CleanAir configurations available on the MA?

A. From Release 3.3 SE, CleanAir configurations are available on the MA. You can use the following two CleanAir commands on the MA:

- **show ap dot11 5ghz cleanair config**
- **show ap dot11 24ghz cleanair config**

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring Interface Characteristics

Interface Types

This section describes the different types of interfaces supported by the device. The rest of the chapter describes configuration procedures for physical interface characteristics.

Note The stack ports on the rear of the stacking-capable devices are not Ethernet ports and cannot be configured.

Port-Based VLANs

A VLAN is a switched network that is logically segmented by function, team, or application, without regard to the physical location of the users. Packets received on a port are forwarded only to ports that belong to the same VLAN as the receiving port. Network devices in different VLANs cannot communicate with one another without a Layer 3 device to route traffic between the VLANs.

VLAN partitions provide hard firewalls for traffic in the VLAN, and each VLAN has its own MAC address table. A VLAN comes into existence when a local port is configured to be associated with the VLAN, when the VLAN Trunking Protocol (VTP) learns of its existence from a neighbor on a trunk, or when a user creates a VLAN. VLANs can be formed with ports across the stack.

To configure VLANs, use the **vlan** *vlan-id* global configuration command to enter VLAN configuration mode. The VLAN configurations for normal-range VLANs (VLAN IDs 1 to 1005) are saved in the VLAN database. If VTP is version 1 or 2, to configure extended-range VLANs (VLAN IDs 1006 to 4094), you must first set VTP mode to transparent. Extended-range VLANs created in transparent mode are not added to the VLAN database but are saved in the device running configuration. With VTP version 3, you can create extended-range VLANs in client or server mode. These VLANs are saved in the VLAN database.

In a switch stack, the VLAN database is downloaded to all switches in a stack, and all switches in the stack build the same VLAN database. The running configuration and the saved configuration are the same for all switches in a stack.

Add ports to a VLAN by using the **switchport** interface configuration commands:

- Identify the interface.
- For a trunk port, set trunk characteristics, and, if desired, define the VLANs to which it can belong.
- For an access port, set and define the VLAN to which it belongs.

Switch Ports

Switch ports are Layer 2-only interfaces associated with a physical port. Switch ports belong to one or more VLANs. A switch port can be an access port or a trunk port. You can configure a port as an access port or trunk port or let the Dynamic Trunking Protocol (DTP) operate on a per-port basis to set the switchport mode by negotiating with the port on the other end of the link. Switch ports are used for managing the physical interface and associated Layer 2 protocols and do not handle routing or bridging.

Configure switch ports by using the **switchport** interface configuration commands.

Access Ports

An access port belongs to and carries the traffic of only one VLAN (unless it is configured as a voice VLAN port). Traffic is received and sent in native formats with no VLAN tagging. Traffic arriving on an access port is assumed to belong to the VLAN assigned to the port. If an access port receives a tagged packet (Inter-Switch Link [ISL] or IEEE 802.1Q tagged), the packet is dropped, and the source address is not learned.

The types of access ports supported are:

- Static access ports are manually assigned to a VLAN (or through a RADIUS server for use with IEEE 802.1x).

You can also configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.

Trunk Ports

A trunk port carries the traffic of multiple VLANs and by default is a member of all VLANs in the VLAN database.

Although by default, a trunk port is a member of every VLAN known to the VTP, you can limit VLAN membership by configuring an allowed list of VLANs for each trunk port. The list of allowed VLANs does not affect any other port but the associated trunk port. By default, all possible VLANs (VLAN ID 1 to 4094) are in the allowed list. A trunk port can become a member of a VLAN only if VTP knows of the VLAN and if the VLAN is in the enabled state. If VTP learns of a new, enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of that VLAN and traffic is forwarded to and from the trunk port for that VLAN. If VTP learns of a new, enabled VLAN that is not in the allowed list for a trunk port, the port does not become a member of the VLAN, and no traffic for the VLAN is forwarded to or from the port.

Tunnel Ports

Tunnel ports are used in IEEE 802.1Q tunneling to segregate the traffic of customers in a service-provider network from other customers who are using the same VLAN number. You configure an asymmetric link from a tunnel port on a service-provider edge switch to an IEEE 802.1Q trunk port on the customer switch. Packets entering the tunnel port on the edge switch, already IEEE 802.1Q-tagged with the customer VLANs, are encapsulated with another layer of an IEEE 802.1Q tag (called the metro tag), containing a VLAN ID unique in the service-provider network, for each customer. The double-tagged packets go through the service-provider network keeping the original customer VLANs separate from those of other customers. At the outbound interface, also a tunnel port, the metro tag is removed, and the original VLAN numbers from the customer network are retrieved.

Tunnel ports cannot be trunk ports or access ports and must belong to a VLAN unique to each customer.

Routed Ports

A routed port is a physical port that acts like a port on a router; it does not have to be connected to a router. A routed port is not associated with a particular VLAN, as is an access port. A routed port behaves like a regular router interface, except that it does not support VLAN subinterfaces. Routed ports can be configured with a Layer 3 routing protocol. A routed port is a Layer 3 interface only and does not support Layer 2 protocols, such as DTP and STP.

Configure routed ports by putting the interface into Layer 3 mode with the **no switchport** interface configuration command. Then assign an IP address to the port, enable routing, and assign routing protocol characteristics by using the **ip routing** and **router protocol** global configuration commands.

Note Entering a **no switchport** interface configuration command shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost.

The number of routed ports that you can configure is not limited by software. However, the interrelationship between this number and the number of other features being configured might impact CPU performance because of hardware limitations.

Note The IP Base image supports static routing and the Routing Information Protocol (RIP). For full Layer 3 routing or for fallback bridging, you must enable the IP Services image on the standalone device, or the active device.

Switch Virtual Interfaces

A switch virtual interface (SVI) represents a VLAN of switch ports as one interface to the routing or bridging function in the system. You can associate only one SVI with a VLAN. You configure an SVI for a VLAN only to route between VLANs or to provide IP host connectivity to the device. By default, an SVI is created for the default VLAN (VLAN 1) to permit remote device administration. Additional SVIs must be explicitly configured.

Note You cannot delete interface VLAN 1.

SVIs provide IP host connectivity only to the system. SVIs are created the first time that you enter the **vlan** interface configuration command for a VLAN interface. The VLAN corresponds to the VLAN tag associated with data frames on an ISL or IEEE 802.1Q encapsulated trunk or the VLAN ID configured for an access port. Configure a VLAN interface for each VLAN for which you want to route traffic, and assign it an IP address.

Although the switch stack or device supports a total of 1005 VLANs and SVIs, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might impact CPU performance because of hardware limitations.

When you create an SVI, it does not become active until it is associated with a physical port.

SVI Autostate Exclude

The line state of an SVI with multiple ports on a VLAN is in the *up* state when it meets these conditions:

- The VLAN exists and is active in the VLAN database on the device
- The VLAN interface exists and is not administratively down.
- At least one Layer 2 (access or trunk) port exists, has a link in the *up* state on this VLAN, and is in the spanning-tree forwarding state on the VLAN.

Note The protocol link state for VLAN interfaces come up when the first switchport belonging to the corresponding VLAN link comes up and is in STP forwarding state.

The default action, when a VLAN has multiple ports, is that the SVI goes down when all ports in the VLAN go down. You can use the SVI autostate exclude feature to configure a port so that it is not included in the SVI line-state up-or-down calculation. For example, if the only active port on the VLAN is a monitoring port, you might configure autostate exclude on that port so that the VLAN goes down when all other ports go down. When enabled on a port, **autostate exclude** applies to all VLANs that are enabled on that port.

The VLAN interface is brought up when one Layer 2 port in the VLAN has had time to converge (transition from STP listening-learning state to forwarding state). This prevents features such as routing protocols from

using the VLAN interface as if it were fully operational and minimizes other problems, such as routing black holes.

EtherChannel Port Groups

EtherChannel port groups treat multiple switch ports as one switch port. These port groups act as a single logical port for high-bandwidth connections between devices or between devices and servers. An EtherChannel balances the traffic load across the links in the channel. If a link within the EtherChannel fails, traffic previously carried over the failed link changes to the remaining links. You can group multiple trunk ports into one logical trunk port, group multiple access ports into one logical access port, group multiple tunnel ports into one logical tunnel port, or group multiple routed ports into one logical routed port. Most protocols operate over either single ports or aggregated switch ports and do not recognize the physical ports within the port group. Exceptions are the DTP, the Cisco Discovery Protocol (CDP), and the Port Aggregation Protocol (PAgP), which operate only on physical ports.

When you configure an EtherChannel, you create a port-channel logical interface and assign an interface to the EtherChannel. For Layer 3 interfaces, you manually create the logical interface by using the **interface port-channel** global configuration command. Then you manually assign an interface to the EtherChannel by using the **channel-group** interface configuration command. For Layer 2 interfaces, use the **channel-group** interface configuration command to dynamically create the port-channel logical interface. This command binds the physical and logical ports together.

10-Gigabit Ethernet Interfaces

A 10-Gigabit Ethernet interface operates only in full-duplex mode. The interface can be configured as a switched or routed port.

For more information about the Cisco TwinGig Converter Module, see the device hardware installation guide and your transceiver module documentation.

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Using the Switch USB Ports

The device has two USB ports on the front panel — a USB mini-Type B console port and a USB Type A port.

USB Mini-Type B Console Port

The device has the following console ports:

- USB mini-Type B console connection
- RJ-45 console port

Console output appears on devices connected to both ports, but console input is active on only one port at a time. By default, the USB connector takes precedence over the RJ-45 connector.

Note Windows PCs require a driver for the USB port. See the hardware installation guide for driver installation instructions.

Use the supplied USB Type A-to-USB mini-Type B cable to connect a PC or other device to the device. The connected device must include a terminal emulation application. When the device detects a valid USB connection to a powered-on device that supports host functionality (such as a PC), input from the RJ-45 console is immediately disabled, and input from the USB console is enabled. Removing the USB connection immediately reenables input from the RJ-45 console connection. An LED on the device shows which console connection is in use.

Console Port Change Logs

At software startup, a log shows whether the USB or the RJ-45 console is active. Each device in a stack issues this log. Every device always first displays the RJ-45 media type.

In the sample output, Device 1 has a connected USB console cable. Because the bootloader did not change to the USB console, the first log from Device 1 shows the RJ-45 console. A short time later, the console changes and the USB console log appears. Device 2 and Device 3 have connected RJ-45 console cables.

```
switch-stack-1
*Mar  1 00:01:00.171: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
*Mar  1 00:01:00.431: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.
```

```
switch-stack-2
*Mar  1 00:01:09.835: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

```
switch-stack-3
*Mar  1 00:01:10.523: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

When the USB cable is removed or the PC de-activates the USB connection, the hardware automatically changes to the RJ-45 console interface:

```
switch-stack-1
Mar  1 00:20:48.635: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

You can configure the console type to always be RJ-45, and you can configure an inactivity timeout for the USB connector.

USB Type A Port

The USB Type A port provides access to external USB flash devices, also known as thumb drives or USB keys. The port supports Cisco USB flash drives with capacities from 128 MB to 8 GB (USB devices with port densities of 128 MB, 256 MB, 1 GB, 4 GB, 8 GB are supported). You can use standard Cisco IOS command-line interface (CLI) commands to read, write, erase, and copy to or from the flash device. You can also configure the device to boot from the USB flash drive.

Interface Connections

Devices within a single VLAN can communicate directly through any switch. Ports in different VLANs cannot exchange data without going through a routing device. With a standard Layer 2 device, ports in different VLANs have to exchange information through a router. By using the device with routing enabled, when you configure both VLAN 20 and VLAN 30 with an SVI to which an IP address is assigned, packets can be sent from Host A to Host B directly through the device with no need for an external router.

Figure 2: Connecting VLANs with the Switch

Note Devices running the LAN Base image support configuring only 16 static routes on SVIs.

When the IP Services image is running on the device or the active device, the device uses two methods to forward traffic between interfaces: routing and fallback bridging. If the IP Base image is on the device or the active device, only basic routing (static routing and RIP) is supported. Whenever possible, to maintain high performance, forwarding is done by the device hardware. However, only IPv4 packets with Ethernet II encapsulation are routed in hardware. Non-IP traffic and traffic with other encapsulation methods are fallback-bridged by hardware.

- The routing function can be enabled on all SVIs and routed ports. The device routes only IP traffic. When IP routing protocol parameters and address configuration are added to an SVI or routed port, any IP traffic received from these ports is routed.
- Fallback bridging forwards traffic that the device does not route or traffic belonging to a nonroutable protocol, such as DECnet. Fallback bridging connects multiple VLANs into one bridge domain by bridging between two or more SVIs or routed ports. When configuring fallback bridging, you assign SVIs or routed ports to bridge groups with each SVI or routed port assigned to only one bridge group. All interfaces in the same group belong to the same bridge domain.

Interface Configuration Mode

The device supports these interface types:

- Physical ports—device ports and routed ports
- VLANs—switch virtual interfaces
- Port channels—EtherChannel interfaces

You can also configure a range of interfaces.

To configure a physical interface (port), specify the interface type, stack member number (only stacking-capable switches), module number, and device port number, and enter interface configuration mode.

- **Type**—Gigabit Ethernet (gigabitethernet or gi) for 10/100/1000 Mb/s Ethernet ports, 10-Gigabit Ethernet (tengigabitethernet or te) for 10,000 Mb/s, or small form-factor pluggable (SFP) module Gigabit Ethernet interfaces (gigabitethernet or gi).
- **Stack member number**—The number that identifies the device within the stack. The device number range is 1 to 9 and is assigned the first time the device initializes. The default device number, before it is integrated into a device stack, is 1. When a device has been assigned a stack member number, it keeps that number until another is assigned to it.

You can use the switch port LEDs in Stack mode to identify the stack member number of a device.

- **Module number**—The module or slot number on the device: switch (downlink) ports are 0, and uplink ports are 1.
- **Port number**—The interface number on the device. The 10/100/1000 port numbers always begin at 1, starting with the far left port when facing the front of the device, for example, gigabitethernet1/0/1 or gigabitethernet1/0/8.

On a device with SFP uplink ports, the module number is 1 and the port numbers restart. For example, if the device has 24 10/100/1000 ports, the SFP module ports are gigabitethernet1/1/1 through gigabitethernet1/1/4 or tengigabitethernet1/1/1 through tengigabitethernet1/1/4.

You can identify physical interfaces by physically checking the interface location on the device. You can also use the **show** privileged EXEC commands to display information about a specific interface or all the interfaces on the switch. The remainder of this chapter primarily provides physical interface configuration procedures.

These are examples of how to identify interfaces on a stacking-capable device:

- To configure 10/100/1000 port 4 on a standalone device, enter this command:

```
Device(config)# interface gigabitethernet1/0/4
```

- To configure 10-Gigabit Ethernet port 1 on a standalone device, enter this command:

```
Device(config)# interface tengigabitethernet1/0/1
```

- To configure 10-Gigabit Ethernet port on stack member 3, enter this command:

```
Device(config)# interface tengigabitethernet3/0/1
```

- To configure the first SFP module (uplink) port on a standalone device, enter this command:

```
Device(config)# interface gigabitethernet1/1/1
```

Default Ethernet Interface Configuration

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the **switchport** interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

This table shows the Ethernet interface default configuration, including some features that apply only to Layer 2 interfaces.

Table 7: Default Layer 2 Ethernet Interface Configuration

Feature	Default Setting
Operating mode	Layer 2 or switching mode (switchport command).
Allowed VLAN range	VLANs 1– 4094.
Default VLAN (for access ports)	VLAN 1 (Layer 2 interfaces only).
Native VLAN (for IEEE 802.1Q trunks)	VLAN 1 (Layer 2 interfaces only).
VLAN trunking	Switchport mode dynamic auto (supports DTP) (Layer 2 interfaces only).
Port enable state	All ports are enabled.
Port description	None defined.
Speed	Autonegotiate. (Not supported on the 10-Gigabit interfaces.)
Duplex mode	Autonegotiate. (Not supported on the 10-Gigabit interfaces.)
Flow control	Flow control is set to receive: off . It is always off for sent packets.
EtherChannel (PAgP)	Disabled on all Ethernet ports.
Port blocking (unknown multicast and unknown unicast traffic)	Disabled (not blocked) (Layer 2 interfaces only).
Broadcast, multicast, and unicast storm control	Disabled.
Protected port	Disabled (Layer 2 interfaces only).
Port security	Disabled (Layer 2 interfaces only).
Port Fast	Disabled.

Feature	Default Setting
Auto-MDIX	Enabled. Note The switch might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the switch through a crossover cable. This is regardless of whether auto-MIDX is enabled on the switch port.
Power over Ethernet (PoE)	Enabled (auto).

Interface Speed and Duplex Mode

Ethernet interfaces on the switch operate at 10, 100, 1000, or 10,000 Mb/s and in either full- or half-duplex mode. In full-duplex mode, two stations can send and receive traffic at the same time. Normally, 10-Mb/s ports operate in half-duplex mode, which means that stations can either receive or send traffic.

Switch models include Gigabit Ethernet (10/100/1000-Mb/s) ports, 10-Gigabit Ethernet ports, and small form-factor pluggable (SFP) module slots supporting SFP modules.

Speed and Duplex Configuration Guidelines

When configuring an interface speed and duplex mode, note these guidelines:

- The 10-Gigabit Ethernet ports do not support the speed and duplex features. These ports operate only at 10,000 Mb/s and in full-duplex mode.
- Do not disable Auto-Negotiation on PoE switches.
- Gigabit Ethernet (10/100/1000-Mb/s) ports support all speed options and all duplex options (auto, half, and full). However, Gigabit Ethernet ports operating at 1000 Mb/s do not support half-duplex mode.
- For SFP module ports, the speed and duplex CLI options change depending on the SFP module type:
 - The 1000BASE-*x* (where *x* is -BX, -CWDM, -LX, -SX, and -ZX) SFP module ports support the **nonegotiate** keyword in the **speed** interface configuration command. Duplex options are not supported.
 - The 1000BASE-T SFP module ports support the same speed and duplex options as the 10/100/1000-Mb/s ports.
- If both ends of the line support autonegotiation, we highly recommend the default setting of **auto** negotiation.
- If one interface supports autonegotiation and the other end does not, configure duplex and speed on both interfaces; do not use the **auto** setting on the supported side.
- When STP is enabled and a port is reconfigured, the device can take up to 30 seconds to check for loops. The port LED is amber while STP reconfigures. As best practice, we suggest configuring the speed and duplex options on a link to auto or to fixed on both the ends. If one side of the link is configured to auto and the other side is configured to fixed, the link will not be up and this is expected.

- As best practice, we suggest configuring the speed and duplex options on a link to auto or to fixed on both the ends. If one side of the link is configured to auto and the other side is configured to fixed, the link will not be up and this is expected.

Caution Changing the interface speed and duplex mode configuration might shut down and re-enable the interface during the reconfiguration.

IEEE 802.3x Flow Control

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If one port experiences congestion and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note Flow control is not supported on Catalyst 3850 and Catalyst 3650 Series Switches (CSCu133405).

Note The switch ports can receive, but not send, pause frames.

You use the **flowcontrol** interface configuration command to set the interface's ability to **receive** pause frames to **on**, **off**, or **desired**. The default state is **off**.

When set to **desired**, an interface can operate with an attached device that is required to send flow-control packets or with an attached device that is not required to but can send flow-control packets.

These rules apply to flow control settings on the device:

- **receive on** (or **desired**): The port cannot send pause frames but can operate with an attached device that is required to or can send pause frames; the port can receive pause frames.
- **receive off**: Flow control does not operate in either direction. In case of congestion, no indication is given to the link partner, and no pause frames are sent or received by either device.

Layer 3 Interfaces

The device supports these types of Layer 3 interfaces:

- **SVIs**: You should configure SVIs for any VLANs for which you want to route traffic. SVIs are created when you enter a VLAN ID following the **interface vlan** global configuration command. To delete an SVI, use the **no interface vlan** global configuration command. You cannot delete interface VLAN 1.

Note When you create an SVI, it does not become active until it is associated with a physical port.

When configuring SVIs, you can also configure SVI autostate exclude on a port in the SVI to exclude that port from being included in determining SVI line-state status.

- Routed ports: Routed ports are physical ports configured to be in Layer 3 mode by using the **no switchport** interface configuration command.
- Layer 3 EtherChannel ports: EtherChannel interfaces made up of routed ports.

A Layer 3 device can have an IP address assigned to each routed port and SVI.

There is no defined limit to the number of SVIs and routed ports that can be configured in a device or in a device stack. However, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might have an impact on CPU usage because of hardware limitations. If the device is using its maximum hardware resources, attempts to create a routed port or SVI have these results:

- If you try to create a new routed port, the device generates a message that there are not enough resources to convert the interface to a routed port, and the interface remains as a switchport.
- If you try to create an extended-range VLAN, an error message is generated, and the extended-range VLAN is rejected.
- If the device is notified by VLAN Trunking Protocol (VTP) of a new VLAN, it sends a message that there are not enough hardware resources available and shuts down the VLAN. The output of the **show vlan** user EXEC command shows the VLAN in a suspended state.
- If the device attempts to boot up with a configuration that has more VLANs and routed ports than hardware can support, the VLANs are created, but the routed ports are shut down, and the device sends a message that this was due to insufficient hardware resources.

All Layer 3 interfaces require an IP address to route traffic. This procedure shows how to configure an interface as a Layer 3 interface and how to assign an IP address to an interface.

Note

If the physical port is in Layer 2 mode (the default), you must enter the **no switchport** interface configuration command to put the interface into Layer 3 mode. Entering a **no switchport** command disables and then re-enables the interface, which might generate messages on the device to which the interface is connected. Furthermore, when you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

How to Configure Interface Characteristics

Configuring Interfaces

These general instructions apply to all interface configuration processes.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface Example: Device(config)# interface gigabitethernet1/0/1 Device(config-if)#	Identifies the interface type, the device number (only on stacking-capable switches), and the number of the connector. Note You do not need to add a space between the interface type and the interface number. For example, in the preceding line, you can specify either gigabitethernet 1/0/1 , gigabitethernet1/0/1 , gi 1/0/1 , or gi1/0/1 .
Step 4	Follow each interface command with the interface configuration commands that the interface requires.	Defines the protocols and applications that will run on the interface. The commands are collected and applied to the interface when you enter another interface command or enter end to return to privileged EXEC mode.
Step 5	interface range or interface range macro	(Optional) Configures a range of interfaces. Note Interfaces configured in a range must be the same type and must be configured with the same feature options.
Step 6	show interfaces	Displays a list of all interfaces on or configured for the switch. A report is provided for each interface that the device supports or for the specified interface.

Adding a Description for an Interface

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **description** *string*
5. **end**

6. **show interfaces *interface-id* description**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/2	Specifies the interface for which you are adding a description, and enter interface configuration mode.
Step 4	description <i>string</i> Example: Device(config-if)# description Connects to Marketing	Adds a description (up to 240 characters) for an interface.
Step 5	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 6	show interfaces <i>interface-id</i> description	Verifies your entry.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring a Range of Interfaces

To configure multiple interfaces with the same configuration parameters, use the **interface range** global configuration command. When you enter the interface-range configuration mode, all command parameters that you enter are attributed to all interfaces within that range until you exit this mode.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface range** {*port-range* | **macro** *macro_name*}
4. **end**
5. **show interfaces** [*interface-id*]
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface range { <i>port-range</i> macro <i>macro_name</i> } Example: Device(config)# interface range macro	Specifies the range of interfaces (VLANs or physical ports) to be configured, and enter interface-range configuration mode. <ul style="list-style-type: none"> • You can use the interface range command to configure up to five port ranges or a previously defined macro. • The macro variable is explained in the Configuring and Using Interface Range Macros, on page 68. • In a comma-separated <i>port-range</i>, you must enter the interface type for each entry and enter spaces before and after the comma. • In a hyphen-separated <i>port-range</i>, you do not need to re-enter the interface type, but you must enter a space before the hyphen.

	Command or Action	Purpose
		Note Use the normal configuration commands to apply the configuration parameters to all interfaces in the range. Each command is executed as it is entered.
Step 4	end Example: Device(config) # end	Returns to privileged EXEC mode.
Step 5	show interfaces [<i>interface-id</i>] Example: Device# show interfaces	Verifies the configuration of the interfaces in the range.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring and Using Interface Range Macros

You can create an interface range macro to automatically select a range of interfaces for configuration. Before you can use the **macro** keyword in the **interface range macro** global configuration command string, you must use the **define interface-range** global configuration command to define the macro.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **define interface-range** *macro_name interface-range*
4. **interface range macro** *macro_name*
5. **end**
6. **show running-config | include define**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> <code>enable</code>	
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	define interface-range <i>macro_name</i> interface-range Example: Device(config)# <code>define interface-range enet_list gigabitethernet1/0/1 - 2</code>	Defines the interface-range macro, and save it in NVRAM. <ul style="list-style-type: none"> • The <i>macro_name</i> is a 32-character maximum character string. • A macro can contain up to five comma-separated interface ranges. • Each <i>interface-range</i> must consist of the same port type. <p>Note Before you can use the macro keyword in the interface range macro global configuration command string, you must use the define interface-range global configuration command to define the macro.</p>
Step 4	interface range macro <i>macro_name</i> Example: Device(config)# <code>interface range macro enet_list</code>	Selects the interface range to be configured using the values saved in the interface-range macro called <i>macro_name</i> . You can now use the normal configuration commands to apply the configuration to all interfaces in the defined macro.
Step 5	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 6	show running-config include define Example: Device# <code>show running-config include define</code>	Shows the defined interface range macro configuration.
Step 7	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring Ethernet Interfaces

Setting the Interface Speed and Duplex Parameters

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **speed** {10 | 100 | 1000 | 2500 | 5000 | 10000 | auto [10 | 100 | 1000 | 2500 | 5000 | 10000] | nonegotiate}
5. **duplex** {auto | full | half}
6. **end**
7. **show interfaces** *interface-id*
8. **copy running-config startup-config**
9. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/3	Specifies the physical interface to be configured, and enter interface configuration mode.
Step 4	speed {10 100 1000 2500 5000 10000 auto [10 100 1000 2500 5000 10000] nonegotiate} Example: Device(config-if)# speed 10	Enter the appropriate speed parameter for the interface: <ul style="list-style-type: none"> • Enter 10, 100, 1000, 2500, 5000, or 10000 to set a specific speed for the interface. • Enter auto to enable the interface to autonegotiate speed with the connected device. If you specify a speed and also set the auto keyword, the port autonegotiates only at the specified speeds. • The nonegotiate keyword is available only for SFP module ports. SFP module ports operate only at 1000 Mb/s but can be configured to not negotiate if

	Command or Action	Purpose
		connected to a device that does not support autonegotiation.
Step 5	duplex {auto full half} Example: <pre>Device(config-if)# duplex half</pre>	<p>This command is not available on a 10-Gigabit Ethernet interface.</p> <p>Enter the duplex parameter for the interface.</p> <p>Enable half-duplex mode (for interfaces operating only at 10 or 100 Mb/s). You cannot configure half-duplex mode for interfaces operating at 1000 Mb/s.</p> <p>You can configure the duplex setting when the speed is set to auto.</p>
Step 6	end Example: <pre>Device(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 7	show interfaces <i>interface-id</i> Example: <pre>Device# show interfaces gigabitethernet1/0/3</pre>	Displays the interface speed and duplex mode configuration.
Step 8	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.
Step 9	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring IEEE 802.3x Flow Control

SUMMARY STEPS

1. **configure terminal**
2. **interface *interface-id***
3. **flowcontrol {receive} {on | off | desired}**
4. **end**
5. **show interfaces *interface-id***
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode
Step 2	interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet1/0/1</code>	Specifies the physical interface to be configured, and enter interface configuration mode.
Step 3	flowcontrol {receive} {on off desired} Example: Device(config-if)# <code>flowcontrol receive on</code>	Configures the flow control mode for the port.
Step 4	end Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.
Step 5	show interfaces <i>interface-id</i> Example: Device# <code>show interfaces gigabitethernet1/0/1</code>	Verifies the interface flow control settings.
Step 6	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring Layer 3 Interfaces

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface {gigabitethernet interface-id} | {vlan vlan-id} | {port-channel port-channel-number}`
4. `no switchport`
5. `ip address ip_address subnet_mask`

6. **no shutdown**
7. **end**
8. **show interfaces** [*interface-id*]
9. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface { gigabitethernet <i>interface-id</i> } { vlan <i>vlan-id</i> } { port-channel <i>port-channel-number</i> } Example: Device(config)# interface gigabitethernet1/0/2	Specifies the interface to be configured as a Layer 3 interface, and enter interface configuration mode.
Step 4	no switchport Example: Device(config-if)# no switchport	For physical ports only, enters Layer 3 mode.
Step 5	ip address <i>ip_address subnet_mask</i> Example: Device(config-if)# ip address 192.20.135.21 255.255.255.0	Configures the IP address and IP subnet.
Step 6	no shutdown Example: Device(config-if)# no shutdown	Enables the interface.
Step 7	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config-if) # end	
Step 8	show interfaces [<i>interface-id</i>]	Verifies the configuration.
Step 9	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring Logical Layer 3 GRE Tunnel Interfaces

Before you begin

Generic Routing Encapsulation (GRE) is a tunneling protocol used to encapsulate network layer protocols inside virtual point-to-point links. A GRE tunnel only provides encapsulation and not encryption.

Attention

Beginning in Cisco IOS XE Release 3.7.2E, GRE tunnels are supported on the hardware on Cisco Catalyst switches. When GRE is configured without tunnel options, packets are hardware-switched. When GRE is configured with tunnel options (such as key, checksum, etc.), packets are switched in the software. A maximum of 10 GRE tunnels are supported.

Note

Other features like Access Control Lists (ACL) and Quality of Service (QoS) are not supported for the GRE tunnels.

To configure a GRE tunnel, perform this task:

SUMMARY STEPS

1. **interface tunnel** *number*
2. **ip address** *ip_address* *subnet_mask*
3. **tunnel source** {*ip_address* | *type_number*}
4. **tunnel destination** {*host_name* | *ip_address*}
5. **tunnel mode gre ip**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	interface tunnel <i>number</i> Example:	Enables tunneling on the interface.

	Command or Action	Purpose
	Device(config)# interface tunnel 2	
Step 2	ip address <i>ip_address</i> <i>subnet_mask</i> Example: Device(config)# ip address 100.1.1.1 255.255.255.0	Configures the IP address and IP subnet.
Step 3	tunnel source { <i>ip_address</i> <i>type_number</i> } Example: Device(config)# tunnel source 10.10.10.1	Configures the tunnel source.
Step 4	tunnel destination { <i>host_name</i> <i>ip_address</i> } Example: Device(config)# tunnel destination 10.10.10.2	Configures the tunnel destination.
Step 5	tunnel mode gre ip Example: Device(config)# tunnel mode gre ip	Configures the tunnel mode.
Step 6	end Example: Device(config)# end	Exist configuration mode.

Configuring SVI Autostate Exclude

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **switchport autostate exclude**
5. **end**
6. **show running config interface** *interface-id*
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet1/0/2</code>	Specifies a Layer 2 interface (physical port or port channel), and enter interface configuration mode.
Step 4	switchport autostate exclude Example: Device(config-if)# <code>switchport autostate exclude</code>	Excludes the access or trunk port when defining the status of an SVI line state (up or down)
Step 5	end Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.
Step 6	show running config interface <i>interface-id</i>	(Optional) Shows the running configuration. Verifies the configuration.
Step 7	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Shutting Down and Restarting the Interface

Shutting down an interface disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface is not mentioned in any routing updates.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface {vlan vlan-id} | { gigabitethernetinterface-id} | {port-channel port-channel-number}`
4. `shutdown`
5. `no shutdown`
6. `end`

7. show running-config

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface {vlan <i>vlan-id</i>} {gigabitethernet <i>interface-id</i>} {port-channel <i>port-channel-number</i>} Example: Device(config)# interface gigabitethernet1/0/2	Selects the interface to be configured.
Step 4	shutdown Example: Device(config-if)# shutdown	Shuts down an interface.
Step 5	no shutdown Example: Device(config-if)# no shutdown	Restarts an interface.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 7	show running-config Example: Device# show running-config	Verifies your entries.

Configuring the Console Media Type

Follow these steps to set the console media type to RJ-45. If you configure the console as RJ-45, USB console operation is disabled, and input comes only through the RJ-45 connector.

This configuration applies to all switches in a stack.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **line console 0**
4. **media-type rj45**
5. **end**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	line console 0 Example: Device(config)# line console 0	Configures the console and enters line configuration mode.
Step 4	media-type rj45 Example: Device(config-line)# media-type rj45	Configures the console media type to be only RJ-45 port. If you do not enter this command and both types are connected, the USB port is used by default.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 6	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring the USB Inactivity Timeout

The configurable inactivity timeout reactivates the RJ-45 console port if the USB console port is activated but no input activity occurs on it for a specified time period. When the USB console port is deactivated due to a timeout, you can restore its operation by disconnecting and reconnecting the USB cable.

Note The configured inactivity timeout applies to all devices in a stack. However, a timeout on one device does not cause a timeout on other devices in the stack.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `line console 0`
4. `usb-inactivity-timeout timeout-minutes`
5. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	line console 0 Example: Device(config)# <code>line console 0</code>	Configures the console and enters line configuration mode.

	Command or Action	Purpose
Step 4	usb-inactivity-timeout <i>timeout-minutes</i> Example: Device(config-line)# usb-inactivity-timeout 30	Specify an inactivity timeout for the console port. The range is 1 to 240 minutes. The default is to have no timeout configured.
Step 5	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Monitoring Interface Characteristics

Monitoring Interface Status

Commands entered at the privileged EXEC prompt display information about the interface, including the versions of the software and the hardware, the configuration, and statistics about the interfaces.

Table 8: Show Commands for Interfaces

Command	Purpose
show interfaces <i>interface-id</i> status [err-disabled]	Displays interface status or a list of interfaces in the error-disabled state.
show interfaces [<i>interface-id</i>] switchport	Displays administrative and operational status of switching (nonrouting) ports. You can use this command to find out if a port is in routing or in switching mode.
show interfaces [<i>interface-id</i>] description	Displays the description configured on an interface or all interfaces and the interface status.
show ip interface [<i>interface-id</i>]	Displays the usability status of all interfaces configured for IP routing or the specified interface.
show interface [<i>interface-id</i>] stats	Displays the input and output packets by the switching path for the interface.
show interfaces <i>interface-id</i>	(Optional) Displays speed and duplex on the interface.
show interfaces transceiver dom-supported-list	(Optional) Displays Digital Optical Monitoring (DOM) status on the connect SFP modules.
show interfaces transceiver properties	(Optional) Displays temperature, voltage, or amount of current on the interface.

Command	Purpose
show interfaces [<i>interface-id</i>] [{ transceiver properties detail }] <i>module number</i>	Displays physical and operational status about an SFP module.
show running-config interface [<i>interface-id</i>]	Displays the running configuration in RAM for the interface.
show version	Displays the hardware configuration, software version, the names and sources of configuration files, and the boot images.
show controllers ethernet-controller <i>interface-id phy</i>	Displays the operational state of the auto-MDIX feature on the interface.

Clearing and Resetting Interfaces and Counters

Table 9: Clear Commands for Interfaces

Command	Purpose
clear counters [<i>interface-id</i>]	Clears interface counters.
clear interface <i>interface-id</i>	Resets the hardware logic on an interface.
clear line [<i>number</i> console 0 <i>vtty number</i>]	Resets the hardware logic on an asynchronous serial line.

Note The **clear counters** privileged EXEC command does not clear counters retrieved by using Simple Network Management Protocol (SNMP), but only those seen with the **show interface** privileged EXEC command.

Configuration Examples for Interface Characteristics

Adding a Description to an Interface: Example

```

Device# configure terminal
Enter configuration commands, one per line. End with CNTRL/Z.
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# description Connects to Marketing
Device(config-if)# end
Device# show interfaces gigabitethernet1/0/2 description
Interface Status      Protocol Description
Gi1/0/2    admin down      down      Connects to Marketing

```

Configuring a Range of Interfaces: Examples

This example shows how to use the **interface range** global configuration command to set the speed to 100 Mb/s on ports 1 to 4 on switch 1:

```
Device# configure terminal
Device(config)# interface range gigabitethernet1/0/1 - 4
Device(config-if-range)# speed 100
```

This example shows how to use a comma to add different interface type strings to the range to enable Gigabit Ethernet ports 1 to 3 and 10-Gigabit Ethernet ports 1 and 2 to receive flow-control pause frames:

```
Device# configure terminal
Device(config)# interface range gigabitethernet1/0/1 - 3 , tengigabitethernet1/0/1 - 2
Device(config-if-range)# flowcontrol receive on
```

If you enter multiple configuration commands while you are in interface-range mode, each command is executed as it is entered. The commands are not batched and executed after you exit interface-range mode. If you exit interface-range configuration mode while the commands are being executed, some commands might not be executed on all interfaces in the range. Wait until the command prompt reappears before exiting interface-range configuration mode.

Configuring and Using Interface Range Macros: Examples

This example shows how to define an interface-range named *enet_list* to include ports 1 and 2 on switch 1 and to verify the macro configuration:

```
Device# configure terminal
Device(config)# define interface-range enet_list gigabitethernet1/0/1 - 2
Device(config)# end
Device# show running-config | include define
define interface-range enet_list GigabitEthernet1/0/1 - 2
```

This example shows how to create a multiple-interface macro named *macro1*:

```
Device# configure terminal
Device(config)# define interface-range macro1 gigabitethernet1/0/1 - 2, gigabitethernet1/0/5
- 7, tengigabitethernet1/0/1 -2
Device(config)# end
```

This example shows how to enter interface-range configuration mode for the interface-range macro *enet_list*:

```
Device# configure terminal
Device(config)# interface range macro enet_list
Device(config-if-range)#
```

This example shows how to delete the interface-range macro *enet_list* and to verify that it was deleted.

```
Device# configure terminal
Device(config)# no define interface-range enet_list
Device(config)# end
Device# show run | include define
```

```
Device#
```

Setting Interface Speed and Duplex Mode: Example

This example shows how to set the interface speed to 100 Mb/s and the duplex mode to half on a 10/100/1000 Mb/s port:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/3
Device(config-if)# speed 10
Device(config-if)# duplex half
```

This example shows how to set the interface speed to 100 Mb/s on a 10/100/1000 Mb/s port:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# speed 100
```

Configuring Layer 3 Interfaces: Example

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 192.20.135.21 255.255.255.0
Device(config-if)# no shutdown
```

Configuring the Console Media Type: Example

This example disables the USB console media type and enables the RJ-45 console media type.

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# media-type rj45
```

This configuration terminates any active USB console media type in the stack. A log shows that this termination has occurred. This example shows that the console on switch 1 reverted to RJ-45.

```
*Mar 1 00:25:36.860: %USB_CONSOLE-6-CONFIG_DISABLE: Console media-type USB disabled by
system configuration, media-type reverted to RJ45.
```

At this point no switches in the stack allow a USB console to have input. A log entry shows when a console cable is attached. If a USB console cable is connected to switch 2, it is prevented from providing input.

```
*Mar 1 00:34:27.498: %USB_CONSOLE-6-CONFIG_DISALLOW: Console media-type USB is disallowed
by system configuration, media-type remains RJ45. (switch-stk-2)
```

This example reverses the previous configuration and immediately activates any USB console that is connected.

```
Device# configure terminal
```

```
Device(config)# line console 0
Device(config-line)# no media-type rj45
```

Configuring the USB Inactivity Timeout: Example

This example configures the inactivity timeout to 30 minutes:

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# usb-inactivity-timeout 30
```

To disable the configuration, use these commands:

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# no usb-inactivity-timeout
```

If there is no (input) activity on a USB console port for the configured number of minutes, the inactivity timeout setting applies to the RJ-45 port, and a log shows this occurrence:

```
*Mar 1 00:47:25.625: %USB_CONSOLE-6-INACTIVITY_DISABLE: Console media-type USB disabled
due to inactivity, media-type reverted to RJ45.
```

At this point, the only way to reactivate the USB console port is to disconnect and reconnect the cable.

When the USB cable on the switch has been disconnected and reconnected, a log similar to this appears:

```
*Mar 1 00:48:28.640: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.
```

CHAPTER 5

Configuring Auto-MDIX

- [Prerequisites for Auto-MDIX, on page 87](#)
- [Restrictions for Auto-MDIX, on page 87](#)
- [Information about Configuring Auto-MDIX, on page 88](#)
- [How to Configure Auto-MDIX, on page 88](#)
- [Example for Configuring Auto-MDIX, on page 89](#)
- [Additional References, on page 90](#)
- [Feature History and Information for Auto-MDIX, on page 90](#)

Prerequisites for Auto-MDIX

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the **switchport** interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

Automatic medium-dependent interface crossover (auto-MDIX) is enabled by default.

Auto-MDIX is supported on all 10/100/1000-Mb/s and on 10/100/1000BASE-TX small form-factor pluggable (SFP)-module interfaces. It is not supported on 1000BASE-SX or -LX SFP module interfaces.

Restrictions for Auto-MDIX

The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MDIX is enabled on the switch port.

Information about Configuring Auto-MDIX

Auto-MDIX on an Interface

When automatic medium-dependent interface crossover (auto-MDIX) is enabled on an interface, the interface automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting devices without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other devices or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

This table shows the link states that result from auto-MDIX settings and correct and incorrect cabling.

Table 10: Link Conditions and Auto-MDIX Settings

Local Side Auto-MDIX	Remote Side Auto-MDIX	With Correct Cabling	With Incorrect Cabling
On	On	Link up	Link up
On	Off	Link up	Link up
Off	On	Link up	Link up
Off	Off	Link up	Link down

How to Configure Auto-MDIX

Configuring Auto-MDIX on an Interface

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **speed auto**
5. **duplex auto**
6. **end**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1	Specifies the physical interface to be configured, and enter interface configuration mode.
Step 4	speed auto Example: Device(config-if)# speed auto	Configures the interface to autonegotiate speed with the connected device.
Step 5	duplex auto Example: Device(config-if)# duplex auto	Configures the interface to autonegotiate duplex mode with the connected device.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Example for Configuring Auto-MDIX

This example shows how to enable auto-MDIX on a port:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
```

```

Device(config-if) # speed auto
Device(config-if) # duplex auto
Device(config-if) # mdix auto
Device(config-if) # end

```

CHAPTER 6

Configuring Ethernet Management Port

- [Finding Feature Information, on page 91](#)
- [Prerequisites for Ethernet Management Ports, on page 91](#)
- [Information about the Ethernet Management Port, on page 91](#)
- [How to Configure the Ethernet Management Port, on page 94](#)
- [Additional References, on page 95](#)
- [Feature Information for Ethernet Management Ports, on page 96](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Ethernet Management Ports

When connecting a PC to the Ethernet management port, you must first assign an IP address.

Information about the Ethernet Management Port

The Ethernet management port, also referred to as the *Gi0/0* or *GigabitEthernet0/0* port, is a VRF (VPN routing/forwarding) interface to which you can connect a PC. You can use the Ethernet management port instead of the device console port for network management. When managing a device stack, connect the PC to the Ethernet management port on a stack member.

Ethernet Management Port Direct Connection to a Device

Figure 3: Connecting a Switch to a PC

This figure displays how to connect the Ethernet management port to the PC for a device or a standalone

Ethernet Management Port Connection to Stack Devices using a Hub

In a stack with only stack devices, all the Ethernet management ports on the stack members are connected to a hub to which the PC is connected. The active link is from the Ethernet management port on the active switch through the hub, to the PC. If the active device fails and a new active device is elected, the active link is now from the Ethernet management port on the new active device to the PC.

Figure 4: Connecting a Device Stack to a PC

This figure displays how a PC uses a hub to connect to a device stack.

1	Switch stack	3	Hub
2	Management port	4	PC

Ethernet Management Port and Routing

By default, the Ethernet management port is enabled. The device cannot route packets from the Ethernet management port to a network port, and the reverse. Even though the Ethernet management port does not support routing, you may need to enable routing protocols on the port.

Figure 5: Network Example with Routing Protocols Enabled

Enable routing protocols on the Ethernet management port when the PC is multiple hops away from the device and the packets must pass through multiple Layer 3 devices to reach the PC.

In the above figure, if the Ethernet management port and the network ports are associated with the same routing process, the routes are propagated as follows:

- The routes from the Ethernet management port are propagated through the network ports to the network.
- The routes from the network ports are propagated through the Ethernet management port to the network.

Because routing is not supported between the Ethernet management port and the network ports, traffic between these ports cannot be sent or received. If this happens, data packet loops occur between the ports, which disrupt the device and network operation. To prevent the loops, configure route filters to avoid routes between the Ethernet management port and the network ports.

Supported Features on the Ethernet Management Port

The Ethernet management port supports these features:

- Express Setup (only in switch stacks)
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SNMP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features
 - Speed—10 Mb/s, 100 Mb/s, 1000 Mb/s, and autonegotiation
 - Duplex mode—Full, half, and autonegotiation
 - Loopback detection
- Cisco Discovery Protocol (CDP)
- DHCP relay agent

- IPv4 access control lists (ACLs)
- Routing protocols

**Caution**

Before enabling a feature on the Ethernet management port, make sure that the feature is supported. If you try to configure an unsupported feature on the Ethernet Management port, the feature might not work properly, and the device might fail.

How to Configure the Ethernet Management Port

Disabling and Enabling the Ethernet Management Port

SUMMARY STEPS

1. **configure terminal**
2. **interface gigabitethernet0/0**
3. **shutdown**
4. **no shutdown**
5. **exit**
6. **show interfaces gigabitethernet0/0**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface gigabitethernet0/0 Example: Device(config)# interface gigabitethernet0/0	Specifies the Ethernet management port in the CLI.
Step 3	shutdown Example: Device(config-if)# shutdown	Disables the Ethernet management port.
Step 4	no shutdown Example: Device(config-if)# no shutdown	Enables the Ethernet management port.
Step 5	exit Example:	Exits interface configuration mode.

	Command or Action	Purpose
	Device(config-if) # exit	
Step 6	show interfaces gigabitethernet0/0 Example: Device# show interfaces gigabitethernet0/0	Displays the link status. To find out the link status to the PC, you can monitor the LED for the Ethernet management port. The LED is green (on) when the link is active, and the LED is off when the link is down. The LED is amber when there is a POST failure.

What to do next

Proceed to manage or configure your switch using the Ethernet management port. Refer to the *Network Management Configuration Guide (Catalyst 3850 Switches)*.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

LLDP, LLDP-MED, and Wired Location Service Overview

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, switches, and controllers). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the device supports the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol

runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.

LLDP Supported TLVs

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. This protocol can advertise details such as configuration information, device capabilities, and device identity.

The switch supports these basic management TLVs. These are mandatory LLDP TLVs.

- Port description TLV
- System name TLV
- System description TLV
- System capabilities TLV
- Management address TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

- Port VLAN ID TLV (IEEE 802.1 organizationally specific TLVs)
- MAC/PHY configuration/status TLV (IEEE 802.3 organizationally specific TLVs)

LLDP and Cisco Device Stacks

A device stack appears as a single device in the network. Therefore, LLDP discovers the device stack, not the individual stack members.

LLDP and Cisco Medianet

When you configure LLDP or CDP location information on a per-port basis, remote devices can send Cisco Medianet location information to the device. For information, go to http://www.cisco.com/en/US/docs/ios/netmgmt/configuration/guide/nm_cdp_discover.html.

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices such as devices. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet, inventory management and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED Supported TLVs

LLDP-MED supports these TLVs:

- LLDP-MED capabilities TLV

Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and has enabled.

- Network policy TLV

Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify a phone of the VLAN number that it should use. The phone can connect to any device, obtain its VLAN number, and then start communicating with the call control.

By defining a network-policy profile TLV, you can create a profile for voice and voice-signaling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

- Power management TLV

Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows devices and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

LLDP-MED also supports an extended power TLV to advertise fine-grained power requirements, end-point power priority, and end-point and network connectivity-device power status. LLDP is enabled and power is applied to a port, the power TLV determines the actual power requirement of the endpoint device so that the system power budget can be adjusted accordingly. The device processes the requests and either grants or denies power based on the current power budget. If the request is granted, the switch updates the power budget. If the request is denied, the device turns off power to the port, generates a syslog message, and updates the power budget. If LLDP-MED is disabled or if the endpoint does not support the LLDP-MED power TLV, the initial allocation value is used throughout the duration of the connection.

You can change power settings by entering the **power inline** {**auto** [**max** *max-wattage*] | **never** | **static** [**max** *max-wattage*]} interface configuration command. By default the PoE interface is in **auto** mode; If no value is specified, the maximum is allowed (30 W).

- Inventory management TLV

Allows an endpoint to send detailed inventory information about itself to the device, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

- Location TLV

Provides location information from the device to the endpoint device. The location TLV can send this information:

- Civic location information

Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

- ELIN location information

Provides the location information of a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

- Geographic location information

Provides the geographical details of a switch location such as latitude, longitude, and altitude of a switch.

- custom location

Provides customized name and value of a switch location.

Wired Location Service

The device uses the location service feature to send location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired device or controller. The device notifies the MSE of device link up and link down events through the Network Mobility Services Protocol (NMSP) location and attachment notifications.

The MSE starts the NMSP connection to the device, which opens a server port. When the MSE connects to the device there are a set of message exchanges to establish version compatibility and service exchange information followed by location information synchronization. After connection, the device periodically sends location and attachment notifications to the MSE. Any link up or link down events detected during an interval are aggregated and sent at the end of the interval.

When the device determines the presence or absence of a device on a link-up or link-down event, it obtains the client-specific information such as the MAC address, IP address, and username. If the client is LLDP-MED- or CDP-capable, the device obtains the serial number and UDI through the LLDP-MED location TLV or CDP.

Depending on the device capabilities, the device obtains this client information at link up:

- Slot and port specified in port connection
- MAC address specified in the client MAC address
- IP address specified in port connection
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *new*
- Serial number, UDI
- Model number
- Time in seconds since the device detected the association

Depending on the device capabilities, the device obtains this client information at link down:

- Slot and port that was disconnected
- MAC address
- IP address
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *delete*
- Serial number, UDI
- Time in seconds since the device detected the disassociation

When the device shuts down, it sends an attachment notification with the state *delete* and the IP address before closing the NMSP connection to the MSE. The MSE interprets this notification as disassociation for all the wired clients associated with the device.

If you change a location address on the device, the device sends an NMSP location notification message that identifies the affected ports and the changed address information.

Default LLDP Configuration

Table 11: Default LLDP Configuration

Feature	Default Setting
LLDP global state	Disabled
LLDP holdtime (before discarding)	120 seconds
LLDP timer (packet update frequency)	30 seconds
LLDP reinitialization delay	2 seconds
LLDP tlv-select	Disabled to send and receive all TLVs
LLDP interface state	Disabled
LLDP receive	Disabled
LLDP transmit	Disabled
LLDP med-tlv-select	Disabled to send all LLDP-MED TLVs. When LLDP is globally enabled, LLDP-MED-TLV is also enabled.

Restrictions for LLDP

- If the interface is configured as a tunnel port, LLDP is automatically disabled.
- If you first configure a network-policy profile on an interface, you cannot apply the **switchport voice vlan** command on the interface. If the **switchport voice vlan *vlan-id*** is already configured on an interface, you can apply a network-policy profile on the interface. This way the interface has the voice or voice-signaling VLAN network-policy profile applied on the interface.
- You cannot configure static secure MAC addresses on an interface that has a network-policy profile.

How to Configure LLDP, LLDP-MED, and Wired Location Service

Enabling LLDP

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **lldp run**

4. `interface interface-id`
5. `lldp transmit`
6. `lldp receive`
7. `end`
8. `show lldp`
9. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	lldp run Example: Device (config)# <code>lldp run</code>	Enables LLDP globally on the device.
Step 4	interface interface-id Example: Device (config)# <code>interface gigabitethernet2/0/1</code>	Specifies the interface on which you are enabling LLDP, and enter interface configuration mode.
Step 5	lldp transmit Example: Device(config-if)# <code>lldp transmit</code>	Enables the interface to send LLDP packets.
Step 6	lldp receive Example: Device(config-if)# <code>lldp receive</code>	Enables the interface to receive LLDP packets.
Step 7	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config-if)# end	
Step 8	show lldp Example: Device# show lldp	Verifies the configuration.
Step 9	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, and the initialization delay time. You can also select the LLDP and LLDP-MED TLVs to send and receive.

Note Steps 2 through 5 are optional and can be performed in any order.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **lldp holdtime *seconds***
4. **lldp reinit *delay***
5. **lldp timer *rate***
6. **lldp tlv-select**
7. **interface *interface-id***
8. **lldp med-tlv-select**
9. **end**
10. **show lldp**
11. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	lldp holdtime <i>seconds</i> Example: Device (config)# lldp holdtime 120	(Optional) Specifies the amount of time a receiving device should hold the information from your device before discarding it. The range is 0 to 65535 seconds; the default is 120 seconds.
Step 4	lldp reinit <i>delay</i> Example: Device (config)# lldp reinit 2	(Optional) Specifies the delay time in seconds for LLDP to initialize on an interface. The range is 2 to 5 seconds; the default is 2 seconds.
Step 5	lldp timer <i>rate</i> Example: Device (config)# lldp timer 30	(Optional) Sets the sending frequency of LLDP updates in seconds. The range is 5 to 65534 seconds; the default is 30 seconds.
Step 6	lldp tlv-select Example: Device (config)# tlv-select	(Optional) Specifies the LLDP TLVs to send or receive.
Step 7	interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet2/0/1	Specifies the interface on which you are enabling LLDP, and enter interface configuration mode.
Step 8	lldp med-tlv-select Example: Device (config-if)# lldp med-tlv-select inventory management	(Optional) Specifies the LLDP-MED TLVs to send or receive.
Step 9	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device (config-if)# end	
Step 10	show lldp Example: Device# show lldp	Verifies the configuration.
Step 11	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring LLDP-MED TLVs

By default, the device only sends LLDP packets until it receives LLDP-MED packets from the end device. It then sends LLDP packets with MED TLVs, as well. When the LLDP-MED entry has been aged out, it again only sends LLDP packets.

By using the **lldp** interface configuration command, you can configure the interface not to send the TLVs listed in the following table.

Table 12: LLDP-MED TLVs

LLDP-MED TLV	Description
inventory-management	LLDP-MED inventory management TLV
location	LLDP-MED location TLV
network-policy	LLDP-MED network policy TLV
power-management	LLDP-MED power management TLV

Follow these steps to enable a TLV on an interface:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **lldp med-tlv-select**
5. **end**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet 2/0/1	Specifies the interface on which you are enabling LLDP, and enter interface configuration mode.
Step 4	lldp med-tlv-select Example: Device(config-if)# lldp med-tlv-select inventory management	Specifies the TLV to enable.
Step 5	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring Network-Policy TLV

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **network-policy profile *profile number***

4. `{voice | voice-signaling} vlan [vlan-id {cos cvalue | dscp dvalue}] | [[dot1p {cos cvalue | dscp dvalue}] | none | untagged]`
5. `exit`
6. `interface interface-id`
7. `network-policy profile number`
8. `lldp med-tlv-select network-policy`
9. `end`
10. `show network-policy profile`
11. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	<p><code>network-policy profile profile number</code></p> <p>Example:</p> <pre>Device(config)# network-policy profile 1</pre>	Specifies the network-policy profile number, and enter network-policy configuration mode. The range is 1 to 4294967295.
Step 4	<p><code>{voice voice-signaling} vlan [vlan-id {cos cvalue dscp dvalue}] [[dot1p {cos cvalue dscp dvalue}] none untagged]</code></p> <p>Example:</p> <pre>Device(config-network-policy)# voice vlan 100 cos 4</pre>	<p>Configures the policy attributes:</p> <ul style="list-style-type: none"> • voice—Specifies the voice application type. • voice-signaling—Specifies the voice-signaling application type. • vlan—Specifies the native VLAN for voice traffic. • <i>vlan-id</i>—(Optional) Specifies the VLAN for voice traffic. The range is 1 to 4094. • <i>cos cvalue</i>—(Optional) Specifies the Layer 2 priority class of service (CoS) for the configured VLAN. The range is 0 to 7; the default is 5. • <i>dscp dvalue</i>—(Optional) Specifies the differentiated services code point (DSCP) value for the configured VLAN. The range is 0 to 63; the default is 46.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • dot1p—(Optional) Configures the telephone to use IEEE 802.1p priority tagging and use VLAN 0 (the native VLAN). • none—(Optional) Do not instruct the IP telephone about the voice VLAN. The telephone uses the configuration from the telephone key pad. • untagged—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone. • untagged—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone.
Step 5	exit Example: Device(config)# exit	Returns to global configuration mode.
Step 6	interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet2/0/1	Specifies the interface on which you are configuring a network-policy profile, and enter interface configuration mode.
Step 7	network-policy <i>profile number</i> Example: Device(config-if)# network-policy 1	Specifies the network-policy profile number.
Step 8	lldp med-tlv-select network-policy Example: Device(config-if)# lldp med-tlv-select network-policy	Specifies the network-policy TLV.
Step 9	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 10	show network-policy profile Example:	Verifies the configuration.

	Command or Action	Purpose
	Device# <code>show network-policy profile</code>	
Step 11	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring Location TLV and Wired Location Service

Beginning in privileged EXEC mode, follow these steps to configure location information for an endpoint and to apply it to an interface.

SUMMARY STEPS

1. **configure terminal**
2. **location** {**admin-tag** *string* | **civic-location identifier** {*id* | **host**} | **elin-location** *string identifier id* | **custom-location identifier** {*id* | **host**} | **geo-location identifier** {*id* | **host**}}
3. **exit**
4. **interface** *interface-id*
5. **location** {**additional-location-information** *word* | **civic-location-id** {*id* | **host**} | **elin-location-id** *id* | **custom-location-id** {*id* | **host**} | **geo-location-id** {*id* | **host**}}
6. **end**
7. Use one of the following:
 - **show location admin-tag** *string*
 - **show location civic-location identifier** *id*
 - **show location elin-location identifier** *id*
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	location { admin-tag <i>string</i> civic-location identifier { <i>id</i> host } elin-location <i>string identifier id</i> custom-location identifier { <i>id</i> host } geo-location identifier { <i>id</i> host }} Example:	Specifies the location information for an endpoint. <ul style="list-style-type: none"> • admin-tag—Specifies an administrative tag or site information. • civic-location—Specifies civic location information.

	Command or Action	Purpose
	<pre>Device(config)# location civic-location identifier 1 Device(config-civic)# number 3550 Device(config-civic)# primary-road-name "Cisco Way" Device(config-civic)# city "San Jose" Device(config-civic)# state CA Device(config-civic)# building 19 Device(config-civic)# room C6 Device(config-civic)# county "Santa Clara" Device(config-civic)# country US</pre>	<ul style="list-style-type: none"> • elin-location—Specifies emergency location information (ELIN). • custom-location—Specifies custom location information. • geo-location—Specifies geo-spatial location information. • identifier <i>id</i>—Specifies the ID for the civic, ELIN, custom, or geo location. • host—Specifies the host civic, custom, or geo location. • <i>string</i>—Specifies the site or location information in alphanumeric format.
Step 3	<p>exit</p> <p>Example:</p> <pre>Device(config-civic)# exit</pre>	Returns to global configuration mode.
Step 4	<p>interface <i>interface-id</i></p> <p>Example:</p> <pre>Device (config)# interface gigabitethernet2/0/1</pre>	Specifies the interface on which you are configuring the location information, and enter interface configuration mode.
Step 5	<p>location {additional-location-information <i>word</i> civic-location-id {<i>id</i> host} elin-location-id <i>id</i> custom-location-id {<i>id</i> host} geo-location-id {<i>id</i> host} }</p> <p>Example:</p> <pre>Device(config-if)# location elin-location-id 1</pre>	<p>Enters location information for an interface:</p> <ul style="list-style-type: none"> • additional-location-information—Specifies additional information for a location or place. • civic-location-id—Specifies global civic location information for an interface. • elin-location-id—Specifies emergency location information for an interface. • custom-location-id—Specifies custom location information for an interface. • geo-location-id—Specifies geo-spatial location information for an interface. • host—Specifies the host location identifier. • <i>word</i>—Specifies a word or phrase with additional location information. • <i>id</i>—Specifies the ID for the civic, ELIN, custom, or geo location. The ID range is 1 to 4095.

	Command or Action	Purpose
Step 6	end Example: <pre>Device(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 7	Use one of the following: <ul style="list-style-type: none"> • show location admin-tag <i>string</i> • show location civic-location identifier <i>id</i> • show location elin-location identifier <i>id</i> Example: <pre>Device# show location admin-tag</pre> <p>or</p> <pre>Device# show location civic-location identifier</pre> <p>or</p> <pre>Device# show location elin-location identifier</pre>	Verifies the configuration.
Step 8	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Enabling Wired Location Service on the Device

Before you begin

For wired location to function, you must first enter the **ip device tracking** global configuration command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **nmsp notification interval {attachment | location} *interval-seconds***
4. **end**
5. **show network-policy profile**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	nmsp notification interval {attachment location} interval-seconds Example: Device(config)# nmsp notification interval location 10	Specifies the NMSP notification interval. attachment —Specifies the attachment notification interval. location —Specifies the location notification interval. <i>interval-seconds</i> —Duration in seconds before the device sends the MSE the location or attachment updates. The range is 1 to 30; the default is 30.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show network-policy profile Example: Device# show network-policy profile	Verifies the configuration.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuration Examples for LLDP, LLDP-MED, and Wired Location Service

Configuring Network-Policy TLV: Examples

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
# configure terminal
(config)# network-policy 1
(config-network-policy)# voice vlan 100 cos 4
(config-network-policy)# exit
(config)# interface gigabitethernet1/0/1
(config-if)# network-policy profile 1
(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
config-network-policy)# voice vlan dot1p cos 4
config-network-policy)# voice vlan dot1p dscp 34
```

Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service

Commands for monitoring and maintaining LLDP, LLDP-MED, and wired location service.

Command	Description
<code>clear lldp counters</code>	Resets the traffic counters to zero.
<code>clear lldp table</code>	Deletes the LLDP neighbor information table.
<code>clear nmosp statistics</code>	Clears the NMSP statistic counters.
<code>show lldp</code>	Displays global information, such as frequency of transmissions, the holdtime for packets being sent, and the delay time before LLDP initializes on an interface.
<code>show lldp entry <i>entry-name</i></code>	Displays information about a specific neighbor. You can enter an asterisk (*) to display all neighbors, or you can enter the neighbor name.

Command	Description
show lldp interface [<i>interface-id</i>]	Displays information about interfaces with LLDP enabled. You can limit the display to a specific interface.
show lldp neighbors [<i>interface-id</i>] [detail]	Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, and port ID. You can limit the display to neighbors of a specific interface or expand the display for more detailed information.
show lldp traffic	Displays LLDP counters, including the number of packets sent and received, number of packets discarded, and number of unrecognized TLVs.
show location admin-tag <i>string</i>	Displays the location information for the specified administrative tag or site.
show location civic-location identifier <i>id</i>	Displays the location information for a specific global civic location.
show location elin-location identifier <i>id</i>	Displays the location information for an emergency location
show network-policy profile	Displays the configured network-policy profiles.
show nmosp	Displays the NMSP information

CHAPTER 8

Configuring System MTU

- [Configuring System MTU](#), on page 117

Configuring System MTU

This module describes how to configure the Maximum Transmission Unit for a system on Catalyst 3650 Series Switches and Catalyst 3850 Series Switches.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information about the MTU

The default maximum transmission unit (MTU) size for frames received and sent on all device interfaces is 1500 bytes.

Restrictions for System MTU

When configuring the system MTU values, follow these guidelines:

- The device does not support the MTU on a per-interface basis.
- If you enter the **system mtu bytes** global configuration command, the command does not take effect on the device. This command only affects the system MTU size on Fast Ethernet switch ports.

System MTU Value Application

In a switch stack, the MTU values applied to member switches depends upon the stack configuration. The following stack configurations are supported:

This table shows how the MTU values are applied.

Table 13: MTU Values

Configuration	system mtu command	ip mtu command	ipv6 mtu command
Standalone switch or switch stack	You can enter the system mtu command on a switch or switch stack, but system MTU value does not take effect. The range is from 1500 to 9198 bytes.	Use the ip mtu bytes command. The range is from 832 up to 1500 bytes. Note The IP MTU value is the applied value, not the configured value.	Use the ipv6 mtu bytes command. The range is from 1280 to the system jumbo MTU value (in bytes). Note The IPv6 MTU value is the applied value, not the configured value.

The upper limit of the IP or IPv6 MTU value is based on the switch or switch stack configuration and refers to the currently applied system MTU value. For more information about setting the MTU sizes, see the **system mtu** global configuration command in the command reference for this release.

Configuring the System MTU

Configuring the System MTU

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **system mtu bytes**
4. **exit**
5. **show system mtu**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Switch> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	system mtu bytes Example: Switch(config)# system mtu 1600	Applies the Maximum Transmission Unit (MTU) size for all Ethernet interfaces on the switch or the switch stack. <ul style="list-style-type: none"> The MTU range is from 1500 to 9198. The default is 1500.
Step 4	exit Example: Switch(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 5	show system mtu Example: Switch# show system mtu	Displays the configured global MTU size.

Configuring Protocol-Specific MTU

When system MTU changes, the range for the **ip mtu** command for interface also changes.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface type number**
4. **ip mtu bytes**
5. **ipv6 mtu bytes**
6. **end**
7. **show system mtu**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 3	interface type number Example: Switch(config)# interface gigabitethernet 0/0	Configures an interface and enters interface configuration mode.
Step 4	ip mtu bytes Example:	Sets the maximum transmission unit (MTU) size of IP packets sent on an interface. <ul style="list-style-type: none"> The range is from 832 to 1500.

	Command or Action	Purpose
	Switch(config-if)# ip mtu 900	
Step 5	ipv6 mtu bytes Example: Switch(config-if)# ipv6 mtu 1300	Set the MTU size of IPv6 packets sent on an interface. <ul style="list-style-type: none"> The range is from 1280 to 1500.
Step 6	end Example: Switch(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.
Step 7	show system mtu Example: Switch# show system mtu	Displays the configured global MTU size.

Configuration Examples for System MTU

Example: Configuring the System MTU

```
Switch# configure terminal
Switch(config)# system mtu 1600
Switch(config)# exit
```

Example: Configuring Protocol-Specific MTU

```
Switch# configure terminal
Switch(config)# interface gigabitethernet 0/0
Switch(config-if)# ip mtu 900
Switch(config-if)# ipv6 mtu 1286
Switch(config-if)# end
```

CHAPTER 9

Configuring Internal Power Supplies

- [Information About Internal Power Supplies](#) , on page 123
- [How to Configure Internal Power Supplies](#), on page 123
- [Monitoring Internal Power Supplies](#), on page 124
- [Configuration Examples for Internal Power Supplies](#), on page 124
- [Additional References](#), on page 125
- [Feature History and Information for Internal Power Supplies](#), on page 126

Information About Internal Power Supplies

See the device installation guide for information about the power supplies.

How to Configure Internal Power Supplies

Configuring Internal Power Supply

You can use the **power supply** EXEC command to configure and manage the internal power supply on the device. The device does not support the **no power supply** EXEC command.

Follow these steps beginning in user EXEC mode:

SUMMARY STEPS

1. **power supply** *switch_number* **slot**{A | B} { **off** | **on** }
2. **show environment power**

DETAILED STEPS

	Command or Action	Purpose
Step 1	power supply <i>switch_number</i> slot {A B} { off on } Example: Device# power supply 1 slot A on	Sets the specified power supply to off or on by using one of these keywords: <ul style="list-style-type: none">• A —Selects the power supply in slot A.• B —Selects power supply in slot B.

	Command or Action	Purpose
		<p>Note Power supply slot B is the closest to the outer edge of the device.</p> <ul style="list-style-type: none"> • off —Set the power supply off. • on —Set the power supply on. <p>By default, the device power supply is on.</p>
Step 2	<p>show environment power</p> <p>Example:</p> <pre>Device# show environment power</pre>	Verifies your settings.

Monitoring Internal Power Supplies

Table 14: Show Commands for Power Supplies

Command	Purpose
<p>show environment power [all switch <i>switch_number</i>]</p>	<p>(Optional) Displays the status of the internal power supplies for each device in the stack or for the specified device. The range is 1 to 9, depending on the device member numbers in the stack.</p> <p>The device keywords are available only on stacking-capable devices.</p>

Configuration Examples for Internal Power Supplies

This example shows how to set the power supply in slot A to off:

```
Device# power supply 1 slot A off
Disabling Power supply A may result in a power loss to PoE devices and/or switches ...
Continue? (yes/[no]): yes
Device#
Jun 10 04:52:54.389: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered off
Jun 10 04:52:56.717: %PLATFORM_ENV-1-FAN_NOT_PRESENT: Fan is not present
Device#
```

This example shows how to set the power supply in slot A to on:

```
Device# power supply 1 slot A on
Jun 10 04:54:39.600: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered on
```

This example shows the output of the **show env power** command:

```
Device# show env power
```

```

SW  PID                Serial#      Status      Sys Pwr  PoE Pwr  Watts
-----
1A  PWR-C1-715WAC        LIT161010UE OK           Good     Good     715
1B  Not Present

```

Device#

Table 15: show env power Status Descriptions

Field	Description
OK	The power supply is present and power is good.
Not Present	No power supply is installed.
No Input Power	The power supply is present but there is no input power.
Disabled	The power supply and input power are present, but power supply is switched off by CLI.
Not Responding	The power supply is not recognizable or is faulty.
Failure-Fan	The power supply fan is faulty.

Cisco IOS XE 3.3SE	The slot keyword replaced the frufep keyword.

CHAPTER 10

Configuring Stack Power

- [Finding Feature Information, on page 127](#)
- [Prerequisites for StackPower, on page 127](#)
- [Restrictions for StackPower, on page 128](#)
- [Information About StackPower, on page 128](#)
- [How to Configure StackPower, on page 130](#)
- [Configuration Examples for Stack Power, on page 134](#)
- [Where to Go Next, on page 137](#)
- [Additional References for StackPower, on page 137](#)
- [Feature History and Information for StackPower, on page 138](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for StackPower

StackPower uses these terms:

- *Available power* is the total power available for PoE from all power supplies in the power stack. To see the available power in a stack, enter the **show power inline** privileged EXEC command.
- *Budgeted power* is the power allocated to all powered devices connected to PoE ports in the stack. Budgeted power is referred to as *Used (Watts)* in the output of the **show power inline** command.
- *Consumed power* is the actual power consumed by the powered devices. Consumed power is typically less than the budgeted power. To see the consumed power in a stack, enter the **show power inline police** privileged EXEC command.

Restrictions for StackPower

StackPower is not supported in switches running the LAN base feature set.

Information About StackPower

Power Supplies for the Stacking Switch

The switch has two power supplies per system, allowing the power load to be split between them. This accommodates the increased maximum power of 30 watts per port provided to a powered device to meet the PoE+ standard (802.3at). With PoE+, a 48-port system would need 1440 Watts to provide 30 Watts per powered device for the PoE ports. Systems with fewer powered devices might require only one power supply. In this case, the additional power supply can provide one-to-one redundancy for the active supply.

In addition, the stacking switch supports StackPower, which allows the power supplies to share the load across multiple systems in a stack. By connecting the switches with power stack cables, you can manage the power supplies of up to four stack members as a one large power supply that provides power to all switches and to the powered devices connected to switch ports. Since power supplies are most effective when running at 30 to 90% of their maximum load, taking some of the power supplies offline provides maximum power efficiency. Switches in a power stack must be members of the same switch (data) stack.

The reasons for connecting individual Switch in a power stack are:

- In case of power supply failure, if there is enough spare power budget in the rest of the power stack, Switch can continue to function.
- You can replace a defective power supply without having to shut down all powered devices in the systems.
- System operation can become more green by maximizing power supply efficiency and working with the most efficient load (30 to 90% of their maximum load).

StackPower Modes

You can configure the power stack to run in one of two modes:

- In power-sharing mode (the default), all input power is available to be used for power loads. The total available power in all switches in the power stack (up to four) is treated as a single large power supply, with power available to all switches and to all powered devices connected to PoE ports. In this mode, the total available power is used for power budgeting decisions and no power is reserved to accommodate power-supply failures. If a power supply fails, powered devices and switches could be shut down (load shedding).
- In redundant mode, the power from the largest power supply in the system is subtracted from the power budget, which reduces the total available power, but provides backup power in case of a power-supply failure. Although there is less available power in the pool for switches and powered devices to draw from, the possibility of having to shut down switches or powered devices in case of a power failure or extreme power load is reduced.

In addition, you can configure the mode to run a strict power budget or a non-strict (relaxed) power budget. In both modes, power is denied when there is no more power available in the power budget.

- In strict mode, when a power supply fails and the available power drops below the budgeted power, the system balances the budget through load shedding of powered devices, even if the actual power being consumed is less than the available power.
- In non-strict mode, the power stack is allowed to run in an over-allocated state and is stable as long as the actual power does not exceed the available power. In this mode, a powered device drawing more than normal power could cause the power stack to start shedding loads. This is normally not a problem because most devices do not run at full power and the chances of multiple powered devices in the stack requiring maximum power at the same time is small.

You configure power modes at a power-stack level (that is, the mode is the same for all switches in the power stack).

You can also configure a switch connected in a power stack to not participate in the power stack by setting the switch to standalone power mode. This mode shuts down both stack power ports.

Power Priority

You can configure the priority of a switch or powered device to receive power. This priority determines the order in which devices are shut down in case of a power shortage. You can configure three priorities per system: the system (or switch) priority, the priority of the high-priority PoE ports on a switch, and the priority of the low-priority PoE ports on a switch.

You set port priority at the interface level for powered devices connected to a PoE port. By default, all ports are low priority.

You configure the priority values of each switch in the power stack and of all high and low priority ports on that switch to set the order in which switches and ports are shut down when power is lost and load shedding must occur. Priority values are from 1 to 27; switches and ports with highest values are shut down first.

Note The 27 priorities are used to accommodate power stacks connected in a star configuration with the expandable power supply. In this configuration, there would be nine members (switches) per system with three priorities per switch.

On any switch, the switch priority must be lower than port priorities. and the high priority value must be set lower than the low priority value. We recommend that you configure different priority values for each switch and for its high priority ports and low priority ports. This limits the number of devices shut down at one time during a loss of power. If you try to configure the same priority value on different switches in a power stack, the configuration is allowed, but you receive a warning message.

The default priority ranges, if none are configured, are 1-9 for switches, 10-18 for high-priority ports, and 19-27 for low-priority ports.

Load Shedding

Load shedding is the process of shutting down devices in case of power supply, cable, or system failures. For power stacks in power-sharing mode, there are two types of load-shedding: immediate and graceful.

- Immediate load shed occurs when a failure could cause the power stack to fail very quickly. For example, if the largest power supply in the power stack fails, this could cause the stack to immediately start shutting down powered devices.
- Graceful load-shedding can occur when a smaller power supply fails. Switches and powered devices are shut down in order of their configured priority, starting with devices with priority 27, until the power budget matches the input power.

Graceful load shedding is always enabled and immediate load shedding occurs only when necessary, so both can occur at the same time.

Note

Load shedding does not occur in redundant mode unless two or more power supplies fail, because the largest power supply is used as a backup power source.

Notes on load shedding:

- The method (immediate or graceful) is not user-configurable, but is based on the power budget.
- Immediate load shedding also occurs in the order of configured priority, but occurs very quickly to prevent hardware damage caused by loss of power.
- If a switch is shut down because of load shedding, the output of the **show stack-power** privileged EXEC command still includes the MAC address of the shut down switch as a neighbor switch, even though the switch is down. This command output shows the StackPower topology, even if there is not enough power to power up a switch.

How to Configure StackPower

Configuring stack power includes these tasks:

Configuring PowerStack Parameters

SUMMARY STEPS

1. **configure terminal**
2. **stack-power stack** *power stack name*

3. `mode {power-sharing | redundant} [strict]`
4. `end`
5. `show stack-power`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	stack-power stack <i>power stack name</i> Example: Device(config)# <code>stack-power stack power 1</code>	Enters the stack power stack name and enter power stack configuration mode. The name can be up to 31 characters.
Step 3	mode {power-sharing redundant} [strict] Example: Device(config-stackpower)# <code>mode redundant</code>	Sets the operating mode for the power stack: <ul style="list-style-type: none"> • power-sharing—The input power from all switches in the power stack can be used for loads, and the total available power appears as one huge power supply. This is the default. • redundant—The largest power supply is removed from the power pool to be used as backup power in case one of the other power supplies fails. This is the recommended mode if enough power is available in the system. • strict—(Optional) Configures the power stack mode to run a strict power budget. The stack power needs cannot exceed the available power. The default is non-strict.
Step 4	end Example: Device(config-stackpower)# <code>end</code>	Returns to privileged EXEC mode.
Step 5	show stack-power Example: Device# <code>show stack-power</code>	Verifies your entries.

Configuring PowerStack Switch Power Parameters

SUMMARY STEPS

1. **configure terminal**
2. **stack-power switch** *switch-number*
3. **stack** [*power-stack-name*]
4. **power-priority switch** *value*
5. **power-priority high** *value*
6. **power-priority low** *value*
7. **end**
8. **show stack-power**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	
Step 2	stack-power switch <i>switch-number</i> Example: Device(config)# stack-power switch 4	Enters global configuration mode. Enters switch stack power configuration mode for the stack member switch number. The range is from 1 to 9. Note Only four switches can belong to the same power stack.
Step 3	stack [<i>power-stack-name</i>] Example: Device(config-switch-stackpower)# stack power2	Enters the name of the power stack to which the switch belongs. The name can be up to 31 characters. If you do not enter a name and no other switches in the power stack have a name configured, a power-stack name is automatically generated.
Step 4	power-priority switch <i>value</i> Example: Device(config-switch-stackpower)# power-priority switch 5	Sets the power priority of the switch. The range is from 1 to 27. This value must be lower than the value set for the low and high-priority ports.
Step 5	power-priority high <i>value</i> Example: Device(config-switch-stackpower)# power-priority high 12	Sets the power priority of the PoE ports on the switch that are configured as high-priority ports. The range is from 1 to 27, with 1 as the highest priority. The high value must be lower than the value set for the low-priority ports and higher than the value set for the switch.
Step 6	power-priority low <i>value</i> Example:	Sets the power priority of the PoE ports on the switch that are configured as low-priority ports. The range is from 1 to

	Command or Action	Purpose
	Device (config-switch-stackpower) # power-priority low 20	27. This value must be higher than the value set for the high-priority ports and the value set for the switch.
Step 7	end Example: Device (config-switch-stackpower) # end	Returns to privileged EXEC mode.
Step 8	show stack-power Example: Device# show stack-power	Verifies your entries.

Configuring PoE Port Priority

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **power inline port priority** {high | low}
4. **end**
5. **show power inline priority**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 1/0/1	Enters the interface ID of the port in the stack and enters interface configuration mode. The interface must be a PoE port.
Step 3	power inline port priority {high low} Example: Device (config-if) # power inline port priority high	Sets the power priority of the port to high or low . Powered devices connected to low priority ports are shut down first in case of a power reduction. The default is low priority.

	Command or Action	Purpose
		Note Although the power inline port priority {high low} command is visible on the nonstacking switch PoE ports, it has no effect because these switches do not participate in stack power.
Step 4	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 5	show power inline priority Example: Device# show power inline priority	Verifies your entries.

Configuration Examples for Stack Power

Immediate Load Shedding: Examples

For power stacks in power-sharing mode, if a large power supply in the power stack fails, the stack immediately starts shutting down powered devices until the power budget matches the input power. This example has a power stack of four switches (*Powerstack1*) in power sharing mode and shows which devices would be shut down in the immediate load shedding process caused by loss of either of two power supplies.

The output of the **show env all** command shows that power supplies included in power sharing are a 715 W power supply in switch 1, and one 350 W and one 1100 W power supply in switch 4. Other power supplies are inactive (disabled or not present).

```
Device# show env all
Switch 1 FAN 1 is OK
Switch 1 FAN 2 is OK
Switch 1 FAN 3 is OK
FAN PS-1 is OK
FAN PS-2 is OK
Switch 1: SYSTEM TEMPERATURE is OK
SW  PID                      Serial#      Status      Sys Pwr  PoE Pwr  Watts
--  -
1A  PWR-C1-715WAC              LIT133705FH  OK          Good     Good     715
1B  PWR-C1-715WAC              DTN1341K018  Disabled    Good     Good     715
2A  Not Present
2B  PWR-C1-350WAC              LIT13330FNM  Disabled    Good     Good     350
3A  PWR-C1-350WAC              LIT13330FN3  Disabled    Good     Good     350
3B  Not Present
4A  PWR-C1-350WAC              DTN1342L00T  OK          Good     Good     350
```

```
4B PWR-C1-1100WAC LIT13370577 OK Good Good 1100
```

The output of the **show stack-power** privileged EXEC command shows the priorities of the powered devices and switches in the power stack.

```
Device# show stack-power
Power stack name: Powerstack1
Stack mode: Power sharing
Switch 1:
  Power budget: 206
  Low port priority value: 17
  High port priority value: 16
  Switch priority value: 2
  Port A status: Not shut
  Port B status: Not shut
  Neighbor on port A: 0022.bdcf.ab00
  Neighbor on port B: 0022.bdd0.4380

Switch 2:
  Power budget: 206
  Low port priority value: 12
  High port priority value: 11
  Switch priority value: 1
  Port A status: Not shut
  Port B status: Not shut
  Neighbor on port A: 0022.bdd0.6d00
  Neighbor on port B: 0022.bdcf.af80

Switch 3:
  Power budget: 656
  Low port priority value: 22
  High port priority value: 21
  Switch priority value: 3
  Port A status: Not shut
  Port B status: Not shut
  Neighbor on port A: 0022.bdcf.af80
  Neighbor on port B: 0022.bdd0.6d00

Switch 4:
  Power budget: 682
  Low port priority value: 27
  High port priority value: 26
  Switch priority value: 4
  Port A status: Not shut
  Port B status: Not shut
  Neighbor on port A: 0022.bdd0.4380
  Neighbor on port B: 0022.bdcf.ab00
```

If the 715 W or 1100 W power supply fails, devices (powered devices connected to PoE ports and the switches themselves) would be shut down in the this order until power consumption drops below 105% of the rated power of the remaining power supplies:

- Devices connected to Switch 4 low priority ports (priority 27)
- Devices connected to Switch 4 high priority ports (priority 26)
- Devices connected to Switch 3 low priority ports (priority 22)
- Devices connected to Switch 3 high priority ports (priority 21)
- Devices connected to Switch 1 low priority ports (priority 17)

- Devices connected to Switch 1 high priority ports (priority 16)
- Devices connected to Switch 2 low priority ports (priority 12)
- Devices connected to Switch 2 high priority ports (priority 11)
- Switch 4 (priority 4)
- Switch 3 (priority 3)
- Switch 1 (priority 2)

Switch 2 would never have to be shut down because all power would have been lost by the time priority 1 devices were reached.

Configuring the Cisco eXpandable Power System (XPS) 2200

This module contains the following sections:

- [Restrictions for Configuring the XPS 2200, on page 139](#)
- [Information About Configuring the XPS 2200, on page 139](#)
- [How to Configure the XPS 2200, on page 143](#)
- [Monitoring and Maintaining the XPS 2200, on page 146](#)
- [Additional References, on page 146](#)

Restrictions for Configuring the XPS 2200

- When using the XPS power supplies in the RPS mode for backing up switch power supplies, the smallest power supply in the XPS must be greater than the largest power supply in a switch connected to an XPS port in RPS mode.
- In RPS mode, each XPS power supply can back up one and only one switch power supply, regardless of the size.
- If you remove a power supply from the power stack (from a switch or the XPS), be sure that removing it does not deplete available power enough to cause load shedding.

Information About Configuring the XPS 2200

Cisco eXpandable Power System (XPS) 2200 Overview

The Cisco eXpandable Power System (XPS) 2200 is a standalone power system that you can connect to Catalyst switches. The XPS 2200 can provide backup power to connected devices that experience a power supply failure or, in a Catalyst switch power stack, it can supply additional power to the power stack budget. The XPS 2200 power ports and internal power supplies can operate in redundant power supply (RPS) mode or stack power (SP) mode.

Stack-power mode is used only on stacking-capable switches in a power stack. With no XPS, a power stack operates in ring topology with a maximum of four switches in the stack. If you merge two stacks, the total

number of switches cannot exceed four. When an XPS is in the power stack, you can connect up to nine switches in the stack plus the XPS, providing power budgets to power stack members similar to stack-power ring topology operation.

All Catalyst switches connected to an XPS on SP ports are part of the same power stack, and all power from the XPS and the switch is shared across all switches in the stack. Power sharing is the default mode, but the XPS supports the same stack power modes that are supported in a ring topology (strict and nonstrict power-sharing or redundant modes).

When two power supplies are present, the system can operate in mixed mode, where one power supply operates in RPS mode and the other in SP mode. You can configure the ports and power supplies for the way that you plan to use the XPS 2200.

The XPS 2000 has nine power ports that can operate in an RPS role or in an automatic stack power (Auto-SP) role (the default), where mode of operation is determined by the type of switch connected to the port. You can also use the CLI to force the mode to be RPS for stackable switches.

- When a Catalyst switch running the LAN base image, or a Catalyst (nonstackable) switch is connected to the port, the mode is RPS, and the XPS 2200 acts as a backup if the switch power supply goes down.
- When a Catalyst (stackable) switch running the IP base or IP services license is connected to the port, the mode is SP, which enables the switch to be part of the stack power system.

You configure the XPS through any switch connected to a power port. You can use any XPS port for configuration, and you can configure any port from any switch connected to the XPS. If you enter XPS configuration commands on more than one switch, the last configuration applied takes effect.

Although all XPS configuration is done through a switch, the XPS 2200 also runs its own software. You can upgrade this software through the XPS Service Port.

XPS 2200 Power Supply Modes

The XPS has two power supplies that can also be in either RPS or SP mode.

In SP mode, all SP ports on the XPS belong to the same power stack. When a power stack includes an XPS, the stack topology is a star topology and consists of up to nine member switches plus the XPS 2200. The XPS power supply or power supplies that are in SP mode are considered in the power budgeting. If both XPS power supplies are in RPS mode, the power stack consists only of the switches connected to XPS ports in SP mode, and the power budget is determined by the power supplies in these switches.

If there is a power supply role mismatch, for example, if an XPS port is configured for RPS and both power supplies are in SP mode, the XPS detects the mismatch, and an error message is sent.

RPS Mode

When both XPS power supplies are in RPS mode, the XPS can back up two power supply failures for switch power supplies of equal value or less. The smallest power supply in the XPS must be greater than the largest power supply in a switch connected to an XPS port in RPS mode.

If only one supply is in RPS mode, the XPS can back up only one power supply, even when the failed power supply is much smaller. For example, if an XPS 1100 W power supply is in RPS mode and two 350 W switch power supplies fail, the XPS can back up only one of the switch power supplies.

When one XPS power supply in RPS mode is backing up a switch power supply and another switch power supply fails, a message appears that the XPS backup is not available. When the failed power supply comes up, the XPS becomes available to back up other power supplies.

If the XPS is backing up two failed power supplies in a single switch (both XPS power supplies in RPS mode), the XPS is not available to back up other switch power supplies until both of the failed supplies are repaired or replaced.

In mixed mode, with one power supply in RPS mode and one in SP mode, if two power supplies in a single switch fail, because the XPS can back up only one of them, it denies power to both power supplies, and the switch shuts down. This occurs only in mixed power mode.

If a switch is connected to a port configured as RPS, but neither of the power supplies is RPS, the RPS port configuration is rejected and the XPS attempts to add the switch to a power stack. If the switch is not capable of operating in SP mode (is not a stackable switch), the port is disabled.

Ports in RPS mode have a configurable priority. The default priority is based on the XPS port number, with port 1 as the highest priority port. A higher priority port has a higher precedence for backup than a lower priority port. If a switch connected to a higher priority port has a power supply failure while a switch connected to a low priority port is being backed up, the XPS drops power to the low priority port to supply power to the high priority port.

Stack Power Mode

Stack-power mode is used only on Catalyst switches in a power stack. With no XPS, a power stack operates in ring topology with a maximum of four switches in the stack. When an XPS is in the power stack, you can connect up to nine switches in the stack plus the XPS, providing power budgets to power stack members similar to stack-power ring topology operation.

All Catalyst switches connected to an XPS on SP ports are part of the same power stack, and all power from the XPS and the switches is shared across all switches in the stack. Power sharing is the default mode, but the XPS supports the same stack power modes that are supported in a ring topology (strict and nonstrict power-sharing or redundant modes).

The XPS uses neighbor discovery to create the power stack. When it discovers a Catalyst switch on an unconfigured port, it marks the port as an SP port, and the switch joins the power stack. The XPS notifies the switch, begins the power-budgeting process, and assigns budgets to each switch in the power stack based on their requirements, priorities, current power allocations, and the stack aggregate power capability.

The XPS sends the power budget to each switch. If not enough input power is available to provide every switch with its maximum requested power, power is distributed based on priority. Switches with the highest priority receive required power first, followed by any powered devices that have already been allocated power, in order of their priority. Any remaining power is distributed equally through the stack.

The RPS port priority (1 through 9) does not affect stack power priority. Each switch participating in stack power has its own system priority and a high and low priority for devices connected to its ports. These priorities are used for stack power, as is the case in a ring topology. You configure stack power priority for the system and for high and low-priority ports by using the **power-priority switch**, **power-priority high**, and **power-priority low** commands in switch stack power configuration mode. If a system or set of powered devices are using the default priority, the XPS automatically assigns a priority (1 through 27), with lower MAC addresses receiving higher priorities.

There are four power stack modes: power sharing, strict power sharing, redundant, or strict redundant. You configure the power stack mode by using the **mode {power-sharing | redundant} [strict]** command in power-stack configuration mode. The **power-sharing** or **redundant** configurations affect the power budgeting aspect of the stack; **strict** or non-strict affects the actions of the PoE application when a budget reduction does not result in load shedding.

- In power sharing modes (strict or nonstrict), the stack power budget is the cumulative capacity of all the power supplies in the stack (minus 30 W reserved power). This is the default.

- In redundant modes (strict or nonstrict), the stack power budget is the total available power (minus 30 W) after the capacity of the largest power supply in the power stack is subtracted. Redundant mode guarantees that no switch or powered device loses power or experiences load sheds if a single power supply fails, but load sheds can occur if more than one power supply fails.
- In strict modes, if a loss of input power results in reduced power budgets but does not result in any hardware load shedding, the XPS automatically begins denying power to low-priority powered devices and then the high-priority powered devices until the amount of allocated power is less than or equal to the amount of available PoE power.
- In nonstrict modes, in the event of a power reduction, the amount of allocated power is allowed to fall under budget.

For example, a system with a total PoE budget (available power) of 400 W can allocate 390 W of the budget (allocated power) to powered devices. The allocated power of a device is the maximum amount of power that the device needs. The actual power consumption (consumed power) for a set of powered devices is usually not equal to the allocated power. In this example, the actual power might be approximately 200 W. If a power loss in the stack reduces the available power to 210 W, this amount is enough to sustain the power being consumed by the powered devices, but less than the worst-case allocated power, which would put the system *under budget*. In strict mode, the stack would immediately deny power to powered devices until the allocated power was 210 W or less. In nonstrict mode, no action is taken, and the state is allowed to persist. In nonstrict mode if the actual power consumption becomes more than 210 W, this triggers a load shed and can result in the loss of power to all powered devices or switches with the lowest priority level.

Mixed Modes

The XPS 2200 can also operate in mixed mode, where some ports connected to switches are RPS and others are SP. At least one power supply must be an RPS power supply in this configuration. The power supply in the XPS can back up only one switch power supply and the XPS supply must be greater than the largest power supply in a switch connected to an XPS port in RPS mode.

Switches connected to SP ports belong to a single power stack. If the SP switches have a large enough power budget, an SP power supply is not required on the XPS. When an XPS power supply is configured, its power is added to the power pool shared by the power stack.

XPS 2200 System Defaults

The default role for a port is Auto-SP, where the power mode is determined by the switch connected to the port (RPS for Catalyst running the LAN base image, or SP for Catalyst switches running the IP base or IP services image).

The default for the XPS power supply A (PS1) is RPS mode. The default for power supply B (PS2) is SP mode.

The default mode for all ports and power supplies is enabled.

On ports configured for RPS, the default priority is the same as the port number.

How to Configure the XPS 2200

You can configure the XPS from any switch connected to an XPS port. If you enter XPS configuration commands on more than one switch, the last configuration applied takes effect. Only the switch and port name are saved in the switch configuration file.

Configuring System Names

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `power xps switch-number name {name | serialnumber}`
4. `power xps switch-number port {name | hostname | serialnumber}`
5. `end`
6. `show env xps system`
7. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<code>configure terminal</code>	Enters global configuration mode.
Step 3	<code>power xps switch-number name {name serialnumber}</code>	<p>Note The <i>switch-number</i> appears only on Catalyst switches and represents the switch number in the data stack, a value from 1 to 9.</p> <p>Configures a name for the XPS 2200 system.</p> <ul style="list-style-type: none"> • <i>name</i>—Enter a name for the XPS 2000 port. The name can have up to 20 characters. • serialnumber—Use the serial number of the XPS 2200 as the system name.
Step 4	<code>power xps switch-number port {name hostname serialnumber}</code>	<p>Note The <i>switch-number</i> appears only on Catalyst switches and represents the device number in the data stack, a value from 1 to 9.</p> <p>Configures a name for an XPS 2200 port connected to the device.</p>

	Command or Action	Purpose
		<ul style="list-style-type: none"> • <i>name</i>—Enter a name for the XPS 2000 port. • serialnumber—Use the serial number of the device connected to the port. • hostname—Use the hostname of the device connected to the port.
Step 5	end	Returns to privileged EXEC mode.
Step 6	show env xps system	Verifies the configured name of the system and ports.
Step 7	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring XPS Ports

SUMMARY STEPS

1. **enable**
2. **power xps *switch-number* port {*number* | **connected**} mode {**disable** | **enable**}**
3. **power xps *switch-number* port {*number* | **connected**} role {**auto** | **rps**}**
4. **power xps *switch-number* port {*number* | **connected**} priority *port-priority***
5. **show env xps port**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	power xps <i>switch-number</i> port {<i>number</i> connected} mode {disable enable}	<p>Note The <i>switch-number</i> appears only on Catalyst switches and represents the switch number in the data stack, a value from 1 to 9.</p> <p>Sets the port to be enabled or disabled.</p> <ul style="list-style-type: none"> • <i>number</i>—Enter the XPS 2200 port number. The range is 1 to 9. • connected—Enter this keyword if you do not know the port number to which the switch is connected.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • mode disable—Disable (shut down) the XPS port. <p>Note Disabling an XPS port is like removing the cable and appears the same in the show command outputs. If the physical cable is connected, you can still use the enable keyword to enable the port.</p> <ul style="list-style-type: none"> • mode enable—Enable the XPS port. This is the default.
Step 3	power xps <i>switch-number</i> port { <i>number</i> connected } role { auto rps }	<p>Note The <i>switch-number</i> represents the switch number in the data stack, a value from 1 to 9.</p> <p>Sets the role of the XPS port.</p> <ul style="list-style-type: none"> • role auto—The port mode is determined by the switch connected to the port. This is the default. • role RPS—The XPS acts as a back up if the switch power supply fails. At least one RPS power supply must be in RPS mode for this configuration.
Step 4	power xps <i>switch-number</i> port { <i>number</i> connected } priority <i>port-priority</i> Example: Device	<p>Note The <i>switch-number</i> represents the switch number in the data stack, a value from 1 to 9.</p> <p>Sets the RPS priority of the port, where higher priority ports take precedence over low priority ports if multiple power supplies fail. This command takes effect only when the port mode is RPS. When the port mode is stack power, you set priority by using the stack power commands.</p> <ul style="list-style-type: none"> • priority <i>port-priority</i>—Set the RPS priority of the port. The range is 1 to 9, with 1 being the highest priority. The default priority is the XPS port number.
Step 5	show env xps port	Verifies the XPS configuration of the port.

Configuring XPS Power Supplies

SUMMARY STEPS

1. **enable**
2. **power xps** *switch-number* **supply** {**A** | **B**} **mode** {**rps** | **sp**}
3. **power xps** *switch-number* **supply** {**A** | **B**} {**on** | **off**}
4. **end**
5. **show env xps power**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	power xps <i>switch-number</i> supply {A B} mode {rps sp}	Note The <i>switch-number</i> represents the switch number in the data stack, a value from 1 to 9. Sets the XPS power supply mode. <ul style="list-style-type: none"> • supply {A B}—Select the power supply to configure. Power supply A is on the left (labeled PS1) and power supply B (PS2) is on the right. • mode rps—Set the power supply mode to RPS, to back up connected switches. This is the default setting for power supply A (PS1). • mode sp—Set the power supply mode to stack power (SP), to participate in the power stack. This is the default setting for power supply B (PS2).
Step 3	power xps <i>switch-number</i> supply {A B} {on off}	Note The <i>switch-number</i> represents the switch number in the data stack, a value from 1 to 9. Sets the XPS power supply to be on or off. The default is for both power supplies to be on.
Step 4	end	Returns to privileged EXEC mode.
Step 5	show env xps power	Displays the status of the XPS power supplies.

Monitoring and Maintaining the XPS 2200

Command	Purpose
show env xps system	Verifies the configured name of the system and ports.
show env xps port	Verifies the XPS configuration of the port.
show env xps power	Displays the status of the XPS power supplies.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information about PoE

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Supported Protocols and Standards

The device uses these protocols and standards to support PoE:

- CDP with power consumption—The powered device notifies the device of the amount of power it is consuming. The device does not reply to the power-consumption messages. The device can only supply power to or remove power from the PoE port.
- Cisco intelligent power management—The powered device and the device negotiate through power-negotiation CDP messages for an agreed-upon power-consumption level. The negotiation allows a high-power Cisco powered device, which consumes more than 7 W, to operate at its highest power mode. The powered device first boots up in low-power mode, consumes less than 7 W, and negotiates to obtain enough power to operate in high-power mode. The device changes to high-power mode only when it receives confirmation from the device.

High-power devices can operate in low-power mode on devices that do not support power-negotiation CDP.

Cisco intelligent power management is backward-compatible with CDP with power consumption; the device responds according to the CDP message that it receives. CDP is not supported on third-party powered devices; therefore, the device uses the IEEE classification to determine the power usage of the device.

- IEEE 802.3af—The major features of this standard are powered-device discovery, power administration, disconnect detection, and optional powered-device power classification. For more information, see the standard.
- The Cisco UPOE feature provides the capability to source up to 60 W of power (2 x 30 W) over both signal and spare pairs of the RJ-45 Ethernet cable by using the Layer-2 power negotiation protocols such as CDP or LLDP. An LLDP and CDP request of 30 W and higher in presence of the 4-wire Cisco Proprietary spare-pair power TLV can provide power on the spare pair.

Powered-Device Detection and Initial Power Allocation

The device detects a Cisco pre-standard or an IEEE-compliant powered device when the PoE-capable port is in the no-shutdown state, PoE is enabled (the default), and the connected device is not being powered by an AC adaptor.

After device detection, the device determines the device power requirements based on its type:

- The initial power allocation is the maximum amount of power that a powered device requires. The device initially allocates this amount of power when it detects and powers the powered device. As the device receives CDP messages from the powered device and as the powered device negotiates power levels with the device through CDP power-negotiation messages, the initial power allocation might be adjusted.
- The device classifies the detected IEEE device within a power consumption class. Based on the available power in the power budget, the device determines if a port can be powered. [Table 18: IEEE Power Classifications, on page 150](#) lists these levels.

Table 18: IEEE Power Classifications

Class	Maximum Power Level Required from the Device
0 (class status unknown)	15.4 W
1	4 W
2	7 W

Class	Maximum Power Level Required from the Device
3	15.4 W
4	30 W (For IEEE 802.3at Type 2 powered devices)

The device monitors and tracks requests for power and grants power only when it is available. The device tracks its power budget (the amount of power available on the device for PoE). The device performs power-accounting calculations when a port is granted or denied power to keep the power budget up to date.

After power is applied to the port, the device uses CDP to determine the *CDP-specific* power consumption requirement of the connected Cisco powered devices, which is the amount of power to allocate based on the CDP messages. The device adjusts the power budget accordingly. This does not apply to third-party PoE devices. The device processes a request and either grants or denies power. If the request is granted, the device updates the power budget. If the request is denied, the device ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. Powered devices can also negotiate with the device for more power.

With PoE+, powered devices use IEEE 802.3at and LLDP power with media dependent interface (MDI) type, length, and value descriptions (TLVs), Power-via-MDI TLVs, for negotiating power up to 30 W. Cisco pre-standard devices and Cisco IEEE powered devices can use CDP or the IEEE 802.3at power-via-MDI power negotiation mechanism to request power levels up to 30 W.

Note The initial allocation for Class 0, Class 3, and Class 4 powered devices is 15.4 W. When a device starts up and uses CDP or LLDP to send a request for more than 15.4 W, it can be allocated up to the maximum of 30 W.

Note The CDP-specific power consumption requirement is referred to as the *actual* power consumption requirement in the software configuration guides and command references.

If the device detects a fault caused by an undervoltage, overvoltage, overtemperature, oscillator-fault, or short-circuit condition, it turns off power to the port, generates a syslog message, and updates the power budget and LEDs.

The PoE feature operates the same whether or not the device is a stack member. The power budget is per device and independent of any other device in the stack. Election of a new active device does not affect PoE operation. The active device keeps track of the PoE status for all devices and ports in the stack and includes the status in output displays.

The stacking-capable device also supports StackPower, which allows the power supplies to share the load across multiple systems in a stack when you connect the devices with power stack cables. You can manage the power supplies of up to four stack members as a one large power supply.

Power Management Modes

The device supports these PoE modes:

- **auto**—The device automatically detects if the connected device requires power. If the device discovers a powered device connected to the port and if the device has enough power, it grants power, updates the

power budget, turns on power to the port on a first-come, first-served basis, and updates the LEDs. For LED information, see the hardware installation guide.

If the device has enough power for all the powered devices, they all come up. If enough power is available for all powered devices connected to the device, power is turned on to all devices. If there is not enough available PoE, or if a device is disconnected and reconnected while other devices are waiting for power, it cannot be determined which devices are granted or are denied power.

If granting power would exceed the system power budget, the device denies power, ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. After power has been denied, the device periodically rechecks the power budget and continues to attempt to grant the request for power.

If a device being powered by the device is then connected to wall power, the device might continue to power the device. The device might continue to report that it is still powering the device whether the device is being powered by the device or receiving power from an AC power source.

If a powered device is removed, the device automatically detects the disconnect and removes power from the port. You can connect a nonpowered device without damaging it.

You can specify the maximum wattage that is allowed on the port. If the IEEE class maximum wattage of the powered device is greater than the configured maximum value, the device does not provide power to the port. If the device powers a powered device, but the powered device later requests through CDP messages more than the configured maximum value, the device removes power to the port. The power that was allocated to the powered device is reclaimed into the global power budget. If you do not specify a wattage, the device delivers the maximum value. Use the **auto** setting on any PoE port. The auto mode is the default setting.

- **static**—The device pre-allocates power to the port (even when no powered device is connected) and guarantees that power will be available for the port. The device allocates the port configured maximum wattage, and the amount is never adjusted through the IEEE class or by CDP messages from the powered device. Because power is pre-allocated, any powered device that uses less than or equal to the maximum wattage is guaranteed to be powered when it is connected to the static port. The port no longer participates in the first-come, first-served model.

However, if the powered-device IEEE class is greater than the maximum wattage, the device does not supply power to it. If the device learns through CDP messages that the powered device is consuming more than the maximum wattage, the device shuts down the powered device.

If you do not specify a wattage, the device pre-allocates the maximum value. The device powers the port only if it discovers a powered device. Use the **static** setting on a high-priority interface.

- **never**—The device disables powered-device detection and never powers the PoE port even if an unpowered device is connected. Use this mode only when you want to make sure that power is never applied to a PoE-capable port, making the port a data-only port.

For most situations, the default configuration (auto mode) works well, providing plug-and-play operation. No further configuration is required. However, perform this task to configure a PoE port for a higher priority, to make it data only, or to specify a maximum wattage to disallow high-power powered devices on a port.

Stacking-capable devices also support StackPower, which allows device power supplies to share the load across multiple systems in a stack by connecting up to four devices with power stack cables.

Power Monitoring and Power Policing

When policing of the real-time power consumption is enabled, the device takes action when a powered device consumes more power than the maximum amount allocated, also referred to as the *cutoff-power value*.

When PoE is enabled, the device senses the real-time power consumption of the powered device. The device monitors the real-time power consumption of the connected powered device; this is called *power monitoring* or *power sensing*. The device also polices the power usage with the *power policing* feature.

Power monitoring is backward-compatible with Cisco intelligent power management and CDP-based power consumption. It works with these features to ensure that the PoE port can supply power to the powered device.

The device senses the real-time power consumption of the connected device as follows:

1. The device monitors the real-time power consumption on individual ports.
2. The device records the power consumption, including peak power usage. The device reports the information through the CISCO-POWER-ETHERNET-EXT-MIB.
3. If power policing is enabled, the device polices power usage by comparing the real-time power consumption to the maximum power allocated to the device. The maximum power consumption is also referred to as the *cutoff power* on a PoE port.

If the device uses more than the maximum power allocation on the port, the device can either turn off power to the port, or the device can generate a syslog message and update the LEDs (the port LED is now blinking amber) while still providing power to the device based on the device configuration. By default, power-usage policing is disabled on all PoE ports.

If error recovery from the PoE error-disabled state is enabled, the device automatically takes the PoE port out of the error-disabled state after the specified amount of time.

If error recovery is disabled, you can manually re-enable the PoE port by using the **shutdown** and **no shutdown** interface configuration commands.

4. If policing is disabled, no action occurs when the powered device consumes more than the maximum power allocation on the PoE port, which could adversely affect the device.

Power Consumption Values

You can configure the initial power allocation and the maximum power allocation on a port. However, these values are only the configured values that determine when the device should turn on or turn off power on the PoE port. The maximum power allocation is not the same as the actual power consumption of the powered device. The actual cutoff power value that the device uses for power policing is not equal to the configured power value.

When power policing is enabled, the device polices the power usage *at the switch port*, which is greater than the power consumption of the device. When you are manually set the maximum power allocation, you must consider the power loss over the cable from the switch port to the powered device. The cutoff power is the sum of the rated power consumption of the powered device and the worst-case power loss over the cable.

We recommend that you enable power policing when PoE is enabled on your device. For example, if policing is disabled and you set the cutoff-power value by using the **power inline auto max 6300** interface configuration command, the configured maximum power allocation on the PoE port is 6.3 W (6300 mW). The device provides power to the connected devices on the port if the device needs up to 6.3 W. If the CDP-power negotiated value or the IEEE classification value exceeds the configured cutoff value, the device does not provide power to the connected device. After the device turns on power on the PoE port, the device does not police the real-time power consumption of the device, and the device can consume more power than the maximum allocated amount, which could adversely affect the device and the devices connected to the other PoE ports.

Because a standalone device supports internal power supplies, the total amount of power available for the powered devices varies depending on the power supply configuration.

- If a power supply is removed and replaced by a new power supply with less power and the device does not have enough power for the powered devices, the device denies power to the PoE ports in auto mode in descending order of the port numbers. If the device still does not have enough power, the device then denies power to the PoE ports in static mode in descending order of the port numbers.
- If the new power supply supports more power than the previous one and the device now has more power available, the device grants power to the PoE ports in static mode in ascending order of the port numbers. If it still has power available, the device then grants power to the PoE ports in auto mode in ascending order of the port numbers.

The stacking-capable device also supports StackPower, which allows power supplies to share the load across multiple systems in a stack by connecting the devices with power stack cables. You can collectively manage the power supplies of up to four stack members as a one large power supply.

Cisco Universal Power Over Ethernet

Cisco Universal Power Over Ethernet (Cisco UPOE) is a Cisco proprietary technology that extends the IEEE 802.3at PoE standard to provide the capability to source up to 60 W of power over standard Ethernet cabling infrastructure (Class D or better) by using the spare pair of an RJ-45 cable (wires 4,5,7,8) with the signal pair (wires 1,2,3,6). Power on the spare pair is enabled when the switch port and end device mutually identify themselves as Cisco UPOE-capable using CDP or LLDP and the end device requests for power to be enabled on the spare pair. When the spare pair is powered, the end device can negotiate up to 60 W of power from the switch using CDP or LLDP.

If the end device is PoE-capable on both signal and spare pairs but does not support the CDP or LLDP extensions required for Cisco UPOE, a 4-pair forced mode configuration automatically enables power on both signal and spare pairs from the switch port.

How to Configure PoE

Configuring a Power Management Mode on a PoE Port

Note When you make PoE configuration changes, the port being configured drops power. Depending on the new configuration, the state of the other PoE ports, and the state of the power budget, the port might not be powered up again. For example, port 1 is in the auto and on state, and you configure it for static mode. The device removes power from port 1, detects the powered device, and repowers the port. If port 1 is in the auto and on state and you configure it with a maximum wattage of 10 W, the device removes power from the port and then redetects the powered device. The device repowers the port only if the powered device is a class 1, class 2, or a Cisco-only powered device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **power inline** {**auto** [**max** *max-wattage*] | **never** | **static** [**max** *max-wattage*]}

5. `end`
6. `show power inline [interface-id | module switch-number]`
7. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	<p><code>interface interface-id</code></p> <p>Example:</p> <pre>Device(config)# interface gigabitethernet2/0/1</pre>	Specifies the physical port to be configured, and enters interface configuration mode.
Step 4	<p><code>power inline {auto [max max-wattage] never static [max max-wattage]}</code></p> <p>Example:</p> <pre>Device(config-if)# power inline auto</pre>	<p>Configures the PoE mode on the port. The keywords have these meanings:</p> <ul style="list-style-type: none"> • auto—Enables powered-device detection. If enough power is available, automatically allocates power to the PoE port after device detection. This is the default setting. • max max-wattage—Limits the power allowed on the port. If no value is specified, the maximum is allowed. • max max-wattage—Limits the power allowed on the port. The range for Cisco UPOE ports is 4000 to 60000 mW. If no value is specified, the maximum is allowed. • never—Disables device detection, and disable power to the port. <p>Note If a port has a Cisco powered device connected to it, do not use the power inline never command to configure the port. A false link-up can occur, placing the port into the error-disabled state.</p> <ul style="list-style-type: none"> • static—Enables powered-device detection. Pre-allocate (reserve) power for a port before the device discovers the powered device. The device reserves power for this port even when no device is connected and guarantees that power will be provided upon device detection.

	Command or Action	Purpose
		The device allocates power to a port configured in static mode before it allocates power to a port configured in auto mode.
Step 5	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 6	show power inline [<i>interface-id</i> module <i>switch-number</i>] Example: Device# show power inline	Displays PoE status for a device or a device stack, for the specified interface, or for a specified stack member. The module <i>switch-number</i> keywords are supported only on stacking-capable devices.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Enabling Power on Signal/Spare Pairs

Note Do not enter this command if the end device cannot source inline power on the spare pair or if the end device supports the CDP or LLDP extensions for Cisco UPOE.

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **power inline four-pair forced**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet2/0/1	Specifies the physical port to be configured, and enters interface configuration mode.

	Command or Action	Purpose
Step 3	power inline four-pair forced Example: Device(config-if) # power inline four-pair forced	Enables power on both signal and spare pairs from a switch port.
Step 4	end Example: Device(config-if) # end	Returns to privileged EXEC mode.

Configuring Power Policing

By default, the device monitors the real-time power consumption of connected powered devices. You can configure the device to police the power usage. By default, policing is disabled.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **power inline police** [action {log | errdisable}]
5. **exit**
6. Use one of the following:
 - **errdisable detect cause inline-power**
 - **errdisable recovery cause inline-power**
 - **errdisable recovery interval** *interval*
7. **exit**
8. Use one of the following:
 - **show power inline police**
 - **show errdisable recovery**
9. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet2/0/1	Specifies the physical port to be configured, and enter interface configuration mode.
Step 4	power inline police [action { log errdisable }] Example: Device(config-if)# power inline police	<p>If the real-time power consumption exceeds the maximum power allocation on the port, configures the device to take one of these actions:</p> <ul style="list-style-type: none"> • power inline police—Shuts down the PoE port, turns off power to it, and puts it in the error-disabled state. <p>Note You can enable error detection for the PoE error-disabled cause by using the errdisable detect cause inline-power global configuration command. You can also enable the timer to recover from the PoE error-disabled state by using the errdisable recovery cause inline-power interval <i>interval</i> global configuration command.</p> <ul style="list-style-type: none"> • power inline police action errdisable—Turns off power to the port if the real-time power consumption exceeds the maximum power allocation on the port. • power inline police action log—Generates a syslog message while still providing power to the port. <p>If you do not enter the action log keywords, the default action shuts down the port and puts the port in the error-disabled state.</p>
Step 5	exit Example: Device(config-if)# exit	Returns to global configuration mode.
Step 6	Use one of the following: <ul style="list-style-type: none"> • errdisable detect cause inline-power • errdisable recovery cause inline-power • errdisable recovery interval <i>interval</i> Example: Device(config)# errdisable detect cause inline-power Device(config)# errdisable recovery cause inline-power Device(config)# errdisable recovery interval 100	<p>(Optional) Enables error recovery from the PoE error-disabled state, and configures the PoE recover mechanism variables.</p> <p>By default, the recovery interval is 300 seconds.</p> <p>For interval <i>interval</i>, specifies the time in seconds to recover from the error-disabled state. The range is 30 to 86400.</p>

	Command or Action	Purpose
Step 7	exit Example: Device(config)# exit	Returns to privileged EXEC mode.
Step 8	Use one of the following: <ul style="list-style-type: none"> • show power inline police • show errdisable recovery Example: Device# show power inline police Device# show errdisable recovery	Displays the power monitoring status, and verify the error recovery settings.
Step 9	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Monitoring Power Status

Table 19: Show Commands for Power Status

Command	Purpose
show env power switch [switch-number]	(Optional) Displays the status of the internal power supplies for each switch in the stack or for the specified switch. The range is 1 to 9, depending on the switch member numbers in the stack. These keywords are available only on stacking-capable switches.
show power inline [interface-id module switch-number]	Displays PoE status for a switch or switch stack, for an interface, or for a specific switch in the stack.
show power inline police	Displays the power policing data.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About EEE

EEE Overview

Energy Efficient Ethernet (EEE) is an IEEE 802.3az standard that is designed to reduce power consumption in Ethernet networks during idle periods.

EEE can be enabled on devices that support low power idle (LPI) mode. Such devices can save power by entering LPI mode during periods of low utilization. In LPI mode, systems on both ends of the link can save power by shutting down certain services. EEE provides the protocol needed to transition into and out of LPI mode in a way that is transparent to upper layer protocols and applications.

Default EEE Configuration

EEE is disabled by default.

Restrictions for EEE

EEE has the following restrictions:

- Changing the EEE configuration resets the interface because the device has to restart Layer 1 autonegotiation.
- You might want to enable the Link Layer Discovery Protocol (LLDP) for devices that require longer wakeup times before they are able to accept data on their receive paths. Doing so enables the device to negotiate for extended system wakeup times from the transmitting link partner.

How to Configure EEE

You can enable or disable EEE on an interface that is connected to an EEE-capable link partner.

Enabling or Disabling EEE

SUMMARY STEPS

1. **configure terminal**
2. **interface *interface-id***
3. **power efficient-ethernet auto**
4. **no power efficient-ethernet auto**
5. **end**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1	Specifies the interface to be configured, and enter interface configuration mode.

	Command or Action	Purpose
Step 3	<p>power efficient-ethernet auto</p> <p>Example:</p> <pre>Device(config-if)# power efficient-ethernet auto</pre>	Enables EEE on the specified interface. When EEE is enabled, the device advertises and autonegotiates EEE to its link partner.
Step 4	<p>no power efficient-ethernet auto</p> <p>Example:</p> <pre>Device(config-if)# no power efficient-ethernet auto</pre>	Disables EEE on the specified interface.
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 6	<p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Monitoring EEE

Table 20: Commands for Displaying EEE Settings

Command	Purpose
show eee capabilities interface <i>interface-id</i>	Displays EEE capabilities for the specified interface.
show eee status interface <i>interface-id</i>	Displays EEE status information for the specified interface.

Configuration Examples for Configuring EEE

This example shows how to enable EEE for an interface:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# power efficient-ethernet auto
```

This example shows how to disable EEE for an interface:

```

Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# no power efficient-ethernet auto

```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring IPv6 MLD Snooping

Note To use IPv6 MLD Snooping, the switch must be running the LAN Base image.

You can use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP Version 6 (IPv6) multicast data to clients and routers in a switched network on the switch. Unless otherwise noted, the term switch refers to a standalone switch and to a switch stack.

Note Stacking is supported only on Catalyst 2960-X switches running the LAN base image.

Note To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch.

On switches running the LAN Base feature set, the routing template is not supported.

Note For complete syntax and usage information for the commands used in this chapter, see the command reference for this release or the Cisco IOS documentation referenced in the procedures.

Understanding MLD Snooping

In IP Version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on the links that are directly attached to the routers and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD Version 1 (MLDv1) is equivalent to IGMPv2, and MLD Version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol Version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

Note The switch does not support MLDv2 enhanced snooping, which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

According to IPv6 multicast standards, the switch derives the MAC multicast address by performing a logical-OR of the four low-order octets of the switch MAC address with the MAC address of 33:33:00:00:00:00. For example, the IPv6 MAC address of FF02:DEAD:BEEF:1:3 maps to the Ethernet MAC address of 33:33:00:01:00:03.

A multicast packet is unmatched when the destination IPv6 address does not match the destination MAC address. The switch forwards the unmatched packet in hardware based the MAC address table. If the destination MAC address is not in the MAC address table, the switch floods the packet to all ports in the same VLAN as the receiving port.

MLD Messages

MLDv1 supports three types of messages:

- Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
- Multicast Listener Reports are the equivalent of IGMPv2 reports
- Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.

MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages.

Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

MLD Queries

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast group address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

Note

When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the Catalyst 2960, 2960-S, 2960-C, 2960-X or 2960-CX switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

Multicast Client Aging Robustness

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

Multicast Router Discovery

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
- IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.
- Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether or not MLD snooping is enabled on the switch.
- After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address is entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port.

The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the **ipv6 mld snooping last-listener-query count** global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the **ipv6 mld snooping last-listener-query-interval** global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

When Immediate Leave is not enabled and a port receives an MLD Done message, the switch generates MASQs on the port and sends them to the IPv6 multicast address for which the Done message was sent. You can optionally configure the number of MASQs that are sent and the length of time the switch waits for a response before deleting the port from the multicast group.

When you enable MLDv1 Immediate Leave, the switch immediately removes a port from a multicast group when it detects an MLD Done message on that port. You should only use the Immediate-Leave feature when there is a single receiver present on every port in the VLAN. When there are multiple clients for a multicast group on the same port, you should not enable Immediate-Leave in a VLAN.

Topology Change Notification Processing

When topology change notification (TCN) solicitation is enabled by using the **ipv6 mld snooping tcn query solicit** global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the **ipv6 mld snooping tcn flood query count** global configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This is same as done in IGMP snooping.

MLD Snooping in Switch Stacks

The MLD IPv6 group address databases are maintained on all switches in the stack, regardless of which switch learns of an IPv6 multicast group. Report suppression and proxy reporting are done stack-wide. During the maximum response time, only one received report for a group is forwarded to the multicast routers, regardless of which switch the report arrives on.

The election of a new stack master does not affect the learning or bridging of IPv6 multicast data; bridging of IPv6 multicast data does not stop during a stack master re-election. When a new switch is added to the stack, it synchronizes the learned IPv6 multicast information from the stack master. Until the synchronization is complete, data ingress on the newly added switch is treated as unknown multicast data.

How to Configure IPv6 MLD Snooping

Default MLD Snooping Configuration

Table 21: Default MLD Snooping Configuration

Feature	Default Setting
MLD snooping (Global)	Disabled.
MLD snooping (per VLAN)	Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place.
IPv6 Multicast addresses	None configured.
IPv6 Multicast router ports	None configured.
MLD snooping Immediate Leave	Disabled.
MLD snooping robustness variable	Global: 2; Per VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.
Last listener query count	Global: 2; Per VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.
Last listener query interval	Global: 1000 (1 second); VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global interval.
TCN query solicit	Disabled.
TCN query count	2.
MLD listener suppression	Disabled.

MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the **ipv6 mld snooping** global configuration command for the configuration to take effect.
- When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500

switch in order for the switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch.
- The maximum number of multicast entries allowed on the switch or switch stack is determined by the configured SDM template.
- The maximum number of address entries allowed for the switch or switch stack is 4000.

Enabling or Disabling MLD Snooping on the Switch (CLI)

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis or for a range of VLANs, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

Beginning in privileged EXEC mode, follow these steps to globally enable MLD snooping on the switch:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ipv6 mld snooping Example: Device(config)# ipv6 mld snooping	Enables MLD snooping on the switch.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 4	copy running-config startup-config Example: Device(config)# copy running-config startup-config	(Optional) Save your entries in the configuration file.

	Command or Action	Purpose
Step 5	reload Example: Device(config) # reload	Reload the operating system.

Enabling or Disabling MLD Snooping on a VLAN (CLI)

Beginning in privileged EXEC mode, follow these steps to enable MLD snooping on a VLAN.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ipv6 mld snooping Example: Device(config) # ipv6 mld snooping	Enables MLD snooping on the switch.
Step 3	ipv6 mld snooping vlan <i>vlan-id</i> Example: Device(config) # ipv6 mld snooping vlan 1	Enables MLD snooping on the VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. Note MLD snooping must be globally enabled for VLAN snooping to be enabled.
Step 4	end Example: Device(config) # ipv6 mld snooping vlan 1	Returns to privileged EXEC mode.

Configuring a Static Multicast Group (CLI)

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

Beginning in privileged EXEC mode, follow these steps to add a Layer 2 port as a member of a multicast group:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode
Step 2	ipv6 mld snooping vlan <i>vlan-id</i> static <i>ipv6_multicast_address</i> interface <i>interface-id</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1 static FF12::3 interface gigabitethernet 0/1</code>	Configures a multicast group with a Layer 2 port as a member of a multicast group: <ul style="list-style-type: none"> • <i>vlan-id</i> is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094. • <i>ipv6_multicast_address</i> is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373. • <i>interface-id</i> is the member port. It can be a physical interface or a port channel (1 to 48).
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 4	Use one of the following: <ul style="list-style-type: none"> • <code>show ipv6 mld snooping address</code> • <code>show ipv6 mld snooping address vlan <i>vlan-id</i></code> Example: Device# <code>show ipv6 mld snooping address</code> OR Device# <code>show ipv6 mld snooping vlan 1</code>	Verifies the static member port and the IPv6 address.

Configuring a Multicast Router Port (CLI)

Note Static connections to multicast routers are supported only on switch ports.

Beginning in privileged EXEC mode, follow these steps to add a multicast router port to a VLAN:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1 mrouter interface gigabitethernet 0/2</code>	Specifies the multicast router VLAN ID, and specify the interface to the multicast router. <ul style="list-style-type: none"> • The VLAN ID range is 1 to 1001 and 1006 to 4094. • The interface can be a physical interface or a port channel. The port-channel range is 1 to 48.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 4	show ipv6 mld snooping mrouter [vlan <i>vlan-id</i>] Example: Device# <code>show ipv6 mld snooping mrouter vlan 1</code>	Verifies that IPv6 MLD snooping is enabled on the VLAN interface.

Enabling MLD Immediate Leave (CLI)

Beginning in privileged EXEC mode, follow these steps to enable MLDv1 Immediate Leave:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ipv6 mld snooping vlan <i>vlan-id</i> immediate-leave Example: Device(config)# <code>ipv6 mld snooping vlan 1 immediate-leave</code>	Enables MLD Immediate Leave on the VLAN interface.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 4	show ipv6 mld snooping vlan <i>vlan-id</i> Example: Device# <code>show ipv6 mld snooping vlan 1</code>	Verifies that Immediate Leave is enabled on the VLAN interface.

Configuring MLD Snooping Queries (CLI)

Beginning in privileged EXEC mode, follow these steps to configure MLD snooping query characteristics for the switch or for a VLAN:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ipv6 mld snooping robustness-variable <i>value</i> Example: Device(config)# <code>ipv6 mld snooping robustness-variable 3</code>	(Optional) Sets the number of queries that are sent before switch will delete a listener (port) that does not respond to a general query. The range is 1 to 3; the default is 2.
Step 3	ipv6 mld snooping vlan <i>vlan-id</i> robustness-variable <i>value</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1 robustness-variable 3</code>	(Optional) Sets the robustness variable on a VLAN basis, which determines the number of general queries that MLD snooping sends before aging out a multicast address when there is no MLD report response. The range is 1 to 3; the default is 0. When set to 0, the number used is the global robustness variable value.
Step 4	ipv6 mld snooping last-listener-query-count <i>count</i> Example: Device(config)# <code>ipv6 mld snooping last-listener-query-count 7</code>	(Optional) Sets the number of MASQs that the switch sends before aging out an MLD client. The range is 1 to 7; the default is 2. The queries are sent 1 second apart.
Step 5	ipv6 mld snooping vlan <i>vlan-id</i> last-listener-query-count <i>count</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1 last-listener-query-count 7</code>	(Optional) Sets the last-listener query count on a VLAN basis. This value overrides the value configured globally. The range is 1 to 7; the default is 0. When set to 0, the global count value is used. Queries are sent 1 second apart.
Step 6	ipv6 mld snooping last-listener-query-interval <i>interval</i> Example:	(Optional) Sets the maximum response time that the switch waits after sending out a MASQ before deleting a port

	Command or Action	Purpose
	Device(config)# ipv6 mld snooping last-listener-query-interval 2000	from the multicast group. The range is 100 to 32,768 thousands of a second. The default is 1000 (1 second).
Step 7	ipv6 mld snooping vlan <i>vlan-id</i> last-listener-query-interval <i>interval</i> Example: Device(config)# ipv6 mld snooping vlan 1 last-listener-query-interval 2000	(Optional) Sets the last-listener query interval on a VLAN basis. This value overrides the value configured globally. The range is 0 to 32,768 thousands of a second. The default is 0. When set to 0, the global last-listener query interval is used.
Step 8	ipv6 mld snooping tcn query solicit Example: Device(config)# ipv6 mld snooping tcn query solicit	(Optional) Enables topology change notification (TCN) solicitation, which means that VLANs flood all IPv6 multicast traffic for the configured number of queries before sending multicast data to only those ports requesting to receive it. The default is for TCN to be disabled.
Step 9	ipv6 mld snooping tcn flood query count <i>count</i> Example: Device(config)# ipv6 mld snooping tcn flood query count 5	(Optional) When TCN is enabled, specifies the number of TCN queries to be sent. The range is from 1 to 10; the default is 2.
Step 10	end	Returns to privileged EXEC mode.
Step 11	show ipv6 mld snooping querier [vlan <i>vlan-id</i>] Example: Device(config)# show ipv6 mld snooping querier vlan 1	(Optional) Verifies that the MLD snooping querier information for the switch or for the VLAN.

Disabling MLD Listener Message Suppression (CLI)

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

Beginning in privileged EXEC mode, follow these steps to disable MLD listener message suppression:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enter global configuration mode.

	Command or Action	Purpose
Step 2	no ipv6 mld snooping listener-message-suppression Example: Device(config)# no ipv6 mld snooping listener-message-suppression	Disable MLD message suppression.
Step 3	end Example: Device(config)# end	Return to privileged EXEC mode.
Step 4	show ipv6 mld snooping Example: Device# show ipv6 mld snooping	Verify that IPv6 MLD snooping report suppression is disabled.

Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display IPv6 group address multicast entries for a VLAN configured for MLD snooping.

Table 22: Commands for Displaying MLD Snooping Information

Command	Purpose
show ipv6 mld snooping [vlan <i>vlan-id</i>]	Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN. (Optional) Enter vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.
show ipv6 mld snooping mrouter [vlan <i>vlan-id</i>]	Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces. (Optional) Enters vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.
show ipv6 mld snooping querier [vlan <i>vlan-id</i>]	Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN. (Optional) Enters vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.

Command	Purpose
show ipv6 mld snooping address [vlan <i>vlan-id</i>] [count dynamic user]	Displays all IPv6 multicast address information or specific IPv6 multicast address information for the switch or a VLAN. <ul style="list-style-type: none"> • Enters count to show the group count on the switch or in a VLAN. • Enters dynamic to display MLD snooping learned group information for the switch or for a VLAN. • Enters user to display MLD snooping user-configured group information for the switch or for a VLAN.
show ipv6 mld snooping address vlan <i>vlan-id</i> [<i>ipv6-multicast-address</i>]	Displays MLD snooping for the specified VLAN and IPv6 multicast address.

Configuration Examples for Configuring MLD Snooping

Configuring a Static Multicast Group: Example

This example shows how to statically configure an IPv6 multicast group:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 2 static FF12::3 interface gigabitethernet
1/0/1
Device(config)# end
```

Configuring a Multicast Router Port: Example

This example shows how to add a multicast router port to VLAN 200:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet
0/2
Device(config)# exit
```

Enabling MLD Immediate Leave: Example

This example shows how to enable MLD Immediate Leave on VLAN 130:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 130 immediate-leave
Device(config)# exit
```

Configuring MLD Snooping Queries: Example

This example shows how to set the MLD snooping global robustness variable to 3:

```
Device# configure terminal  
Device(config)# ipv6 mld snooping robustness-variable 3  
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```
Device# configure terminal  
Device(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3  
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```
Device# configure terminal  
Device(config)# ipv6 mld snooping last-listener-query-interval 2000  
Device(config)# exit
```

CHAPTER 15

Configuring IPv6 Unicast Routing

- [Finding Feature Information, on page 183](#)
- [Information About Configuring IPv6 Unicast Routing, on page 183](#)
- [Configuring DHCP for IPv6 Address Assignment, on page 206](#)
- [Configuration Examples for IPv6 Unicast Routing, on page 210](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring IPv6 Unicast Routing

This chapter describes how to configure IPv6 unicast routing on the switch.

Note To use all IPv6 features in this chapter, the switch or stack master must be running the IP services feature set. Switches running the IP base feature set support IPv6 static routing, RIP for IPv6, and OSPF. Switches running the LAN base feature set support only IPv6 host functionality.

Understanding IPv6

IPv4 users can move to IPv6 and receive services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to:

http://www.cisco.com/en/US/products/ps6553/products_ios_technology_home.html

For information about IPv6 and other features in this chapter

- See the *Cisco IOS IPv6 Configuration Library*.
- Use the Search field on Cisco.com to locate the Cisco IOS software documentation. For example, if you want information about static routes, you can enter *Implementing Static Routes for IPv6* in the search field to learn about static routes.

IPv6 Addresses

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses, or anycast addresses.

The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: n:n:n:n:n:n:n:n. This is an example of an IPv6 address:

```
2031:0000:130F:0000:0000:09C0:080F:130B
```

For easier implementation, leading zeros in each field are optional. This is the same address without leading zeros:

```
2031:0:130F:0:0:9C0:80F:130B
```

You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:

```
2031:0:130F::09C0:080F:130B
```

For more information about IPv6 address formats, address types, and the IPv6 packet header, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of *Cisco IOS IPv6 Configuration Library* on Cisco.com.

In the “Information About Implementing Basic Connectivity for IPv6” chapter, these sections apply to the switch:

- IPv6 Address Formats
- IPv6 Address Type: Unicast
- IPv6 Address Type: Multicast
- IPv6 Address Output Display
- Simplified IPv6 Packet Header

Supported IPv6 Unicast Routing Features

These sections describe the IPv6 protocol features supported by the switch:

The switch provides IPv6 routing capability over Routing Information Protocol (RIP) for IPv6, and Open Shortest Path First (OSPF) Version 3 Protocol. It supports up to 16 equal-cost routes and can simultaneously forward IPv4 and IPv6 frames at line rate.

128-Bit Wide Unicast Addresses

The switch supports aggregatable global unicast addresses and link-local unicast addresses. It does not support site-local unicast addresses.

- Aggregatable global unicast addresses are IPv6 addresses from the aggregatable global unicast prefix. The address structure enables strict aggregation of routing prefixes and limits the number of routing table entries in the global routing table. These addresses are used on links that are aggregated through organizations and eventually to the Internet service provider.

These addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). Addresses with a prefix of 2000::/3(001) through E000::/3(111) must have 64-bit interface identifiers in the extended unique identifier (EUI)-64 format.

- Link local unicast addresses can be automatically configured on any interface by using the link-local prefix FE80::/10(1111 1110 10) and the interface identifier in the modified EUI format. Link-local addresses are used in the neighbor discovery protocol (NDP) and the stateless autoconfiguration process. Nodes on a local link use link-local addresses and do not require globally unique addresses to communicate. IPv6 routers do not forward packets with link-local source or destination addresses to other links.

For more information, see the section about IPv6 unicast addresses in the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

DNS for IPv6

IPv6 supports Domain Name System (DNS) record types in the DNS name-to-address and address-to-name lookup processes. The DNS AAAA resource record types support IPv6 addresses and are equivalent to an A address record in IPv4. The switch supports DNS resolution for IPv4 and IPv6.

Path MTU Discovery for IPv6 Unicast

The switch supports advertising the system maximum transmission unit (MTU) to IPv6 nodes and path MTU discovery. Path MTU discovery allows a host to dynamically discover and adjust to differences in the MTU size of every link along a given data path. In IPv6, if a link along the path is not large enough to accommodate the packet size, the source of the packet handles the fragmentation.

ICMPv6

The Internet Control Message Protocol (ICMP) in IPv6 generates error messages, such as ICMP destination unreachable messages, to report errors during processing and other diagnostic functions. In IPv6, ICMP packets are also used in the neighbor discovery protocol and path MTU discovery.

Neighbor Discovery

The switch supports NDP for IPv6, a protocol running on top of ICMPv6, and static neighbor entries for IPv6 stations that do not support NDP. The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), to verify the reachability of the neighbor, and to keep track of neighboring routers.

The switch supports ICMPv6 redirect for routes with mask lengths less than 64 bits. ICMP redirect is not supported for host routes or for summarized routes with mask lengths greater than 64 bits.

Neighbor discovery throttling ensures that the switch CPU is not unnecessarily burdened while it is in the process of obtaining the next hop forwarding information to route an IPv6 packet. The switch drops any additional IPv6 packets whose next hop is the same neighbor that the switch is actively trying to resolve. This drop avoids further load on the CPU.

Default Router Preference

The switch supports IPv6 default router preference (DRP), an extension in router advertisement messages. DRP improves the ability of a host to select an appropriate router, especially when the host is multihomed and the routers are on different links. The switch does not support the Route Information Option in RFC 4191.

An IPv6 host maintains a default router list from which it selects a router for traffic to offlink destinations. The selected router for a destination is then cached in the destination cache. NDP for IPv6 specifies that routers that are reachable or probably reachable are preferred over routers whose reachability is unknown or suspect. For reachable or probably reachable routers, NDP can either select the same router every time or cycle through the router list. By using DRP, you can configure an IPv6 host to prefer one router over another, provided both are reachable or probably reachable.

For more information about DRP for IPv6, see the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

IPv6 Stateless Autoconfiguration and Duplicate Address Detection

The switch uses stateless autoconfiguration to manage link, subnet, and site addressing changes, such as management of host and mobile IP addresses. A host autonomously configures its own link-local address, and booting nodes send router solicitations to request router advertisements for configuring interfaces.

For more information about autoconfiguration and duplicate address detection, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of *Cisco IOS IPv6 Configuration Library* on Cisco.com.

IPv6 Applications

The switch has IPv6 support for these applications:

- Ping, traceroute, Telnet, and TFTP
- Secure Shell (SSH) over an IPv6 transport
- HTTP server access over IPv6 transport
- DNS resolver for AAAA over IPv4 transport
- Cisco Discovery Protocol (CDP) support for IPv6 addresses

For more information about managing these applications, see the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

DHCP for IPv6 Address Assignment

DHCPv6 enables DHCP servers to pass configuration parameters, such as IPv6 network addresses, to IPv6 clients. The address assignment feature manages non-duplicate address assignment in the correct prefix based on the network where the host is connected. Assigned addresses can be from one or multiple prefix pools. Additional options, such as default domain and DNS name-server address, can be passed back to the client. Address pools can be assigned for use on a specific interface, on multiple interfaces, or the server can automatically find the appropriate pool.

For more information and to configure these features, see the *Cisco IOS IPv6 Configuration Guide*.

This document describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Static Routes for IPv6

Static routes are manually configured and define an explicit route between two networking devices. Static routes are useful for smaller networks with only one path to an outside network or to provide security for certain types of traffic in a larger network.

For more information about static routes, see the “Implementing Static Routes for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

RIP for IPv6

Routing Information Protocol (RIP) for IPv6 is a distance-vector protocol that uses hop count as a routing metric. It includes support for IPv6 addresses and prefixes and the all-RIP-routers multicast group address FF02::9 as the destination address for RIP update messages.

For more information about RIP for IPv6, see the “Implementing RIP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

OSPF for IPv6

The switch running the IP Base feature set supports Open Shortest Path First (OSPF) for IPv6, a link-state protocol for IP. For more information, see *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Configuring HSRP for IPv6

HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.

An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address. Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

Note When configuring HSRP for IPv6, you must enable HSRP version 2 (HSRPv2) on the interface.

EIGRP IPv6

Switches support the Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address. Switches running IP Lite only support EIGRPv6 stub routing.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv6 address, so any IPv6 node always has an available router ID. However, EIGRP IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv6 router ID.

For more information about EIGRP for IPv6, see the “Implementing EIGRP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

EIGRPv6 Stub Routing

The EIGRPv6 stub routing feature, reduces resource utilization by moving routed traffic closer to the end user.

In a network using EIGRPv6 stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with EIGRPv6 stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRPv6 stub routing, you need to configure the distribution and remote routers to use EIGRPv6 and to configure only the switch as a stub. Only specified routes are propagated from the switch. The switch responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In the figure given below, switch B is configured as an EIGRPv6 stub router. Switches A and C are connected to the rest of the WAN. Switch B advertises connected, static, redistribution, and summary routes to switch A and C. Switch B does not advertise any routes learned from switch A (and the reverse).

Figure 6: EIGRP Stub Router Configuration

For more information about EIGRPv6 stub routing, see “Implementing EIGRP for IPv6” section of the *Cisco IOS IP Configuration Guide, Volume 2 of 3: Routing Protocols, Release 12.4*.

SNMP and Syslog Over IPv6

To support both IPv4 and IPv6, IPv6 network management requires both IPv6 and IPv4 transports. Syslog over IPv6 supports address data types for these transports.

SNMP and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and to modify the SNMP agent to support traps for an IPv6 host
- SNMP- and syslog-related MIBs to support IPv6 addressing
- Configuration of IPv6 hosts as trap receivers

For support over IPv6, SNMP modifies the existing IP transport mapping to simultaneously support IPv4 and IPv6. These SNMP actions support IPv6 transport management:

- Opens User Datagram Protocol (UDP) SNMP socket with default settings
- Provides a new transport mechanism called `SR_IPV6_TRANSPORT`

- Sends SNMP notifications over IPv6 transport
- Supports SNMP-named access lists for IPv6 transport
- Supports SNMP proxy forwarding using IPv6 transport
- Verifies SNMP Manager feature works with IPv6 transport

For information on SNMP over IPv6, including configuration procedures, see the “Managing Cisco IOS Applications over IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

For information about syslog over IPv6, including configuration procedures, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

HTTP(S) Over IPv6

The HTTP client sends requests to both IPv4 and IPv6 HTTP servers, which respond to requests from both IPv4 and IPv6 HTTP clients. URLs with literal IPv6 addresses must be specified in hexadecimal using 16-bit values between colons.

The accept socket call chooses an IPv4 or IPv6 address family. The accept socket is either an IPv4 or IPv6 socket. The listening socket continues to listen for both IPv4 and IPv6 signals that indicate a connection. The IPv6 listening socket is bound to an IPv6 wildcard address.

The underlying TCP/IP stack supports a dual-stack environment. HTTP relies on the TCP/IP stack and the sockets for processing network-layer interactions.

Basic network connectivity (**ping**) must exist between the client and the server hosts before HTTP connections can be made.

For more information, see the “Managing Cisco IOS Applications over IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Unsupported IPv6 Unicast Routing Features

The switch does not support these IPv6 features:

- IPv6 virtual private network (VPN) routing and forwarding (VRF) table support
- IPv6 packets destined to site-local addresses
- Tunneling protocols, such as IPv4-to-IPv6 or IPv6-to-IPv4
- The switch as a tunnel endpoint supporting IPv4-to-IPv6 or IPv6-to-IPv4 tunneling protocols
- IPv6 unicast reverse-path forwarding
- IPv6 Web Cache Communication Protocol (WCCP)

IPv6 Feature Limitations

Because IPv6 is implemented in switch hardware, some limitations occur due to the IPv6 compressed addresses in the hardware memory. These hardware limitations result in some loss of functionality and limits some features.

These are feature limitations.

- The switch cannot forward SNAP-encapsulated IPv6 packets in hardware. They are forwarded in software.

- The switch cannot apply QoS classification on source-routed IPv6 packets in hardware.

IPv6 and Switch Stacks

The switch supports IPv6 forwarding across the stack and IPv6 host functionality on the stack master. The stack master runs the IPv6 unicast routing protocols and computes the routing tables. They receive the tables and create hardware IPv6 routes for forwarding. The stack master also runs all IPv6 applications.

Note To route IPv6 packets in a stack, all switches in the stack should be running the IP Base feature set.

If a new switch becomes the stack master, it recomputes the IPv6 routing tables and distributes them to the member switches. While the new stack master is being elected and is resetting, the switch stack does not forward IPv6 packets. The stack MAC address changes, which also changes the IPv6 address. When you specify the stack IPv6 address with an extended unique identifier (EUI) by using the **ipv6 address ipv6-prefix/prefix length eui-64** interface configuration command, the address is based on the interface MAC address. See the [Configuring IPv6 Addressing and Enabling IPv6 Routing \(CLI\)](#), on page 191.

If you configure the persistent MAC address feature on the stack and the stack master changes, the stack MAC address does not change for approximately 4 minutes.

These are the functions of IPv6 stack master and members:

- Stack master:
 - runs IPv6 routing protocols
 - generates routing tables
 - distributes routing tables to stack members that use dCEFv6
 - runs IPv6 host functionality and IPv6 applications
- Stack member (must be running the IP services feature set):
 - receives CEFv6 routing tables from the stack master
 - programs the routes into hardware

Note IPv6 packets are routed in hardware across the stack if the packet does not have exceptions (IPv6 Options) and the switches in the stack have not run out of hardware resources.

- flushes the CEFv6 tables on master re-election

Default IPv6 Configuration

Table 23: Default IPv6 Configuration

Feature	Default Setting
SDM template	Advance desktop. Default is advanced template
IPv6 routing	Disabled globally and on all interfaces
CEFv6 or dCEFv6	Disabled (IPv4 CEF and dCEF are enabled by default) Note When IPv6 routing is enabled, CEFv6 and dCEF6 are automatically enabled.
IPv6 addresses	None configured

Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI)

This section describes how to assign IPv6 addresses to individual Layer 3 interfaces and to globally forward IPv6 traffic on the switch.

Before configuring IPv6 on the switch, consider these guidelines:

- Not all features discussed in this chapter are supported by the switch. See the [Unsupported IPv6 Unicast Routing Features, on page 189](#).
- In the **ipv6 address** interface configuration command, you must enter the *ipv6-address* and *ipv6-prefix* variables with the address specified in hexadecimal using 16-bit values between colons. The *prefix-length* variable (preceded by a slash [/]) is a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address).

To forward IPv6 traffic on an interface, you must configure a global IPv6 address on that interface. Configuring an IPv6 address on an interface automatically configures a link-local address and activates IPv6 for the interface. The configured interface automatically joins these required multicast groups for that link:

- solicited-node multicast group FF02:0:0:0:1:ff00::/104 for each unicast address assigned to the interface (this address is used in the neighbor discovery process.)
- all-nodes link-local multicast group FF02::1
- all-routers link-local multicast group FF02::2

To remove an IPv6 address from an interface, use the **no ipv6 address *ipv6-prefix/prefix length eui-64*** or **no ipv6 address *ipv6-address link-local*** interface configuration command. To remove all manually configured IPv6 addresses from an interface, use the **no ipv6 address** interface configuration command without arguments. To disable IPv6 processing on an interface that has not been explicitly configured with an IPv6 address, use the **no ipv6 enable** interface configuration command. To globally disable IPv6 routing, use the **no ipv6 unicast-routing** global configuration command.

For more information about configuring IPv6 routing, see the “Implementing Addressing and Basic Connectivity for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to assign an IPv6 address to a Layer 3 interface and enable IPv6 routing:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	sdm prefer dual-ipv4-and-ipv6 { advanced vlan } Example: Device(config)# <code>sdm prefer dual-ipv4-and-ipv6 default</code>	Selects an SDM template that supports IPv4 and IPv6. <ul style="list-style-type: none"> • advanced—Sets the switch to the default template to balance system resources. • vlan—Maximizes VLAN configuration on the switch with no routing supported in hardware. Note Advanced is available at all license levels. VLAN template is available only in LAN Base license.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 4	reload Example: Device# <code>reload</code>	Reloads the operating system.
Step 5	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode after the switch reloads.
Step 6	interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet 1/0/1</code>	Enters interface configuration mode, and specifies the Layer 3 interface to configure. The interface can be a physical interface, a switch virtual interface (SVI), or a Layer 3 EtherChannel.
Step 7	no switchport Example:	Removes the interface from Layer 2 configuration mode (if it is a physical interface).

	Command or Action	Purpose
	Device(config-if)# no switchport	
Step 8	<p>Use one of the following:</p> <ul style="list-style-type: none"> • ipv6 address <i>ipv6-prefix/prefix length eui-64</i> • ipv6 address <i>ipv6-address/prefix length</i> • ipv6 address <i>ipv6-address link-local</i> • ipv6 enable • ipv6 address <i>WORD</i> • ipv6 address <i>autoconfig</i> • ipv6 address <i>dhcp</i> <p>Example:</p> <pre>Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64</pre> <pre>Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64</pre> <pre>Device(config-if)# ipv6 address 2001:0DB8:c18:1:: link-local</pre> <pre>Device(config-if)# ipv6 enable</pre>	<ul style="list-style-type: none"> • Specifies a global IPv6 address with an extended unique identifier (EUI) in the low-order 64 bits of the IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address. This enables IPv6 processing on the interface. • Manually configures an IPv6 address on the interface. • Specifies a link-local address on the interface to be used instead of the link-local address that is automatically configured when IPv6 is enabled on the interface. This command enables IPv6 processing on the interface. • Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link.
Step 9	<p>exit</p> <p>Example:</p> <pre>Device(config-if)# exit</pre>	Returns to global configuration mode.
Step 10	<p>ip routing</p> <p>Example:</p> <pre>Device(config)# ip routing</pre>	Enables IP routing on the switch.
Step 11	<p>ipv6 unicast-routing</p> <p>Example:</p> <pre>Device(config)# ipv6 unicast-routing</pre>	Enables forwarding of IPv6 unicast data packets.
Step 12	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 13	show ipv6 interface <i>interface-id</i> Example: Device# show ipv6 interface gigabitethernet 1/0/1	Verifies your entries.
Step 14	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring IPv4 and IPv6 Protocol Stacks (CLI)

Beginning in privileged EXEC mode, follow these steps to configure a Layer 3 interface to support both IPv4 and IPv6 and to enable IPv6 routing.

Note To disable IPv6 processing on an interface that has not been configured with an IPv6 address, use the **no ipv6 enable** interface configuration command.

SUMMARY STEPS

1. **configure terminal**
2. **ip routing**
3. **ipv6 unicast-routing**
4. **interface** *interface-id*
5. **no switchport**
6. **ip address** *ip-address mask* [**secondary**]
7. Use one of the following:
 - **ipv6 address** *ipv6-prefix/prefix length* **eui-64**
 - **ipv6 address** *ipv6-address/prefix length*
 - **ipv6 address** *ipv6-address* **link-local**
 - **ipv6 enable**
 - **ipv6 address** *WORD*
 - **ipv6 address** *autoconfig*
 - **ipv6 address** *dhcp*
8. **end**
9. Use one of the following:
 - **show interface** *interface-id*
 - **show ip interface** *interface-id*
 - **show ipv6 interface** *interface-id*

10. copy running-config startup-config

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	ip routing Example: Switch(config)# ip routing	Enables routing on the switch.
Step 3	ipv6 unicast-routing Example: Switch(config)# ipv6 unicast-routing	Enables forwarding of IPv6 data packets on the switch.
Step 4	interface interface-id Example: Switch(config)# interface gigabitethernet 1/0/1	Enters interface configuration mode, and specifies the Layer 3 interface to configure.
Step 5	no switchport Example: Switch(config-if)# no switchport	Removes the interface from Layer 2 configuration mode (if it is a physical interface).
Step 6	ip address ip-address mask [secondary] Example: Switch(config-if)# ip address 10.1.2.3 255.255.255	Specifies a primary or secondary IPv4 address for the interface.
Step 7	Use one of the following: <ul style="list-style-type: none"> • ipv6 address ipv6-prefix/prefix length eui-64 • ipv6 address ipv6-address/prefix length • ipv6 address ipv6-address link-local • ipv6 enable • ipv6 address WORD • ipv6 address autoconfig 	<ul style="list-style-type: none"> • Specifies a global IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address. • Specifies a link-local address on the interface to be used instead of the automatically configured link-local address when IPv6 is enabled on the interface.

	Command or Action	Purpose
	<ul style="list-style-type: none"> • <code>ipv6 address dhcp</code> 	<ul style="list-style-type: none"> • Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link. <p>Note To remove all manually configured IPv6 addresses from an interface, use the no ipv6 address interface configuration command without arguments.</p>
Step 8	<p><code>end</code></p> <p>Example:</p> <pre>Switch(config)# end</pre>	Returns to privileged EXEC mode.
Step 9	<p>Use one of the following:</p> <ul style="list-style-type: none"> • <code>show interface interface-id</code> • <code>show ip interface interface-id</code> • <code>show ipv6 interface interface-id</code> 	Verifies your entries.
Step 10	<p><code>copy running-config startup-config</code></p> <p>Example:</p> <pre>Switch# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring Default Router Preference (CLI)

Router advertisement messages are sent with the default router preference (DRP) configured by the **ipv6 nd router-preference** interface configuration command. If no DRP is configured, RAs are sent with a medium preference.

A DRP is useful when two routers on a link might provide equivalent, but not equal-cost routing, and policy might dictate that hosts should prefer one of the routers.

For more information about configuring DRP for IPv6, see the “Implementing IPv6 Addresses and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to configure a DRP for a router on an interface.

Procedure

	Command or Action	Purpose
Step 1	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1	Enters interface configuration mode and identifies the Layer 3 interface on which you want to specify the DRP.
Step 3	ipv6 nd router-preference {high medium low} Example: Device(config-if)# ipv6 nd router-preference medium	Specifies a DRP for the router on the switch interface.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show ipv6 interface Example: Device# show ipv6 interface	Verifies the configuration.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring IPv6 ICMP Rate Limiting (CLI)

ICMP rate limiting is enabled by default with a default interval between error messages of 100 milliseconds and a bucket size (maximum number of tokens to be stored in a bucket) of 10.

Beginning in privileged EXEC mode, follow these steps to change the ICMP rate-limiting parameters:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ipv6 icmp error-interval <i>interval</i> [<i>bucketsize</i>] Example: <pre>Device(config)# ipv6 icmp error-interval 50 20</pre>	Configures the interval and bucket size for IPv6 ICMP error messages: <ul style="list-style-type: none"> • <i>interval</i>—The interval (in milliseconds) between tokens being added to the bucket. The range is from 0 to 2147483647 milliseconds. • <i>bucketsize</i>—(Optional) The maximum number of tokens stored in the bucket. The range is from 1 to 200.
Step 3	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.
Step 4	show ipv6 interface [<i>interface-id</i>] Example: <pre>Device# show ipv6 interface gigabitethernet 1/0/1</pre>	Verifies your entries.
Step 5	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring CEF and dCEF for IPv6

Cisco Express Forwarding (CEF) is a Layer 3 IP switching technology to improve network performance. CEF implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. It is less CPU-intensive than fast-switching route-caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed CEF (dCEF) in the stack. IPv4 CEF and dCEF are enabled by default. IPv6 CEF and dCEF are disabled by default, but automatically enabled when you configure IPv6 routing.

IPv6 CEF and dCEF are automatically disabled when IPv6 routing is unconfigured. IPv6 CEF and dCEF cannot be disabled through configuration. You can verify the IPv6 state by entering the **show ipv6 cef** privileged EXEC command.

To route IPv6 unicast packets, you must first globally configure forwarding of IPv6 unicast packets by using the **ipv6 unicast-routing** global configuration command, and you must configure an IPv6 address and IPv6 processing on an interface by using the **ipv6 address** interface configuration command.

For more information about configuring CEF and dCEF, see *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Configuring Static Routing for IPv6 (CLI)

Before configuring a static IPv6 route, you must enable routing by using the **ip routing** global configuration command, enable the forwarding of IPv6 packets by using the **ipv6 unicast-routing** global configuration command, and enable IPv6 on at least one Layer 3 interface by configuring an IPv6 address on the interface.

For more information about configuring static IPv6 routing, see the “Implementing Static Routes for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Procedure

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 2	<p>ipv6 route <i>ipv6-prefix/prefix length</i> {<i>ipv6-address</i> <i>interface-id</i> [<i>ipv6-address</i>]} [<i>administrative distance</i>]</p> <p>Example:</p> <pre>Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130</pre>	<p>Configures a static IPv6 route.</p> <ul style="list-style-type: none"> • <i>ipv6-prefix</i>—The IPv6 network that is the destination of the static route. It can also be a hostname when static host routes are configured. • <i>/prefix length</i>—The length of the IPv6 prefix. A decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark must precede the decimal value. • <i>ipv6-address</i>—The IPv6 address of the next hop that can be used to reach the specified network. The IPv6 address of the next hop need not be directly connected; recursion is done to find the IPv6 address of the directly connected next hop. The address must be in the form documented in RFC 2373, specified in hexadecimal using 16-bit values between colons. • <i>interface-id</i>—Specifies direct static routes from point-to-point and broadcast interfaces. With point-to-point interfaces, there is no need to specify the IPv6 address of the next hop. With broadcast interfaces, you should always specify the IPv6 address of the next hop, or ensure that the specified prefix is assigned to the link, specifying a link-local address as the next hop. You can optionally specify the IPv6 address of the next hop to which packets are sent. <p>Note You must specify an <i>interface-id</i> when using a link-local address as the next hop (the link-local next hop must also be an adjacent router).</p>

	Command or Action	Purpose
		<ul style="list-style-type: none"> • <i>administrative distance</i>—(Optional) An administrative distance. The range is 1 to 254; the default value is 1, which gives static routes precedence over any other type of route except connected routes. To configure a floating static route, use an administrative distance greater than that of the dynamic routing protocol.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 4	Use one of the following: <ul style="list-style-type: none"> • show ipv6 static [<i>ipv6-address</i> <i>ipv6-prefix/prefix length</i>] [interface <i>interface-id</i>] [detail][recursive] [detail] • show ipv6 route static [<i>updated</i>] Example: Device# show ipv6 static 2001:0DB8::/32 interface gigabitethernet2/0/1 or Device# show ipv6 route static	Verifies your entries by displaying the contents of the IPv6 routing table. <ul style="list-style-type: none"> • interface <i>interface-id</i>—(Optional) Displays only those static routes with the specified interface as an egress interface. • recursive—(Optional) Displays only recursive static routes. The recursive keyword is mutually exclusive with the interface keyword, but it can be used with or without the IPv6 prefix included in the command syntax. • detail—(Optional) Displays this additional information: <ul style="list-style-type: none"> • For valid recursive routes, the output path set, and maximum resolution depth. • For invalid routes, the reason why the route is not valid.
Step 5	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring RIP for IPv6 (CLI)

Before configuring the switch to run IPv6 RIP, you must enable routing by using the **ip routing** global configuration command, enable the forwarding of IPv6 packets by using the **ipv6 unicast-routing** global configuration command, and enable IPv6 on any Layer 3 interfaces on which IPv6 RIP is to be enabled.

For more information about configuring RIP routing for IPv6, see the “Implementing RIP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com,

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ipv6 router rip name Example: Device(config)# <code>ipv6 router rip cisco</code>	Configures an IPv6 RIP routing process, and enters router configuration mode for the process.
Step 3	maximum-paths number-paths Example: Device(config-router)# <code>maximum-paths 6</code>	(Optional) Define the maximum number of equal-cost routes that IPv6 RIP can support. The range is from 1 to 32, and the default is 16 routes.
Step 4	exit Example: Device(config-router)# <code>exit</code>	Returns to global configuration mode.
Step 5	interface interface-id Example: Device(config)# <code>interface gigabitethernet 1/0/1</code>	Enters interface configuration mode, and specifies the Layer 3 interface to configure.
Step 6	ipv6 rip name enable Example: Device(config-if)# <code>ipv6 rip cisco enable</code>	Enables the specified IPv6 RIP routing process on the interface.
Step 7	ipv6 rip name default-information {only originate} Example: Device(config-if)# <code>ipv6 rip cisco default-information only</code>	(Optional) Originates the IPv6 default route (::/0) into the RIP routing process updates sent from the specified interface. Note To avoid routing loops after the IPv6 default route (::/0) is originated from any interface, the routing process ignores all default routes received on any interface. <ul style="list-style-type: none"> • only—Select to originate the default route, but suppress all other routes in the updates sent on this interface.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • originate—Select to originate the default route in addition to all other routes in the updates sent on this interface.
Step 8	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 9	Use one of the following: <ul style="list-style-type: none"> • show ipv6 rip [<i>name</i>] [interface<i>interface-id</i>] [database] [next-hops] • show ipv6 rip Example: Device# show ipv6 rip cisco interface gigabitethernet2/0/1 or Device# show ipv6 rip	<ul style="list-style-type: none"> • Displays information about current IPv6 RIP processes. • Displays the current contents of the IPv6 routing table.
Step 10	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring OSPF for IPv6 (CLI)

You can customize OSPF for IPv6 for your network. However, the defaults for OSPF in IPv6 are set to meet the requirements of most customers and features.

Follow these guidelines:

- Be careful when changing the defaults for IPv6 commands. Changing the defaults might adversely affect OSPF for the IPv6 network.
- Before you enable IPv6 OSPF on an interface, you must enable routing by using the **ip routing** global configuration command, enable the forwarding of IPv6 packets by using the **ipv6 unicast-routing** global configuration command, and enable IPv6 on Layer 3 interfaces on which you are enabling IPv6 OSPF.

For more information about configuring OSPF routing for IPv6, see the “Implementing OSPF for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ipv6 router ospf <i>process-id</i> Example: Device(config)# <code>ipv6 router ospf 21</code>	Enables OSPF router configuration mode for the process. The process ID is the number assigned administratively when enabling the OSPF for IPv6 routing process. It is locally assigned and can be a positive integer from 1 to 65535.
Step 3	area <i>area-id</i> range {<i>ipv6-prefix/prefix length</i>} [advertise not-advertise] [cost <i>cost</i>] Example: Device(config)# <code>area .3 range 2001:0DB8::/32 not-advertise</code>	(Optional) Consolidates and summarizes routes at an area boundary. <ul style="list-style-type: none"> • <i>area-id</i>—Identifier of the area about which routes are to be summarized. It can be specified as either a decimal value or as an IPv6 prefix. • <i>ipv6-prefix/prefix length</i>—The destination IPv6 network and a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark (/) must precede the decimal value. • advertise—(Optional) Sets the address range status to advertise and generate a Type 3 summary link-state advertisement (LSA). • not-advertise—(Optional) Sets the address range status to DoNotAdvertise. The Type 3 summary LSA is suppressed, and component networks remain hidden from other networks. • cost <i>cost</i>—(Optional) Sets the metric or cost for this summary route, which is used during OSPF SPF calculation to determine the shortest paths to the destination. The value can be 0 to 16777215.
Step 4	maximum paths <i>number-paths</i> Example: Device(config)# <code>maximum paths 16</code>	(Optional) Defines the maximum number of equal-cost routes to the same destination that IPv6 OSPF should enter in the routing table. The range is from 1 to 32, and the default is 16 paths.
Step 5	exit Example:	Returns to global configuration mode.

	Command or Action	Purpose
	Device (config-if) # exit	
Step 6	interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 1/0/1	Enters interface configuration mode, and specifies the Layer 3 interface to configure.
Step 7	ipv6 ospf <i>process-id</i> area <i>area-id</i> [instance <i>instance-id</i>] Example: Device (config-if) # ipv6 ospf 21 area .3	Enables OSPF for IPv6 on the interface. • instance <i>instance-id</i> —(Optional) Instance identifier.
Step 8	end Example: Device (config) # end	Returns to privileged EXEC mode.
Step 9	Use one of the following: • show ipv6 ospf [<i>process-id</i>] [<i>area-id</i>] interface [<i>interface-id</i>] • show ipv6 ospf [<i>process-id</i>] [<i>area-id</i>] Example: Device# show ipv6 ospf 21 interface gigabitethernet2/0/1 or Device# show ipv6 ospf 21	• Displays information about OSPF interfaces. • Displays general information about OSPF routing processes.
Step 10	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring EIGRP for IPv6

Before configuring the switch to run IPv6 EIGRP, enable routing by entering the **ip routing global configuration** command, enable the forwarding of IPv6 packets by entering the **ipv6 unicast-routing global configuration** command, and enable IPv6 on any Layer 3 interfaces on which you want to enable IPv6 EIGRP.

To set an explicit router ID, use the **show ipv6 eigrp** command to see the configured router IDs, and then use the **router-id** command.

As with EIGRP IPv4, you can use EIGRPv6 to specify your EIGRP IPv6 interfaces and to select a subset of those as passive interfaces. Use the **passive-interface** command to make an interface passive, and then use the **no passive-interface** command on selected interfaces to make them active. EIGRP IPv6 does not need to be configured on a passive interface.

For more configuration procedures, see the “Implementing EIGRP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Configuring IPv6 Unicast Reverse Path Forwarding

The unicast Reverse Path Forwarding (unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

- Unicast RPF is supported only in IP services.
- Do not configure Unicast RPF if the switch is in a mixed hardware stack combining more than one switch type.

For detailed IP unicast RPF configuration information, see the *Other Security Features* chapter in the *Cisco IOS Security Configuration Guide, Release 12.4*.

Displaying IPv6

For complete syntax and usage information on these commands, see the Cisco IOS command reference publications.

Table 24: Command for Monitoring IPv6

Command	Purpose
show ipv6 access-list	Displays a summary of access lists.
show ipv6 cef	Displays Cisco Express Forwarding for IPv6.
show ipv6 interface <i>interface-id</i>	Displays IPv6 interface status and configuration.
show ipv6 mtu	Displays IPv6 MTU per destination cache.
show ipv6 neighbors	Displays IPv6 neighbor cache entries.
show ipv6 ospf	Displays IPv6 OSPF information.
show ipv6 prefix-list	Displays a list of IPv6 prefix lists.
show ipv6 protocols	Displays a list of IPv6 routing protocols on the switch.
show ipv6 rip	Displays IPv6 RIP routing protocol status.
show ipv6 rip	Displays IPv6 RIP routing protocol status.

Command	Purpose
<code>show ipv6 route</code>	Displays IPv6 route table entries.
<code>show ipv6 routers</code>	Displays the local IPv6 routers.
<code>show ipv6 static</code>	Displays IPv6 static routes.
<code>show ipv6 traffic</code>	Displays IPv6 traffic statistics.

Table 25: Command for Displaying EIGRP IPv6 Information

Command	Purpose
<code>show ipv6 eigrp [as-number] interface</code>	Displays information about interfaces configured for EIGRP IPv6.
<code>show ipv6 eigrp [as-number] neighbor</code>	Displays the neighbors discovered by EIGRP IPv6.
<code>show ipv6 interface[as-number] traffic</code>	Displays the number of EIGRP IPv6 packets sent and received.
<code>show ipv6 eigrptopology [as-number ipv6-address] [active all-links detail-links pending summary zero-successors Base]</code>	Displays EIGRP entries in the IPv6 topology table.

Configuring DHCP for IPv6 Address Assignment

This section describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Default DHCPv6 Address Assignment Configuration

By default, no DHCPv6 features are configured on the switch.

DHCPv6 Address Assignment Configuration Guidelines

When configuring DHCPv6 address assignment, consider these guidelines:

- In the procedures, the specified interface must be one of these Layer 3 interfaces:
 - DHCPv6 IPv6 routing must be enabled on a Layer 3 interface.
 - SVI: a VLAN interface created by using the **interface vlan *vlan_id*** command.
 - EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the **interface port-channel *port-channel-number*** command.
- The switch can act as a DHCPv6 client, server, or relay agent. The DHCPv6 client, server, and relay function are mutually exclusive on an interface.

- The DHCPv6 client, server, or relay agent runs only on the master switch. When there is a stack master re-election, the new master switch retains the DHCPv6 configuration. However, the local RAM copy of the DHCP server database lease information is not retained.

Enabling DHCPv6 Server Function (CLI)

Use the **no** form of the DHCP pool configuration mode commands to change the DHCPv6 pool characteristics. To disable the DHCPv6 server function on an interface, use the **no ipv6 dhcp server** interface configuration command.

Beginning in privileged EXEC mode, follow these steps to enable the DHCPv6 server function on an interface.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ipv6 dhcp pool <i>poolname</i> Example: Device(config)# ipv6 dhcp pool 7	Enters DHCP pool configuration mode, and define the name for the IPv6 DHCP pool. The pool name can be a symbolic string (such as Engineering) or an integer (such as 0).
Step 3	address prefix <i>IPv6-prefix</i> {lifetime} {tl tl infinite} Example: Device(config-dhcpv6)# address prefix 2001:1000::0/64 lifetime 3600	(Optional) Specifies an address prefix for address assignment. This address must be in hexadecimal, using 16-bit values between colons. lifetime <i>tl tl</i> —Specifies a time interval (in seconds) that an IPv6 address prefix remains in the valid state. The range is 5 to 4294967295 seconds. Specify infinite for no time interval.
Step 4	link-address <i>IPv6-prefix</i> Example: Device(config-dhcpv6)# link-address 2001:1002::0/64	(Optional) Specifies a link-address IPv6 prefix. When an address on the incoming interface or a link-address in the packet matches the specified IPv6 prefix, the server uses the configuration information pool. This address must be in hexadecimal, using 16-bit values between colons.
Step 5	vendor-specific <i>vendor-id</i> Example: Device(config-dhcpv6)# vendor-specific 9	(Optional) Enters vendor-specific configuration mode and specifies a vendor-specific identification number. This number is the vendor IANA Private Enterprise Number. The range is 1 to 4294967295.

	Command or Action	Purpose
Step 6	<p>suboption <i>number</i> {address <i>IPv6-address</i> ascii <i>ASCII-string</i> hex <i>hex-string</i>}</p> <p>Example:</p> <pre>Device(config-dhcpv6-vs)# suboption 1 address 1000:235D::</pre>	(Optional) Enters a vendor-specific suboption number. The range is 1 to 65535. Enter an IPv6 address, ASCII text, or a hex string as defined by the suboption parameters.
Step 7	<p>exit</p> <p>Example:</p> <pre>Device(config-dhcpv6-vs)# exit</pre>	Returns to DHCP pool configuration mode.
Step 8	<p>exit</p> <p>Example:</p> <pre>Device(config-dhcpv6)# exit</pre>	Returns to global configuration mode.
Step 9	<p>interface <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# interface gigabitethernet 1/0/1</pre>	Enters interface configuration mode, and specifies the interface to configure.
Step 10	<p>ipv6 dhcp server [<i>poolname</i> automatic] [rapid-commit] [preference value] [allow-hint]</p> <p>Example:</p> <pre>Device(config-if)# ipv6 dhcp server automatic</pre>	<p>Enables DHCPv6 server function on an interface.</p> <ul style="list-style-type: none"> • poolname—(Optional) User-defined name for the IPv6 DHCP pool. The pool name can be a symbolic string (such as Engineering) or an integer (such as 0). • automatic—(Optional) Enables the system to automatically determine which pool to use when allocating addresses for a client. • rapid-commit—(Optional) Allows two-message exchange method. • preference value—(Optional) Configures the preference value carried in the preference option in the advertise message sent by the server. The range is from 0 to 255. The preference value default is 0. • allow-hint—(Optional) Specifies whether the server should consider client suggestions in the SOLICIT message. By default, the server ignores client hints.
Step 11	<p>end</p> <p>Example:</p>	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config)# end	
Step 12	Do one of the following: <ul style="list-style-type: none"> • show ipv6 dhcp pool • show ipv6 dhcp interface Example: Device# show ipv6 dhcp pool or Device# show ipv6 dhcp interface	<ul style="list-style-type: none"> • Verifies DHCPv6 pool configuration. • Verifies that the DHCPv6 server function is enabled on an interface.
Step 13	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Enabling DHCPv6 Client Function (CLI)

This task explains how to enable the DHCPv6 client on an interface.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface interface-id Example: Device(config)# interface gigabitethernet 1/0/1	Enters interface configuration mode, and specifies the interface to configure.
Step 3	ipv6 address dhcp [rapid-commit] Example: Device(config-if)# ipv6 address dhcp rapid-commit	Enables the interface to acquire an IPv6 address from the DHCPv6 server. rapid-commit —(Optional) Allow two-message exchange method for address assignment.
Step 4	ipv6 dhcp client request [vendor-specific] Example:	(Optional) Enables the interface to request the vendor-specific option.

	Command or Action	Purpose
	Device(config-if)# ipv6 dhcp client request vendor-specific	
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 6	show ipv6 dhcp interface Example: Device# show ipv6 dhcp interface	Verifies that the DHCPv6 client is enabled on an interface.

Configuration Examples for IPv6 Unicast Routing

Configuring IPv6 Addressing and Enabling IPv6 Routing: Example

This example shows how to enable IPv6 with both a link-local address and a global address based on the IPv6 prefix 2001:0DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the **show ipv6 interface EXEC** command is included to show how the interface ID (20B:46FF:FE2F:D940) is appended to the link-local prefix FE80::/64 of the interface.

```
Device(config)# ipv6 unicast-routing
Device(config)# interface gigabitethernet1/0/11
Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
Device# show ipv6 interface gigabitethernet1/0/11
GigabitEthernet1/0/11 is up, line protocol is up
  IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
  Global unicast address(es):
  2001:0DB8:c18:1:20B:46FF:FE2F:D940, subnet is 2001:0DB8:c18:1::/64 [EUI]
  Joined group address(es):
    FE02::1
    FE02::2
    FE02::1:FE2F:D940
  MTU is 1500 bytes
  ICMP error messages limited to one every 100 milliseconds
  ICMP redirects are enabled
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisements are sent every 200 seconds
  ND router advertisements live for 1800 seconds
  Hosts use stateless autoconfig for addresses.
```

Configuring Default Router Preference: Example

This example shows how to configure a DRP of *high* for the router on an interface.

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ipv6 nd router-preference high
Device(config-if)# end
```

Configuring IPv4 and IPv6 Protocol Stacks: Example

This example shows how to enable IPv4 and IPv6 routing on an interface.

```
Device(config)# ip routing
Device(config)# ipv6 unicast-routing
Device(config)# interface fastethernet1/0/11
Device(config-if)# no switchport
Device(config-if)# ip address 192.168.99.1 255.255.255.0
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
```

Enabling DHCPv6 Server Function: Example

This example shows how to configure a pool called *engineering* with an IPv6 address prefix:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool engineering
Device(config-dhcpv6)# address prefix 2001:1000::0/64
Device(config-dhcpv6)# end
```

This example shows how to configure a pool called *testgroup* with three link-addresses and an IPv6 address prefix:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool testgroup
Device(config-dhcpv6)# link-address 2001:1001::0/64
Device(config-dhcpv6)# link-address 2001:1002::0/64
Device(config-dhcpv6)# link-address 2001:2000::0/48
Device(config-dhcpv6)# address prefix 2001:1003::0/64
Device(config-dhcpv6)# end
```

This example shows how to configure a pool called *350* with vendor-specific options:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool 350
Device(config-dhcpv6)# address prefix 2001:1005::0/48
Device(config-dhcpv6)# vendor-specific 9
Device(config-dhcpv6-vs)# suboption 1 address 1000:235D::1
Device(config-dhcpv6-vs)# suboption 2 ascii "IP-Phone"
Device(config-dhcpv6-vs)# end
```

Enabling DHCPv6 Client Function: Example

This example shows how to acquire an IPv6 address and to enable the rapid-commit option:

```
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ipv6 address dhcp rapid-commit
```

Configuring IPv6 ICMP Rate Limiting: Example

This example shows how to configure an IPv6 ICMP error message interval of 50 milliseconds and a bucket size of 20 tokens.

```
Device(config)#ipv6 icmp error-interval 50 20
```

Configuring Static Routing for IPv6: Example

This example shows how to configure a floating static route to an interface with an administrative distance of 130:

```
Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130
```

Configuring RIP for IPv6: Example

This example shows how to enable the RIP routing process *cisco* with a maximum of eight equal-cost routes and to enable it on an interface:

```
Device(config)# ipv6 router rip cisco
Device(config-router)# maximum-paths 8
Device(config)# exit
Device(config)# interface gigabitethernet2/0/11
Device(config-if)# ipv6 rip cisco enable
```

Displaying IPv6: Example

This is an example of the output from the **show ipv6 interface** privileged EXEC command:

```
Device# show ipv6 interface
Vlan1 is up, line protocol is up
  IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
  Global unicast address(es):
    3FFE:C000:0:1:20B:46FF:FE2F:D940, subnet is 3FFE:C000:0:1::/64 [EUI]
  Joined group address(es):
    FF02::1
    FF02::2
    FF02::1:FF2F:D940
  MTU is 1500 bytes
  ICMP error messages limited to one every 100 milliseconds
  ICMP redirects are enabled
```

```
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
<output truncated>
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Implementing IPv6 Multicast Routing

This chapter describes how to implement IPv6 multicast routing on the switch.

Traditional IP communication allows a host to send packets to a single host (unicast transmission) or to all hosts (broadcast transmission). IPv6 multicast provides a third scheme, allowing a host to send a single data stream to a subset of all hosts (group transmission) simultaneously.

IPv6 Multicast Overview

An IPv6 multicast group is an arbitrary group of receivers that want to receive a particular data stream. This group has no physical or geographical boundaries--receivers can be located anywhere on the Internet or in any private network. Receivers that are interested in receiving data flowing to a particular group must join the group by signaling their local switch. This signaling is achieved with the MLD protocol.

Switches use the MLD protocol to learn whether members of a group are present on their directly attached subnets. Hosts join multicast groups by sending MLD report messages. The network then delivers data to a potentially unlimited number of receivers, using only one copy of the multicast data on each subnet. IPv6 hosts that wish to receive the traffic are known as group members.

Packets delivered to group members are identified by a single multicast group address. Multicast packets are delivered to a group using best-effort reliability, just like IPv6 unicast packets.

The multicast environment consists of senders and receivers. Any host, regardless of whether it is a member of a group, can send to a group. However, only members of a group can listen to and receive the message.

A multicast address is chosen for the receivers in a multicast group. Senders use that address as the destination address of a datagram to reach all members of the group.

Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time.

How active a multicast group is, its duration, and its membership can vary from group to group and from time to time. A group that has members may have no activity.

IPv6 Multicast Routing Implementation

The Cisco IOS software supports the following protocols to implement IPv6 multicast routing:

- MLD is used by IPv6 switches to discover multicast listeners (nodes that want to receive multicast packets destined for specific multicast addresses) on directly attached links. There are two versions of MLD: MLD version 1 is based on version 2 of the Internet Group Management Protocol (IGMP) for IPv4, and MLD version 2 is based on version 3 of the IGMP for IPv4. IPv6 multicast for Cisco IOS software uses both MLD version 2 and MLD version 1. MLD version 2 is fully backward-compatible with MLD version 1 (described in RFC 2710). Hosts that support only MLD version 1 will interoperate with a switch running MLD version 2. Mixed LANs with both MLD version 1 and MLD version 2 hosts are likewise supported.
- PIM-SM is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs.
- PIM in Source Specific Multicast (PIM-SSM) is similar to PIM-SM with the additional ability to report interest in receiving packets from specific source addresses (or from all but the specific source addresses) to an IP multicast address.

IPv6 Multicast Listener Discovery Protocol

To start implementing multicasting in the campus network, users must first define who receives the multicast. The MLD protocol is used by IPv6 switches to discover the presence of multicast listeners (for example, nodes that want to receive multicast packets) on their directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes. It is used for discovering local group and source-specific group membership.

The MLD protocol provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

Multicast Queriers and Hosts

A multicast querier is a network device, such as a switch, that sends query messages to discover which network devices are members of a given multicast group.

A multicast host is a receiver, including switches, that send report messages to inform the querier of a host membership.

A set of queriers and hosts that receive multicast data streams from the same source is called a multicast group. Queriers and hosts use MLD reports to join and leave multicast groups and to begin receiving group traffic.

MLD uses the Internet Control Message Protocol (ICMP) to carry its messages. All MLD messages are link-local with a hop limit of 1, and they all have the switch alert option set. The switch alert option implies an implementation of the hop-by-hop option header.

MLD Access Group

The MLD access group provides receiver access control in Cisco IOS IPv6 multicast switches. This feature limits the list of groups a receiver can join, and it allows or denies sources used to join SSM channels.

Explicit Tracking of Receivers

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network. This feature also enables the fast leave mechanism to be used with MLD version 2 host reports.

Protocol Independent Multicast

Protocol Independent Multicast (PIM) is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs. PIM works independently of the unicast routing protocol to perform send or receive multicast route updates like other protocols. Regardless of which unicast routing protocols are being used in the LAN to populate the unicast routing table, Cisco IOS PIM uses the existing unicast table content to perform the Reverse Path Forwarding (RPF) check instead of building and maintaining its own separate routing table.

You can configure IPv6 multicast to use either PIM-SM or PIM-SSM operation, or you can use both PIM-SM and PIM-SSM together in your network.

PIM-Sparse Mode

IPv6 multicast provides support for intradomain multicast routing using PIM-SM. PIM-SM uses unicast routing to provide reverse-path information for multicast tree building, but it is not dependent on any particular unicast routing protocol.

PIM-SM is used in a multicast network when relatively few switches are involved in each multicast and these switches do not forward multicast packets for a group, unless there is an explicit request for the traffic. PIM-SM distributes information about active sources by forwarding data packets on the shared tree. PIM-SM initially uses shared trees, which requires the use of an RP.

Requests are accomplished via PIM joins, which are sent hop by hop toward the root node of the tree. The root node of a tree in PIM-SM is the RP in the case of a shared tree or the first-hop switch that is directly connected to the multicast source in the case of a shortest path tree (SPT). The RP keeps track of multicast groups and the hosts that send multicast packets are registered with the RP by that host's first-hop switch.

As a PIM join travels up the tree, switches along the path set up multicast forwarding state so that the requested multicast traffic will be forwarded back down the tree. When multicast traffic is no longer needed, a switch sends a PIM prune up the tree toward the root node to prune (or remove) the unnecessary traffic. As this PIM prune travels hop by hop up the tree, each switch updates its forwarding state appropriately. Ultimately, the forwarding state associated with a multicast group or source is removed.

A multicast data sender sends data destined for a multicast group. The designated switch (DR) of the sender takes those data packets, unicast-encapsulates them, and sends them directly to the RP. The RP receives these encapsulated data packets, de-encapsulates them, and forwards them onto the shared tree. The packets then

follow the (*, G) multicast tree state in the switches on the RP tree, being replicated wherever the RP tree branches, and eventually reaching all the receivers for that multicast group. The process of encapsulating data packets to the RP is called registering, and the encapsulation packets are called PIM register packets.

IPv6 BSR: Configure RP Mapping

PIM switches in a domain must be able to map each multicast group to the correct RP address. The BSR protocol for PIM-SM provides a dynamic, adaptive mechanism to distribute group-to-RP mapping information rapidly throughout a domain. With the IPv6 BSR feature, if an RP becomes unreachable, it will be detected and the mapping tables will be modified so that the unreachable RP is no longer used, and the new tables will be rapidly distributed throughout the domain.

Every PIM-SM multicast group needs to be associated with the IP or IPv6 address of an RP. When a new multicast sender starts sending, its local DR will encapsulate these data packets in a PIM register message and send them to the RP for that multicast group. When a new multicast receiver joins, its local DR will send a PIM join message to the RP for that multicast group. When any PIM switch sends a (*, G) join message, the PIM switch needs to know which is the next switch toward the RP so that G (Group) can send a message to that switch. Also, when a PIM switch is forwarding data packets using (*, G) state, the PIM switch needs to know which is the correct incoming interface for packets destined for G, because it needs to reject any packets that arrive on other interfaces.

A small set of switches from a domain are configured as candidate bootstrap switches (C-BSRs) and a single BSR is selected for that domain. A set of switches within a domain are also configured as candidate RPs (C-RPs); typically, these switches are the same switches that are configured as C-BSRs. Candidate RPs periodically unicast candidate-RP-advertisement (C-RP-Adv) messages to the BSR of that domain, advertising their willingness to be an RP. A C-RP-Adv message includes the address of the advertising C-RP, and an optional list of group addresses and mask length fields, indicating the group prefixes for which the candidacy is advertised. The BSR then includes a set of these C-RPs, along with their corresponding group prefixes, in bootstrap messages (BSMs) it periodically originates. BSMs are distributed hop-by-hop throughout the domain.

Bidirectional BSR support allows bidirectional RPs to be advertised in C-RP messages and bidirectional ranges in the BSM. All switches in a system must be able to use the bidirectional range in the BSM; otherwise, the bidirectional RP feature will not function.

PIM-Source Specific Multicast

PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM-SM. However, unlike PIM-SM where data from all multicast sources are sent when there is a PIM join, the SSM feature forwards datagram traffic to receivers from only those multicast sources that the receivers have explicitly joined, thus optimizing bandwidth utilization and denying unwanted Internet broadcast traffic. Further, instead of the use of RP and shared trees, SSM uses information found on source addresses for a multicast group. This information is provided by receivers through the source addresses relayed to the last-hop switches by MLD membership reports, resulting in shortest-path trees directly to the sources.

In SSM, delivery of datagrams is based on (S, G) channels. Traffic for one (S, G) channel consists of datagrams with an IPv6 unicast source address S and the multicast group address G as the IPv6 destination address. Systems will receive this traffic by becoming members of the (S, G) channel. Signaling is not required, but receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources.

MLD version 2 is required for SSM to operate. MLD allows the host to provide source information. Before SSM can run with MLD, SSM must be supported in the Cisco IOS IPv6 switch, the host where the application is running, and the application itself.

Routable Address Hello Option

When an IPv6 interior gateway protocol is used to build the unicast routing table, the procedure to detect the upstream switch address assumes the address of a PIM neighbor is always same as the address of the next-hop switch, as long as they refer to the same switch. However, it may not be the case when a switch has multiple addresses on a link.

Two typical situations can lead to this situation for IPv6. The first situation can occur when the unicast routing table is not built by an IPv6 interior gateway protocol such as multicast BGP. The second situation occurs when the address of an RP shares a subnet prefix with downstream switches (note that the RP switch address has to be domain-wide and therefore cannot be a link-local address).

The routable address hello option allows the PIM protocol to avoid such situations by adding a PIM hello message option that includes all the addresses on the interface on which the PIM hello message is advertised. When a PIM switch finds an upstream switch for some address, the result of RPF calculation is compared with the addresses in this option, in addition to the PIM neighbor's address itself. Because this option includes all the possible addresses of a PIM switch on that link, it always includes the RPF calculation result if it refers to the PIM switch supporting this option.

Because of size restrictions on PIM messages and the requirement that a routable address hello option fits within a single PIM hello message, a limit of 16 addresses can be configured on the interface.

PIM IPv6 Stub Routing

The PIM stub routing feature reduces resource usage by moving routed traffic closer to the end user.

In a network using PIM stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IPv6 multicast routing and configure only the switch as a PIM stub router. The switch does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the switch. The switch uplink port cannot be used with SVIs.

You must also configure EIGRP stub routing when configuring PIM stub routing on the switch. For more information, see the [EIGRPv6 Stub Routing, on page 187](#) section.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM assert and designated router election mechanisms are not supported on the PIM passive interfaces. Only the non-redundant access router topology is supported by the PIM stub feature. By using a non-redundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

In the figure shown below, Switch A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source. See the [Configuring PIM IPv6 Stub Routing, on page 231](#) section for more information.

Figure 7: PIM Stub Router Configuration

Static Mroutes

IPv6 static mroutes behave much in the same way as IPv4 static mroutes used to influence the RPF check. IPv6 static mroutes share the same database as IPv6 static routes and are implemented by extending static route support for RPF checks. Static mroutes support equal-cost multipath mroutes, and they also support unicast-only static routes.

MRIB

The Multicast Routing Information Base (MRIB) is a protocol-independent repository of multicast routing entries instantiated by multicast routing protocols (routing clients). Its main function is to provide independence between routing protocols and the Multicast Forwarding Information Base (MFIB). It also acts as a coordination and communication point among its clients.

Routing clients use the services provided by the MRIB to instantiate routing entries and retrieve changes made to routing entries by other clients. Besides routing clients, MRIB also has forwarding clients (MFIB instances) and special clients such as MLD. MFIB retrieves its forwarding entries from MRIB and notifies the MRIB of any events related to packet reception. These notifications can either be explicitly requested by routing clients or spontaneously generated by the MFIB.

Another important function of the MRIB is to allow for the coordination of multiple routing clients in establishing multicast connectivity within the same multicast session. MRIB also allows for the coordination between MLD and routing protocols.

MFIB

The MFIB is a platform-independent and routing-protocol-independent library for IPv6 software. Its main purpose is to provide a Cisco IOS platform with an interface with which to read the IPv6 multicast forwarding table and notifications when the forwarding table changes. The information provided by the MFIB has clearly defined forwarding semantics and is designed to make it easy for the platform to translate to its specific hardware or software forwarding mechanisms.

When routing or topology changes occur in the network, the IPv6 routing table is updated, and those changes are reflected in the MFIB. The MFIB maintains next-hop address information based on the information in the IPv6 routing table. Because there is a one-to-one correlation between MFIB entries and routing table entries, the MFIB contains all known routes and eliminates the need for route cache maintenance that is associated with switching paths such as fast switching and optimum switching.

MFIB

Note Distributed MFIB has its significance only in a stacked environment where the Master distributes the MFIB information to the other stack members. In the following section the line cards are nothing but the member switches in the stack.

MFIB (MFIB) is used to switch multicast IPv6 packets on distributed platforms. MFIB may also contain platform-specific information on replication across line cards. The basic MFIB routines that implement the core of the forwarding logic are common to all forwarding environments.

MFIB implements the following functions:

- Relays data-driven protocol events generated in the line cards to PIM.
- Provides an MFIB platform application program interface (API) to propagate MFIB changes to platform-specific code responsible for programming the hardware acceleration engine. This API also includes entry points to switch a packet in software (necessary if the packet is triggering a data-driven event) and to upload traffic statistics to the software.

The combination of MFIB and MRIB subsystems also allows the switch to have a "customized" copy of the MFIB database in each line card and to transport MFIB-related platform-specific information from the RP to the line cards.

IPv6 Multicast Process Switching and Fast Switching

A unified MFIB is used to provide both fast switching and process switching support for PIM-SM and PIM-SSM in IPv6 multicast. In process switching, the IOS daemon must examine, rewrite, and forward each packet. The packet is first received and copied into the system memory. The switch then looks up the Layer 3 network address in the routing table. The Layer 2 frame is then rewritten with the next-hop destination address and sent to the outgoing interface. The IOSd also computes the cyclic redundancy check (CRC). This switching method is the least scalable method for switching IPv6 packets.

IPv6 multicast fast switching allows switches to provide better packet forwarding performance than process switching. Information conventionally stored in a route cache is stored in several data structures for IPv6 multicast switching. The data structures provide optimized lookup for efficient packet forwarding.

In IPv6 multicast forwarding, the first packet is fast-switched if the PIM protocol logic allows it. In IPv6 multicast fast switching, the MAC encapsulation header is precomputed. IPv6 multicast fast switching uses the MFIB to make IPv6 destination prefix-based switching decisions. In addition to the MFIB, IPv6 multicast fast switching uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all MFIB entries.

The adjacency table is populated as adjacencies are discovered. Each time an adjacency entry is created (such as through ARP), a link-layer header for that adjacent node is precomputed and stored in the adjacency table. Once a route is determined, it points to a next hop and corresponding adjacency entry. It is subsequently used for encapsulation during switching of packets.

A route might have several paths to a destination prefix, such as when a switch is configured for simultaneous load balancing and redundancy. For each resolved path, a pointer is added for the adjacency corresponding to the next-hop interface for that path. This mechanism is used for load balancing across several paths.

Multiprotocol BGP for the IPv6 Multicast Address Family

The multiprotocol BGP for the IPv6 multicast address family feature provides multicast BGP extensions for IPv6 and supports the same features and functionality as IPv4 BGP. IPv6 enhancements to multicast BGP include support for an IPv6 multicast address family and network layer reachability information (NLRI) and next hop (the next switch in the path to the destination) attributes that use IPv6 addresses.

Multicast BGP is an enhanced BGP that allows the deployment of interdomain IPv6 multicast. Multiprotocol BGP carries routing information for multiple network layer protocol address families; for example, IPv6 address family and for IPv6 multicast routes. The IPv6 multicast address family contains routes used for RPF lookup by the IPv6 PIM protocol, and multicast BGP IPv6 provides for interdomain transport of the same. Users must use multiprotocol BGP for IPv6 multicast when using IPv6 multicast with BGP because the unicast BGP learned routes will not be used for IPv6 multicast.

Multicast BGP functionality is provided through a separate address family context. A subsequent address family identifier (SAFI) provides information about the type of the network layer reachability information that is carried in the attribute. Multiprotocol BGP unicast uses SAFI 1 messages, and multiprotocol BGP multicast uses SAFI 2 messages. SAFI 1 messages indicate that the routes are only usable for IP unicast, but not IP multicast. Because of this functionality, BGP routes in the IPv6 unicast RIB must be ignored in the IPv6 multicast RPF lookup.

A separate BGP routing table is maintained to configure incongruent policies and topologies (for example, IPv6 unicast and multicast) by using IPv6 multicast RPF lookup. Multicast RPF lookup is very similar to the IP unicast route lookup.

No MRIB is associated with the IPv6 multicast BGP table. However, IPv6 multicast BGP operates on the unicast IPv6 RIB when needed. Multicast BGP does not insert or update routes into the IPv6 unicast RIB.

Implementing IPv6 Multicast

Enabling IPv6 Multicast Routing

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	ipv6 multicast-routing Example: Device (config)# ipv6 multicast-routing	Enables multicast routing on all IPv6-enabled interfaces and enables multicast forwarding for PIM and MLD on all enabled interfaces of the switch.
Step 3	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Customizing and Verifying the MLD Protocol

Customizing and Verifying MLD on an Interface

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	interface <i>type number</i> Example: (config)# interface GigabitEthernet 1/0/1	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 3	ipv6 mld join-group [<i>group-address</i>] [include exclude] { <i>source-address</i> source-list [<i>acl</i>]} Example: (config-if) # ipv6 mld join-group FF04::10	Configures MLD reporting for a specified group and source.
Step 4	ipv6 mld access-group <i>access-list-name</i> Example: (config-if) # ipv6 access-list acc-grp-1	Allows the user to perform IPv6 multicast receiver access control.
Step 5	ipv6 mld static-group [<i>group-address</i>] [include exclude] { <i>source-address</i> source-list [<i>acl</i>]} Example: (config-if) # ipv6 mld static-group ff04::10 include 100::1	Statically forwards traffic for the multicast group onto a specified interface and cause the interface to behave as if a MLD joiner were present on the interface.
Step 6	ipv6 mld query-max-response-time <i>seconds</i> Example: (config-if) # ipv6 mld query-max-response-time 20	Configures the maximum response time advertised in MLD queries.
Step 7	ipv6 mld query-timeout <i>seconds</i> Example: (config-if) # ipv6 mld query-timeout 130	Configures the timeout value before the switch takes over as the querier for the interface.
Step 8	exit Example:	Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.

	Command or Action	Purpose
	<code>(config-if) # exit</code>	
Step 9	show ipv6 mld groups [link-local] [<i>group-name</i> <i>group-address</i>] [<i>interface-type interface-number</i>] [detail explicit] Example: <code># show ipv6 mld groups GigabitEthernet 1/0/1</code>	Displays the multicast groups that are directly connected to the switch and that were learned through MLD.
Step 10	show ipv6 mld groups summary Example: <code># show ipv6 mld groups summary</code>	Displays the number of (*, G) and (S, G) membership reports present in the MLD cache.
Step 11	show ipv6 mld interface [<i>type number</i>] Example: <code># show ipv6 mld interface GigabitEthernet 1/0/1</code>	Displays multicast-related information about an interface.
Step 12	debug ipv6 mld [<i>group-name</i> <i>group-address</i> <i>interface-type</i>] Example: <code># debug ipv6 mld</code>	Enables debugging on MLD protocol activity.
Step 13	debug ipv6 mld explicit [<i>group-name</i> <i>group-address</i>] Example: <code># debug ipv6 mld explicit</code>	Displays information related to the explicit tracking of hosts.
Step 14	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Implementing MLD Group Limits

Per-interface and global MLD limits operate independently of each other. Both per-interface and global MLD limits can be configured on the same switch. The number of MLD limits, globally or per interface, is not configured by default; the limits must be configured by the user. A membership report that exceeds either the per-interface or the global state limit is ignored.

Implementing MLD Group Limits Globally

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ipv6 mld** [*vrf vrf-name*] **state-limit** *number*

4. copy running-config startup-config

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters global configuration mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	ipv6 mld [vrf vrf-name] state-limit number Example: Device(config)# ipv6 mld state-limit 300	Limits the number of MLD states globally.
Step 4	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Implementing MLD Group Limits per Interface

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface type number**
4. **ipv6 mld limit number [except]access-list**
5. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters global configuration mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	interface type <i>number</i> Example: Device(config)# interface GigabitEthernet 1/0/1	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 4	ipv6 mld limit <i>number</i> [except] <i>access-list</i> Example: Device(config-if)# ipv6 mld limit 100	Limits the number of MLD states on a per-interface basis.
Step 5	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring Explicit Tracking of Receivers to Track Host Behavior

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network and enables the fast leave mechanism to be used with MLD version 2 host reports.

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	interface type <i>number</i> Example: (config)# interface GigabitEthernet 1/0/1	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 3	ipv6 mld explicit-tracking <i>access-list-name</i> Example: (config-if)# ipv6 mld explicit-tracking list1	Enables explicit tracking of hosts.
Step 4	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Resetting the MLD Traffic Counters

Beginning in privileged EXEC mode, follow these steps.

Procedure

	Command or Action	Purpose
Step 1	clear ipv6 mld traffic Example: # clear ipv6 mld traffic	Resets all MLD traffic counters.

	Command or Action	Purpose
Step 2	show ipv6 mld traffic Example: <pre># show ipv6 mld traffic</pre>	Displays the MLD traffic counters.
Step 3	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Clearing the MLD Interface Counters

Beginning in privileged EXEC mode, follow these steps.

Procedure

	Command or Action	Purpose
Step 1	clear ipv6 mld counters <i>interface-type</i> Example: <pre># clear ipv6 mld counters Ethernet1/0</pre>	Clears the MLD interface counters.
Step 2	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring PIM

This section explains how to configure PIM.

Configuring PIM-SM and Displaying PIM-SM Information for a Group Range

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	ipv6 pim rp-address <i>ipv6-address</i>[<i>group-access-list</i>] Example: <pre>(config) # ipv6 pim rp-address 2001:DB8::01:800:200E:8C6C acc-grp-1</pre>	Configures the address of a PIM RP for a particular group range.
Step 3	exit Example: <pre>(config) # exit</pre>	Exits global configuration mode, and returns the switch to privileged EXEC mode.

	Command or Action	Purpose
Step 4	show ipv6 pim interface [state-on] [state-off] [type-number] Example: <pre># show ipv6 pim interface</pre>	Displays information about interfaces configured for PIM.
Step 5	show ipv6 pim group-map [group-name group-address] [group-range group-mask] [info-source {bsr default embedded-rp static}] Example: <pre># show ipv6 pim group-map</pre>	Displays an IPv6 multicast group mapping table.
Step 6	show ipv6 pim neighbor [detail] [interface-type interface-number count] Example: <pre># show ipv6 pim neighbor</pre>	Displays the PIM neighbors discovered by the Cisco IOS software.
Step 7	show ipv6 pim range-list [config] [rp-address rp-name] Example: <pre># show ipv6 pim range-list</pre>	Displays information about IPv6 multicast range lists.
Step 8	show ipv6 pim tunnel [interface-type interface-number] Example: <pre># show ipv6 pim tunnel</pre>	Displays information about the PIM register encapsulation and de-encapsulation tunnels on an interface.
Step 9	debug ipv6 pim [group-name group-address interface interface-type bsr group mvpn neighbor] Example: <pre># debug ipv6 pim</pre>	Enables debugging on PIM protocol activity.
Step 10	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring PIM Options

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.

	Command or Action	Purpose
Step 2	ipv6 pim spt-threshold infinity [group-list <i>access-list-name</i>] Example: <pre>(config) # ipv6 pim spt-threshold infinity group-list acc-grp-1</pre>	Configures when a PIM leaf switch joins the SPT for the specified groups.
Step 3	ipv6 pim accept-register { list <i>access-list</i> route-map <i>map-name</i> } Example: <pre>(config) # ipv6 pim accept-register route-map reg-filter</pre>	Accepts or rejects registers at the RP.
Step 4	interface <i>type number</i> Example: <pre>(config) # interface GigabitEthernet 1/0/1</pre>	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 5	ipv6 pim dr-priority <i>value</i> Example: <pre>(config-if) # ipv6 pim dr-priority 3</pre>	Configures the DR priority on a PIM switch.
Step 6	ipv6 pim hello-interval <i>seconds</i> Example: <pre>(config-if) # ipv6 pim hello-interval 45</pre>	Configures the frequency of PIM hello messages on an interface.
Step 7	ipv6 pim join-prune-interval <i>seconds</i> Example: <pre>(config-if) # ipv6 pim join-prune-interval 75</pre>	Configures periodic join and prune announcement intervals for a specified interface.
Step 8	exit Example: <pre>(config-if) # exit</pre>	Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.
Step 9	ipv6 pim join-prune statistic [<i>interface-type</i>] Example: <pre>(config-if) # show ipv6 pim join-prune statistic</pre>	Displays the average join-prune aggregation for the most recently aggregated packets for each interface.
Step 10	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Resetting the PIM Traffic Counters

If PIM malfunctions or in order to verify that the expected number of PIM packets are received and sent, the user can clear PIM traffic counters. Once the traffic counters are cleared, the user can enter the `show ipv6 pim traffic` command to verify that PIM is functioning correctly and that PIM packets are being received and sent correctly.

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	clear ipv6 pim traffic Example: <pre># clear ipv6 pim traffic</pre>	Resets the PIM traffic counters.
Step 2	show ipv6 pim traffic Example: <pre># show ipv6 pim traffic</pre>	Displays the PIM traffic counters.
Step 3	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Clearing the PIM Topology Table to Reset the MRIB Connection

No configuration is necessary to use the MRIB. However, users may in certain situations want to clear the PIM topology table in order to reset the MRIB connection and verify MRIB information.

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	clear ipv6 pim topology [<i>group-name</i> <i>group-address</i>] Example: <pre># clear ipv6 pim topology FF04::10</pre>	Clears the PIM topology table.
Step 2	show ipv6 mrib client [<i>filter</i>] [<i>name</i> { <i>client-name</i> <i>client-name</i> : <i>client-id</i> }] Example: <pre># show ipv6 mrib client</pre>	Displays multicast-related information about an interface.
Step 3	show ipv6 mrib route { <i>link-local</i> <i>summary</i> [<i>sourceaddress-or-name</i> *] [<i>groupname-or-address</i> [<i>prefix-length</i>]]] Example:	Displays the MRIB route information.

	Command or Action	Purpose
	# show ipv6 mrib route	
Step 4	show ipv6 pim topology [<i>groupname-or-address</i> [<i>sourceaddress-or-name</i>] link-local route-count [detail]] Example: # show ipv6 pim topology	Displays PIM topology table information for a specific group or all groups.
Step 5	debug ipv6 mrib client Example: # debug ipv6 mrib client	Enables debugging on MRIB client management activity.
Step 6	debug ipv6 mrib io Example: # debug ipv6 mrib io	Enables debugging on MRIB I/O events.
Step 7	debug ipv6 mrib proxy Example: # debug ipv6 mrib proxy	Enables debugging on MRIB proxy activity between the switch processor and line cards on distributed switch platforms.
Step 8	debug ipv6 mrib route [<i>group-name</i> <i>group-address</i>] Example: # debug ipv6 mrib route	Displays information about MRIB routing entry-related activity.
Step 9	debug ipv6 mrib table Example: # debug ipv6 mrib table	Enables debugging on MRIB table management activity.
Step 10	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring PIM IPv6 Stub Routing

The PIM Stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards MLD traffic.

PIM IPv6 Stub Routing Configuration Guidelines

- Before configuring PIM stub routing, you must have IPv6 multicast routing configured on both the stub router and the central router. You must also have PIM mode (sparse-mode) configured on the uplink interface of the stub router.
- The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior. For more information, see the [EIGRPv6 Stub Routing, on page 187](#) section.
- Only directly connected multicast (MLD) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- The redundant PIM stub router topology is not supported.

Default IPv6 PIM Routing Configuration

This table displays the default IPv6 PIM routing configuration for the Device.

Table 26: Default Multicast Routing Configuration

Feature	Default Setting
Multicast routing	Disabled on all interfaces.
PIM version	Version 2.
PIM mode	No mode is defined.
PIM stub routing	None configured.
PIM RP address	None configured.
PIM domain border	Disabled.
PIM multicast boundary	None.
Candidate BSRs	Disabled.
Candidate RPs	Disabled.
Shortest-path tree threshold rate	0 kb/s.
PIM router query message interval	30 seconds.

Enabling IPv6 PIM Stub Routing

Before you begin

PIM stub routing is disabled in IPv6 by default. Beginning in privileged EXEC mode, follow these steps to enable PIM stub routing on an interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. `ipv6 multicast pim-passive-enable`
4. `interface interface-id`
5. `ipv6 pim`
6. `ipv6 pim {bsr} | {dr-priority | value} | {hello-interval | seconds} | {join-prune-interval | seconds} | {passive}`
7. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	<p><code>ipv6 multicast pim-passive-enable</code></p> <p>Example:</p> <pre>Device(config-if)# ipv6 multicast pim-passive-enable</pre>	Enables IPv6 Multicast PIM routing on the switch.
Step 4	<p><code>interface interface-id</code></p> <p>Example:</p> <pre>Device(config)# interface gigabitethernet 9/0/6</pre>	<p>Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode.</p> <p>The specified interface must be one of the following:</p> <ul style="list-style-type: none"> • A routed port—A physical port that has been configured as a Layer 3 port by entering the no switchport interface configuration command. You will also need to enable IP PIM sparse mode on the interface, and join the interface as a statically connected member to an MLD static group. • An SVI—A VLAN interface created by using the interface vlan vlan-id global configuration command. You will also need to enable IP PIM sparse mode on the VLAN, join the VLAN as a statically connected member to an MLD static group, and then enable MLD snooping on the VLAN, the MLD static group, and physical interface. <p>These interfaces must have IPv6 addresses assigned to them.</p>

	Command or Action	Purpose
Step 5	ipv6 pim Example: <pre>Device(config-if)# ipv6 pim</pre>	Enables the PIM on the interface.
Step 6	ipv6 pim {bsr} {dr-priority value} {hello-interval seconds} {join-prune-interval seconds} {passive} Example: <pre>Device(config-if)# ipv6 pim bsr dr-priority hello-interval join-prune-interval passive</pre>	Configures the various PIM stub features on the interface. Enter bsr to configure BSR on a PIM switch Enter dr-priority to configure the DR priority on a PIM switch. Enter hello-interval to configure the frequency of PIM hello messages on an interface. Enter join-prune-interval to configure periodic join and prune announcement intervals for a specified interface. Enter passive to configure the PIM in the passive mode.
Step 7	end Example: <pre>Device(config-if)# end</pre>	Returns to privileged EXEC mode.

Monitoring IPv6 PIM Stub Routing

Table 27: PIM Stub Configuration show Commands

Command	Purpose
show ipv6 pim interface <pre>Device# show ipv6 pim interface</pre>	Displays the PIM stub that is enabled on each interface.
show ipv6 mld groups <pre>Device# show ipv6 mld groups</pre>	Displays the interested clients that have joined the specific multicast source group.
show ipv6 mroute <pre>Device# show ipv6 mroute</pre>	Verifies that the multicast stream forwards from the source to the interested clients.

Configuring a BSR

The tasks included here are described below.

Configuring a BSR and Verifying BSR Information

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	ipv6 pim bsr candidate bsr <i>ipv6-address[hash-mask-length] [priority priority-value]</i> Example: <pre>(config) # ipv6 pim bsr candidate bsr 2001:DB8:3000:3000::42 124 priority 10</pre>	Configures a switch to be a candidate BSR.
Step 3	interface type number Example: <pre>(config) # interface GigabitEthernet 1/0/1</pre>	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 4	ipv6 pim bsr border Example: <pre>(config-if) # ipv6 pim bsr border</pre>	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 5	exit Example: <pre>(config-if) # exit</pre>	Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.
Step 6	show ipv6 pim bsr {election rp-cache candidate-rp} Example: <pre>(config-if) # show ipv6 pim bsr election</pre>	Displays information related to PIM BSR protocol processing.
Step 7	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Sending PIM RP Advertisements to the BSR

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.

	Command or Action	Purpose
Step 2	ipv6 pim bsr candidate rp <i>ipv6-address</i> [group-list <i>access-list-name</i>] [priority <i>priority-value</i>] [interval <i>seconds</i>] Example: <pre>(config) # ipv6 pim bsr candidate rp 2001:DB8:3000:3000::42 priority 0</pre>	Sends PIM RP advertisements to the BSR.
Step 3	interface <i>type number</i> Example: <pre>(config) # interface GigabitEthernet 1/0/1</pre>	Specifies an interface type and number, and places the switch in interface configuration mode.
Step 4	ipv6 pim bsr border Example: <pre>(config-if) # ipv6 pim bsr border</pre>	Configures a border for all BSMs of any scope on a specified interface.
Step 5	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring BSR for Use Within Scoped Zones

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	ipv6 pim bsr candidate rp <i>ipv6-address</i> [<i>hash-mask-length</i>] [priority <i>priority-value</i>] Example: <pre>(config) # ipv6 pim bsr candidate bsr 2001:DB8:1:1:4</pre>	Configures a switch to be a candidate BSR.
Step 3	ipv6 pim bsr candidate rp <i>ipv6-address</i> [group-list <i>access-list-name</i>] [priority <i>priority-value</i>] [interval <i>seconds</i>] Example: <pre>(config) # ipv6 pim bsr candidate rp 2001:DB8:1:1:1 group-list list scope 6</pre>	Configures the candidate RP to send PIM RP advertisements to the BSR.
Step 4	interface <i>type number</i> Example:	Specifies an interface type and number, and places the switch in interface configuration mode.

	Command or Action	Purpose
	<code>(config-if) # interface GigabitEthernet 1/0/1</code>	
Step 5	ipv6 multicast boundary scope <i>scope-value</i> Example: <code>(config-if) # ipv6 multicast boundary scope 6</code>	Configures a multicast boundary on the interface for a specified scope.
Step 6	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring BSR Switches to Announce Scope-to-RP Mappings

IPv6 BSR switches can be statically configured to announce scope-to-RP mappings directly instead of learning them from candidate-RP messages. A user might want to configure a BSR switch to announce scope-to-RP mappings so that an RP that does not support BSR is imported into the BSR. Enabling this feature also allows an RP positioned outside the enterprise's BSR domain to be learned by the known remote RP on the local candidate BSR switch.

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	ipv6 pim bsr announced rp <i>ipv6-address</i> [group-list <i>access-list-name</i>] [priority <i>priority-value</i>] Example: <code>(config)# ipv6 pim bsr announced rp 2001:DB8:3000:3000::42 priority 0</code>	Announces scope-to-RP mappings directly from the BSR for the specified candidate RP.
Step 3	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring SSM Mapping

When the SSM mapping feature is enabled, DNS-based SSM mapping is automatically enabled, which means that the switch will look up the source of a multicast MLD version 1 report from a DNS server.

You can use either DNS-based or static SSM mapping, depending on your switch configuration. If you choose to use static SSM mapping, you can configure multiple static SSM mappings. If multiple static SSM mappings are configured, the source addresses of all matching access lists will be used.

Note To use DNS-based SSM mapping, the switch needs to find at least one correctly configured DNS server, to which the switch may be directly attached.

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.
Step 2	ipv6 mld ssm-map enable Example: (config) # ipv6 mld ssm-map enable	Enables the SSM mapping feature for groups in the configured SSM range.
Step 3	no ipv6 mld ssm-map query dns Example: (config) # no ipv6 mld ssm-map query dns	Disables DNS-based SSM mapping.
Step 4	ipv6 mld ssm-map static <i>access-list source-address</i> Example: (config-if) # ipv6 mld ssm-map static SSM_MAP_ACL_2 2001:DB8:1::1	Configures static SSM mappings.
Step 5	exit Example: (config-if) # exit	Exits global configuration mode, and returns the switch to privileged EXEC mode.
Step 6	show ipv6 mld ssm-map [<i>source-address</i>] Example: (config-if) # show ipv6 mld ssm-map	Displays SSM mapping information.
Step 7	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Configuring Static Mroutes

Static multicast routes (mroutes) in IPv6 can be implemented as an extension of IPv6 static routes. You can configure your switch to use a static route for unicast routing only, to use a static multicast route for multicast RPF selection only, or to use a static route for both unicast routing and multicast RPF selection.

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enter global configuration mode.

	Command or Action	Purpose
Step 2	ipv6 route { <i>ipv6-prefix / prefix-length ipv6-address interface-type interface-number ipv6-address</i> } [<i>administrative-distance</i>] [<i>administrative-multicast-distance</i>] [<i>unicast</i> <i>multicast</i>] [tag tag] Example: <pre>(config) # ipv6 route 2001:DB8::/64 6::6 100</pre>	Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.
Step 3	exit Example: <pre># exit</pre>	Exits global configuration mode, and returns the switch to privileged EXEC mode.
Step 4	show ipv6 mroute [<i>link-local</i> [<i>group-name</i> <i>group-address</i> [<i>source-address</i> <i>source-name</i>]]] [summary] [count] Example: <pre># show ipv6 mroute ff07::1</pre>	Displays the contents of the IPv6 multicast routing table.
Step 5	show ipv6 mroute [<i>link-local</i> <i>group-name</i> <i>group-address</i>] active [<i>kpbs</i>] Example: <pre>(config-if) # show ipv6 mroute active</pre>	Displays the active multicast streams on the switch.
Step 6	show ipv6 rpf [<i>ipv6-prefix</i>] Example: <pre>(config-if) # show ipv6 rpf 2001::1:1:2</pre>	Checks RPF information for a given unicast host address and prefix.
Step 7	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Using MFIB in IPv6 Multicast

Multicast forwarding is automatically enabled when IPv6 multicast routing is enabled.

Verifying MFIB Operation in IPv6 Multicast

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	show ipv6 mfib [linkscope verbose <i>group-address-name</i> <i>ipv6-prefix / prefix-length</i> <i>source-address-name</i> count interface status summary]	Displays the forwarding entries and interfaces in the IPv6 MFIB.

	Command or Action	Purpose
	Example: <pre># show ipv6 mfib</pre>	
Step 2	show ipv6 mfib [all linkscope group-name group-address [source-name source-address]] count Example: <pre># show ipv6 mfib ff07::1</pre>	Displays the contents of the IPv6 multicast routing table.
Step 3	show ipv6 mfib interface Example: <pre># show ipv6 mfib interface</pre>	Displays information about IPv6 multicast-enabled interfaces and their forwarding status.
Step 4	show ipv6 mfib status Example: <pre># show ipv6 mfib status</pre>	Displays general MFIB configuration and operational status.
Step 5	show ipv6 mfib summary Example: <pre># show ipv6 mfib summary</pre>	Displays summary information about the number of IPv6 MFIB entries and interfaces.
Step 6	debug ipv6 mfib [group-name group-address] [adjacency db fs init interface mrib [detail] nat pak platform ppr ps signal table] Example: <pre># debug ipv6 mfib FF04::10 pak</pre>	Enables debugging output on the IPv6 MFIB.

Resetting MFIB Traffic Counters

Beginning in privileged EXEC mode, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	clear ipv6 mfib counters [group-name group-address [source-address source-name]] Example: <pre># clear ipv6 mfib counters FF04::10</pre>	Resets all active MFIB traffic counters.

Prerequisites for IPv6 Client Address Learning

Before configuring IPv6 client address learning, configure the wireless clients to support IPv6.

Related Topics

[Configuring RA Guard Policy \(CLI\)](#), on page 247

Information About IPv6 Client Address Learning

Client Address Learning is configured on device to learn the wireless client's IPv4 and IPv6 address and clients transition state maintained by the device on an association, re-association, de-authentication and timeout.

There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static Configuration

For all of these methods, the IPv6 client always sends neighbor solicitation DAD (Duplicate Address Detection) request to ensure there is no duplicate IP address on the network. The device snoops the client's NDP and DHCPv6 packets to learn about its client IP addresses.

SLAAC Address Assignment

The most common method for IPv6 client address assignment is Stateless Address Auto-Configuration (SLAAC). SLAAC provides simple plug-and-play connectivity where clients self-assign an address based on the IPv6 prefix. This process is achieved

Stateless Address Auto-Configuration (SLAAC) is configured as follows:

- Host sends a router solicitation message.
- Hosts wait for a Router Advertisement message.
- Hosts take the first 64 bits of the IPv6 prefix from the Router Advertisement message and combine it with the 64 bit EUI-64 address (in the case of ethernet, this is created from the MAC Address) to create a global unicast message. The host also uses the source IP address, in the IP header, of the Router Advertisement message, as its default gateway.
- Duplicate Address Detection is performed by IPv6 clients in order to ensure that random addresses that are picked do not collide with other clients.
- The choice of algorithm is up to the client and is often configurable.

The last 64 bits of the IP v6 address can be learned based on the following 2 algorithms:

- EUI-64 which is based on the MAC address of the interface, or
- Private addresses that are randomly generated.

Figure 8: SLAAC Address Assignment

The following Cisco IOS configuration commands from a Cisco-capable IPv6 router are used to enable SLAAC addressing and router advertisements:

```
ipv6 unicast-routing
interface Vlan20
```

```

description IPv6-SLAAC
ip address 192.168.20.1 255.255.255.0
ipv6 address FE80:DB8:0:20::1 linklocal
ipv6 address 2001:DB8:0:20::1/64
ipv6 enable
end

```

Stateful DHCPv6 Address Assignment

Figure 9: Stateful DHCPv6 Address Assignment

The use of DHCPv6 is not required for IPv6 client connectivity if SLAAC is already deployed. There are two modes of operation for DHCPv6 called Stateless and Stateful.

The DHCPv6 Stateless mode is used to provide clients with additional network information that is not available in the router advertisement, but not an IPv6 address as this is already provided by SLAAC. This information can include the DNS domain name, DNS server(s), and other DHCP vendor-specific options. This interface configuration is for a Cisco IOS IPv6 router implementing stateless DHCPv6 with SLAAC enabled:

```

ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPv6-DHCP-Stateless
ip address 192.168.20.1 255.255.255.0
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPPPOOL
ipv6 address 2001:DB8:0:20::1/64
end

```

The DHCPv6 Stateful option, also known as managed mode, operates similarly to DHCPv4 in that it assigns unique addresses to each client instead of the client generating the last 64 bits of the address as in SLAAC. This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on a local Device:

```

ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20

```

```

description IPv6-DHCP-Stateful
ip address 192.168.20.1 255.255.255.0
ipv6 address 2001:DB8:0:20::1/64
ipv6 nd prefix 2001:DB8:0:20::/64 no-advertise
ipv6 nd managed-config-flag
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPOOL
end

```

This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on an external DHCP server:

```

ipv6 unicast-routing
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPv6-DHCP-Stateful
ip address 192.168.20.1 255.255.255.0
ipv6 address 2001:DB8:0:20::1/64
ipv6 nd prefix 2001:DB8:0:20::/64 no-advertise
ipv6 nd managed-config-flag
ipv6 nd other-config-flag
ipv6 dhcp_relay destination 2001:DB8:0:20::2
end

```

Static IP Address Assignment

Statically configured address on a client.

Router Solicitation

A Router Solicitation message is issued by a host controller to facilitate local routers to transmit Router Advertisement from which it can obtain information about local routing or perform Stateless Auto-configuration. Router Advertisements are transmitted periodically and the host prompts with an immediate Router Advertisement using a Router Solicitation such as - when it boots or following a restart operation.

- [Configuring IPv6 ND Suppress Policy \(CLI\), on page 252](#)

Router Advertisement

A Router Advertisement message is issued periodically by a router or in response to a Router Solicitation message from a host. The information contained in these messages is used by hosts to perform Stateless Auto-configuration and to modify its routing table.

Related Topics

Neighbor Discovery

IPv6 Neighbor Discovery is a set of messages and processes that determine relationships between neighboring nodes. Neighbor Discovery replaces ARP, ICMP Router Discovery, and ICMP Redirect used in IPv4.

IPv6 Neighbor Discovery inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery packets that do not comply are dropped. The neighbor binding table in the switch tracks each IPv6 address and its associated MAC address. Clients are expired from the table according to Neighbor Binding timers.

Related Topics

Neighbor Discovery Suppression

The IPv6 addresses of wireless clients are cached by the device. When the device receives an NS multicast looking for an IPv6 address, and if the target address is known to the device and belongs to one of its clients, the device will reply with an NA message on behalf of the client. The result of this process generates the equivalent of the Address Resolution Protocol (ARP) table of IPv4 but is more efficient - uses generally fewer messages.

Note The device acts like proxy and respond with NA, only when the **ipv6 nd suppress** command is configured

If the device does not have the IPv6 address of a wireless client, the device will not respond with NA and forward the NS packet to the wireless side. To resolve this, an NS Multicast Forwarding knob is provided. If this knob is enabled, the device gets the NS packet for the IPv6 address that it does not have (cache miss) and forwards it to the wireless side. This packet reaches the intended wireless client and the client replies with NA.

This cache miss scenario occurs rarely, and only very few clients which do not implement complete IPv6 stack may not advertise their IPv6 address during NDP.

RA Guard

IPv6 clients configure IPv6 addresses and populate their router tables based on IPv6 router advertisement (RA) packets. The RA guard feature is similar to the RA guard feature of wired networks. RA guard increases the security of the IPv6 network by dropping the unwanted or rogue RA packets that come from wireless clients. If this feature is not configured, malicious IPv6 wireless clients announce themselves as the router for the network often with high priority, which would take higher precedence over legitimate IPv6 routers.

RA-Guard also examines the incoming RA's and decides whether to switch or block them based solely on information found in the message or in the switch configuration. The information available in the frames received is useful for RA validation:

- Port on which the frame is received
- IPv6 source address

- Prefix list

The following configuration information created on the switch is available to RA-Guard to validate against the information found in the received RA frame:

- Trusted/Untrusted ports for receiving RA-guard messages
- Trusted/Untrusted IPv6 source addresses of RA-sender
- Trusted/Untrusted Prefix list and Prefix ranges
- Router Preference

RA guard occurs at the device. You can configure the device to drop RA messages at the device. All IPv6 RA messages are dropped, which protects other wireless clients and upstream wired network from malicious IPv6 clients.

```
//Create a policy for RA Guard//
ipv6 nd raguard policy raguard-router
trusted-port
device-role router

//Applying the RA Guard Policy on port/interface//
interface tengigabitethernet1/0/1 (Katana)
interface gigabitethernet1/0/1 (Edison)

ipv6 nd raguard attach-policy raguard-router
```

RA Throttling

RA throttling allows the controller to enforce limits to RA packets headed toward the wireless network. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will still maintain an IPv6 client connectivity. If a client sends an RS packet, an RA is sent back to the client. This RA is allowed through the controller and unicast to the client. This process ensures that the new clients or roaming clients are not affected by the RA throttling.

Configuring IPv6 Unicast (CLI)

IPv6 unicasting must always be enabled on the switch and the controller. IPv6 unicast routing is disabled.

Before you begin

To enable the forwarding of IPv6 unicast datagrams, use the **ipv6 unicast-routing** command in global configuration mode. To disable the forwarding of IPv6 unicast datagrams, use the **no** form of this command.

SUMMARY STEPS

1. **configure terminal**
2. **ipv6 unicast routing**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 2	ipv6 unicast routing Example: Device (config)# <code>ipv6 unicast routing</code>	enable the forwarding of IPv6 unicast datagrams

Configuring RA Guard Policy (CLI)

Configure RA Guard policy on the device to add IPv6 client addresses and populate the router table based on IPv6 router advertisement packets.

SUMMARY STEPS

1. **configure terminal**
2. **ipv6 nd rguard policy rguard-router**
3. **trustedport**
4. **device-role router**
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 2	ipv6 nd rguard policy rguard-router Example:	Defines the RA guard policy name and enters RA guard policy configuration mode.

	Command or Action	Purpose
	Device(config)# ipv6 nd rguard policy rguard-router	
Step 3	trustedport Example: Device(config-ra-guard)# trustedport	(Optional) Specifies that this policy is being applied to trusted ports.
Step 4	device-role router Example: Device(config-ra-guard)# device-role router	Specifies the role of the device attached to the port.
Step 5	exit Example: Device(config-ra-guard)# exit	Exits RA guard policy configuration mode and returns to global configuration mode.

Applying RA Guard Policy (CLI)

Applying the RA Guard policy on the device will block all the untrusted RA's.

SUMMARY STEPS

1. **configure terminal**
2. **interface tengigabitethernet 1/0/1**
3. **ipv6 nd rguard attach-policy rguard-router**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	interface tengigabitethernet 1/0/1 Example:	Specifies an interface type and number, and places the device in interface configuration mode.

	Command or Action	Purpose
	Device (config)# interface tengigabitethernet 1/0/1	
Step 3	ipv6 nd rguard attach-policy rguard-router Example: Device(config-if)# ipv6 nd rguard attach-policy rguard-router	Applies the IPv6 RA Guard feature to a specified interface.
Step 4	exit Example: Device(config-if)# exit	Exits interface configuration mode.

Configuring RA Throttle Policy (CLI)

Configure RA Throttle policy to allow the enforce the limits

SUMMARY STEPS

1. **configure terminal**
2. **ipv6 nd ra-throttler policy ra-throttler1**
3. **throttleperiod500**
4. **max-through10**
5. **allow-atleast 5 at-most 10**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ipv6 nd ra-throttler policy ra-throttler1 Example: Device(config)# ipv6 nd ra-throttler policy ra-throttler1	Define the router advertisement (RA) throttler policy name and enter IPv6 RA throttle policy configuration mode.

	Command or Action	Purpose
Step 3	throttleperiod500 Example: Device(config-nd-ra-throttle)# throttleperiod 500	Configures the throttle period in an IPv6 RA throttler policy.
Step 4	max-through10 Example: Device(config-nd-ra-throttle)# max-through 500	Limits multicast RAs per VLAN per throttle period.
Step 5	allow-atleast 5 at-most 10 Example: Device(config-nd-ra-throttle)# allow-atleast 5 at-most 10	Limits the number of multicast RAs per device per throttle period in an RA throttler policy.

Applying RA Throttle Policy on VLAN (CLI)

Applying the RA Throttle policy on a VLAN. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will still maintain an IPv6 client connectivity.

SUMMARY STEPS

1. **configure terminal**
2. **vlan configuration 1**
3. **ipv6 nd ra throttler attach-policy ra-throttler1**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	vlan configuration 1 Example: Device(config)# vlan configuration 1	Configures a VLAN or a collection of VLANs and enters VLAN configuration mode.

	Command or Action	Purpose
Step 3	ipv6 nd ra throttler attach-policy ra-throttler1 Example: Device(config-vlan)# ipv6 nd ra throttler attach-policy ra-throttler1	Attaches an IPv6 RA throttler policy to a VLAN or a collection of VLANs.

Configuring IPv6 Snooping (CLI)

IPv6 snooping must always be enabled on the switch and the controller.

Before you begin

Enable IPv6 on the client machine.

SUMMARY STEPS

1. **vlan configuration 1**
2. **ipv6 snooping**
3. **ipv6 nd suppress**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	vlan configuration 1 Example: Device(config)# vlan configuration 1	Enters Vlan configuration mode.
Step 2	ipv6 snooping Example: Device(config-vlan)# ipv6 snooping	Enables IPv6 snooping on the Vlan.
Step 3	ipv6 nd suppress Example: Device(config-vlan-config)# ipv6 nd suppress	Enables the IPv6 ND suppress on the Vlan.

	Command or Action	Purpose
Step 4	exit Example: Device(config-vlan-config)# exit	Saves the configuration and comes out of the Vlan configuration mode.

Configuring IPv6 ND Suppress Policy (CLI)

The IPv6 neighbor discovery (ND) multicast suppress feature stops as many ND multicast neighbor solicit (NS) messages as possible by dropping them (and responding to solicitations on behalf of the targets) or converting them into unicast traffic. This feature runs on a layer 2 switch or a wireless controller and is used to reduce the amount of control traffic necessary for proper link operations.

When an address is inserted into the binding table, an address resolution request sent to a multicast address is intercepted, and the device either responds on behalf of the address owner or, at layer 2, converts the request into a unicast message and forwards it to its destination.

SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 nd suppress policy

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device(config)# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	ipv6 nd suppress policy Example: Device (config)# ipv6 nd suppress policy	Defines the ND suppress policy name and enters ND suppress policy configuration mode.

Configuring IPv6 Snooping on VLAN/PortChannel

Neighbor Discover (ND) suppress can be enabled or disabled on either the VLAN or a switchport.

Before you begin

SUMMARY STEPS

1. `vlan config901`
2. `ipv6 nd suppress`
3. `end`
4. `interface gi1/0/1`
5. `ipv6 nd suppress`
6. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	vlan config901 Example: Device(config)# vlan config901	Creates a VLAN and enter the VLAN configuration mode
Step 2	ipv6 nd suppress Example: Device(config-vlan)# ipv6 nd suppress	Applies the IPv6 nd suppress on VLAN.
Step 3	end Example: Device(config-vlan)# end	Exits vlan configuration mode and enters the global configuration mode.
Step 4	interface gi1/0/1 Example: Device (config)# interface gi1/0/1	Creates a gigabitethernet port interface.
Step 5	ipv6 nd suppress Example: Device(config-vlan)# ipv6 nd suppress	Applies the IPv6 nd suppress on the interface.
Step 6	end Example: Device(config-vlan)# end	Exits vlan configuration mode and enters the global configuration mode.

Configuring IPv6 on Switch (CLI)

Use this configuration example to configure IPv6 on an interface.

Before you begin

Enable IPv6 on the client and IPv6 support on the wired infrastructure.

SUMMARY STEPS

1. **interface vlan 1**
2. **ip address fe80::1 link-local**
3. **ipv6 enable**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	interface vlan 1 Example: Device(config)# interface vlan 1	Creates a interface and enters interface configuration mode.
Step 2	ip address fe80::1 link-local Example: Device(config-if)# ip address 198.51.100.1 255.255.255.0 Device(config-if)# ipv6 address fe80::1 link-local Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64 Device(config-if)# ipv6 address 2001:DB8:0:0:E000::F/64	Configures IPv6 address on the interface using the link-local option.
Step 3	ipv6 enable Example: Device(config)# ipv6 enable	(Optional) Enables IPv6 on the interface.
Step 4	end Example: Device(config)# end	Exits from the interface mode.

Configuring DHCP Pool (CLI)

SUMMARY STEPS

1. **ipv6 dhcp pool Vlan21**

2. **address prefix 2001:DB8:0:1:FFFF:1234::/64 lifetime 300 10**
3. **dns-server 2001:100:0:1::1**
4. **domain-name example.com**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	ipv6 dhcp pool vlan21 Example: Device(config)# ipv6 dhcp pool vlan1	Enters the configuration mode and configures the IPv6 DHCP pool on the Vlan.
Step 2	address prefix 2001:DB8:0:1:FFFF:1234::/64 lifetime 300 10 Example: Device(config-dhcpv6)# address prefix 2001:DB8:0:1:FFFF:1234::/64 lifetime 300 10	Enters the configuration-dhcp mode and configures the address pool and its lifetime on a Vlan.
Step 3	dns-server 2001:100:0:1::1 Example: Device(config-dhcpv6)# dns-server 2001:20:21::1	Configures the DNS servers for the DHCP pool.
Step 4	domain-name example.com Example: Device(config-dhcpv6)# domain-name example.com	Configures the domain name to complete unqualified host names.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

12. **ipv6 nd prefix 2001:db8::/64 no-advertise**
13. **ipv6 nd managed-config-flag**
14. **ipv6 nd other-config-flag**
15. **ipv6 dhcp server IPv6_DHCPPPOOL**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ipv6 unicast-routing Example: Device(config)# ipv6 unicast-routing	Configures IPv6 for unicasting.
Step 3	ipv6 dhcp pool IPv6_DHCPPPOOL Example: Device (config)# ipv6 dhcp pool IPv6_DHCPPPOOL	Enters the configuration mode and configures the IPv6 DHCP pool on the VLAN.
Step 4	address prefix 2001:DB8:0:1:FFFF:1234::/64 Example:	Specifies the address range to provide in the pool.

	Command or Action	Purpose
	Device (config-dhcpv6)# address prefix 2001:DB8:0:1:FFFF:1234::/64	
Step 5	dns-server 2001:100:0:1::1 Example: Device (config-dhcpv6)# dns-server 2001:100:0:1::1	Provides the DNS server option to DHCP clients.
Step 6	domain-name example.com Example: Device (config-dhcpv6)# domain-name example.com	Provides the domain name option to DHCP clients.
Step 7	exit Example: Device (config-dhcpv6)# exit	Returns to the previous mode.
Step 8	interface vlan1 Example: Device (config)# interface vlan 1	Enters the interface mode to configure the stateful DHCP.
Step 9	description IPv6-DHCP-Stateful Example: Device (config-if)# description IPv6-DHCP-Stateful	Enter description for the stateful IPv6 DHCP.
Step 10	ipv6 address 2001:DB8:0:20::1/64 Example: Device (config-if)# ipv6 address 2001:DB8:0:20::1/64	Enters the IPv6 address for the stateful IPv6 DHCP.
Step 11	ip address 192.168.20.1 255.255.255.0 Example: Device (config-if)# ip address 192.168.20.1 255.255.255.0	Enters the IPv6 address for the stateful IPv6 DHCP.
Step 12	ipv6 nd prefix 2001:db8::/64 no-advertise Example: Device (config-if)# ipv6 nd prefix 2001:db8::/64 no-advertise	Configures the IPv6 routing prefix advertisement that must not be advertised.
Step 13	ipv6 nd managed-config-flag Example: Device (config-if)# ipv6 nd managed-config-flag	Configures IPv6 interfaces neighbor discovery to allow the hosts to uses DHCP for address configuration.
Step 14	ipv6 nd other-config-flag Example: Device (config-if)# ipv6 nd other-config-flag	Configures IPv6 interfaces neighbor discovery to allow the hosts to uses DHCP for non-address configuration.

	Command or Action	Purpose
Step 15	ipv6 dhcp server IPv6_DHCPPPOOL Example: Device (config-if)# ipv6 dhcp server IPv6_DHCPPPOOL	Configures the DHCP server on the interface.

Monitoring IPv6 Clients (GUI)

To view the IPv6 clients associated with the Device

Select **Monitor > Clients**

The Clients page is displayed. The Clients page contains the following details:

- Client MAC Address— Displays the MAC address of the client.
- AP Name— Displays the access point name to which the client is connected to.
- WLAN— Displays the WLAN associated with the client.
- State— Displays the client authentication.
- Protocol— Displays the protocol used.

To view the client related general details, click the **Client MAC Address** parameter in the Clients page. The **Client > Detail** page displays IPv6 addresses of the client under the **General** tab.

Verifying IPv6 Address Learning Configuration

This example displays the output of the **show ipv6 dhcp pool** command. This command displays the IPv6 service configuration on the device. The vlan 21 configured pool detail displays 6 clients that are currently using addresses from the pool.

SUMMARY STEPS

1. **show ipv6 dhcp pool**

DETAILED STEPS

	Command or Action	Purpose
Step 1	show ipv6 dhcp pool Example: <pre>Device# show ipv6 dhcp pool DHCPv6 pool: vlan21 Address allocation prefix: 2001:DB8:0:1:FFFF:1234::/64 valid 86400 preferred 86400 (6 in use, 0 conflicts)</pre>	Displays the IPv6 service configuration on the device.

	Command or Action	Purpose
	DNS server: 2001:100:0:1::1 Domain name: example.com Active clients: 6

- [Feature Information for IPv6 WLAN Security, on page 285](#)

Prerequisites for IPv6 WLAN Security

A client VLAN must be mapped to the WLAN configured on the device

Restrictions for IPv6 WLAN Security

RADIUS Server Support

- If multiple RADIUS servers are configured for redundancy, the user database must be identical in all the servers for the backup to work properly.

Radius ACS Support

- You must configure RADIUS on both your Cisco Secure Access Control Server (ACS) and your device
- RADIUS is supported on Cisco Secure ACS version 3.2 and later releases.

Information About IPv6 WLAN Security

Information About RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a client/server protocol that provides centralized security for users attempting to gain management access to a network. It serves as a back-end database similar to Local EAP and provides authentication and accounting services.

- **Authentication**—The process of verifying users when they attempt to log into the device

Users must enter a valid username and password for the device to authenticate users to the RADIUS server. If multiple databases are configured, then specify the sequence in which the backend database must be tried.

- **Accounting**— The process of recording user actions and changes.

Whenever a user successfully executes an action, the RADIUS accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided. If the RADIUS accounting server is unreachable, the users can continue their sessions uninterrupted.

User Datagram Protocol— RADIUS uses User Datagram Protocol (UDP) for its transport. It maintains a database and listens on UDP port 1812 for incoming authentication requests and UDP port 1813 for incoming accounting requests. The device, which requires access control, acts as the client and requests AAA services from the server. The traffic between the device and the server is encrypted by an algorithm defined in the protocol and a shared secret key configured on both devices.

Configures multiple RADIUS accounting and authentication servers. For example, you can have one central RADIUS authentication server but several RADIUS accounting servers in different regions. If you configure multiple servers of the same type and the first one fails or becomes unreachable, the controller automatically tries the second one, then the third one if necessary, and so on.

When RADIUS method is configured for the WLAN, the device will use the RADIUS method configured for the WLAN. When the WLAN is configured to use local EAP, the RADIUS method configured on the WLAN points to Local. The WLAN must also be configured with the name of the local EAP profile to use.

If no RADIUS method is configured in the WLAN, the device will use the default RADIUS method defined in global mode.

Information About Local EAP

Local EAP is an authentication method that allows users and wireless clients to be authenticated locally. It is designed for use in remote offices that maintain connectivity to wireless clients when the back-end system is disrupted or the external authentication server goes down. When you enable local EAP, the device serves as the authentication server and the local user database, which removes dependence on an external authentication server. Local EAP retrieves user credentials from the local user database or the LDAP back-end database to authenticate users. Local EAP supports LEAP, EAP-FAST, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC authentication between the controller and wireless clients.

Without an EAP profile name being provided, or if a name was provided for an EAP profile that does not exist, then EAP by default allows no EAP method for local authentication.

Note

The LDAP back-end database supports these local EAP methods: EAP-TLS, EAP-FAST/GTC, and PEAPv1/GTC. LEAP, EAP-FAST/MSCHAPv2, and PEAPv0. MSCHAPv2 is supported only if the LDAP server is set up to return a clear-text password.

Note Device support Local EAP authentication against external LDAP databases such as Microsoft Active Directory and Novell's eDirectory. For more information about configuring the controller for Local EAP authentication against Novell's eDirectory, see the [Configure Unified Wireless Network for Authentication Against Novell's eDirectory Database whitepaper](#).

How to Configure IPv6 WLAN Security

Configuring Local Authentication

Creating a Local User

SUMMARY STEPS

1. `configure terminal`
2. `username aaa_test`
3. `password 0 aaa_test`
4. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>configure terminal</code> Example: Device# <code>configure terminal</code>	Enters global command mode.
Step 2	<code>username aaa_test</code> Example: Device(config)# <code>username aaa_test</code>	Creates a username.
Step 3	<code>password 0 aaa_test</code> Example: Device(config)# <code>usernameaaa_test password 0 aaa_test</code>	Assigns a password for the username.
Step 4	<code>end</code> Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.

```
Device# configure terminal
Device(config)# username aaa_test password 0 aaa_test
Device(config)# end
```

[Information About IPv6 WLAN Security](#), on page 265

Creating an Client VLAN and Interface

SUMMARY STEPS

1. `configure terminal`

2. **vlan**
3. **exit**
4. **interface vlan vlan_ID**
5. **ip address**
6. **ipv6 address**
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global command mode.
Step 2	vlan Example: Device(config)# vlan 137	Creates a VLAN.
Step 3	exit Example: Device (config-vlan)# exit	Exits VLAN configuration mode.
Step 4	interface vlan vlan_ID Example: Device (config)# interface vlan 137	Associates the VLAN to an interface.
Step 5	ip address Example: Device(config-if)# ip address 10.7.137.10 255.255.255.0	Assigns an IP address to the VLAN interface.
Step 6	ipv6 address Example: Device(config-if)# ipv6 address 2001:db8::20:1/64	Assigns an IPv6 address to the VLAN interface.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.

Example

```
Device# configure terminal
Device(config)# vlan 137
Device(config-vlan)#exit
Device(config)#interface vlan 137
Device(config-if)#ip address 10.7.137.10 255.255.255.0
```

```
Device(config-if)#ipv6 address 2001:db8::20:1/64
Device(config-if)#end
```

Configuring a EAP Profile

SUMMARY STEPS

1. **eap profile name**
2. **method leap**
3. **method tls**
4. **method peap**
5. **method mschapv2**
6. **method md5**
7. **method gtc**
8. **method fast profile my-fast**
9. **description my_local leap profile**
10. **exit**
11. **eap method fast profile myFast**
12. **authority-id [identity|information]**
13. **local-key 0 key-name**
14. **pac-password 0 password**
15. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	eap profile name Example: Device(config)# eap profile wcm_eap_prof	Creates a EAP profile.
Step 2	method leap Example: Device(config-eap-profile)# method leap	Configures EAP-LEAP method on the profile.
Step 3	method tls Example: Device(config-eap-profile)# method tls	Configures EAP-TLS method on the profile.
Step 4	method peap Example: Device(config-eap-profile)# method peap	Configures PEAP method on the profile.

	Command or Action	Purpose
Step 5	method mschapv2 Example: Device(config-eap-profile)# method mschapv2	Configures EAP-MSCHAPV2 method on the profile.
Step 6	method md5 Example: Device(config-eap-profile)# method md5	Configures EAP-MD5 method on the profile.
Step 7	method gtc Example: Device(config-eap-profile)# method gtc	Configures EAP-GTC method on the profile.
Step 8	method fast profile my-fast Example: Device(config-eap-profile)# eap method fast profile my-fast Device (config-eap-profile)#description my_local eap profile	Creates a EAP profile named my-fast.
Step 9	description my_local eap profile Example: Device (config-eap-profile)#description my_local eap profile	Provides a description for the local profile.
Step 10	exit Example: Device (config-eap-profile)# exit	Exits the eap-profile configuration mode.
Step 11	eap method fast profile myFast Example: Device (config)# eap method fast profile myFast	Configures the EAP method profile.
Step 12	authority-id [identity information] Example: Device(config-eap-method-profile)# authority-id identity my_identity Device(config-eap-method-profile)#authority-id information my_information	Configure the authority ID and information for the EAP method profile.
Step 13	local-key 0 key-name Example: Device(config-eap-method-profile)# local-key 0 test	Configures the local server key.
Step 14	pac-password 0 password Example:	Configures the PAC password for manual PAC provisioning.

	Command or Action	Purpose
	Device(config-eap-method-profile)# pac-password 0 test	
Step 15	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.

Example

```

Device(config)#eap profile wcm_eap_prof
Device(config-eap-profile)#method leap
Device(config-eap-profile)#method tls
Device(config-eap-profile)#method peap
Device(config-eap-profile)#method mschapv2
Device(config-eap-profile)#method md5
Device(config-eap-profile)#method gtc
Device(config-eap-profile)#eap method fast profile my-fast
Device (config-eap-profile)#description my_local eap profile
Device(config-eap-profile)# exit
Device (config)# eap method fast profile myFast
Device(config-eap-method-profile)#authority-id identity my_identity
Device(config-eap-method-profile)#authority-id information my_information
Device(config-eap-method-profile)#local-key 0 test
Device(config-eap-method-profile)#pac-password 0 test
Device(config-eap-method-profile)# end

```

Creating a Local Authentication Model

SUMMARY STEPS

1. **aaa new-model**
2. **authentication dot1x default local**
3. **dot1x method_list local**
4. **aaa authentication dot1x dot1x_name local**
5. **aaa authorization credential-download name local**
6. **aaa local authentication auth-name authorization authorization-name**
7. **session ID**
8. **dot1x system-auth-control**

DETAILED STEPS

	Command or Action	Purpose
Step 1	aaa new-model Example: Device(config)# aaa new-model	Creates a AAA authentication model.

	Command or Action	Purpose
Step 2	authentication dot1x default local Example: Device(config)# aaa authentication dot1x default local	Implies that the dot1x must use the default local RADIUS when no other method is found.
Step 3	dot1x method_list local Example: Device(config)# aaa authentication dot1x wcm_local local	Assigns the local authentication for wcm_local method list.
Step 4	aaa authentication dot1x dot1x_name local Example: Device(config)# aaa authentication dot1x aaa_auth local	Configures the local authentication for the dot1x method.
Step 5	aaa authorization credential-download name local Example: Device(config)# aaa authorization credential-download wcm_author local	Configures local database to download EAP credentials from Local/RADIUS/LDAP.
Step 6	aaa local authentication auth-name authorization authorization-name Example: Device(config)# aaa local authentication wcm_local authorization wcm_author	Selects local authentication and authorization.
Step 7	session ID Example: Device(config)# aaa session-id common	Configures a session ID for AAA.
Step 8	dot1x system-auth-control Example: Device(config)# dot1x system-auth-control	Enables dot.1x system authentication control.

Example

```

Device(config)# aaa new-model
Device(config)# aaa authentication dot1x default local
Device(config)# aaa authentication dot1x wcm-local local
Device(config)# aaa authentication dot1x aaa_auth local
Device(config)# aaa authorization credential-download wcm_author local
Device(config)# aaa local authentication wcm_local authorization wcm_author
Device(config)# aaa session-id common
Device(config)# dot1x system-auth-control

```

Creating a Client WLAN

Note This example uses 802.1x with dynamic WEP. You can use any other security mechanism supported by the wireless client and configurable on the device

SUMMARY STEPS

1. **configure terminal**
2. **wlan wlan name <identifier> SSID**
3. **broadcast-ssid**
4. **no security wpa**
5. **security dot1x**
6. **security dot1x authentication-list wcm-local**
7. **local-auth wcm_eap_prof**
8. **client vlan 137**
9. **no shutdown**
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global command mode.
Step 2	wlan wlan name <identifier> SSID Example: Device(config)# <code>wlan wlanProfileName 1 ngwcSSID</code>	Creates a WLAN.
Step 3	broadcast-ssid Example: Device(config-wlan)# <code>broadcast-ssid</code>	Configures to broadcast the SSID on a WLAN.
Step 4	no security wpa Example: Device(config-wlan)# <code>no security wpa</code>	Disables the wpa for WLAN to enable 802.1x.
Step 5	security dot1x Example: Device(config-wlan)# <code>security dot1x</code>	Configures the 802.1x encryption security for the WLAN.
Step 6	security dot1x authentication-list wcm-local Example:	Configures the server group mapping to the WLAN for dot1x authentication.

	Command or Action	Purpose
	Device(config-wlan)# security dot1x authentication-list wcm-local	
Step 7	local-auth wcm_eap_prof Example: Device (config-wlan)# local-auth wcm_eap_profile	Configures the eap profile on the WLAN for local authentication.
Step 8	client vlan 137 Example: Device(config-wlan)# client vlan 137	Associates the VLAN to a WLAN.
Step 9	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN.
Step 10	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.

Example

```
Device# config terminal
Device(config)#wlan wlanProfileName 1 ngwcSSID
Device(config-wlan)#broadcast-ssid
Device(config-wlan)#no security wpa
Device(config-wlan)#security dot1x
Device(config-wlan)#security dot1x authentication-list wcm-local
Device (config-wlan)# local-auth wcm_eap_prof
Device(config-wlan)#client vlan 137
Device(config-wlan)#no shutdown
Device(config-wlan)#end
Device#
```

[Creating Client VLAN for WPA2+AES](#), on page 277

Configuring Local Authentication with WPA2+AES

SUMMARY STEPS

1. **configure terminal**
2. **aaa new model**
3. **dot1x system-auth-control**
4. **aaa authentication dot1x default local**
5. **aaa local authorization credential-download default local**
6. **aaa local authentication default authorization default**
7. **eap profile wcm_eap_profile**
8. **method leap**

9. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global command mode.
Step 2	aaa new model Example: Device(config)# <code>aaa new-model</code>	Creates a AAA authentication model.
Step 3	dot1x system-auth-control Example: Device(config)# <code>dot1x system-auth-control</code>	Enables dot1x system authentication control.
Step 4	aaa authentication dot1x default local Example: Device(config)# <code>aaa authentication dot1x default local</code>	Configures the local authentication for the default dot1x method.
Step 5	aaa local authorization credential-download default local Example: Device(config)# <code>aaa authorization credential-download default local</code>	Configures default database to download EAP credentials from local server.
Step 6	aaa local authentication default authorization default Example: Device(config)# <code>aaa local authentication default authorization default</code>	Selects the default local authentication and authorization.
Step 7	eap profile wcm_eap_profile Example: Device(config)# <code>eap profile wcm_eap_profile</code>	Creates an EAP profile.
Step 8	method leap Example: Device(config)# <code>method leap</code>	Configures EAP-LEAP method on the profile.
Step 9	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.

```
Device# configure terminal
Device(config)# aaa new-model
```

```

Device(config)# dot1x system-auth-control
Device(config)# aaa authentication dot1x default local
Device(config)# aaa authorization credential-download default local
Device(config)# aaa local authentication default authorization default
Device(config)# eap profile wcm_eap_profile
Device(config)# method leap
Device(config)# end

```

Creating Client VLAN for WPA2+AES

Create a VLAN for the WPA2+AES type of local authentication. This VLAN is later mapped to a WLAN.

SUMMARY STEPS

1. **configure terminal**
2. **vlan `vlan_ID`**
3. **exit**
4. **interface vlan `vlan_ID`**
5. **ip address**
6. **ipv6 address**
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global command mode.
Step 2	vlan <code>vlan_ID</code> Example: Device (config)# vlan 105	Creates a VLAN.
Step 3	exit Example: Device (config-vlan)# exit	Exits from the VLAN mode.
Step 4	interface vlan <code>vlan_ID</code> Example: Device(config)# interface vlan 105	Associates the VLAN to the interface.
Step 5	ip address Example: Device(config-if)# ip address 10.8.105.10 255.255.255.0	Assigns IP address to the VLAN interface.
Step 6	ipv6 address Example: Device(config-if)# ipv6 address 2001:db8::10:1/64	Assigns IPv6 address to the VLAN interface.

	Command or Action	Purpose
Step 7	exit Example: Device (config-if)# exit	Exits from the interface mode.

```

Device# configure terminal
Device(config)# vlan105
Device (config-vlan)# exit
Device (config)# interface vlan 105
Device(config-if)#ip address 10.8.105.10 255.255.255.0
Device(config-if)#ipv6 address 2001:db8::10:1/64
Device(config-if)#exit
Device(config)#

```

Creating WLAN for WPA2+AES

Create a WLAN and map it to the client VLAN created for WPA2+AES.

SUMMARY STEPS

1. **configure terminal**
2. **wlan wpa2-aes-wlan 1 wpa2-aes-wlan**
3. **client vlan 105**
4. **local-auth wcm_eap_profile**
5. **security dot1x authentication-list default**
6. **no shutdown**
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global command mode.
Step 2	wlan wpa2-aes-wlan 1 wpa2-aes-wlan Example: Device(config)#wlan wpa2-aes-wlan 1 wpa2-aes-wlan Device(config-wlan)#	Creates a WLAN.
Step 3	client vlan 105 Example: Device(config-wlan)#client vlan 105 Device(config-wlan)#	Maps the WLAN to the client VLAN.

	Command or Action	Purpose
Step 4	local-auth wcm_eap_profile Example: Device(config-wlan)#local-auth wcm_eap_profile	Creates and sets the EAP profile on the WLAN.
Step 5	security dot1x authentication-list default Example: Device(config-wlan)#security dot1x authentication-list default	Uses the default dot1x authentication list.
Step 6	no shutdown Example: Device(config-wlan)#no shutdown Device(config-wlan)#	Enables the WLAN.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

```

Device# configure terminal
Device(config)#wlan wpa2-aes-wlan 1 wpa2-aes-wlan
Device(config-wlan)#client vlan 105
Device(config-wlan)#local-auth wcm_eap_profile
Device(config-wlan)#security dot1x authentication-list default
Device(config-wlan)#no shutdown
Device(config-wlan)# exit

```

Configuring External RADIUS Server

Configuring RADIUS Authentication Server Host

SUMMARY STEPS

1. **configure terminal**
2. **radius server One**
3. **address ipv4 address auth-portauth_port_number acct-port acct_port_number**
4. **address ipv6 address auth-portauth_port_number acct-port acct_port_number**
5. **key 0cisco**
- 6.

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global command mode.

	Command or Action	Purpose
Step 2	radius server One Example: Device (config)# radius server One	Creates a radius server.
Step 3	address ipv4 address auth-port auth_port_number acct-port acct_port_number Example: Device (config-radius-server)# address ipv4 10.10.10.10 auth-port 1812 acct-port 1813	Configures the IPv4 address for the radius server.
Step 4	address ipv6 address auth-port auth_port_number acct-port acct_port_number Example: Device (config-radius-server)# address ipv6 2001:db8::25:2 auth-port 1812 acct-port 1813	Configures the IPv6 address for the radius server.
Step 5	key 0 cisco Example: Device (config-radius-server)# key 0 cisco	exit
Step 6	Example: Device (config-radius-server)# exit	Exits from the radius server mode.

```

Device# configure terminal
Device (config)# radius server One
Device (config-radius-server)# address ipv4 10.10.10.10 auth-port 1812 acct-port 1813
Device (config-radius-server)# address ipv6 2001:db8::25:2 auth-port 1812 acct-port 1813
Device (config-radius-server)# key 0 cisco
Device (config-radius-server)# exit

```

Configuring RADIUS Authentication Server Group

SUMMARY STEPS

1. **configure terminal**
2. **aaa new-model**
3. **aaa group server radius wcm_rad**
4. **server <ip address>auth-port1812acct-port1813**
5. **aaa authentication dot1x method_list group wcm_rad**
6. **dot1x system-auth-control**
7. **aaa session-idcommon**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global command mode.
Step 2	aaa new-model Example: Device(config)# <code>aaa new-model</code>	Creates a AAA authentication model.
Step 3	aaa group server radius wcm_rad Example: Device(config)# <code>aaa group server radius wcm_rad</code> Device(config-sg-radius)#	Creates an radius server-group.
Step 4	server <ip address>auth-port1812acct-port1813 Example: Device(config-sg-radius)# <code>server One auth-port 1812 acct-port 1813</code> Device(config-sg-radius)# <code>server Two auth-port 1812 acct-port 1813</code> Device(config-sg-radius)# <code>server Three auth-port 1812 acct-port 1813</code>	Adds servers to the radius group created in Step 3. Configures the UDP port for RADIUS accounting server and authentication server.
Step 5	aaa authentication dot1x method_list group wcm_rad Example: Device(config)# <code>aaa authentication dot1x method_list group wcm_rad</code>	Maps the method list to the radius group.
Step 6	dot1x system-auth-control Example: Device(config)# <code>dot1x system-auth-control</code>	Enables the system authorization control for the radius group.
Step 7	aaa session-idcommon Example: Device(config)# <code>aaa session-id common</code>	Ensures that all session IDs information sent out, from the radius group, for a given call are identical.

```

Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa group server radius wcm_rad
Device(config-sg-radius)# server One auth-port 1812 acct-port 1813
Device(config-sg-radius)# server Two auth-port 1812 acct-port 1813
Device(config-sg-radius)# server Three auth-port 1812 acct-port 1813

Creating a Client VLAN**SUMMARY STEPS**

1. **configure terminal**
2. **vlan 137**
3. **exit**
4. **interface vlan 137**
5. **ip address 10.7.137.10 255.255.255.0**
6. **ipv6 address 2001:db8::30:1/64**
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global command mode.
Step 2	vlan 137 Example: Device(config)# <code>vlan 137</code>	Creates a VLAN and associate it to the interface.
Step 3	exit Example: Device (config-vlan)# <code>exit</code>	Exits from the VLAN mode.
Step 4	interface vlan 137 Example: Device (config)# <code>interface vlan 137</code>	Assigns a VLAN to an interface.
Step 5	ip address 10.7.137.10 255.255.255.0 Example: Device(config-if)# <code>ip address 10.7.137.10 255.255.255.0</code>	Assigns an IPv4 address to the VLAN interface.
Step 6	ipv6 address 2001:db8::30:1/64 Example: Device(config-if)# <code>ipv6 address 2001:db8::30:1/64</code>	Assigns an IPv6 address to the VLAN interface.
Step 7	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

```

Device# configure terminal
Device(config)# vlan137
Device(config-vlan)# exit
Device(config)# interface vlan137
Device(config-if)# ip address 10.7.137.10 255.255.255.0
Device(config-if)# ipv6 address 2001:db8::30:1/64
Device(config-if)# end

```

Creating 802.1x WLAN Using an External RADIUS Server

SUMMARY STEPS

1. **configure terminal**
2. **wlan ngwc-1x<ssid>ngwc-1x**
3. **broadcast-ssid**
4. **no security wpa**
5. **security dot1x**
6. **security dot1x authentication-list wcm-rad**
7. **client vlan 137**
8. **no shutdown**
9. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global command mode.
Step 2	wlan ngwc-1x<ssid>ngwc-1x Example: Device(config)# wlan ngwc_8021x 2 ngwc_8021x	Creates a new WLAN for 802.1x authentication.
Step 3	broadcast-ssid Example: Device(config-wlan)# broadcast-ssid	Configures to broadcast the SSID on WLAN.
Step 4	no security wpa Example: Device(config-wlan)# no security wpa	Disables the WPA for WLAN to enable 802.1x.
Step 5	security dot1x Example: Device(config-wlan)# security dot1x	Configures the 802.1x encryption security for the WLAN.

	Command or Action	Purpose
Step 6	security dot1x authentication-list wcm-rad Example: Device(config-wlan)# security dot1x authentication-list wcm-rad	Configures the server group mapping to the WLAN for dot1x authentication.
Step 7	client vlan 137 Example: Device(config-wlan)# client vlan 137	Associates the VLAN to a WLAN.
Step 8	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN.
Step 9	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.

Example

```

Device# configure terminal
Device(config)#wlan ngwc_8021x 2 ngwc_8021x
Device(config-wlan)# broadcast-ssid
Device(config-wlan)# no security wpa
Device(config-wlan)# security dot1x
Device(config-wlan)# security dot1x authentication-list wcm-rad
Device(config-wlan)# client vlan 137
Device(config-wlan)# no shutdown
Device(config-wlan)# end

```

Prerequisites for IPv6 ACL

You can filter IP Version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP Version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic when the switch is running the IP base feature set.

Related Topics

[Creating IPv6 ACL, on page 291](#)

Restrictions for IPv6 ACL

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs.

The device supports most of the Cisco IOS-supported IPv6 ACLs with some exceptions:

- The device does not support matching on these keywords: **flowlabel**, **routing header**, and **undetermined-transport**.
- The device does not support reflexive ACLs (the **reflect** keyword).
- The device does not apply MAC-based ACLs on IPv6 frames.
- When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware

forwarding (physical ports or SVIs), the device checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.

- If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the device does not allow the ACE to be added to the ACL that is currently attached to the interface

Information About IPv6 ACL

An access control list (ACL) is a set of rules used to limit access to a particular interface (for example, if you want to restrict a wireless client from pinging the management interface of the controller). ACLs are configured on the device and applied to the management interface, the AP-manager interface, any of the dynamic interfaces, or a WLAN to control data traffic to and from wireless clients or to the controller central processing unit (CPU) to control all traffic destined for the CPU.

You can also create a preauthentication ACL for web authentication. Such an ACL is used to allow certain types of traffic before authentication is complete.

IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source and destination ports.

Note You can enable only IPv4 traffic in your network by blocking IPv6 traffic. That is, you can configure an IPv6 ACL to deny all IPv6 traffic and apply it on specific or all WLANs.

Understanding IPv6 ACLs

A switch supports two types of IPv6 ACLs:

- IPv6 router ACLs are supported on outbound or inbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. IPv6 router ACLs apply only to IPv6 packets that are routed.
- IPv6 port ACLs are supported on inbound traffic on Layer 2 interfaces only. IPv6 port ACLs are applied to all IPv6 packets entering the interface.

A switch running the IP base feature set supports only input router IPv6 ACLs. It does not support port ACLs or output IPv6 router ACLs.

Note If you configure unsupported IPv6 ACLs, an error message appears and the configuration does not take effect.

The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.

You can apply both IPv4 and IPv6 ACLs to an interface. As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs:

- When an input router ACL and input port ACL exist in an SVI, packets received on ports to which a port ACL is applied are filtered by the port ACL. Routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.

- When an output router ACL and input port ACL exist in an SVI, packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IPv6 packets are filtered by the router ACL. Other packets are not filtered.

Note If any port ACL (IPv4, IPv6, or MAC) is applied to an interface, that port ACL is used to filter packets, and any router ACLs attached to the SVI of the port VLAN are ignored.

[Displaying IPv6 ACLs](#), on page 297

Types of ACL

Per User IPv6 ACL

For the per-user ACL, the full access control entries (ACE) as the text strings are configured on the ACS.

The ACE is not configured on the Controller. The ACE is sent to the device in the `ACCESS-Accept` attribute and applies it directly for the client. When a wireless client roams into an foreign device, the ACEs are sent to the foreign device as an AAA attribute in the mobility Handoff message. Output direction, using per-user ACL is not supported.

Filter ID IPv6 ACL

For the filter-Id ACL, the full ACEs and the `acl name (filter-id)` is configured on the device and only the `filter-id` is configured on the ACS. The `filter-id` is sent to the device in the `ACCESS-Accept` attribute, and the device looks up the `filter-id` for the ACEs, and then applies the ACEs to the client. When the client L2 roams to the foreign device, only the `filter-id` is sent to the foreign device in the mobility Handoff message. Output filtered ACL, using per-user ACL is not supported. The foreign device has to configure the `filter-id` and ACEs beforehand.

Downloadable IPv6 ACL

For the downloadable ACL (dACL), the full ACEs and the `dac1 name` are all configured on the ACS only.

Note The controller does not configure any ACL.

The ACS sends the `dac1 name` to the device in its `ACCESS-Accept` attribute, which takes the `dac1 name` and sends the `dACL name` back to the ACS, for the ACEs, using the `access-request` attribute.

The ACS responds to the corresponding ACEs of the device in the `access-accept` attribute. When the wireless client roams to an foreign device, only the `dac1 name` is sent to the foreign device in the mobility Handoff message. The foreign device contacts the ACS server with the `dac1 name` to retrieve the ACEs.

IPv6 ACLs and Switch Stacks

The stack master supports IPv6 ACLs in hardware and distributes the IPv6 ACLs to the stack members.

Note For full IPv6 functionality in a switch stack, all stack members must be running the IP services feature set.

If a new switch takes over as stack master, it distributes the ACL configuration to all stack members. The member switches sync up the configuration distributed by the new stack master and flush out entries that member switches sync up the configuration distributed by the new stack master and flush out entries that are not required.

When an ACL is modified, attached to, or detached from an interface, the stack master distributes the change to all stack members.

Configuring IPv6 ACLs

To filter IPv6 traffic, you perform these steps:

Before you begin

Before configuring IPv6 ACLs, you must select one of the dual IPv4 and IPv6 SDM templates.

SUMMARY STEPS

1. Create an IPv6 ACL, and enter IPv6 access list configuration mode.
2. Configure the IPv6 ACL to block (deny) or pass (permit) traffic.
3. Apply the IPv6 ACL to the interface where the traffic needs to be filtered.
4. Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Create an IPv6 ACL, and enter IPv6 access list configuration mode.	
Step 2	Configure the IPv6 ACL to block (deny) or pass (permit) traffic.	
Step 3	Apply the IPv6 ACL to the interface where the traffic needs to be filtered.	
Step 4	Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.	

Default IPv6 ACL Configuration

There are no IPv6 ACLs configured or applied.

Interaction with Other Features and Switches

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.
- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.
- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.
- If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.

Note Only packets of the same type as the ACL that could not be added (ipv4, ipv6, MAC) will be dropped on the interface.

How To Configure an IPv6 ACL

Creating IPv6 ACL

Beginning in privileged EXEC mode, follow these steps to create an IPv6 ACL:

SUMMARY STEPS

1. **configure terminal**
2. **ipv6 access-list *acl_name***
3. **{deny|permit} protocol**
4. **{deny|permit} tcp**
5. **{deny|permit} udp**
6. **{deny|permit} icmp**
7. **end**
8. **show ipv6 access-list**
9. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ipv6 access-list <i>acl_name</i> Example: ipv6 access-list access-list-name	Use a name to define an IPv6 access list and enter IPv6 access-list configuration mode.
Step 3	{deny permit} protocol Example: <pre>{deny permit} protocol {source-ipv6-prefix/prefix-length any host source-ipv6-address} [operator [port-number]][destination-ipv6-prefix/prefix-length any host destination-ipv6-address} [operator [port-number]][dscp value] [fragments][log] [log-input] [routing][sequence value] [time-range name]</pre>	<p>Enter deny or permit to specify whether to deny or permit the packet if conditions are matched. These are the conditions:</p> <ul style="list-style-type: none"> • For protocol, enter the name or number of an Internet protocol: ahp, esp, icmp, ipv6, pcp, stcp, tcp, or udp, or an integer in the range 0 to 255 representing an IPv6 protocol number. • The source-ipv6-prefix/prefix-length or destination-ipv6-prefix/ prefix-length is the source or destination IPv6 network or class of networks for which to set deny or permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373). • Enter any as an abbreviation for the IPv6 prefix ::/0. • For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons. • (Optional) For operator, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range. <p>If the operator follows the source-ipv6-prefix/prefix-length argument, it must match the source port. If the operator follows the destination-ipv6- prefix/prefix-length argument, it must match the destination port.</p> <ul style="list-style-type: none"> • (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP. • (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value

	Command or Action	Purpose
		<p>in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63.</p> <ul style="list-style-type: none"> • (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6. • (Optional) Enter log to cause an logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs. • (Optional) Enter routing to specify that IPv6 packets be routed. • (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295 • (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement.
Step 4	<p>{deny permit} tcp</p> <p>Example:</p> <pre>{deny permit} tcp {source-ipv6-prefix/prefix-length any hostsource-ipv6-address} [operator [port-number]]{destination-ipv6-prefix/prefix-length any hostdestination-ipv6-address} [operator [port-number]][ack] [dscp value][established] [fin] [log][log-input] [neq {port protocol}] [psh] [range{port protocol}] [rst][routing] [sequence value] [syn] [time-range name][urg]</pre>	<p>(Optional) Define a TCP access list and the access conditions.</p> <p>Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:</p> <ul style="list-style-type: none"> • ack—Acknowledgment bit set. • established—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set. • fin—Finished bit set; no more data from sender. • neq {port protocol}—Matches only packets that are not on a given port number. • psh—Push function bit set. • range {port protocol}—Matches only packets in the port number range. • rst—Reset bit set. • syn—Synchronize bit set. • urg—Urgent pointer bit set.
Step 5	<p>{deny permit} udp</p> <p>Example:</p>	<p>(Optional) Define a UDP access list and the access conditions.</p>

	Command or Action	Purpose
	<pre>{deny permit} udp {source-ipv6-prefix/prefix-length any hostsource-ipv6-address} [operator [port-number]][destination-ipv6-prefix/prefix-length any hostdestination-ipv6-address} [operator [port-number]][dscp value] [log][log-input] [neq {port protocol}] [range {port protocol}] [routing][sequence value][time-range name]</pre>	Enter udp for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the operator [port] port number or name must be a UDP port number or name, and the established parameter is not valid for UDP.
Step 6	<p>{deny permit} icmp</p> <p>Example:</p> <pre>{deny permit} icmp {source-ipv6-prefix/prefix-length any hostsource-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length any hostdestination-ipv6-address} [operator [port-number]][icmp-type [icmp-code] icmp-message] [dscpvalue] [log] [log-input] [routing] [sequence value][time-range name]</pre>	<p>(Optional) Define an ICMP access list and the access conditions.</p> <p>Enter icmp for Internet Control Message Protocol. The ICMP parameters are the same as those described for most IP protocols in Step 3a, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:</p> <ul style="list-style-type: none"> • icmp-type—Enter to filter by ICMP message type, a number from 0 to 255. • icmp-code—Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255. • icmp-message—Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name. To see a list of ICMP message type names and code names, use the ? key or see command reference for this release.
Step 7	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 8	<p>show ipv6 access-list</p> <p>Example:</p> <pre>show ipv6 access-list</pre>	Verify the access list configuration.
Step 9	<p>copy running-config startup-config</p> <p>Example:</p> <pre>copy running-config startup-config</pre>	(Optional) Save your entries in the configuration file.

Applying an IPv6 to an Interface

This section describes how to apply IPv6 ACLs to network interfaces. You can apply an IPv6 ACL to outbound or inbound traffic on layer 2 and Layer 3 interfaces. You can apply IPv6 ACLs only to inbound management traffic on Layer 3 interfaces.

Beginning in privileged EXEC mode, follow these steps to control access to an interface:

SUMMARY STEPS

1. **configure terminal**
2. **interface interface_id**
3. **no switchport**
4. **ipv6 address ipv6_address**
5. **ipv6 traffic-filter acl_name**
6. **end**
7. **show running-config interface tenGigabitEthernet 1/0/3**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	interface interface_id Example: Device# <code>interface interface-id</code>	Identifies a Layer 2 interface (for port ACLs) or Layer 3 Switch Virtual interface (for router ACLs) on which to apply an access list, and enters interface configuration mode.
Step 3	no switchport Example: Device# <code>no switchport</code>	Changes the interface from Layer 2 mode (the default) to Layer 3 mode (only if applying a router ACL).
Step 4	ipv6 address ipv6_address Example: Device# <code>ipv6 address ipv6-address</code>	Configures an IPv6 address on a Layer 3 interface (for router ACLs). Note This command is not required on Layer 2 interfaces or if the interface has already been configured with an explicit IPv6 address.
Step 5	ipv6 traffic-filter acl_name Example: Device# <code>ipv6 traffic-filter access-list-name {in out}</code>	Applies the access list to incoming or outgoing traffic on the interface.
Step 6	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

	Command or Action	Purpose
Step 7	show running-config interface tenGigabitEthernet 1/0/3 Example: <pre>Device# show running-config interface tenGigabitEthernet 1/0/3 Building configuration Current configuration : 98 bytes ! interface TenGigabitEthernet1/0/3 switchport mode trunk ipv6 traffic-filter MyFilter out end</pre>	Shows the configuration summary.
Step 8	copy running-config startup-config Example: <pre>copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Creating WLAN IPv6 ACL

SUMMARY STEPS

1. `ipv6 traffic-filter acl acl_name`
2. `ipv6 traffic-filter acl web`

DETAILED STEPS

	Command or Action	Purpose
Step 1	ipv6 traffic-filter acl <i>acl_name</i> Example: <pre>Device(config-wlan)# ipv6 traffic-filter acl <acl_name></pre>	Creates a named WLAN ACL.
Step 2	ipv6 traffic-filter acl web Example: <pre>Device(config-wlan)# ipv6 traffic-filter acl web <acl_name-preauth></pre>	Creates a pre-authentication for WLAN ACL.

```
Device(config-wlan)# ipv6 traffic-filter acl <acl_name>
Device(config-wlan)#ipv6 traffic-filter acl web <acl_name-preauth>
```

Verifying IPv6 ACL

Displaying IPv6 ACLs

You can display information about all configured access lists, all IPv6 access lists, or a specific access list by using one or more of the privileged EXEC commands.

Procedure

	Command or Action	Purpose
Step 1	show access-list Example: Device# show access-lists	Displays all access lists configured on the device
Step 2	show ipv6 access-list <i>acl_name</i> Example: Device# show ipv6 access-list [<i>access-list-name</i>]	Displays all configured IPv6 access list or the access list specified by name.

Related Topics

Configuration Examples for IPv6 ACL

Example: Creating IPv6 ACL

This example configures the IPv6 access list named CISCO. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny -all condition is at the end of each IPv6 access list.

Note Logging is supported only on Layer 3 interfaces.

```
Device(config)# ipv6 access-list CISCO
Device(config-ipv6-acl)# deny tcp any any gt 5000
Device (config-ipv6-acl)# deny ::/0 lt 5000 ::/0 log
Device(config-ipv6-acl)# permit icmp any any
Device(config-ipv6-acl)# permit any any
```

Example: Applying IPv6 ACLs

This example shows how to apply the access list Cisco to outbound traffic on a Layer 3 interface.

```
Device(config)# interface TenGigabitEthernet 1/0/3

Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001::/64 eui-64
Device(config-if)# ipv6 traffic-filter CISCO out
```

Example: Displaying IPv6 ACLs

This is an example of the output from the **show access-lists** privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

```
Device #show access-lists
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10
```

This is an example of the output from the **show ipv6 access-lists** privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

```
Device# show ipv6 access-list
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30

IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20
```

Example: Configuring RA Throttling and NS Suppression

This task describes how to create an RA throttle policy in order to help the power-saving wireless clients from being disturbed by frequent unsolicited periodic RA's. The unsolicited multicast RA is throttled by the controller.

Before you begin

Enable IPv6 on the client machine.

SUMMARY STEPS

1. **configure terminal**

2. `ipv6 nd ra-throttler policy Mythrottle`
3. `throttle-period 20`
4. `max-through 5`
5. `allow at-least 3 at-most 5`
6. `switch (config)# vlan configuration 100`
7. `ipv6 nd suppress`
8. `ipv6 nd ra-th attach-policy attach-policy_name`
9. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ipv6 nd ra-throttler policy Mythrottle Example: Device (config)# <code>ipv6 nd ra-throttler policy Mythrottle</code>	Creates a RA throttler policy called Mythrottle.
Step 3	throttle-period 20 Example: Device (config-nd-ra-throttle)# <code>throttle-period 20</code>	Determines the time interval segment during which throttling applies.
Step 4	max-through 5 Example: Device (config-nd-ra-throttle)# <code>max-through 5</code>	Determines how many initial RA's are allowed.
Step 5	allow at-least 3 at-most 5 Example: Device (config-nd-ra-throttle)# <code>allow at-least 3 at-most 5</code>	Determines how many RA's are allowed after the initial RAs have been transmitted, until the end of the interval segment.
Step 6	switch (config)# vlan configuration 100 Example: Device (config)# <code>vlan configuration 100</code>	Creates a per vlan configuration.
Step 7	ipv6 nd suppress Example: Device (config)# <code>ipv6 nd suppress</code>	Disables the neighbor discovery on the Vlan.
Step 8	ipv6 nd ra-th attach-policy attach-policy_name Example: Device (config)# <code>ipv6 nd ra-throttle attach-policy attach-policy_name</code>	Enables the router advertisement throttling.

	Command or Action	Purpose
Step 9	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Example: Configuring RA Guard Policy

SUMMARY STEPS

1. **ipv6 nd rguard policy MyPolicy**
2. **trusted-port**
3. **device-role router**
4. **interface tenGigabitEthernet 1/0/1**
5. **ipv6 nd rguard attach-policy MyPolicy**
6. **vlan configuration 19-21, 23**
7. **ipv6 nd suppress**
8. **ipv6 snooping**
9. **ipv6 nd rguard attach-policy MyPolicy**
10. **ipv6 nd ra-throttler attach-policy MyThrottle**

DETAILED STEPS

	Command or Action	Purpose
Step 1	ipv6 nd rguard policy MyPolicy Example: Device (config)# ipv6 nd rguard policy MyPolicy	
Step 2	trusted-port Example: Device (config-nd-rguard)# trusted-port	Configures the trusted port for the policy created above.
Step 3	device-role router Example: Device (config-nd-rguard)# device-role [host monitor router switch] Device (config-nd-rguard)# device-role router	Defines the trusted device that can send RAs to the trusted port created above.
Step 4	interface tenGigabitEthernet 1/0/1 Example: Device (config)# interface tenGigabitEthernet 1/0/1	Configures the interface to the trusted device.
Step 5	ipv6 nd rguard attach-policy MyPolicy Example:	Configures and attaches the policy to trust the RA's received from the port.

	Command or Action	Purpose
	Device (config-if)# ipv6 nd rguard attach-policy Mypolicy	
Step 6	vlan configuration 19–21, 23 Example: Device (config)# vlan configuration 19-21,23	Configures the wireless client vlans.
Step 7	ipv6 nd suppress Example: Device (config-vlan-config)# ipv6 nd suppress	Suppresses the ND messages over wireless.
Step 8	ipv6 snooping Example: Device (config-vlan-config)# ipv6 snooping	Captures IPv6 traffic.
Step 9	ipv6 nd rguard attach-policy MyPolicy Example: Device (config-vlan-config)# ipv6 nd rguard attach-policy Mypolicy	Attaches the RA Guard policy to the wireless client vlans.
Step 10	ipv6 nd ra-throttler attach-policy Mythrottle Example: Device (config-vlan-config)#ipv6 nd ra-throttler attach-policy Mythrottle	Attaches the RA throttling policy to the wireless client vlans.

Example: Configuring IPv6 Neighbor Binding

SUMMARY STEPS

1. **ipv6 neighbor binding [vlan]19 2001:db8::25:4 interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc**

DETAILED STEPS

	Command or Action	Purpose
Step 1	ipv6 neighbor binding [vlan]19 2001:db8::25:4 interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc Example: Device (config)# ipv6 neighbor binding vlan 19 2001:db8::25:4 interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc	Sets and validates the neighbor 2001:db8::25:4 only valid when transmitting on VLAN 19 through interface te1/0/3 with the source mac-address as aaa.bbb.ccc.

Prerequisites for IPv6 Web Authentication

The following configurations must be in place before you start with IPv6 Web Authentication:

- IPv6 Device Tracking.
- IPv6 DHCP Snooping.
- Disable security of type 802.1x on the wlan.
- Each WLAN must have a vlan associated to it.
- Change the default wlan setting from **shutdown** to **no shutdown**.

Information About IPv6 Web Authentication

Web authentication is a Layer 3 security feature and the device disallows IP traffic (except DHCP and DNS -related packets) from a particular client until it supplies a valid username and password. It is a simple authentication method without the need for a supplicant or client utility. Web authentication is typically used by customers who deploy a guest-access network. Traffic from both, HTTP and HTTPS, page is allowed to display the login page.

Note Web authentication does not provide data encryption and is typically used as simple guest access for either a hot spot or campus atmosphere, where connectivity is always a factor.

A WLAN is configured as **security webauth** for web based authentication. The device supports the following types of web based authentication:

- Web Authentication – The client enters the credentials in a web page which is then validated by the Wlan controller.
- Web Consent – The Wlan controller presents a policy page with Accept/Deny buttons. Click Accept button to access the network.

Note Maximum consecutive Web Auth sessions supported in device is 40 per second.

A Wlan is typically configured for open authentication, that is without Layer 2 authentication, when web-based authentication mechanism is used.

Web Authentication Process

The following events occur when a WLAN is configured for web authentication:

- The user opens a web browser and enters a URL address, for example, *http://www.example.com*. The client sends out a DNS request for this URL to get the IP address for the destination. The device bypasses the DNS request to the DNS server, which in turn responds with a DNS reply that contains the IP address of the destination *www.example.com*. This, in turn, is forwarded to the wireless clients.
- The client then tries to open a TCP connection with the destination IP address. It sends out a TCP SYN packet destined to the IP address of *www.example.com*.
- The device has rules configured for the client and cannot act as a proxy for *www.example.com*. It sends back a TCP SYN-ACK packet to the client with source as the IP address of *www.example.com*. The client sends back a TCP ACK packet in order to complete the three-way TCP handshake and the TCP connection is fully established.
- The client sends an HTTP GET packet destined to *www.example.com*. The device intercepts this packet and sends it for redirection handling. The HTTP application gateway prepares an HTML body and sends it back as the reply to the HTTP GET requested by the client. This HTML makes the client go to the default web-page of the device, for example, *http://<Virtual-Server-IP>/login.html*.
- The client closes the TCP connection with the IP address, for example, *www.example.com*.

- If the client wants to go to virtual IP, the client tries to open a TCP connection with the virtual IP address of the device. It sends a TCP SYN packet for virtual IP to the device.
- The device responds back with a TCP SYN-ACK and the client sends back a TCP ACK to the device in order to complete the handshake.
- The client sends an HTTP GET for */login.html* destined to virtual IP in order to request for the login page.
- This request is allowed to the web server of the device, and the server responds with the default login page. The client receives the login page in the browser window where the user can log in.

How to Configure IPv6 Web Authentication

Disabling WPA

Before you begin

Disable 802.1x. A typical web authentication does not use Layer 2 security. Use this configuration to remove Layer 2 security.

SUMMARY STEPS

1. `configure terminal`
2. `wlan test1 2 test1`
3. `no security wpa`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.

	Command or Action	Purpose
Step 2	wlan test1 2 test1 Example: Device(config)# wlan test1 2 test1	Creates a WLAN and assign an SSID to it.
Step 3	no security wpa Example: Device(config-wlan)# no security wpa	Disables the WPA support for Wlan.

What to do next

Enable the following:

- Security Web Authentication.
- Parameter Local.
- Authentication List.

Related Topics

Enabling Security on the WLAN

SUMMARY STEPS

1. **parameter-map type web-auth global**
2. **virtual-ip ipv4 192.0.2.1**
3. **virtual-ip ipv6 2001:db8::24:2**

DETAILED STEPS

	Command or Action	Purpose
Step 1	parameter-map type web-auth global Example: Device(config)# parameter-map type web-auth global	Applies the parameter map to all the web-auth wlans.
Step 2	virtual-ip ipv4 192.0.2.1 Example: Device(config-params-parameter-map)# virtual-ip ipv4 192.0.2.1	Defines the virtual gateway IPv4 address.
Step 3	virtual-ip ipv6 2001:db8::24:2 Example: Device(config-params-parameter-map)# virtual-ip ipv6 2001:db8::24:2	Defines the virtual gateway IPv6 address.

Configuring a Global WebAuth WLAN Parameter Map

Use this example to configure a global web auth WLAN and add a parameter map to it.

SUMMARY STEPS

1. `parameter-map type webauth global`
2. `virtual-ip ipv6 2001:db8:4::1`
3. `ratelimit init-state-sessions 120`
4. `max-https-conns 70`

DETAILED STEPS

	Command or Action	Purpose
Step 1	parameter-map type webauth global Example: Device (config)# parameter-map type webauth global	Configures a global webauth and adds a parameter map to it.
Step 2	virtual-ip ipv6 2001:db8:4::1 Example: Device (config-params-parameter-map)# virtual-ip ipv6 2001:db8:4::1	Defines a virtual gateway IP address that appears to the wireless clients for authentication.
Step 3	ratelimit init-state-sessions 120 Example: Device (config-params-parameter-map)# ratelimit init-state-sessions 120	Sets the global ratelimit to limit the bandwidth that the web clients can use on the device to avoid over-flooding attacks.
Step 4	max-https-conns 70 Example: Device (config-params-parameter-map)# max-http-conns 70	Sets the maximum number of attempted http connections on the device to avoid over-flooding attacks.

Configuring the WLAN

Before you begin

- The WLAN must have a Vlan associated with it. By default, a new Wlan is always associated with Vlan 1, which can be changed as per the configuration requirements.
- Configure and enable the WLAN to *no shutdown*. By default, the Wlan is configured with the *shutdown* parameter and is disabled.

SUMMARY STEPS

1. `wlan 1`
2. `client vlan interface ID`
3. `security web-auth authentication list webauthlistlocal`

4. `security web-auth parameter-map global`
5. `no security wpa`
6. `no shutdown`
7. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	wlan <i>l</i> Example: Device(config-wlan)# wlan 1 name vicweb ssid vicweb	Creates a wlan and assign an SSID to it.
Step 2	client vlan <i>interface ID</i> Example: Device(config-wlan)# client vlan VLAN0136	Assigns the client to vlan interface.
Step 3	security web-auth authentication list webauthlistlocal Example: Device(config-wlan)# security web-auth authentication-list webauthlistlocal	Configures web authentication for the wlan.
Step 4	security web-auth parameter-map global Example: Device(config-wlan)# security web-auth parameter-map global	Configures the parameter map on the wlan.
Step 5	no security wpa Example: Device(config-wlan)# no security wpa	Configures the security policy for a wlan. This enables the wlan.
Step 6	no shutdown Example: Device(config-wlan)# no shutdown	Configures and enables the Wlan.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Feature	Release	Modification
IPv6 Web Authentication Functionality	Cisco IOS XE 3.2SE Cisco IOS XE 3.2SE	This feature was introduced.

CHAPTER 21

Configuring IPv6 Client Mobility

- [Prerequisites for IPv6 Client Mobility, on page 317](#)
- [Restrictions For IPv6 Client Mobility, on page 317](#)
- [Information About IPv6 Client Mobility, on page 318](#)
- [Verifying IPv6 Client Mobility, on page 321](#)
- [Monitoring IPv6 Client Mobility, on page 321](#)
- [Additional References, on page 322](#)
- [Feature Information For IPv6 Client Mobility, on page 323](#)

Prerequisites for IPv6 Client Mobility

To enable wireless IPv6 client connectivity, the underlying wired network must support IPv6 routing and an address assignment mechanism such as SLAAC or DHCPv6. The device must have L2 adjacency to the IPv6 router, and the VLAN needs to be tagged when the packets enter the device. APs do not require connectivity on an IPv6 network, as all traffic is encapsulated inside the IPv4 CAPWAP tunnel between the AP and device.

Restrictions For IPv6 Client Mobility

- When using the IPv6 Client Mobility, clients must support IPv6 with either static stateless auto configuration (such as Windows XP clients) or stateful DHCPv6 IP addressing (such as Windows 7 clients).
- To allow smooth operation of stateful DHCPv6 IP addressing, you must have a switch or router that supports the DHCP for IPv6 feature (such as the device) that is configured to act like a DHCPv6 server, or you need a dedicated server such as a Windows 2008 server with a built-in DHCPv6 server. Cisco Catalyst 3850 switch and Cisco Catalyst 5700 switch can act as (internal) a DHCPv6 server.

Note To load the SDM IPv6 template in the Cisco Catalyst 3850 switch, enter the **sdm prefer dual-ipv4 and v6 default** command and then reset the switch.

Information About IPv6 Client Mobility

The Device supports IPv6 mobility for IPv6-only or dual-stack nodes. The IPv6 Client Mobility is divided into:

- Link Layer and
- Network Layer

The link layer is handled by the 802.11 protocol which enables the client to roam to any AP in the same BSS (basic service set) identified by the same SSID without losing the link layer connectivity.

However, link layer mobility is not enough to make wireless client Layer 3 applications continue to work seamlessly while roaming. Cisco IOSd's wireless mobility module uses mobility tunneling to retain seamless connectivity for the client's Layer 3 PoP (point of presence) when the client roams across different subnets on different switches.

IPv6 is the next-generation network layer Internet protocol intended to replace IPv4 in the TCP/IP suite of protocols. This new version increases the internet global address space to accommodate users and applications that require unique global IP addresses. IPv6 incorporates 128-bit source and destination addresses, which provide significantly more addresses than the 32-bit IPv4 addresses.

To support IPv6 clients across controllers, ICMPv6 messages must be dealt with specially to ensure the IPv6 client remains on the same Layer 3 network. The device keep track of IPv6 clients by intercepting the ICMPv6 messages to provide seamless mobility and protect the network from network attacks. The NDP (neighbor discovery packets) packets are converted from multicast to unicast and delivered individually per client. This unique solution ensures that Neighbor Discovery and Router Advertisement packets are not leaked across Vlans. Clients can receive specific Neighbor Discovery and Router Advertisement packets ensuring correct IPv6 addressing and avoids unnecessary multicast traffic.

The configuration for IPv6 mobility is the same as IPv4 mobility and requires no separate software on the client side to achieve seamless roaming. The device must be part of the same mobility group. Both IPv4 and IPv6 client mobility are enabled by default.

IPv6 client mobility is used for the following:

- Retaining the client IPv6 multiple addresses in Layer-2 and Layer-3 roaming.
- IPv6 Neighbor Discovery Protocol (NDP) packet management.
- Client IPv6 addresses learning.

Using Router Advertisement

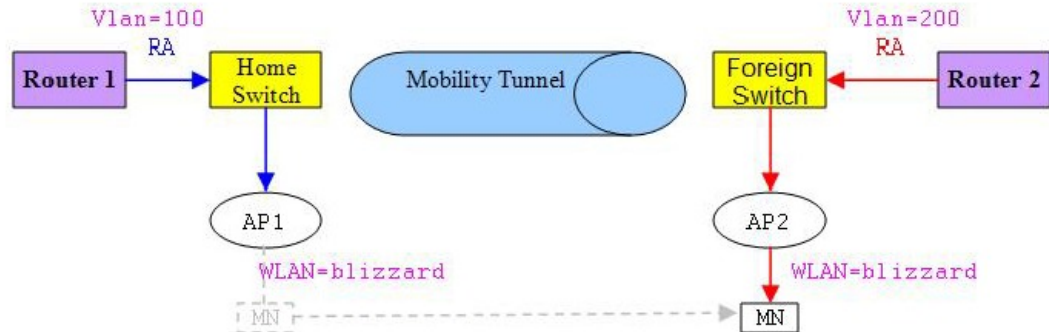

The Neighbor Discovery Protocol(NDP) operates in the link-layer and is responsible for the discovery of other nodes on the link. It determines the link-layer addresses of other nodes, finds the available routers, and maintains reachability information about the paths to other active neighbor nodes.

Router Advertisement (RA) is one of the IPv6 Neighbor Discovery Protocol (NDP) packets that is used by the hosts to discover available routers, acquire the network prefix to generate the IPv6 addresses, link MTU, and so on. The routers send RA on a regular basis, or in response to hosts Router Solicitation messages.

IPv6 wireless client mobility manages the IPv6 RA packet. The converged access device forwards the link-local all-nodes multicast RA packets to the local and roaming wireless nodes mapped on same VLAN the RA was received on.

Figure 1 illustrates the link-local all-nodes mcast RA forwarding issue in the wireless node mobility.

Figure 11: Roaming Client Receiving Invalid RA from Router 2

334007

Figure 2 illustrates how a roaming client “MN” receives RA from VLAN 200 in a foreign switch and how it acquires a new IP address and breaks into L3 mobility's point of presence.

Figure 12: Roaming Client Receives Valid RA from Router 1

334008

Related Topics

[Verifying IPv6 Client Mobility](#), on page 321

[Monitoring IPv6 Client Mobility](#), on page 321

RA Throttling and NS suppression

To safeguard the power-saving wireless clients from being disturbed by frequent unsolicited periodic RAs, the controller can throttle the unsolicited multicast RA.

Related Topics

[Verifying IPv6 Client Mobility](#), on page 321

[Monitoring IPv6 Client Mobility](#), on page 321

IPv6 Address Learning

There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static configuration

For these methods, the IPv6 client always sends NS DAD (duplicate address detection) to ensure that there is no duplicated IP address on the network. The device snoops the clients NDP and DHCPv6 packets to learn about its client IP addresses and then updates the controllers database. The database then informs the controller for the clients new IP address.

Related Topics

[Verifying IPv6 Client Mobility](#), on page 321

[Monitoring IPv6 Client Mobility](#), on page 321

Handling Multiple IP Addresses

In the case when the new IP address is received after RUN state, whether an addition or removal, the controller updates the new IP addresses on its local database for display purposes. Essentially, the IPv6 uses the existing or same PEM state machine code flow as in IPv4. When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller will include all the available IP addresses, IPv4 and IPv6, in the API/SPI interface to the external entities.

An IPv6 client can acquire multiple IP addresses from stack for different purposes. For example, a link-local address for link local traffic, and a routable unique local or global address.

When the client is in the DHCP request state and the controller receives the first IP address notification from the database for either an IPv4 or IPv6 address, the PEM moves the client into the RUN state.

When a new IP address is received after the RUN state, either for addition or removal, the controller updates the new IP addresses on its local database for display purposes.

When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller provides the available IP addresses, both IPv4 and IPv6, to the external entities.

Related Topics

[Verifying IPv6 Client Mobility](#), on page 321

[Monitoring IPv6 Client Mobility](#), on page 321

IPv6 Configuration

The device supports IPv6 client as seamlessly as the IPv4 clients. The administrator must manually configure the Vlans to enable the IPV6, IPv6's snooping and throttling functionality. This will enable the NDP packets to throttle between the device and its various clients

Related Topics

[Verifying IPv6 Client Mobility](#), on page 321

[Monitoring IPv6 Client Mobility](#), on page 321

High Availability

The switch will sync with the wireless clients when the clients IP address is hard to learn. When a switchover happens, the IPv6 neighbor binding table is synced to standby state. However, the wireless client will itself disassociate and reassociate to a new active state once the switchover is complete and the neighbor binding table is updated with latest information for that client.

If, during the reassociation, the client moves to another AP then the original entry in the binding table is marked as down for sometime and will be aged-out.

For the new entries joining the switch from another AP, the new IP address is learned and notified to the controller's database.

Note This feature is available only for the Cisco Catalyst 3850 Switch.

Pre-requisites for IPv6 Mobility

The mobility and its related infrastructure must be configured and ready for use.

Information About IPv6 Mobility

Mobility, or roaming, is a wireless LAN client's ability to maintain its association seamlessly from one access point to another securely and with as little latency as possible. This section explains how mobility works when devices are included in a wireless network.

When a wireless client associates and authenticates to an access point, the access point's device places an entry for that client in its client database. This entry includes the client's MAC and IP addresses, security context and associations, quality of service (QoS) contexts, the WLAN, and the associated access point. The device uses this information to forward frames and manage traffic to and from the wireless client.

When the wireless client moves its association from one access point to another, the device simply updates the client database with the newly associated access point. If necessary, new security context and associations are established as well. The process becomes more complicated, however, when a client roams from an access point joined to one device to an access point joined to a different device. It also varies based on whether the devices are operating on the same subnet.

Inter Controller Roaming

When the client associates to an access point joined to a new device, the new device exchanges mobility messages with the original device, and the client database entry is moved to the new device if sticky anchoring is disabled.

Related Topics

[Monitoring IPv6 Mobility](#), on page 326

Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming

Inter-subnet roaming is similar to inter-controller roaming in that the device exchange mobility messages on the client roam. However, instead of moving the client database entry to the new device, the original device marks the client with an "Anchor" entry in its own client database. The database entry is copied to the new device client database and marked with a "Foreign" entry in the new device. The roam remains transparent to the wireless client, and the client maintains its original IP address.

In inter-subnet roaming, WLANs on both anchor and foreign device need to have the same network access privileges and no source-based routing or source-based firewalls in place. Otherwise, the clients may have network connectivity issues after the handoff.

For more information on configuring mobility see, the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE, Release 3.2SE.

How to Configure IPv6 Mobility

Monitoring IPv6 Mobility

This chapter displays the mobility related IPv6 configuration. To see the mobility related configurations refer to the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE 3.2SE.

SUMMARY STEPS

1. `show ipv6 neighbors binding mac C0C1.C06B.C4E2`

DETAILED STEPS

	Command or Action	Purpose
Step 1	show ipv6 neighbors binding mac C0C1.C06B.C4E2 Example: Device# show ipv6 neighbors binding mac C0C1.C06B.C4E2	Displays the IPv6 related mobility configurations.

Example

```
Device# show ipv6 neighbors binding mac C0C1.C06B.C4E2
Binding Table has 45 entries, 37 dynamic (limit 100)
Codes: L - Local, S - Static, ND - Neighbor Discovery, DH - DHCP, PKT - Other Packet, API
- API created
Preflevel flags (prlvl):
0001:MAC and LLA match      0002:Orig trunk          0004:Orig access
```

0008:Orig trusted trunk 0010:Orig trusted access 0020:DHCP assigned
 0040:Cga authenticated 0080:Cert authenticated 0100:Statically assigned

Configuring HSRP

- [Configuring HSRP](#) , on page 333

Configuring HSRP

This chapter describes how to use Hot Standby Router Protocol (HSRP) to provide routing redundancy for routing IP traffic without being dependent on the availability of any single router.

You can also use a version of HSRP in Layer 2 mode to configure a redundant command switch to take over cluster management if the cluster command switch fails.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring HSRP

HSRP Overview

HSRP is Cisco's standard method of providing high network availability by providing first-hop redundancy for IP hosts on an IEEE 802 LAN configured with a default gateway IP address. HSRP routes IP traffic without relying on the availability of any single router. It enables a set of router interfaces to work together to present the appearance of a single virtual router or default gateway to the hosts on a LAN. When HSRP is configured on a network or segment, it provides a virtual Media Access Control (MAC) address and an IP address that is shared among a group of configured routers. HSRP allows two or more HSRP-configured routers to use the MAC address and IP network address of a virtual router. The virtual router does not exist; it represents the common target for routers that are configured to provide backup to each other. One of the routers is selected to be the active router and another to be the standby router, which assumes control of the group MAC address and IP address should the designated active router fail.

Note Routers in an HSRP group can be any router interface that supports HSRP, including routed ports and switch virtual interfaces (SVIs).

HSRP provides high network availability by providing redundancy for IP traffic from hosts on networks. In a group of router interfaces, the active router is the router of choice for routing packets; the standby router is the router that takes over the routing duties when an active router fails or when preset conditions are met.

HSRP is useful for hosts that do not support a router discovery protocol and cannot switch to a new router when their selected router reloads or loses power. When HSRP is configured on a network segment, it provides a virtual MAC address and an IP address that is shared among router interfaces in a group of router interfaces running HSRP. The router selected by the protocol to be the active router receives and routes packets destined for the group's MAC address. For n routers running HSRP, there are $n + 1$ IP and MAC addresses assigned.

HSRP detects when the designated active router fails, and a selected standby router assumes control of the Hot Standby group's MAC and IP addresses. A new standby router is also selected at that time. Devices running HSRP send and receive multicast UDP-based hello packets to detect router failure and to designate active and standby routers. When HSRP is configured on an interface, Internet Control Message Protocol (ICMP) redirect messages are automatically enabled for the interface.

You can configure multiple Hot Standby groups among switches and switch stacks that are operating in Layer 3 to make more use of the redundant routers. To do so, specify a group number for each Hot Standby command group you configure for an interface. For example, you might configure an interface on switch 1 as an active router and one on switch 2 as a standby router and also configure another interface on switch 2 as an active router with another interface on switch 1 as its standby router.

The following figure shows a segment of a network configured for HSRP. Each router is configured with the MAC address and IP network address of the virtual router. Instead of configuring hosts on the network with the IP address of Router A, you configure them with the IP address of the virtual router as their default router. When Host C sends packets to Host B, it sends them to the MAC address of the virtual router. If for any reason, Router A stops transferring packets, Router B responds to the virtual IP address and virtual MAC address and becomes the active router, assuming the active router duties. Host C continues to use the IP address of the virtual router to address packets destined for Host B, which Router B now receives and sends to Host B. Until Router A resumes operation, HSRP allows Router B to provide uninterrupted service to users on Host C's segment that need to communicate with users on Host B's segment and also continues to perform its normal function of handling packets between the Host A segment and Host B.

Figure 13: Typical HSRP Configuration

You can configure multiple Hot Standby groups among switches and switch stacks that are operating in Layer 3 to make more use of the redundant routers. To do so, specify a group number for each Hot Standby command group you configure for an interface. For example, you might configure an interface on switch 1 as an active router and one on switch 2 as a standby router and also configure another interface on switch 2 as an active router with another interface on switch 1 as its standby router.

HSRP Versions

Cisco IOS XE Release 3.3SE and later support these Hot Standby Router Protocol (HSRP) versions:

The switch supports these HSRP versions:

- HSRPv1- Version 1 of the HSRP, the default version of HSRP. It has these features:
 - The HSRP group number can be from 0 to 255.
 - HSRPv1 uses the multicast address 224.0.0.2 to send hello packets, which can conflict with Cisco Group Management Protocol (CGMP) leave processing. You cannot enable HSRPv1 and CGMP at the same time; they are mutually exclusive.
- HSRPv2- Version 2 of the HSRP has these features:
 - HSRPv2 uses the multicast address 224.0.0.102 to send hello packets. HSRPv2 and CGMP leave processing are no longer mutually exclusive, and both can be enabled at the same time.
 - HSRPv2 has a different packet format than HRSPv1.
 - The HSRP group number can be from 0 to 4095.

A switch running HSRPv1 cannot identify the physical router that sent a hello packet because the source MAC address of the router is the virtual MAC address.

HSRPv2 has a different packet format than HSRPv1. A HSRPv2 packet uses the type-length-value (TLV) format and has a 6-byte identifier field with the MAC address of the physical router that sent the packet.

If an interface running HSRPv1 gets an HSRPv2 packet, the type field is ignored.

Multiple HSRP

The switch supports Multiple HSRP (MHSRP), an extension of HSRP that allows load sharing between two or more HSRP groups. You can configure MHSRP to achieve load-balancing and to use two or more standby groups (and paths) from a host network to a server network.

In the figure below, half the clients are configured for Router A, and half the clients are configured for Router B. Together, the configuration for Routers A and B establishes two HSRP groups. For group 1, Router A is the default active router because it has the assigned highest priority, and Router B is the standby router. For group 2, Router B is the default active router because it has the assigned highest priority, and Router A is the standby router. During normal operation, the two routers share the IP traffic load. When either router becomes unavailable, the other router becomes active and assumes the packet-transfer functions of the router that is unavailable.

Note For MHSRP, you need to enter the **standby preempt** interface configuration command on the HSRP interfaces so that if a router fails and then comes back up, preemption restores load sharing.

Figure 14: MSHRP Load Sharing

SSO HSRP

SSO HSRP alters the behavior of HSRP when a device with redundant Route Processors (RPs) is configured for stateful switchover (SSO) redundancy mode. When an RP is active and the other RP is standby, SSO enables the standby RP to take over if the active RP fails.

With this functionality, HSRP SSO information is synchronized to the standby RP, allowing traffic that is sent using the HSRP virtual IP address to be continuously forwarded during a switchover without a loss of data or a path change. Additionally, if both RPs fail on the active HSRP device, then the standby HSRP device takes over as the active HSRP device.

The feature is enabled by default when the redundancy mode of operation is set to SSO.

HSRP and Switch Stacks

HSRP hello messages are generated by the stack master. If an HSRP-active stack master fails, a flap in the HSRP active state might occur. This is because HSRP hello messages are not generated while a new stack master is elected and initialized, and the standby router might become active after the stack master fails.

Configuring HSRP for IPv6

Switches running the IP Services and IP Base feature set support the Hot Standby Router Protocol (HSRP) for IPv6. HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.

An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address.

Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

Note When configuring HSRP for IPv6, you must enable HSRP version 2 (HSRPv2) on the interface.

How to Configure HSRP

Default HSRP Configuration

Table 30: Default HSRP Configuration

Feature	Default Setting
HSRP version	Version 1
HSRP groups	None configured
Standby group number	0
Standby MAC address	System assigned as: 0000.0c07.acXX, where XX is the HSRP group number
Standby priority	100
Standby delay	0 (no delay)
Standby track interface priority	10
Standby hello time	3 seconds
Standby holdtime	10 seconds

HSRP Configuration Guidelines

- HSRPv2 and HSRPv1 are mutually exclusive. HSRPv2 is not interoperable with HSRPv1 on an interface and the reverse.
- In the procedures, the specified interface must be one of these Layer 3 interfaces:
 - Routed port: A physical port configured as a Layer 3 port by entering the **no switchport** command in interface configuration mode.
 - SVI: A VLAN interface created by using the **interface vlan** *vlan_id* in global configuration mode, and by default a Layer 3 interface.
 - Etherchannel port channel in Layer 3 mode: A port-channel logical interface created by using the **interface port-channel** *port-channel-number* in global configuration mode, and binding the Ethernet interface into the channel group.
- All Layer 3 interfaces must have IP addresses assigned to them.
- If you change the HSRP version on an interface, each HSRP group resets because it now has a new virtual MAC address.
- Only on mixed stacks of Catalyst switches:
 - HSRP for IPv4 and HSRP for IPv6 are mutually exclusive. You cannot enable both at the same time.
 - When configuring group numbers for HSRPv2 and HSRP, you must use group numbers in ranges that are multiples of 256. Valid ranges are 0 to 255, 256 to 511, 512 to 767, 3840 to 4095, and so on.
 - Examples of valid and invalid group numbers:
 - If you configure groups with the numbers 2, 150, and 225, you cannot configure another group with the number 3850. It is not in the range of 0 to 255.
 - If you configure groups with the numbers 520, 600, and 700, you cannot configure another group with the number 900. It is not in the range of 512 to 767.

Note You can configure up to 128 groups at the configuration level but the recommended HSRP group number limit is 64.

Note HSRP millisecond timers are not supported.

Enabling HSRP

The **standby ip** interface configuration command activates HSRP on the configured interface. If an IP address is specified, that address is used as the designated address for the Hot Standby group. If no IP address is specified, the address is learned through the standby function. You must configure at least one Layer 3 port on the LAN with the designated address. Configuring an IP address always overrides another designated address currently in use.

When the **standby ip** command is enabled on an interface and proxy ARP is enabled, if the interface's Hot Standby state is active, proxy ARP requests are answered using the Hot Standby group MAC address. If the interface is in a different state, proxy ARP responses are suppressed.

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **standby version** { 1 | 2 }
4. **standby** [*group-number*] **ip** [*ip-address*] [**secondary**]
5. **end**
6. **show standby** [*interface-id*] [*group*]
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Switch(config)# configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Switch(config)# interface gigabitethernet1/0/1	Enters interface configuration mode, and enter the Layer 3 interface on which you want to enable HSRP.
Step 3	standby version { 1 2 } Example: Switch(config-if)# standby version 1	(Optional) Configures the HSRP version on the interface. <ul style="list-style-type: none">• 1- Selects HSRPv1.• 2- Selects HSRPv2. If you do not enter this command or do not specify a keyword, the interface runs the default HSRP version, HSRP v1.
Step 4	standby [<i>group-number</i>] ip [<i>ip-address</i>] [secondary]	Creates (or enable) the HSRP group using its number and virtual IP address. <ul style="list-style-type: none">• (Optional) group-number- The group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number.• (Optional on all but one interface) ip-address- The virtual IP address of the hot standby router interface. You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces.• (Optional) secondary- The IP address is a secondary hot standby router interface. If neither router is designated as a secondary or standby router and no priorities are set, the primary IP addresses are

	Command or Action	Purpose
		compared and the higher IP address is the active router, with the next highest as the standby router.
Step 5	end Example: Switch(config-if)# end	Returns to privileged EXEC mode
Step 6	show standby [<i>interface-id</i> [<i>group</i>]] Example: Switch # show standby	Verifies the configuration of the standby groups.
Step 7	copy running-config startup-config Example: Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring HSRP Priority

The **standby priority**, **standby preempt**, and **standby track** interface configuration commands are all used to set characteristics for finding active and standby routers and behavior regarding when a new active router takes over.

When configuring HSRP priority, follow these guidelines:

- Assigning a priority allows you to select the active and standby routers. If preemption is enabled, the router with the highest priority becomes the active router. If priorities are equal, the current active router does not change.
- The highest number (1 to 255) represents the highest priority (most likely to become the active router).
- When setting the priority, preempt, or both, you must specify at least one keyword (**priority**, **preempt**, or both)
- The priority of the device can change dynamically if an interface is configured with the **standby track** command and another interface on the router goes down.
- The **standby track** interface configuration command ties the router hot standby priority to the availability of its interfaces and is useful for tracking interfaces that are not configured for HSRP. When a tracked interface fails, the hot standby priority on the device on which tracking has been configured decreases by 10. If an interface is not tracked, its state changes do not affect the hot standby priority of the configured device. For each interface configured for hot standby, you can configure a separate list of interfaces to be tracked
- The **standby track interface-priority** interface configuration command specifies how much to decrement the hot standby priority when a tracked interface goes down. When the interface comes back up, the priority is incremented by the same amount.
- When multiple tracked interfaces are down and *interface-priority* values have been configured, the configured priority decrements are cumulative. If tracked interfaces that were not configured with priority values fail, the default decrement is 10, and it is noncumulative.
- When routing is first enabled for the interface, it does not have a complete routing table. If it is configured to preempt, it becomes the active router, even though it is unable to provide adequate routing services. To solve this problem, configure a delay time to allow the router to update its routing table.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP priority characteristics on an interface:

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **standby** [*group-number*] **priority***priority*
4. **standby** [*group-number*] **preempt** [**delay** [*minimumseconds*] [**reloadseconds**] [*syncseconds*]]
5. **standby** [*group-number*] **track** *type number* [*interface-priority*]
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Switch # configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Switch(config)# interface gigabitethernet1/0/1	Enters interface configuration mode, and enter the HSRP interface on which you want to set priority.
Step 3	standby [<i>group-number</i>] priority <i>priority</i> Example: Switch(config-if)# standby 120 priority 50	Sets a priority value used in choosing the active router. The range is 1 to 255; the default priority is 100. The highest number represents the highest priority. <ul style="list-style-type: none"> • (Optional) group-number—The group number to which the command applies. Use the no form of the command to restore the default values.
Step 4	standby [<i>group-number</i>] preempt [delay [<i>minimumseconds</i>] [reloadseconds] [<i>syncseconds</i>]] Example: Switch(config-if)# standby 1 preempt delay 300	Configures the router to preempt , which means that when the local router has a higher priority than the active router, it becomes the active router. <ul style="list-style-type: none"> • (Optional) group-number—The group number to which the command applies. • (Optional) delay minimum—Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). • (Optional) delay reload—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to

	Command or Action	Purpose
		<p>3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload).</p> <ul style="list-style-type: none"> (Optional) delay sync—Set to cause the local router to postpone taking over the active role so that IP redundancy clients can reply (either with an ok or wait reply) for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). <p>Use the no form of the command to restore the default values.</p>
Step 5	<p>standby [<i>group-number</i>] track <i>type number</i> [<i>interface-priority</i>]</p> <p>Example:</p> <pre>Switch(config-if)# standby track interface gigabitethernet1/1/1</pre>	<p>Configures an interface to track other interfaces so that if one of the other interfaces goes down, the device's Hot Standby priority is lowered.</p> <ul style="list-style-type: none"> (Optional) <i>group-number</i>- The group number to which the command applies. <i>type</i>- Enter the interface type (combined with interface number) that is tracked. <i>number</i>- Enter the interface number (combined with interface type) that is tracked. (Optional) <i>interface-priority</i>- Enter the amount by which the hot standby priority for the router is decremented or incremented when the interface goes down or comes back up. The default value is 10.
Step 6	<p>end</p> <p>Example:</p> <pre>Switch(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 7	show running-config	Verifies the configuration of the standby groups.
Step 8	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring MHSRP

To enable MHSRP and load-balancing, you configure two routers as active routers for their groups, with virtual routers as standby routers as shown in the *MHSRP Load Sharing* figure in the Multiple HSRP section. You need to enter the **standby preempt** interface configuration command on each HSRP interface so that if a router fails and comes back up, the preemption occurs and restores load-balancing.

Router A is configured as the active router for group 1, and Router B is configured as the active router for group 2. The HSRP interface for Router A has an IP address of 10.0.0.1 with a group 1 standby priority of 110 (the default is 100). The HSRP interface for Router B has an IP address of 10.0.0.2 with a group 2 standby priority of 110.

Group 1 uses a virtual IP address of 10.0.0.3 and group 2 uses a virtual IP address of 10.0.0.4.

Configuring Router A

SUMMARY STEPS

1. **configure terminal**
2. **interface** *type number*
3. **no switchport**
4. **ip address** *ip-address mask*
5. **standby** [*group-number*] **ip** [*ip-address* [**secondary**]]
6. **standby** [*group-number*] **priority** *priority*
7. **standby** [*group-number*] **preempt** [**delay** [*minimum seconds*] [**reload** *seconds*] [**sync** *seconds*]]
8. **standby** [*group-number*] **ip** [*ip-address* [**secondary**]]
9. **standby** [*group-number*] **preempt** [**delay** [*minimum seconds*] [**reload** *seconds*] [**sync** *seconds*]]
10. **end**
11. **show running-config**
12. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Switch # configure terminal	Enters global configuration mode.
Step 2	interface <i>type number</i> Example: Switch (config)# interface gigabitethernet1/0/1	Configures an interface type and enters interface configuration mode.
Step 3	no switchport Example: Switch (config)# no switchport	Switches an interface that is in Layer 2 mode into Layer 3 mode for Layer 3 configuration.
Step 4	ip address <i>ip-address mask</i> Example: Switch (config-if)# 10.0.0.1 255.255.255.0	Specifies an IP address for an interface.
Step 5	standby [<i>group-number</i>] ip [<i>ip-address</i> [secondary]] Example: Switch (config-if)# standby 1 ip 10.0.0.3	Creates the HSRP group using its number and virtual IP address. <ul style="list-style-type: none"> • (Optional) <i>group-number</i>- The group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number. • (Optional on all but one interface) <i>ip-address</i>- The virtual IP address of the hot standby router interface. You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces.

	Command or Action	Purpose
		<ul style="list-style-type: none"> (Optional) secondary- The IP address is a secondary hot standby router interface. If neither router is designated as a secondary or standby router and no priorities are set, the primary IP addresses are compared and the higher IP address is the active router, with the next highest as the standby router.
Step 6	standby [<i>group-number</i>] priority <i>priority</i> Example: Switch(config-if)# standby 1 priority 110	Sets a priority value used in choosing the active router. The range is 1 to 255; the default priority is 100. The highest number represents the highest priority. <ul style="list-style-type: none"> (Optional) <i>group-number</i>—The group number to which the command applies. Use the no form of the command to restore the default values.
Step 7	standby [<i>group-number</i>] preempt [delay [minimum <i>seconds</i>] [reload <i>seconds</i>] [sync <i>seconds</i>]] Example: Switch(config-if)# standby 1 preempt delay 300	Configures the router to preempt , which means that when the local router has a higher priority than the active router, it becomes the active router. <ul style="list-style-type: none"> (Optional) <i>group-number</i>—The group number to which the command applies. (Optional) delay minimum—Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). (Optional) delay reload—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload). (Optional) delay sync—Set to cause the local router to postpone taking over the active role so that IP redundancy clients can reply (either with an ok or wait reply) for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). Use the no form of the command to restore the default values.
Step 8	standby [<i>group-number</i>] ip [<i>ip-address</i> [secondary]] Example: Switch (config-if)# standby 2 ip 10.0.0.4	Creates the HSRP group using its number and virtual IP address. <ul style="list-style-type: none"> (Optional) <i>group-number</i>- The group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number. (Optional on all but one interface) <i>ip-address</i>- The virtual IP address of the hot standby router interface.

	Command or Action	Purpose
		<p>You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces.</p> <ul style="list-style-type: none"> (Optional) secondary- The IP address is a secondary hot standby router interface. If neither router is designated as a secondary or standby router and no priorities are set, the primary IP addresses are compared and the higher IP address is the active router, with the next highest as the standby router.
Step 9	<p>standby [<i>group-number</i>] preempt [delay [<i>minimum seconds</i>] [reload <i>seconds</i>] [sync <i>seconds</i>]]</p> <p>Example:</p> <pre>Switch(config-if)# standby 2 preempt delay 300</pre>	<p>Configures the router to preempt, which means that when the local router has a higher priority than the active router, it becomes the active router.</p> <ul style="list-style-type: none"> (Optional) group-number-The group number to which the command applies. (Optional) delay minimum—Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). (Optional) delay reload—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload). (Optional) delay sync—Set to cause the local router to postpone taking over the active role so that IP redundancy clients can reply (either with an ok or wait reply) for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). <p>Use the no form of the command to restore the default values.</p>
Step 10	<p>end</p> <p>Example:</p> <pre>Switch(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 11	show running-config	Verifies the configuration of the standby groups.
Step 12	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring Router B

SUMMARY STEPS

1. **configure terminal**
2. **interface** *type number*

3. **no switchport**
4. **ip address** *ip-address mask*
5. **standby** [*group-number*] **ip** [*ip-address* [**secondary**]]

The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload). • (Optional) delay sync—Set to cause the local router to postpone taking over the active role so that IP redundancy clients can reply (either with an ok or wait reply) for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). <p>Use the no form of the command to restore the default values.</p>
Step 10	<p>end</p> <p>Example:</p> <pre>Switch(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 11	show running-config	Verifies the configuration of the standby groups.
Step 12	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring HSRP Authentication and Timers

You can optionally configure an HSRP authentication string or change the hello-time interval and holdtime.

When configuring these attributes, follow these guidelines:

- The authentication string is sent unencrypted in all HSRP messages. You must configure the same authentication string on all routers and access servers on a cable to ensure interoperability. Authentication mismatch prevents a device from learning the designated Hot Standby IP address and timer values from other routers configured with HSRP.
- Routers or access servers on which standby timer values are not configured can learn timer values from the active or standby router. The timers configured on an active router always override any other timer settings.

- All routers in a Hot Standby group should use the same timer values. Normally, the *holdtime* is greater than or equal to 3 times the *hellotime*.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP authentication and timers on an interface:

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **standby** [*group-number*] **authentication** *string*
4. **standby** [*group-number*] **timers** *hellotime holdtime*
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Switch # configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Switch(config) # interface gigabitethernet1/0/1	Enters interface configuration mode, and enter the HSRP interface on which you want to set priority.
Step 3	standby [<i>group-number</i>] authentication <i>string</i> Example: Switch(config-if) # standby 1 authentication word	(Optional) authentication string —Enter a string to be carried in all HSRP messages. The authentication string can be up to eight characters in length; the default string is cisco . (Optional) <i>group-number</i> —The group number to which the command applies.
Step 4	standby [<i>group-number</i>] timers <i>hellotime holdtime</i> Example: Switch(config-if) # standby 1 timers 5 15	(Optional) Configure the time between hello packets and the time before other routers declare the active router to be down. <ul style="list-style-type: none"> • <i>group-number</i>—The group number to which the command applies. • <i>hellotime</i> —Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over). • <i>holdtime</i>—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload).

	Command or Action	Purpose
Step 5	end Example: <pre>Switch(config-if) # end</pre>	Returns to privileged EXEC mode.
Step 6	show running-config	Verifies the configuration of the standby groups.
Step 7	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Enabling HSRP Support for ICMP Redirect Messages

ICMP redirect messages are automatically enabled on interfaces configured with HSRP. ICMP is a network layer Internet protocol that provides message packets to report errors and other information relevant to IP processing. ICMP provides diagnostic functions, such as sending and directing error packets to the host. This feature filters outgoing ICMP redirect messages through HSRP, in which the next hop IP address might be changed to an HSRP virtual IP address. For more information, see the Cisco IOS IP Configuration Guide, Release 12.4.

Configuring HSRP Groups and Clustering

When a device is participating in an HSRP standby routing and clustering is enabled, you can use the same standby group for command switch redundancy and HSRP redundancy. Use the **cluster standby-group** *HSRP-group-name* [**routing-redundancy**] global configuration command to enable the same HSRP standby group to be used for command switch and routing redundancy. If you create a cluster with the same HSRP standby group name without entering the **routing-redundancy** keyword, HSRP standby routing is disabled for the group.

Verifying HSRP

Verifying HSRP Configurations

From privileged EXEC mode, use this command to display HSRP settings:

```
show standby [interface-id [group]] [brief] [detail]
```

You can display HSRP information for the whole switch, for a specific interface, for an HSRP group, or for an HSRP group on an interface. You can also specify whether to display a concise overview of HSRP information or detailed HSRP information. The default display is **detail**. If there are a large number of HSRP groups, using the **show standby** command without qualifiers can result in an unwieldy display.

Example

```
Switch #show standby
VLAN1 - Group 1
Local state is Standby, priority 105, may preempt
Hellotime 3 holdtime 10
Next hello sent in 00:00:02.182
Hot standby IP address is 172.20.128.3 configured
Active router is 172.20.128.1 expires in 00:00:09
Standby router is local
```

```

Standby virtual mac address is 0000.0c07.ac01
Name is bbb

VLAN1 - Group 100
Local state is Standby, priority 105, may preempt
Hellotime 3 holdtime 10
Next hello sent in 00:00:02.262
Hot standby IP address is 172.20.138.51 configured
Active router is 172.20.128.1 expires in 00:00:09
Active router is local
Standby router is unknown expired
Standby virtual mac address is 0000.0c07.ac64
Name is test

```

Configuration Examples for Configuring HSRP

Enabling HSRP: Example

This example shows how to activate HSRP for group 1 on an interface. The IP address used by the hot standby group is learned by using HSRP.

Note This procedure is the minimum number of steps required to enable HSRP. Other configurations are optional.

```

Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 ip
Switch(config-if) # end
Switch # show standby

```

Configuring HSRP Priority: Example

This example activates a port, sets an IP address and a priority of 120 (higher than the default value), and waits for 300 seconds (5 minutes) before attempting to become the active router:

```

Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby ip 172.20.128.3
Switch(config-if) # standby priority 120 preempt delay 300
Switch(config-if) # end
Switch # show standby

```

Configuring MHSRP: Example

This example shows how to enable the MHSRP configuration shown in the figure *MHSRP Load Sharing*

Router A Configuration

```

Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport

```

```
Switch(config-if) # ip address 10.0.0.1 255.255.255.0
Switch(config-if) # standby ip 10.0.0.3
Switch(config-if) # standby 1 priority 110
Switch(config-if) # standby 1 preempt
Switch(config-if) # standby 2 ip 10.0.0.4
Switch(config-if) # standby 2 preempt
Switch(config-if) # end
```

Router B Configuration

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # ip address 10.0.0.2 255.255.255.0
Switch(config-if) # standby ip 10.0.0.3
Switch(config-if) # standby 1 preempt
Switch(config-if) # standby 2 ip 10.0.0.4
Switch(config-if) # standby 1 priority 110
Switch(config-if) # standby 2 preempt
Switch(config-if) # end
```

Configuring HSRP Authentication and Timer: Example

This example shows how to configure word as the authentication string required to allow Hot Standby routers in group 1 to interoperate:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 authentication word
Switch(config-if) # end
```

This example shows how to set the timers on standby group 1 with the time between hello packets at 5 seconds and the time after which a router is considered down to be 15 seconds:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 ip
Switch(config-if) # standby 1 timers 5 15
Switch(config-if) # end
```

Configuring HSRP Groups and Clustering: Example

This example shows how to bind standby group my_hsrp to the cluster and enable the same HSRP group to be used for command switch redundancy and router redundancy. The command can only be executed on the cluster command switch. If the standby group name or number does not exist, or if the switch is a cluster member switch, an error message appears.

```
Switch # configure terminal
Switch(config) # cluster standby-group my_hsrp routing-redundancy
Switch(config-if) # end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for STP

- An attempt to configure a device as the root device fails if the value necessary to be the root device is less than 1.
- If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected devices running older software.
- The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About Spanning Tree Protocol

Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Devices might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

The STP uses a spanning-tree algorithm to select one device of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

- Root—A forwarding port elected for the spanning-tree topology
- Designated—A forwarding port elected for every switched LAN segment
- Alternate—A blocked port providing an alternate path to the root bridge in the spanning tree
- Backup—A blocked port in a loopback configuration

The device that has *all* of its ports as the designated role or as the backup role is the root device. The device that has at least *one* of its ports in the designated role is called the designated device.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Devices send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The devices do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending device and its ports, including device and MAC addresses, device priority, port priority, and path cost. Spanning tree uses this information to elect the root device and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a device are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

Note

By default, the device sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the **[no] keepalive** interface configuration command with no keywords.

Spanning-Tree Topology and BPDUs

The stable, active spanning-tree topology of a switched network is controlled by these elements:

- The unique bridge ID (device priority and MAC address) associated with each VLAN on each device. In a device stack, all devices use the same bridge ID for a given spanning-tree instance.
- The spanning-tree path cost to the root device.
- The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the devices in a network are powered up, each functions as the root device. Each device sends a configuration BPDU through all of its ports. The BPDUs communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the device that the sending device identifies as the root device
- The spanning-tree path cost to the root
- The bridge ID of the sending device
- Message age
- The identifier of the sending interface
- Values for the hello, forward delay, and max-age protocol timers

When a device receives a configuration BPDU that contains *superior* information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the device, the device also forwards it with an updated message to all attached LANs for which it is the designated device.

If a device receives a configuration BPDU that contains *inferior* information to that currently stored for that port, it discards the BPDU. If the device is a designated device for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:

- One device in the network is elected as the root device (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.

For each VLAN, the device with the highest device priority (the lowest numerical priority value) is elected as the root device. If all devices are configured with the default priority (32768), the device with the lowest MAC address in the VLAN becomes the root device. The device priority value occupies the most significant bits of the bridge ID, as shown in the following figure.

- A root port is selected for each device (except the root device). This port provides the best path (lowest cost) when the device forwards packets to the root device.

When selecting the root port on a device stack, spanning tree follows this sequence:

- Selects the lowest root bridge ID
- Selects the lowest path cost to the root device
- Selects the lowest designated bridge ID
- Selects the lowest designated path cost

- Selects the lowest port ID
- Only one outgoing port on the stack root device is selected as the root port. The remaining devices in the stack become its designated devices (Device 2 and Device 3) as shown in the following figure.
- The shortest distance to the root device is calculated for each device based on the path cost.
- A designated device for each LAN segment is selected. The designated device incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.

Figure 15: Spanning-Tree Port States in a Device Stack

One stack member is elected as the stack root device. The stack root device contains the outgoing root port (Device 1).

All paths that are not needed to reach the root device from anywhere in the switched network are placed in the spanning-tree blocking mode.

[Restrictions for STP](#), on page 357

Bridge ID, Device Priority, and Extended System ID

The IEEE 802.1D standard requires that each device has a unique bridge identifier (bridge ID), which controls the selection of the root device. Because each VLAN is considered as a different *logical bridge* with PVST+ and Rapid PVST+, the same device must have a different bridge ID for each configured VLAN. Each VLAN on the device has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the device priority, and the remaining 6 bytes are derived from the device MAC address.

The device supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the device priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for the device, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.

The 2 bytes previously used for the device priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

Table 32: Device Priority Value and Extended System ID

Priority Value				Extended System ID (Set Equal to the VLAN ID)											
Bit 16	Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1
32768	16384	8192	4096	2048	1024	512	256	128	64	32	16	8	4	2	1

Spanning tree uses the extended system ID, the device priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the device stack appears as a single device to the rest of the network, all devices in the stack use the same bridge ID for a given spanning tree. If the stack master fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack master.

Support for the extended system ID affects how you manually configure the root device, the secondary root device, and the device priority of a VLAN. For example, when you change the device priority value, you change the probability that the device will be elected as the root device. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root device for the specified VLAN has a device priority lower than 24576, the device sets its own priority for the specified VLAN to 4096 less than the lowest device priority. 4096 is the value of the least-significant bit of a 4-bit device priority value as shown in the table.

Port Priority Versus Path Cost

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your device is a member of a device stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see [Related Topics](#).

Spanning-Tree Interface States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

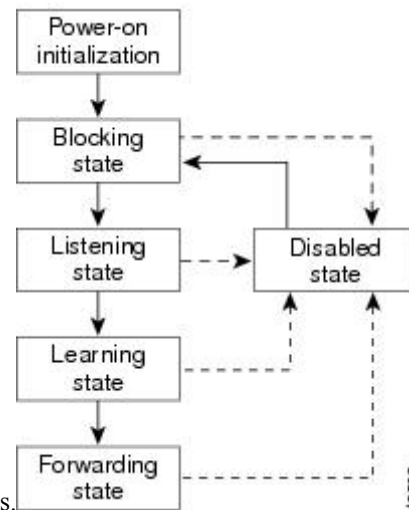

Each Layer 2 interface on a device using spanning tree exists in one of these states:

- **Blocking**—The interface does not participate in frame forwarding.
- **Listening**—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.
- **Learning**—The interface prepares to participate in frame forwarding.
- **Forwarding**—The interface forwards frames.
- **Disabled**—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:

- From initialization to blocking
- From blocking to listening or to disabled
- From listening to learning or to disabled
- From learning to forwarding or to disabled
- From forwarding to disabled

Figure 16: Spanning-Tree Interface States

An interface moves through the states.

When you power up the device, spanning tree is enabled by default, and every interface in the device, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:

1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.
2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.
3. In the learning state, the interface continues to block frame forwarding as the device learns end-station location information for the forwarding database.
4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

Blocking State

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each device interface. A device initially functions as the root until it exchanges BPDUs with other devices. This exchange establishes which device in the network is the root or root device. If there is only one device in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after device initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

Listening State

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

Learning State

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs

Forwarding State

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface
- Forwards frames switched from another interface
- Learns addresses
- Receives BPDUs

Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Does not receive BPDUs

How a Device or Port Becomes the Root Device or Root Port

If all devices in a network are enabled with default spanning-tree settings, the device with the lowest MAC address becomes the root device.

Figure 17: Spanning-Tree Topology

Device A is elected as the root device because the device priority of all the devices is set to the default (32768) and Device A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Device A might not be the ideal root device. By increasing the priority (lowering the numerical value) of the ideal device so that it becomes the root device, you force a spanning-tree recalculation

to form a new topology with the ideal device as the root. RP = Root Port
DP = Designated Port

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.

For example, assume that one port on Device B is a Gigabit Ethernet link and that another port on Device B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.

Related Topics

[Configuring Port Priority \(CLI\)](#), on page 375

Spanning Tree and Redundant Connectivity

Figure 18: Spanning Tree and Redundant Connectivity

You can create a redundant backbone with spanning tree by connecting two device interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds

are the same, the port priority and port ID are added together, and spanning tree disables the link with the

highest value.

You can also create redundant links between devices by using EtherChannel groups.

Spanning-Tree Address Management

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C2000000 to 0x0180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each device in the stack receives but does not forward packets destined for addresses between 0x0180C2000000 and 0x0180C200000F.

If spanning tree is enabled, the CPU on the device or on each device in the stack receives packets destined for 0x0180C2000000 and 0x0180C2000010. If spanning tree is disabled, the device or each device in the stack forwards those packets as unknown multicast addresses.

Accelerated Aging to Retain Connectivity

The default for aging dynamic addresses is 5 minutes, the default setting of the **mac address-table aging-time** global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (**spanning-tree vlan *vlan-id* forward-time seconds** global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the device accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the device.

[Restrictions for STP](#), on page 357

Spanning-Tree Modes and Protocols

The device supports these spanning-tree modes and protocols:

- **PVST+**—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. The PVST+ runs on each VLAN on the device up to the maximum supported, ensuring that each has a loop-free path through the network.

The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root device. This root device propagates the spanning-tree information associated with that VLAN to all other devices in the network. Because each device has the same information about the network, this process ensures that the network topology is maintained.

- **Rapid PVST+**—This spanning-tree mode is the same as PVST+ except that it uses a rapid convergence based on the IEEE 802.1w standard. Beginning from 15.2(4)E release, the STP default mode is Rapid PVST+. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to re-provision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

- **MSTP**—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a device stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

Related Topics

[Changing the Spanning-Tree Mode \(CLI\)](#), on page 370

Supported Spanning-Tree Instances

In PVST+ or Rapid PVST+ mode, the device or device stack supports up to 128 spanning-tree instances.

In MSTP mode, the device or device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

Related Topics

[Disabling Spanning Tree \(CLI\)](#), on page 371

[Default Spanning-Tree Configuration](#), on page 369

[Default MSTP Configuration](#), on page 401

Spanning-Tree Interoperability and Backward Compatibility

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ device cannot connect to multiple MST regions.

When a network contains devices running Rapid PVST+ and devices running PVST+, we recommend that the Rapid PVST+ devices and PVST+ devices be configured for different spanning-tree instances. In the

Rapid PVST+ spanning-tree instances, the root device must be a Rapid PVST+ device. In the PVST+ instances, the root device must be a PVST+ device. The PVST+ devices should be at the edge of the network.

All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

Table 33: PVST+, MSTP, and Rapid-PVST+ Interoperability and Compatibility

	PVST+	MSTP	Rapid PVST+
PVST+	Yes	Yes (with restrictions)	Yes (reverts to PVST+)
MSTP	Yes (with restrictions)	Yes	Yes (reverts to PVST+)
Rapid PVST+	Yes (reverts to PVST+)	Yes (reverts to PVST+)	Yes

Related Topics

[MSTP Configuration Guidelines](#), on page 387

[Multiple Spanning-Tree Regions](#), on page 389

STP and IEEE 802.1Q Trunks

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for *all* VLANs allowed on the trunks. However, in a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for *each* VLAN allowed on the trunks.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the device uses it instead of PVST+. The device combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.

Rapid PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

Spanning Tree and Device Stacks

When the device stack is operating in PVST+ or Rapid PVST+ mode:

- A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.
- When a new device joins the stack, it sets its bridge ID to the active switch bridge ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root.
- When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

- If the device stack is the spanning-tree root and the active switch fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.
- If a neighboring device external to the device stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a device in the active topology.
- If a new device external to the device stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a device in the network.

Default Spanning-Tree Configuration

Table 34: Default Spanning-Tree Configuration

Feature	Default Setting
Enable state	Enabled on VLAN 1.
Spanning-tree mode	Rapid PVST+ (PVST+ and MSTP are disabled.)
Device priority	32768
Spanning-tree port priority (configurable on a per-interface basis)	128
Spanning-tree port cost (configurable on a per-interface basis)	1000 Mb/s: 4 100 Mb/s: 19 10 Mb/s: 100
Spanning-tree VLAN port priority (configurable on a per-VLAN basis)	128
Spanning-tree VLAN port cost (configurable on a per-VLAN basis)	1000 Mb/s: 4 100 Mb/s: 19 10 Mb/s: 100
Spanning-tree timers	Hello time: 2 seconds Forward-delay time: 15 seconds Maximum-aging time: 20 seconds Transmit hold count: 6 BPDUs

Note Beginning in Cisco IOS Release 15.2(4)E, the default STP mode is Rapid PVST+.

How to Configure Spanning-Tree Features

Changing the Spanning-Tree Mode (CLI)

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the device runs the Rapid PVST+ protocol.

If you want to enable a mode that is different from the default mode, this procedure is required.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mode {pvst | mst | rapid-pvst}**
4. **interface *interface-id***
5. **spanning-tree link-type point-to-point**
6. **end**
7. **clear spanning-tree detected-protocols**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mode {pvst mst rapid-pvst} Example: Device(config)# spanning-tree mode pvst	Configures a spanning-tree mode. All stack members run the same version of spanning tree. <ul style="list-style-type: none"> • Select pvst to enable PVST+. • Select mst to enable MSTP. • Select rapid-pvst to enable rapid PVST+.
Step 4	interface <i>interface-id</i> Example:	Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port channels. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48.

	Command or Action	Purpose
	Device(config)# interface GigabitEthernet1/0/1	
Step 5	spanning-tree link-type point-to-point Example: Device(config-if)# spanning-tree link-type point-to-point	Specifies that the link type for this port is point-to-point. If you connect this port (local port) to a remote port through a point-to-point link and the local port becomes a designated port, the device negotiates with the remote port and rapidly changes the local port to the forwarding state.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 7	clear spanning-tree detected-protocols Example: Device# clear spanning-tree detected-protocols	If any port on the device is connected to a port on a legacy IEEE 802.1D device, this command restarts the protocol migration process on the entire device. This step is optional if the designated device detects that this device is running rapid PVST+.

[Spanning-Tree Modes and Protocols](#), on page 366

Disabling Spanning Tree (CLI)

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

Caution When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no spanning-tree vlan** *vlan-id*
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	no spanning-tree vlan <i>vlan-id</i> Example: Device(config)# no spanning-tree vlan 300	For <i>vlan-id</i> , the range is 1 to 4094.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

[Default Spanning-Tree Configuration](#), on page 369

Configuring the Root Device (CLI)

To configure a device as the root for the specified VLAN, use the **spanning-tree vlan *vlan-id* root** global configuration command to modify the device priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the device priority of the root devices for each VLAN. Because of the extended system ID support, the device sets its own priority for the specified VLAN to 24576 if this value will cause this device to become the root for the specified VLAN.

Use the **diameter** keyword to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* root primary [*diameter net-diameter*]**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree vlan <i>vlan-id</i> root primary [<i>diameter net-diameter</i>] Example: Device(config)# spanning-tree vlan 20-24 root primary diameter 4	Configures a device to become the root for the specified VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • (Optional) For diameter <i>net-diameter</i>, specify the maximum number of devices between any two end stations. The range is 2 to 7.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

What to do next

After configuring the device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the **spanning-tree vlan *vlan-id* hello-time**, **spanning-tree vlan *vlan-id* forward-time**, and the **spanning-tree vlan *vlan-id* max-age** global configuration commands.

Configuring a Secondary Root Device (CLI)

When you configure a device as the secondary root, the device priority is modified from the default value (32768) to 28672. With this priority, the device is likely to become the root device for the specified VLAN

if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768, and therefore, are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the **spanning-tree vlan *vlan-id* root primary** global configuration command.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* root secondary [diameter *net-diameter*]**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree vlan <i>vlan-id</i> root secondary [diameter <i>net-diameter</i>] Example: Device(config)# spanning-tree vlan 20-24 root secondary diameter 4	Configures a device to become the secondary root for the specified VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • (Optional) For diameter <i>net-diameter</i>, specify the maximum number of devices between any two end stations. The range is 2 to 7. Use the same network diameter value that you used when configuring the primary root device.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring Port Priority (CLI)

Note If your device is a member of a device stack, you must use the **spanning-tree [vlan *vlan-id*] cost *cost*** interface configuration command instead of the **spanning-tree [vlan *vlan-id*] port-priority *priority*** interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **spanning-tree port-priority *priority***
5. **spanning-tree vlan *vlan-id* port-priority *priority***
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/2	Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces (port-channel <i>port-channel-number</i>).
Step 4	spanning-tree port-priority <i>priority</i> Example: Device(config-if)# spanning-tree port-priority 0	Configures the port priority for an interface. For <i>priority</i> , the range is 0 to 240, in increments of 16; the default is 128. Valid values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. The lower the number, the higher the priority.
Step 5	spanning-tree vlan <i>vlan-id</i> port-priority <i>priority</i>	Configures the port priority for a VLAN.

	Command or Action	Purpose
	Example: Device(config-if)# spanning-tree vlan 20-25 port-priority 0	<ul style="list-style-type: none"> For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. For <i>priority</i>, the range is 0 to 240, in increments of 16; the default is 128. Valid values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. The lower the number, the higher the priority.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

[Port Priority Versus Path Cost](#), on page 361

[How a Device or Port Becomes the Root Device or Root Port](#), on page 365

Configuring Path Cost (CLI)

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree cost** *cost*
5. **spanning-tree vlan** *vlan-id* **cost** *cost*
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.

	Command or Action	Purpose
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1	Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces (port-channel <i>port-channel-number</i>).
Step 4	spanning-tree cost <i>cost</i> Example: Device(config-if)# spanning-tree cost 250	Configures the cost for an interface. If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission. For <i>cost</i> , the range is 1 to 200000000; the default value is derived from the media speed of the interface.
Step 5	spanning-tree vlan <i>vlan-id</i> cost <i>cost</i> Example: Device(config-if)# spanning-tree vlan 10,12-15,20 cost 300	Configures the cost for a VLAN. If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>cost</i>, the range is 1 to 200000000; the default value is derived from the media speed of the interface.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

The **show spanning-tree interface** *interface-id* privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the **show running-config** privileged EXEC command to confirm the configuration.

Related Topics

[Port Priority Versus Path Cost](#), on page 361

Configuring the Device Priority of a VLAN (CLI)

You can configure the device priority and make it more likely that a standalone device or a device in the stack will be chosen as the root device.

Note Exercise care when using this command. For most situations, we recommend that you use the **spanning-tree vlan** *vlan-id* **root primary** and the **spanning-tree vlan** *vlan-id* **root secondary** global configuration commands to modify the device priority.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* priority *priority***
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree vlan <i>vlan-id</i> priority <i>priority</i> Example: Device(config)# spanning-tree vlan 20 priority 8192	Configures the device priority of a VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>priority</i>, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device. Valid priority values are 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. All other values are rejected.
Step 4	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Configuring the Hello Time (CLI)

The hello time is the time interval between configuration messages generated and sent by the root device.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **spanning-tree vlan *vlan-id* hello-time *seconds***
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	spanning-tree vlan <i>vlan-id</i> hello-time <i>seconds</i> Example: Device(config)# spanning-tree vlan 20-24 hello-time 3	Configures the hello time of a VLAN. The hello time is the time interval between configuration messages generated and sent by the root device. These messages mean that the device is alive. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>seconds</i>, the range is 1 to 10; the default is 2.
Step 3	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Configuring the Forwarding-Delay Time for a VLAN (CLI)

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* forward-time *seconds***
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree vlan <i>vlan-id</i> forward-time <i>seconds</i> Example: Device(config)# spanning-tree vlan 20,25 forward-time 18	Configures the forward time of a VLAN. The forwarding delay is the number of seconds an interface waits before changing from its spanning-tree learning and listening states to the forwarding state. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>seconds</i>, the range is 4 to 30; the default is 15.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring the Maximum-Aging Time for a VLAN (CLI)

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* max-age *seconds***
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree vlan <i>vlan-id</i> max-age <i>seconds</i> Example: Device(config)# spanning-tree vlan 20 max-age 30	Configures the maximum-aging time of a VLAN. The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>seconds</i>, the range is 6 to 40; the default is 20.
Step 4	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Configuring the Transmit Hold-Count (CLI)

You can configure the BPDU burst size by changing the transmit hold count value.

Note Changing this parameter to a higher value can have a significant impact on CPU utilization, especially in Rapid PVST+ mode. Lowering this value can slow down convergence in certain scenarios. We recommend that you maintain the default setting.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree transmit hold-count *value***
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree transmit hold-count <i>value</i> Example: Device(config)# spanning-tree transmit hold-count 6	Configures the number of BPDUs that can be sent before pausing for 1 second. For <i>value</i> , the range is 1 to 20; the default is 6.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Monitoring Spanning-Tree Status

Table 35: Commands for Displaying Spanning-Tree Status

show spanning-tree active	Displays spanning-tree information on active interfaces only.
show spanning-tree detail	Displays a detailed summary of interface information.
show spanning-tree vlan <i>vlan-id</i>	Displays spanning-tree information for the specified VLAN.
show spanning-tree interface <i>interface-id</i>	Displays spanning-tree information for the specified interface.
show spanning-tree interface <i>interface-id</i> portfast	Displays spanning-tree portfast information for the specified interface.
show spanning-tree summary [totals]	Displays a summary of interface states or displays the total lines of the STP state section.

To clear spanning-tree counters, use the **clear spanning-tree** [**interface** *interface-id*] privileged EXEC command.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for MSTP

- For two or more devices to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.
- For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.
- For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a device stack by manually configuring the path cost.
- For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the internal spanning tree (IST) master of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST regions must contain the CST root, and all of the other MST regions must have a better path to the root.

contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the devices in the clouds.

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 402

[MSTP Configuration Guidelines](#), on page 387

[Multiple Spanning-Tree Regions](#), on page 389

Restrictions for MSTP

- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
- The device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.
- PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)
- All stack members must run the same version of spanning tree (all PVST+, Rapid PVST+, or MSTP).
- VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each device within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.
- Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.
- A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.
- After configuring a device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the **spanning-tree mst hello-time**, **spanning-tree mst forward-time**, and the **spanning-tree mst max-age** global configuration commands.

Table 36: PVST+, MSTP, and Rapid PVST+ Interoperability and Compatibility

	PVST+	MSTP	Rapid PVST+
PVST+	Yes	Yes (with restrictions)	Yes (reverts to PVST+)
MSTP	Yes (with restrictions)	Yes	Yes (reverts to PVST+)
Rapid PVST+	Yes (reverts to PVST+)	Yes (reverts to PVST+)	Yes

Information About MSTP

MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing, and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

Note The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment.

When the device is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.

Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same device ID.

MSTP Configuration Guidelines

- When you enable MST by using the **spanning-tree mode mst** global configuration command, RSTP is automatically enabled.
- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.
- When the device is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

Speed	Path Cost Value
10 Mb/s	2,000,000
100 Mb/s	200,000
1 Gb/s	20,000

Speed	Path Cost Value
10 Gb/s	2,000
100 Gb/s	200

Root Switch

The device maintains a spanning-tree instance for the group of VLANs mapped to it. A device ID, consisting of the device priority and the device MAC address, is associated with each instance. For a group of VLANs, the device with the lowest device ID becomes the root device.

When you configure a device as the root, you modify the device priority from the default value (32768) to a significantly lower value so that the device becomes the root device for the specified spanning-tree instance. When you enter this command, the device checks the device priorities of the root devices. Because of the extended system ID support, the device sets its own priority for the specified instance to 24576 if this value will cause this devices to become the root for the specified spanning-tree instance.

If any root device for the specified instance has a device priority lower than 24576, the device sets its own priority to 4096 less than the lowest device priority. (4096 is the value of the least-significant bit of a 4-bit device priority value. For more information, select "Bridge ID, Device Priority, and Extended System ID" link in Related Topics.

If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected switches running older software.

The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Use the **diameter** keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

Multiple Spanning-Tree Regions

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each device belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the device for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the "Specifying the MST Region Configuration and Enabling MSTP" link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

IST, CIST, and CST

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- An internal spanning tree (IST), which is the spanning tree that runs in an MST region.

Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because the MSTP BPDUs carry information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root device ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- A common and internal spanning tree (CIST), which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.

The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

Operations Within an MST Region

The IST connects all the MSTP switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the *IST master* before the implementation of the IEEE 802.1s standard). It is the device within the region with the lowest device ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MSTP switches at the boundary of the region is selected as the CIST regional root.

When an MSTP device initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The device also initializes all of its MST instances and claims to be the root for all of them. If the device receives superior MST root information (lower device ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

Related Topics

[Illustration of MST Regions](#), on page 391

Operations Between MST Regions

If there are multiple regions or legacy IEEE 802.1D devices within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP devices in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP devices in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual device to adjacent STP devices and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring devices and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPDU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, device priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.

MSTP devices use Version 3 RSTP BPDUs or IEEE 802.1D STP BPDUs to communicate with legacy IEEE 802.1D devices. MSTP devices use MSTP BPDUs to communicate with MSTP devices.

IEEE 802.1s Terminology

Some MST naming conventions used in Cisco's prestandard implementation have been changed to identify some *internal* or *regional* parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root device for the unique instance that spans the whole network, the CIST.
- The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single device for the CIST. The CIST external root path cost is the root path cost calculated between these virtual devices and devices that do not belong to any region.
- The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest device to the CIST root in the region. The CIST regional root acts as a root device for the IST.
- The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

Table 37: Prestandard and Standard Terminology

IEEE Standard	Cisco Prestandard	Cisco Standard
CIST regional root	IST master	CIST regional root
CIST internal root path cost	IST master path cost	CIST internal path cost
CIST external root path cost	Root path cost	Root path cost
MSTI regional root	Instance root	Instance root
MSTI internal root path cost	Root path cost	Root path cost

Illustration of MST Regions

This figure displays three MST regions and a legacy IEEE 802.1D device (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.

Hop Count

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the **spanning-tree mst max-hops** global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root device of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a device receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDUs it generates. When the count reaches zero, the device discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.

Boundary Ports

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both devices and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

Note If there is a legacy STP device on the segment, messages are always considered external.

The other change from the Cisco prestandard implementation is that the CIST regional root device ID field is now inserted where an RSTP or legacy IEEE 802.1Q device has the sender device ID. The whole region performs like a single virtual device by sending a consistent sender device ID to neighboring devices. In this example, device C would receive a BPDU with the same consistent sender device ID of root, whether or not A or B is designated for the segment.

IEEE 802.1s Implementation

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

Port Role Naming Change

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco's implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special *master* role.

- The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the **show** commands identify a port as boundary in the *type* column of the output.

Interoperation Between Legacy and Standard Devices

Because automatic detection of prestandard devices can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard device, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a device receives a prestandard BPDU on a port that has not been configured for prestandard BPDU transmission.

Figure 20: Standard and Prestandard Device Interoperation

Assume that A is a standard device and B a prestandard device, both configured to be in the same region. A is the root device for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPDU, AY cannot detect that a prestandard device is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology

Note We recommend that you minimize the interaction between standard and prestandard MST implementations.

Detecting Unidirectional Link Failure

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

Figure 21: Detecting Unidirectional Link Failure

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Device A is the root device, and its BPDUs are lost on the link leading to device B. RSTP and MST BPDUs include the role and state of the sending port. With this information, device A can detect that device B does not react to the superior BPDUs it sends and that device B is the designated, not root device. As a result, device A blocks (or keeps

blocking) its port, which prevents the bridging loop.

92
93

MSTP and Device Stacks

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

The active switch is the stack root when the stack is the root of the network and no root selection has been made within the stack.

If the device stack is the spanning-tree root and the active switch fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.

If a device that does not support MSTP is added to a device stack that does support MSTP or the reverse, the device is put into a version mismatch state. If possible, the device is automatically upgraded or downgraded to the same version of software that is running on the device stack.

Interoperability with IEEE 802.1D STP

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device might also continue to assign a boundary role to a port when the device to which this device is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring devices), use the **clear spanning-tree detected-protocols** privileged EXEC command.

If all the legacy devices on the link are RSTP devices, they can process MSTP BPDUs as if they are RSTP BPDUs. Therefore, MSTP devices send either a Version 0 configuration and TCN BPDUs or Version 3 MSTP BPDUs on a boundary port. A boundary port connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).

Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the device with the highest device priority (lowest numerical priority value) as the root device. The RSTP then assigns one of these port roles to individual ports:

- Root port—Provides the best path (lowest cost) when the device forwards packets to the root device.
- Designated port—Connects to the designated device, which incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
- Alternate port—Offers an alternate path toward the root device to that provided by the current root port.
- Backup port—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a device has two or more connections to a shared LAN segment.
- Disabled port—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

Table 38: Port State Comparison

Operational Status	STP Port State (IEEE 802.1D)	RSTP Port State	Is Port Included in the Active Topology?
Enabled	Blocking	Discarding	No
Enabled	Listening	Discarding	No
Enabled	Learning	Learning	Yes
Enabled	Forwarding	Forwarding	Yes
Disabled	Disabled	Discarding	No

To be consistent with Cisco STP implementations, this guide defines the port state as *blocking* instead of *discarding*. Designated ports start in the listening state.

Rapid Convergence

The RSTP provides for rapid recovery of connectivity following the failure of a device, a device port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

- Edge ports—If you configure a port as an edge port on an RSTP device by using the **spanning-tree portfast** interface configuration command, the edge port immediately transitions to the forwarding state. An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.
- Root ports—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.
- Point-to-point links—If you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

Figure 22: Proposal and Agreement Handshaking for Rapid Convergence

Device A is connected to Device B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Device A is a smaller numerical value than the priority of Device B. Device A sends a proposal message (a configuration BPDU with the proposal flag set) to Device B, proposing itself as the designated device.

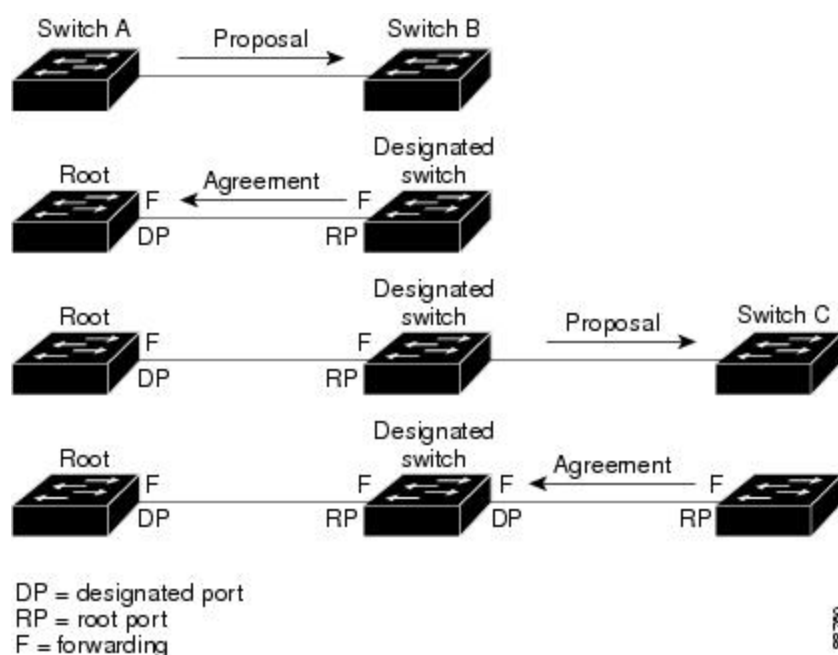

After receiving the proposal message, Device B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Device B's agreement message, Device A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Device B blocked all of its nonedge ports and because there is a point-to-point link between Devices A and B.

When Device C is connected to Device B, a similar set of handshaking messages are exchanged. Device C selects the port connected to Device B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more device joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a device stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the device is in MST mode.

The device learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the **spanning-tree link-type** interface configuration command.

Synchronization of Port Roles

When the device receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The device is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the device is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

Figure 23: Sequence of Events During Rapid Convergence

After ensuring that all of the ports are synchronized, the device sends an agreement message to the designated device corresponding to its root port. When the devices connected by a point-to-point link are in agreement

about their port roles, the RSTP immediately transitions the port states to forwarding.

Bridge Protocol Data Unit Format and Processing

The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

Table 39: RSTP BPDU Flags

Bit	Function
0	Topology change (TC)
1	Proposal
2–3:	Port role:
00	Unknown
01	Alternate port
10	Root port
11	Designated port
4	Learning
5	Forwarding
6	Agreement
7	Topology change acknowledgement (TCA)

The sending device sets the proposal flag in the RSTP BPDU to propose itself as the designated device on that LAN. The port role in the proposal message is always set to the designated port.

The sending device sets the agreement flag in the RSTP BPDUs to accept the previous proposal. The port role in the agreement message is always set to the root port.

The RSTP does not have a separate topology change notification (TCN) BPDUs. It uses the topology change (TC) flag to show the topology changes. However, for interoperability with IEEE 802.1D devices, the RSTP device processes and generates TCN BPDUs.

The learning and forwarding flags are set according to the state of the sending port.

Processing Superior BPDUs

If a port receives superior root information (lower device ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDUs received is an RSTP BPDUs with the proposal flag set, the device sends an agreement message after all of the other ports are synchronized. If the BPDUs is an IEEE 802.1D BPDUs, the device does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

Processing Inferior BPDUs

If a designated port receives an inferior BPDUs (such as a higher device ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.

Topology Changes

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- **Detection**—Unlike IEEE 802.1D in which *any* transition between the blocking and the forwarding state causes a topology change, *only* transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP device detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.
- **Notification**—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP device processes and generates TCN BPDUs.
- **Acknowledgement**—When an RSTP device receives a TCN message on a designated port from an IEEE 802.1D device, it replies with an IEEE 802.1D configuration BPDUs with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D device and a configuration BPDUs with the TCA bit set is received, the TC-while timer is reset.

This behavior is only required to support IEEE 802.1D devices. The RSTP BPDUs never have the TCA bit set.

- **Propagation**—When an RSTP device receives a TC message from another device through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding

the port on which it is received). The device starts the TC-while timer for all such ports and flushes the information learned on them.

- Protocol migration—For backward compatibility with IEEE 802.1D devices, RSTP selectively sends IEEE 802.1D configuration BPDUs and TCN BPDUs on a per-port basis.

When a port is initialized, the migrate-delay timer is started (specifies the minimum time during which RSTP BPDUs are sent), and RSTP BPDUs are sent. While this timer is active, the device processes all BPDUs received on that port and ignores the protocol type.

If the device receives an IEEE 802.1D BPDU after the port migration-delay timer has expired, it assumes that it is connected to an IEEE 802.1D device and starts using only IEEE 802.1D BPDUs. However, if the RSTP device is using IEEE 802.1D BPDUs on a port and receives an RSTP BPDU after the timer has expired, it restarts the timer and starts using RSTP BPDUs on that port.

Protocol Migration Process

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device also might continue to assign a boundary role to a port when the device to which it is connected has joined the region.

How to Configure MSTP Features

Specifying the MST Region Configuration and Enabling MSTP (CLI)

For two or more switches to be in the same MST region, they must have the same VLAN-to-instance mapping, the same configuration revision number, and the same name.

A region can have one member or multiple members with the same MST configuration; each member must be capable of processing RSTP BPDUs. There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mst configuration**
4. **instance *instance-id* vlan *vlan-range***
5. **name *name***
6. **revision *version***
7. **show pending**
8. **exit**
9. **spanning-tree mode mst**
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	<p>spanning-tree mst configuration</p> <p>Example:</p> <pre>Device(config)# spanning-tree mst configuration</pre>	Enters MST configuration mode.
Step 4	<p>instance <i>instance-id</i> vlan <i>vlan-range</i></p> <p>Example:</p> <pre>Device(config-mst)# instance 1 vlan 10-20</pre>	<p>Maps VLANs to an MST instance.</p> <ul style="list-style-type: none"> • For <i>instance-id</i>, the range is 0 to 4094. • For vlan <i>vlan-range</i>, the range is 1 to 4094. <p>When you map VLANs to an MST instance, the mapping is incremental, and the VLANs specified in the command are added to or removed from the VLANs that were previously mapped.</p> <p>To specify a VLAN range, use a hyphen; for example, instance 1 vlan 1-63 maps VLANs 1 through 63 to MST instance 1.</p> <p>To specify a VLAN series, use a comma; for example, instance 1 vlan 10, 20, 30 maps VLANs 10, 20, and 30 to MST instance 1.</p>
Step 5	<p>name <i>name</i></p> <p>Example:</p> <pre>Device(config-mst)# name region1</pre>	Specifies the configuration name. The <i>name</i> string has a maximum length of 32 characters and is case sensitive.
Step 6	<p>revision <i>version</i></p> <p>Example:</p> <pre>Device(config-mst)# revision 1</pre>	Specifies the configuration revision number. The range is 0 to 65535.
Step 7	<p>show pending</p> <p>Example:</p>	Verifies your configuration by displaying the pending configuration.

	Command or Action	Purpose
	Device(config-mst) # show pending	
Step 8	exit Example: Device(config-mst) # exit	Applies all changes, and returns to global configuration mode.
Step 9	spanning-tree mode mst Example: Device(config) # spanning-tree mode mst	Enables MSTP. RSTP is also enabled. Changing spanning-tree modes can disrupt traffic because all spanning-tree instances are stopped for the previous mode and restarted in the new mode. You cannot run both MSTP and PVST+ or both MSTP and Rapid PVST+ at the same time.
Step 10	end Example: Device(config) # end	Returns to privileged EXEC mode.

Configuring the Root Device (CLI)

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. Step 2 in the example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mst *instance-id* root primary**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mst <i>instance-id</i> root primary Example: Device(config)# spanning-tree mst 0 root primary	Configures a device as the root device. <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

[Bridge ID, Device Priority, and Extended System ID](#), on page 360

[Configuring a Secondary Root Device \(CLI\)](#), on page 406

Configuring a Secondary Root Device (CLI)

When you configure a device with the extended system ID support as the secondary root, the device priority is modified from the default value (32768) to 28672. The device is then likely to become the root device for the specified instance if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768 and therefore are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the **spanning-tree mst *instance-id* root primary** global configuration command.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mst *instance-id* root secondary**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mst <i>instance-id</i> root secondary Example:	Configures a device as the secondary root device. <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series

	Command or Action	Purpose
	Device (config) # spanning-tree mst 0 root secondary	of instances separated by a comma. The range is 0 to 4094.
Step 4	end Example: Device (config) # end	Returns to privileged EXEC mode.

Related Topics

[Configuring the Root Device \(CLI\)](#), on page 405

Configuring Port Priority (CLI)

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

Note If the device is a member of a device stack, you must use the **spanning-tree mst [instance-id] cost cost** interface configuration command instead of the **spanning-tree mst [instance-id] port-priority priority** interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree mst** *instance-id* **port-priority** *priority*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface GigabitEthernet1/0/1	Specifies an interface to configure, and enters interface configuration mode.
Step 4	spanning-tree mst <i>instance-id</i> port-priority <i>priority</i> Example: Device(config-if)# spanning-tree mst 0 port-priority 64	Configures port priority. <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. • For <i>priority</i>, the range is 0 to 240 in increments of 16. The default is 128. The lower the number, the higher the priority. The priority values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected.
Step 5	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

The **show spanning-tree mst interface *interface-id*** privileged EXEC command displays information only if the port is in a link-up operative state. Otherwise, you can use the **show running-config interface** privileged EXEC command to confirm the configuration.

Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 402

[Configuring Path Cost \(CLI\)](#), on page 409

Configuring Path Cost (CLI)

The MSTP path cost default value is derived from the media speed of an interface. If a loop occurs, the MSTP uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree mst** *instance-id* **cost** *cost*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1	Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces. The port-channel range is 1 to 48.
Step 4	spanning-tree mst <i>instance-id</i> cost <i>cost</i> Example:	Configures the cost.

	Command or Action	Purpose
	<pre>Device(config-if)# spanning-tree mst 0 cost 17031970</pre>	<p>If a loop occurs, the MSTP uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.</p> <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. • For <i>cost</i>, the range is 1 to 200000000; the default value is derived from the media speed of the interface.
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre>	Returns to privileged EXEC mode.

The **show spanning-tree mst interface** *interface-id* privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the **show running-config** privileged EXEC command to confirm the configuration.

Configuring the Device Priority (CLI)

Changing the priority of a device makes it more likely to be chosen as the root device whether it is a standalone device or a device in the stack.

Note Exercise care when using this command. For normal network configurations, we recommend that you use the **spanning-tree mst instance-id root primary** and the **spanning-tree mst instance-id root secondary** global configuration commands to specify a device as the root or secondary root device. You should modify the device priority only in circumstances where these commands do not work.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **spanning-tree mst *instance-id* priority *priority***
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mst <i>instance-id</i> priority <i>priority</i> Example: Device(config)# spanning-tree mst 0 priority 40960	Configures the device priority. <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. • For <i>priority</i>, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device. Priority values are 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. These are the only acceptable values.
Step 4	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Configuring the Hello Time (CLI)

The hello time is the time interval between configuration messages generated and sent by the root device.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mst hello-time *seconds***
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mst hello-time <i>seconds</i> Example: Device(config)# spanning-tree mst hello-time 4	Configures the hello time for all MST instances. The hello time is the time interval between configuration messages generated and sent by the root device. These messages indicate that the device is alive. For <i>seconds</i> , the range is 1 to 10; the default is 3.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

Configuring the Forwarding-Delay Time (CLI)**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mst forward-time seconds`
4. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	spanning-tree mst forward-time seconds Example: Device(config)# <code>spanning-tree mst forward-time 25</code>	Configures the forward time for all MST instances. The forwarding delay is the number of seconds a port waits before changing from its spanning-tree learning and listening states to the forwarding state. For <i>seconds</i> , the range is 4 to 30; the default is 20.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.

Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 402

Configuring the Maximum-Aging Time (CLI)**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mst max-age seconds`

4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mst max-age <i>seconds</i> Example: Device(config)# spanning-tree mst max-age 40	Configures the maximum-aging time for all MST instances. The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration. For <i>seconds</i> , the range is 6 to 40; the default is 20.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

Configuring the Maximum-Hop Count (CLI)

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mst max-hops *hop-count*
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree mst max-hops <i>hop-count</i> Example: Device(config)# spanning-tree mst max-hops 25	Specifies the number of hops in a region before the BPDU is discarded, and the information held for a port is aged. For <i>hop-count</i> , the range is 1 to 255; the default is 20.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 402

Specifying the Link Type to Ensure Rapid Transitions (CLI)

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote device running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **spanning-tree link-type point-to-point**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface GigabitEthernet1/0/1	Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port-channel logical interfaces. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48.
Step 4	spanning-tree link-type point-to-point Example: Device(config-if)# spanning-tree link-type point-to-point	Specifies that the link type of a port is point-to-point.
Step 5	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 402

Designating the Neighbor Type (CLI)

A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.

You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the **show** commands, even if the port is in STP compatibility mode.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree mst pre-standard**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface GigabitEthernet1/0/1	Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports.
Step 4	spanning-tree mst pre-standard Example: Device(config-if)# spanning-tree mst pre-standard	Specifies that the port can send only prestandard BPDUs.
Step 5	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 402

Restarting the Protocol Migration Process (CLI)

This procedure restarts the protocol migration process and forces renegotiation with neighboring devices. It reverts the device to MST mode. It is needed when the device no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Follow these steps to restart the protocol migration process (force the renegotiation with neighboring devices) on the device.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

If you want to use the interface version of the command, you must also know the MST interface used. This example uses GigabitEthernet1/0/1 as the interface because that was the interface set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. **enable**
2. Enter one of the following commands:
 - **clear spanning-tree detected-protocols**
 - **clear spanning-tree detected-protocols interface *interface-id***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Enter one of the following commands: <ul style="list-style-type: none"> • clear spanning-tree detected-protocols • clear spanning-tree detected-protocols interface <i>interface-id</i> Example: Device# clear spanning-tree detected-protocols OR Device# clear spanning-tree detected-protocols interface GigabitEthernet1/0/1	The device reverts to the MSTP mode, and the protocol migration process restarts.

What to do next

This procedure may need to be repeated if the device receives more legacy IEEE 802.1D configuration BPDUs (BPDUs with the protocol version set to 0).

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restriction for Optional Spanning-Tree Features

- PortFast minimizes the time that interfaces must wait for spanning tree to converge, so it is effective only when used on interfaces connected to end stations. If you enable PortFast on an interface connecting to another switch, you risk creating a spanning-tree loop.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Related Topics

[Enabling PortFast \(CLI\), on page 432](#)

[PortFast, on page 422](#)

Information About Optional Spanning-Tree Features

PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

Figure 24: PortFast-Enabled Interfaces

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to

converge. Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.

Related Topics

[Enabling PortFast \(CLI\)](#), on page 432

[Restriction for Optional Spanning-Tree Features](#), on page 421

BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast edge-enabled ports, spanning tree shuts down ports that are in a PortFast edge-operational state if any BPDU is received on them. In a valid configuration, PortFast edge-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast edge-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast edge feature, and the port receives a BPDU, it is put in the error-disabled state.

The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.

Related Topics

[Enabling BPDU Guard \(CLI\)](#), on page 433

BPDU Filtering

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast edge-enabled interfaces at the global level keeps those interfaces that are in a PortFast edge-operational state from sending or receiving BPDUs. The interfaces still send a few BPDUs at link-up before the switch begins to filter outbound BPDUs. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDUs. If a BPDU is received on a PortFast edge-enabled interface, the interface loses its PortFast edge-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast edge feature keeps the interface from sending or receiving BPDUs.

**Caution**

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature for the entire switch or for an interface.

Related Topics

[Enabling BPDU Filtering \(CLI\)](#), on page 435

UplinkFast

Figure 25: Switches in a Hierarchical Network

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one

redundant link that spanning tree blocks to prevent

loops.

If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.

When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

Note

UplinkFast is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.

Figure 26: UplinkFast Example Before Direct Link Failure

This topology has no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in

a blocking state.

Figure 27: UplinkFast Example After Direct Link Failure

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked interface on Switch C and transitions it to the forwarding state without going through the listening and learning states. This change takes approximately 1 to

5 seconds.

[Events That Cause Fast Convergence](#), on page 427

Cross-Stack UplinkFast

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see [Related Topics](#).

Related Topics

[Enabling UplinkFast for Use with Redundant Links \(CLI\)](#), on page 436

[Events That Cause Fast Convergence](#), on page 427

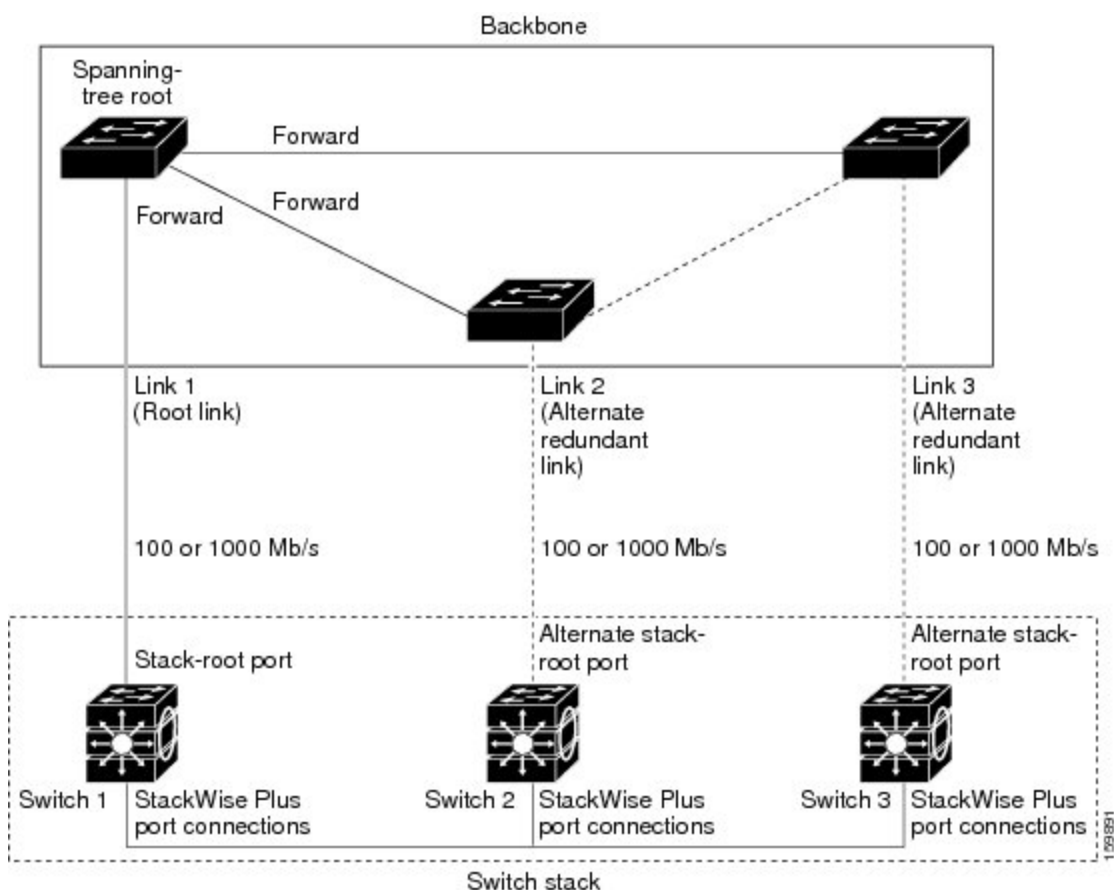

How Cross-Stack UplinkFast Works

Cross-Stack UplinkFast (CSUF) ensures that one link in the stack is elected as the path to the root.

Figure 28: Cross-Stack UplinkFast Topology

The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.

When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.

Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate ($2 * \text{forward-delay time} + \text{max-age time}$).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

Related Topics

[Enabling UplinkFast for Use with Redundant Links \(CLI\)](#), on page 436

[Events That Cause Fast Convergence](#), on page 427

Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur.

Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.

If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.

- The failed link, which connects the stack root to the spanning-tree root, recovers.
- A network reconfiguration causes a new stack-root switch to be selected.
- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

Note The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.
- The stack-root switch, which was powered off or failed, is powered on.
- A new switch, which might become the stack root, is added to the stack.

[How Cross-Stack UplinkFast Works](#), on page 426

BackboneFast

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches.

BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDUs from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDUs for the maximum aging time (default is 20 seconds).

The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.

Figure 29: BackboneFast Example Before Indirect Link Failure

This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B

Figure 30: BackboneFast Example After Indirect Link Failure

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDUs to Switch C, identifying itself as the root. When Switch C receives the inferior BPDUs from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is set. BackboneFast reconfigures the topology to account for the failure of link

Figure 31: Adding a Switch in a Shared-Medium Topology

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDUs did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDUs that indicate it is the root switch. However, the other switches ignore these inferior

BPDUs, and the new switch learns that Switch B is the designated switch to Switch A, the root

switch.

EtherChannel Guard

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel, but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.

Related Topics

[Enabling EtherChannel Guard \(CLI\)](#), on page 440

Root Guard

Figure 32: Root Guard in a Service-Provider Network

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer's network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer's switch from becoming the root switch or being in the path to the root.

If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer's switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

Caution

Misuse of the root guard feature can cause a loss of connectivity.

Related Topics

[Enabling Root Guard \(CLI\)](#), on page 441

Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in MST mode, BPDUs are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.

Related Topics

[Enabling Loop Guard \(CLI\)](#), on page 442

How to Configure Optional Spanning-Tree Features

Enabling PortFast (CLI)

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

**Caution**

Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree portfast** [trunk]
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example:	Specifies an interface to configure, and enters interface configuration mode.

	Command or Action	Purpose
	Device(config)# <code>interface gigabitethernet1/0/2</code>	
Step 4	spanning-tree portfast [trunk] Example: Device(config-if)# <code>spanning-tree portfast trunk</code>	Enables PortFast on an access port connected to a single workstation or server. By specifying the trunk keyword, you can enable PortFast on a trunk port. Note To enable PortFast on trunk ports, you must use the spanning-tree portfast trunk interface configuration command. The spanning-tree portfast command will not work on trunk ports. Make sure that there are no loops in the network between the trunk port and the workstation or server before you enable PortFast on a trunk port. By default, PortFast is disabled on all interfaces.
Step 5	end Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.

What to do next

You can use the **spanning-tree portfast default** global configuration command to globally enable the PortFast feature on all nontrunking ports.

Related Topics

[PortFast](#), on page 422

[Restriction for Optional Spanning-Tree Features](#), on page 421

Enabling BPDU Guard (CLI)

You can enable the BPDU guard feature if your switch is running PVST+, Rapid PVST+, or MSTP.

**Caution**

Configure PortFast edge only on ports that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree portfast edge bpduguard default`
4. `interface interface-id`

5. `spanning-tree portfast edge`
6. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	spanning-tree portfast edge bpduguard default Example: Device(config)# <code>spanning-tree portfast edge bpduguard default</code>	Globally enables BPDU guard. By default, BPDU guard is disabled.
Step 4	interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet1/0/2</code>	Specifies the interface connected to an end station, and enters interface configuration mode.
Step 5	spanning-tree portfast edge Example: Device(config-if)# <code>spanning-tree portfast edge</code>	Enables the PortFast edge feature.
Step 6	end Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.

What to do next

To prevent the port from shutting down, you can use the **errdisable detect cause bpduguard shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

You also can use the **spanning-tree bpduguard enable** interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put it in the error-disabled state.

Related Topics

[BPDU Guard](#), on page 422

Enabling BPDU Filtering (CLI)

You can also use the **spanning-tree bpdudfilter enable** interface configuration command to enable BPDU filtering on any interface without also enabling the PortFast edge feature. This command prevents the interface from sending or receiving BPDUs.

Caution Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution Configure PortFast edge only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree portfast edge bpdudfilter default**
4. **interface *interface-id***
5. **spanning-tree portfast edge**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree portfast edge bpdudfilter default Example: Device(config)# spanning-tree portfast edge bpdudfilter default	Globally enables BPDU filtering. By default, BPDU filtering is disabled.

	Command or Action	Purpose
Step 4	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/2	Specifies the interface connected to an end station, and enters interface configuration mode.
Step 5	spanning-tree portfast edge Example: Device(config-if)# spanning-tree portfast edge	Enables the PortFast edge feature on the specified interface.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Related Topics

[BPDU Filtering](#), on page 423

Enabling UplinkFast for Use with Redundant Links (CLI)

Note When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable UplinkFast and CSUF.

Before you begin

UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the **no spanning-tree vlan *vlan-id* priority** global configuration command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree uplinkfast** [**max-update-rate** *pkts-per-second*]
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	spanning-tree uplinkfast [max-update-rate pkts-per-second] Example: <pre>Device(config)# spanning-tree uplinkfast max-update-rate 200</pre>	Enables UplinkFast. (Optional) For <i>pkts-per-second</i> , the range is 0 to 32000 packets per second; the default is 150. If you set the rate to 0, station-learning frames are not generated, and the spanning-tree topology converges more slowly after a loss of connectivity. When you enter this command, CSUF also is enabled on all nonstack port interfaces.
Step 4	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

When UplinkFast is enabled, the switch priority of all VLANs is set to 49152. If you change the path cost to a value less than 3000 and you enable UplinkFast or UplinkFast is already enabled, the path cost of all interfaces and VLAN trunks is increased by 3000 (if you change the path cost to 3000 or above, the path cost is not altered). The changes to the switch priority and the path cost reduce the chance that a switch will become the root switch.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you enable the UplinkFast feature using these instructions, CSUF is automatically globally enabled on nonstack port interfaces.

Related Topics

[How Cross-Stack UplinkFast Works](#), on page 426

[Events That Cause Fast Convergence](#), on page 427

Disabling UplinkFast (CLI)

This procedure is optional.

Follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

Before you begin

UplinkFast must be enabled.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no spanning-tree uplinkfast**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	no spanning-tree uplinkfast Example: Device(config)# no spanning-tree uplinkfast	Disables UplinkFast and CSUF on the switch and all of its VLANs.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you disable the UplinkFast feature using these instructions, CSUF is automatically globally disabled on nonstack port interfaces.

Enabling BackboneFast (CLI)

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable BackboneFast on the switch.

Before you begin

If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree backbonefast**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree backbonefast Example: Device(config)# spanning-tree backbonefast	Enables BackboneFast.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

[BackboneFast](#), on page 428

Enabling EtherChannel Guard (CLI)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable EtherChannel Guard on the device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree etherchannel guard misconfig**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	spanning-tree etherchannel guard misconfig Example: Device(config)# spanning-tree etherchannel guard misconfig	Enables EtherChannel guard.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

What to do next

You can use the **show interfaces status err-disabled** privileged EXEC command to show which device ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the **show etherchannel summary** privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the **shutdown** and **no shutdown** interface configuration commands on the port-channel interfaces that were misconfigured.

Related Topics

[EtherChannel Guard](#), on page 430

Enabling Root Guard (CLI)

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.

Note You cannot enable both root guard and loop guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable root guard on the switch.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree guard root**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/2	Specifies an interface to configure, and enters interface configuration mode.
Step 4	spanning-tree guard root	Enables root guard on the interface.

	Command or Action	Purpose
	Example: Device(config-if) # spanning-tree guard root	By default, root guard is disabled on all interfaces.
Step 5	end Example: Device(config-if) # end	Returns to privileged EXEC mode.

Related Topics

Enabling Loop Guard (CLI)

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

Note You cannot enable both loop guard and root guard at the same time.

You can enable this feature if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional. Follow these steps to enable loop guard on the device.

SUMMARY STEPS

1. Enter one of the following commands:
 - **show spanning-tree active**
 - **show spanning-tree mst**
2. **configure terminal**
3. **spanning-tree loopguard default**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	Enter one of the following commands: <ul style="list-style-type: none"> • show spanning-tree active • show spanning-tree mst Example: Device# show spanning-tree active or	Verifies which interfaces are alternate or root ports.

	Command or Action	Purpose
	Device# <code>show spanning-tree mst</code>	
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	spanning-tree loopguard default Example: Device(config)# <code>spanning-tree loopguard default</code>	Enables loop guard. By default, loop guard is disabled.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for EtherChannels

The following are restrictions for EtherChannels:

- All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.
- Layer 3 EtherChannels are not supported if running the LAN Base license feature set.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About EtherChannels

EtherChannel Overview

EtherChannel provides fault-tolerant high-speed links between switches, routers, and servers. You can use the EtherChannel to increase the bandwidth between the wiring closets and the data center, and you can deploy it anywhere in the network where bottlenecks are likely to occur. EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention.

An EtherChannel consists of individual Ethernet links bundled into a single logical link.

Figure 33: Typical EtherChannel Configuration

The EtherChannel provides full-duplex bandwidth up to 8 Gb/s (Gigabit EtherChannel) or 80 Gb/s (10-Gigabit EtherChannel) between your switch and another switch or host.

Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The number of EtherChannels is limited to 128.

The LAN Base feature set supports up to 24 EtherChannels.

All ports in each EtherChannel must be configured as either Layer 2 or Layer 3 ports. The EtherChannel Layer 3 ports are made up of routed ports. Routed ports are physical ports configured to be in Layer 3 mode by using the **no switchport** interface configuration command. For more information, see the Configuring Interface Characteristics chapter.

- [EtherChannel Configuration Guidelines](#), on page 461
- [Default EtherChannel Configuration](#), on page 460
- [Layer 2 EtherChannel Configuration Guidelines](#), on page 462

EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as would any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.
- When you configure an EtherChannel in the **on** mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the **on** mode; otherwise, packet loss can occur.

[Layer 2 EtherChannel Configuration Guidelines](#), on page 462

EtherChannel on Devices

You can create an EtherChannel on a device, on a single device in the stack, or on multiple devices in the stack (known as cross-stack EtherChannel).

Figure 34: Single-Switch EtherChannel

Figure 35: Cross-Stack EtherChannel

Figure 36: Single Controller EtherChannel

This figure shows the recommended cross-stack EtherChannel configuration with three active links and three standby links.

Figure 37: Cross-Stack EtherChannel

[Default EtherChannel Configuration](#), on page 460

[Layer 2 EtherChannel Configuration Guidelines](#), on page 462

EtherChannel Link Failover

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

Channel Groups and Port-Channel Interfaces

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.

Figure 38: Relationship of Physical Ports, Channel Group and Port-Channel Interface

The **channel-group** command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 128. This port-channel interface number corresponds to the one specified with the **channel-group** interface configuration command.

- With Layer 2 ports, use the **channel-group** interface configuration command to dynamically create the port-channel interface.

You also can use the **interface port-channel** *port-channel-number* global configuration command to manually create the port-channel interface, but then you must use the **channel-group** *channel-group-number* command to bind the logical interface to a physical port. The *channel-group-number* can be the same as the *port-channel-number*, or you can use a new number. If you use a new number, the **channel-group** command dynamically creates a new port channel.

- With Layer 3 ports, you should manually create the logical interface by using the **interface port-channel** global configuration command followed by the **no switchport** interface configuration command. You then manually assign an interface to the EtherChannel by using the **channel-group** interface configuration command.
- With Layer 3 ports, use the **no switchport** interface command to configure the interface as a Layer 3 interface, and then use the **channel-group** interface configuration command to dynamically create the port-channel interface.

Port Aggregation Protocol

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco devices and on those devices licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP can be enabled on cross-stack EtherChannels.

By using PAgP, the device or device stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single device in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single device port.

PAgP Modes

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

Table 42: EtherChannel PAgP Modes

Mode	Description
auto	Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets.
desirable	Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel).

Switch ports exchange PAgP packets only with partner ports configured in the **auto** or **desirable** modes. Ports configured in the **on** mode do not exchange PAgP packets.

Both the **auto** and **desirable** modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed. and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the **desirable** mode can form an EtherChannel with another port that is in the **desirable** or **auto** mode.
- A port in the **auto** mode can form an EtherChannel with another port in the **desirable** mode.

A port in the **auto** mode cannot form an EtherChannel with another port that is also in the **auto** mode because neither port starts PAgP negotiation.

Silent Mode

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the **non-silent** keyword. If you do not specify **non-silent** with the **auto** or **desirable** mode, silent mode is assumed.

Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

PAgP Learn Method and Priority

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.

When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.

PAgP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn

addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the **pagp port-priority** interface configuration command. The higher the priority, the more likely that the port will be selected.

Note The device supports address learning only on aggregate ports even though the **physical-port** keyword is provided in the CLI. The **pagp learn-method** command and the **pagp port-priority** command have no effect on the device hardware, but they are required for PAgP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the device is a physical learner, we recommend that you configure the device as a physical-port learner by using the **pagp learn-method physical-port** interface configuration command. Set the load-distribution method based on the source MAC address by using the **port-channel load-balance src-mac** global configuration command. The device then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the **pagp learn-method** command in this situation.

[Default EtherChannel Configuration](#), on page 460

[Monitoring EtherChannel, PAgP, and LACP Status](#), on page 482

[Layer 2 EtherChannel Configuration Guidelines](#), on page 462

PAgP Interaction with Other Features

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAgP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created (through the **interface port-channel** global configuration command).

PAgP sends and receives PAgP PDUs only from ports that are up and have PAgP enabled for the auto or desirable mode.

Link Aggregation Control Protocol

The LACP is defined in IEEE 802.3ad and enables Cisco devices to manage Ethernet channels between devices that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the device or device stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and

port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single device port.

The independent mode behavior of ports in a port channel is changed. With CSCtn96950, by default, standalone mode is enabled. When no response is received from an LACP peer, ports in the port channel are moved to suspended state.

LACP Modes

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

Table 43: EtherChannel LACP Modes

Mode	Description
active	Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.
passive	Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets.

Both the **active** and **passive LACP** modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the **active** mode can form an EtherChannel with another port that is in the **active** or **passive** mode.
- A port in the **passive** mode cannot form an EtherChannel with another port that is also in the **passive** mode because neither port starts LACP negotiation.

LACP and Link Redundancy

LACP port-channel operation, bandwidth availability, and link redundancy can be further refined with the LACP port-channel min-links and the LACP max-bundle features.

The LACP port-channel min-links feature:

- Configures the minimum number of ports that must be linked up and bundled in the LACP port channel.
- Prevents a low-bandwidth LACP port channel from becoming active.
- Causes an LACP port channel to become inactive if there are too few active members ports to supply the required minimum bandwidth.

The LACP max-bundle feature:

- Defines an upper limit on the number of bundled ports in an LACP port channel.
- Allows hot-standby ports with fewer bundled ports. For example, in an LACP port channel with five ports, you can specify a max-bundle of three, and the two remaining ports are designated as hot-standby ports.

Related Topics

[Configuring the LACP Max Bundle Feature \(CLI\)](#), on page 474

[Configuring LACP Hot-Standby Ports: Example](#), on page 485

[Configuring the LACP Port Channel Min-Links Feature \(CLI\)](#), on page 476

LACP Interaction with Other Features

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created through the **interface port-channel** global configuration command.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

EtherChannel On Mode

EtherChannel **on** mode can be used to manually configure an EtherChannel. The **on** mode forces a port to join an EtherChannel without negotiations. The **on** mode can be useful if the remote device does not support PAgP or LACP. In the **on** mode, a usable EtherChannel exists only when the devices at both ends of the link are configured in the **on** mode.

Ports that are configured in the **on** mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the **on** mode.

Caution

You should use care when using the **on** mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

Load-Balancing and Forwarding Methods

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the device.

Note Layer 3 Equal-cost multi path (ECMP) load balancing is based on source IP address, destination IP address, source port, destination port, and layer 4 protocol. Fragmented packets will be treated on two different links based on the algorithm calculated using these parameters. Any changes in one of these parameters will result in load balancing.

You configure the load-balancing and forwarding method by using the **port-channel load-balance** and the **port-channel load-balance extended** global configuration commands.

[Layer 3 EtherChannel Configuration Guidelines](#), on page 463

MAC Address Forwarding

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host's MAC address of the incoming packet. Therefore, packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular device. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

Related Topics

[Layer 2 EtherChannel Configuration Guidelines](#), on page 462

[Default EtherChannel Configuration](#), on page 460

[Layer 3 EtherChannel Configuration Guidelines](#), on page 463

IP Address Forwarding

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel.

Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular device. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

Load-Balancing Advantages

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the device in the network and the kind of traffic that needs to be load-distributed.

Figure 39: Load Distribution and Forwarding Methods

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the device EtherChannel ensures that the device uses all available bandwidth to the router. The router is configured for destination-based forwarding because the large number of workstations ensures that the traffic is evenly distributed from the router EtherChannel.

10-1239

Figure 40: Load Distribution and Forwarding

In the figure below the controller does source MAC-based forwarding over the EtherChannel links and evenly distributes the traffic over multiple links of the EtherChannel.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

EtherChannel and Device Stacks

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active device removes the failed stack member device ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a device is added to an existing stack, the new device receives the running configuration from the active device and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAGP or LACP configuration on a winning device stack is not affected, but the PAGP or LACP configuration on the losing device stack is lost after the stack reboots.

Device Stack and PAGP

With PAGP, if the active device fails or leaves the stack, the standby device becomes the new active device. A spanning-tree reconvergence is not triggered unless there is a change in the EtherChannel bandwidth. The new active device synchronizes the configuration of the stack members to that of the active device. The PAGP

configuration is not affected after an active device change unless the EtherChannel has ports residing on the old active device.

Device Stacks and LACP

With LACP, the system ID uses the stack MAC address from the active device. When an active device fails or leaves the stack and the standby device becomes the new active device change, the LACP system ID is unchanged. By default, the LACP configuration is not affected after the active device changes.

Default EtherChannel Configuration

The default EtherChannel configuration is described in this table.

Table 44: Default EtherChannel Configuration

Feature	Default Setting
Channel groups	None assigned.
Port-channel logical interface	None defined.
PAgP mode	No default.
PAgP learn method	Aggregate-port learning on all ports.
PAgP priority	128 on all ports.
LACP mode	No default.
LACP learn method	Aggregate-port learning on all ports.
LACP port priority	32768 on all ports.
LACP system priority	32768.
LACP system ID	LACP system priority and the device or stack MAC address.
Load-balancing	Load distribution on the device is based on the source-MAC address of the incoming packet.

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

- Do not try to configure more than 128 EtherChannels on the device or device stack.
- Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
- Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
- Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
- Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the **shutdown** interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.
- When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:
 - Allowed-VLAN list
 - Spanning-tree path cost for each VLAN
 - Spanning-tree port priority for each VLAN
 - Spanning-tree Port Fast setting
- Do not configure a port to be a member of more than one EtherChannel group.
- Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same device or on different devices in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.
- Do not configure a secure port as part of an EtherChannel or the reverse.
- Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.

- If EtherChannels are configured on device interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a device by using the **dot1x system-auth-control** global configuration command.
- If cross-stack EtherChannel is configured and the device stack partitions, loops and forwarding issues can occur.

Layer 2 EtherChannel Configuration Guidelines

When configuring Layer 2 EtherChannels, follow these guidelines:

- Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.
- An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAGP is set to the **auto** or **desirable** mode.
- Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

Auto-LAG

The auto-LAG feature provides the ability to auto create EtherChannels on ports connected to a switch. By default, auto-LAG is disabled globally and is enabled on all port interfaces. The auto-LAG applies to a switch only when it is enabled globally.

On enabling auto-LAG globally, the following scenarios are possible:

- All port interfaces participate in creation of auto EtherChannels provided the partner port interfaces have EtherChannel configured on them. For more information, see the *"The supported auto-LAG configurations between the actor and partner devices"* table below.
- Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.
- When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:

Table 45: The supported auto-LAG configurations between the actor and partner devices

Actor/Partner	Active	Passive	Auto
Active	Yes	Yes	Yes
Passive	Yes	No	Yes
Auto	Yes	Yes	Yes

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels.

You cannot add any configurations in an existing auto created EtherChannel. To add, you should first convert it into a manual EtherChannel by executing the **port-channel<channel-number>persistent**.

Note Auto-LAG uses the LACP protocol to create auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

Auto-LAG Configuration Guidelines

Follow these guidelines when configuring the auto-LAG feature.

- When auto-LAG is enabled globally and on the port interface, and if you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.
- A port interface will not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.
- When auto-LAG is enabled and auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.
- The auto-LAG is supported only on Layer 2 EtherChannel. It is not supported on Layer 3 interface and Layer 3 EtherChannel.
- The auto-LAG is supported on cross-stack EtherChannel.

How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

Configuring Layer 2 EtherChannels (CLI)

You configure Layer 2 EtherChannels by assigning ports to a channel group with the **channel-group** interface configuration command. This command automatically creates the port-channel logical interface.

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **switchport mode** {access | trunk}
4. **switchport access vlan** *vlan-id*
5. **channel-group** *channel-group-number* **mode** {auto [non-silent] | desirable [non-silent] | on } | { active | passive}
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet2/0/1	Specifies a physical port, and enters interface configuration mode. Valid interfaces are physical ports. For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group. For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
Step 3	switchport mode {access trunk} Example: Device(config-if)# switchport mode access	Assigns all ports as static-access ports in the same VLAN, or configure them as trunks. If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.

	Command or Action	Purpose
Step 4	<p>switchport access vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config-if)# switchport access vlan 22</pre>	<p>(Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.</p>
Step 5	<p>channel-group <i>channel-group-number</i> mode {auto non-silent desirable [non-silent] on } { active passive }</p> <p>Example:</p> <pre>Device(config-if)# channel-group 5 mode auto</pre>	<p>Assigns the port to a channel group, and specifies the PAgP or the LACP mode.</p> <p>For <i>channel-group-number</i>, the range is 1 to 128.</p> <p>For mode, select one of these keywords:</p> <ul style="list-style-type: none"> • auto —Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack. • desirable —Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack. • on —Forces the port to channel without PAgP or LACP. In the on mode, an EtherChannel exists only when a port group in the on mode is connected to another port group in the on mode. • non-silent —(Optional) If your device is connected to a partner that is PAgP-capable, configures the device port for nonsilent operation when the port is in the auto or desirable mode. If you do not specify non-silent, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission. • active —Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets. • passive —Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.

	Command or Action	Purpose
Step 6	end Example: Device(config-if) # end	Returns to privileged EXEC mode.

Configuring Layer 3 EtherChannels (CLI)

Follow these steps to assign an Ethernet port to a Layer 3 EtherChannel. This procedure is required.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **no ip address**
5. **no switchport**
6. **channel-group** *channel-group-number* **mode** { **auto** [**non-silent**] | **desirable** [**non-silent**] | **on** } | { **active** | **passive** }
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 3	<p><code>interface interface-id</code></p> <p>Example:</p> <p>Device(config)# <code>interface gigabitethernet 1/0/2</code></p>	<p>Specifies a physical port, and enters interface configuration mode.</p> <p>Valid interfaces include physical ports.</p> <p>For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group.</p> <p>For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.</p>
Step 4	<p><code>no ip address</code></p> <p>Example:</p> <p>Device(config-if)# <code>no ip address</code></p>	Ensures that there is no IP address assigned to the physical port.
Step 5	<p><code>no switchport</code></p> <p>Example:</p> <p>Device(config-if)# <code>no switchport</code></p>	Puts the port into Layer 3 mode.
Step 6	<p><code>channel-group channel-group-number mode { auto [non-silent] desirable [non-silent] on } { active passive }</code></p> <p>Example:</p> <p>Device(config-if)# <code>channel-group 5 mode auto</code></p>	<p>Assigns the port to a channel group, and specifies the PAgP or the LACP mode.</p> <p>For mode, select one of these keywords:</p> <ul style="list-style-type: none"> • auto—Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack. • desirable—Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack. • on—Forces the port to channel without PAgP or LACP. In the on mode, an EtherChannel exists only when a port group in the on mode is connected to another port group in the on mode. • non-silent—(Optional) If your device is connected to a partner that is PAgP capable, configures the device

	Command or Action	Purpose
		<p>port for nonsilent operation when the port is in the auto or desirable mode. If you do not specify non-silent, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAGP to operate, to attach the port to a channel group, and to use the port for transmission.</p> <ul style="list-style-type: none"> • active—Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets. • passive—Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.
Step 7	<p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre>	Returns to privileged EXEC mode.

Configuring EtherChannel Load-Balancing (CLI)

You can configure EtherChannel load-balancing to use one of several different forwarding methods.

This task is optional.

SUMMARY STEPS

1. **configure terminal**
2. **port-channel load-balance { dst-ip | dst-mac | dst-mixed-ip-port | dst-port | extended [dst-ip | dst-mac | dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port] | src-dst-ip | src-dst-mac src-dst-mixed-ip-port src-dst-portsrc-ip | src-mac | src-mixed-ip-port | src-port }**
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	<p>port-channel load-balance { dst-ip dst-mac dst-mixed-ip-port dst-port extended [dst-ip dst-mac dst-port ipv6-label l3-proto src-ip src-mac src-port] src-dst-ip src-dst-mac src-dst-mixed-ip-port src-dst-portsrc-ip src-mac src-mixed-ip-port src-port}</p> <p>Example:</p> <pre>Device(config)# port-channel load-balance src-mac</pre>	<p>Configures an EtherChannel load-balancing method.</p> <p>The default is src-mac.</p> <p>Select one of these load-distribution methods:</p> <ul style="list-style-type: none"> • dst-ip—Specifies destination-host IP address. • dst-mac—Specifies the destination-host MAC address of the incoming packet. • dst-mixed-ip-port—Specifies the host IP address and TCP/UDP port. • dst-port—Specifies the destination TCP/UDP port. • extended—Specifies extended load balance methods--combinations of source and destination methods beyond those available with the standard command. • ipv6-label—Specifies the IPv6 flow label. • l3-proto—Specifies the Layer 3 protocol. • src-dst-ip—Specifies the source and destination host IP address. • src-dst-mac—Specifies the source and destination host MAC address. • src-dst-mixed-ip-port—Specifies the source and destination host IP address and TCP/UDP port. • src-dst-port—Specifies the source and destination TCP/UDP port. • src-ip—Specifies the source host IP address. • src-mac—Specifies the source MAC address of the incoming packet. • src-mixed-ip-port—Specifies the source host IP address and TCP/UDP port. • src-port—Specifies the source TCP/UDP port.
Step 3	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode.</p>

Configuring EtherChannel Extended Load-Balancing (CLI)

Configure EtherChannel extended load-balancing when you want to use a combination of load-balancing methods.

This task is optional.

SUMMARY STEPS

1. **configure terminal**
2. **port-channel load-balance extended** [**dst-ip** | **dst-mac dst-port** | **ipv6-label** | **l3-proto** | **src-ip** | **src-mac** | **src-port**]
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	port-channel load-balance extended [dst-ip dst-mac dst-port ipv6-label l3-proto src-ip src-mac src-port] Example: Device (config)# port-channel load-balance extended dst-ip dst-mac src-ip	Configures an EtherChannel extended load-balancing method. The default is src-mac . Select one of these load-distribution methods: <ul style="list-style-type: none"> • dst-ip—Specifies destination-host IP address. • dst-mac—Specifies the destination-host MAC address of the incoming packet. • dst-port—Specifies the destination TCP/UDP port. • ipv6-label—Specifies the IPv6 flow label. • l3-proto—Specifies the Layer 3 protocol. • src-ip—Specifies the source host IP address. • src-mac—Specifies the source MAC address of the incoming packet.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • src-port—Specifies the source TCP/UDP port.
Step 3	end Example: Device (config) # end	Returns to privileged EXEC mode.

Configuring the PAgP Learn Method and Priority (CLI)

This task is optional.

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **pagp learn-method physical-port**
4. **pagp port-priority** *priority*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 1/0/2	Specifies the port for transmission, and enters interface configuration mode.
Step 3	pagp learn-method physical-port Example: Device (config-if) # pagp learn-method physical port	<p>Selects the PAgP learning method.</p> <p>By default, aggregation-port learning is selected, which means the device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.</p> <p>Selects physical-port to connect with another device that is a physical learner. Make sure to configure the port-channel load-balance global configuration command to src-mac.</p>

	Command or Action	Purpose
		The learning method must be configured the same at both ends of the link.
Step 4	pagp port-priority <i>priority</i> Example: Device(config-if) # pagp port-priority 200	Assigns a priority so that the selected port is chosen for packet transmission. For <i>priority</i> , the range is 0 to 255. The default is 128. The higher the priority, the more likely that the port will be used for PAGP transmission.
Step 5	end Example: Device(config-if) # end	Returns to privileged EXEC mode.

Related Topics

Configuring LACP Hot-Standby Ports

When LACP is enabled, the software, by default, tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time; the remaining eight links are placed in hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.

You can override the default behavior by specifying the maximum number of active ports in a channel, in which case, the remaining ports become hot-standby ports. For example, if you specify a maximum of five ports in a channel, up to 11 ports become hot-standby ports.

If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the device MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system

decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

Configuring the LACP Max Bundle Feature (CLI)

When you specify the maximum number of bundled LACP ports allowed in a port channel, the remaining ports in the port channel are designated as hot-standby ports.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of LACP ports in a port channel. This procedure is optional.

SUMMARY STEPS

1. **configure terminal**
2. **interface port-channel** *channel-number*
3. **lacp max-bundle** *max-bundle-number*
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface port-channel <i>channel-number</i> Example: Device(config)# interface port-channel 2	Enters interface configuration mode for a port channel. The range is 1 to 128.
Step 3	lacp max-bundle <i>max-bundle-number</i> Example: Device(config-if)# lacp max-bundle 3	Specifies the maximum number of LACP ports in the port-channel bundle. The range is 1 to 8.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring LACP Port-Channel Standalone Disable

To disable the standalone EtherChannel member port state on a port channel, perform this task on the port channel interface:

SUMMARY STEPS

1. **configure terminal**
2. **interface port-channel** *channel-group*
3. **port-channel standalone-disable**
4. **end**
5. **show etherchannel**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	interface port-channel <i>channel-group</i> Example: Device(config)# interface port-channel <i>channel-group</i>	Selects a port channel interface to configure.
Step 3	port-channel standalone-disable Example: Device(config-if)# port-channel standalone-disable	Disables the standalone mode on the port-channel interface.
Step 4	end Example: Device(config-if)# end	Exits configuration mode.
Step 5	show etherchannel Example: Device# show etherchannel <i>channel-group</i> port-channel Device# show etherchannel <i>channel-group</i> detail	Verifies the configuration.

Related Topics

[Configuring LACP Hot-Standby Ports: Example](#), on page 485

Configuring the LACP Port Channel Min-Links Feature (CLI)

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

To configure the minimum number of links that are required for a port channel. Perform the following tasks.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface port-channel** *channel-number*
4. **port-channel min-links** *min-links-number*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface port-channel <i>channel-number</i> Example: Device(config)# interface port-channel 2	Enters interface configuration mode for a port-channel. For <i>channel-number</i> , the range is 1 to 63.
Step 4	port-channel min-links <i>min-links-number</i> Example: Device(config-if)# port-channel min-links 3	Specifies the minimum number of member ports that must be in the link-up state and bundled in the EtherChannel for the port channel interface to transition to the link-up state. For <i>min-links-number</i> , the range is 2 to 8.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

[LACP and Link Redundancy](#) , on page 455

[Configuring LACP Hot-Standby Ports: Example](#), on page 485

Configuring the LACP System Priority (CLI)

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the **lacp system-priority** global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Follow these steps to configure the LACP system priority. This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **lacp system-priority** *priority*
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	lacp system-priority <i>priority</i> Example: Device(config)# lacp system-priority 32000	Configures the LACP system priority. The range is 1 to 65535. The default is 32768. The lower the value, the higher the system priority.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Related Topics

- [EtherChannel Configuration Guidelines](#), on page 461
- [Default EtherChannel Configuration](#), on page 460
- [Layer 2 EtherChannel Configuration Guidelines](#), on page 462
- [Monitoring EtherChannel, PAgP, and LACP Status](#), on page 482

Configuring the LACP Port Priority (CLI)

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Note If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Follow these steps to configure the LACP port priority. This procedure is optional.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **lacp port-priority** *priority*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example:	Specifies the port to be configured, and enters interface configuration mode.

	Command or Action	Purpose
	Device(config)# <code>interface gigabitethernet 1/0/2</code>	
Step 4	lACP port-priority <i>priority</i> Example: Device(config-if)# <code>lACP port-priority 32000</code>	Configures the LACP port priority. The range is 1 to 65535. The default is 32768. The lower the value, the more likely that the port will be used for LACP transmission.
Step 5	end Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.

Configuring Auto-LAG Globally

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `[no] port-channel auto`
4. `end`
5. `show etherchannel auto`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.

	Command or Action	Purpose
Step 3	[no] port-channel auto Example: Device(config) # <code>port-channel auto</code>	Enables the auto-LAG feature on a switch globally. Use the no form of this command to disable the auto-LAG feature on the switch globally. Note By default, the auto-LAG feature is enabled on the port.
Step 4	end Example: Device(config) # <code>end</code>	Returns to privileged EXEC mode.
Step 5	show etherchannel auto Example: Device# <code>show etherchannel auto</code>	Displays that EtherChannel is created automatically.

Configuring Auto-LAG on a Port Interface

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `[no] channel-group auto`
5. `end`
6. `show etherchannel auto`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example:	Enters the global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 3	<code>interface interface-id</code> Example: Device(config)# <code>interface gigabitethernet 1/0/1</code>	Specifies the port interface to be enabled for auto-LAG, and enters interface configuration mode.
Step 4	<code>[no] channel-group auto</code> Example: Device(config-if)# <code>channel-group auto</code>	(Optional) Enables auto-LAG feature on individual port interface. Use the no form of this command to disable the auto-LAG feature on individual port interface. Note By default, the auto-LAG feature is enabled on the port.
Step 5	<code>end</code> Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.
Step 6	<code>show etherchannel auto</code> Example: Device# <code>show etherchannel auto</code>	Displays that EtherChannel is created automatically.

Configuring Persistence with Auto-LAG

You use the persistence command to convert the auto created EtherChannel into a manual one and allow you to add configuration on the existing EtherChannel.

SUMMARY STEPS

1. `enable`
2. `port-channel channel-number persistent`
3. `show etherchannel summary`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	port-channel <i>channel-number</i> persistent Example: Device# port-channel 1 persistent	Converts the auto created EtherChannel into a manual one and allows you to add configuration on the EtherChannel.
Step 3	show etherchannel summary Example: Device# show etherchannel summary	Displays the EtherChannel information.

Monitoring EtherChannel, PAgP, and LACP Status

You can display EtherChannel, PAgP, and LACP status using the commands listed in this table.

Table 46: Commands for Monitoring EtherChannel, PAgP, and LACP Status

Command	Description
clear lacp { <i>channel-group-number</i> counters counters }	Clears LACP channel-group information and traffic counters.
clear pagp { <i>channel-group-number</i> counters counters }	Clears PAgP channel-group information and traffic counters.
show etherchannel [<i>channel-group-number</i> { detail load-balance port port-channel protocol summary }] [detail load-balance port port-channel protocol auto summary]	Displays EtherChannel information in a brief, detailed, and one-line summary form. Also displays the load-balance or frame-distribution scheme, port, port-channel, protocol, and Auto-LAG information.
show pagp [<i>channel-group-number</i>] { counters internal neighbor }	Displays PAgP information such as traffic information, the internal PAgP configuration, and neighbor information.

Command	Description
show pagp [<i>channel-group-number</i>] dual-active	Displays the dual-active detection status.
show lacp [<i>channel-group-number</i>] { counters internal neighbor sys-id }	Displays LACP information such as traffic information, the internal LACP configuration, and neighbor information.
show running-config	Verifies your configuration entries.
show etherchannel load-balance	Displays the load balance or frame distribution scheme among ports in the port channel.

Configuration Examples for Configuring EtherChannels

Configuring Layer 2 EtherChannels: Examples

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAGP mode **desirable**:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode desirable non-silent
Device(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode **active**:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
```

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

```
Device# configure terminal
```

```

Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode passive
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# switchport mode access
Device(config-if)# switchport access vlan 10
Device(config-if)# channel-group 5 mode passive
Device(config-if)# exit

```

PoE or LACP negotiation errors may occur if you configure two ports from switch to the access point (AP). This scenario can be avoided if the port channel configuration is on the switch side. For more details, see the following example:

```

interface Port-channel1
  switchport access vlan 20
  switchport mode access
  switchport nonegotiate
  no port-channel standalone-disable <--this one
  spanning-tree portfast

```

Note If the port reports LACP errors on port flap, you should include the following command as well: **no errdisable detect cause pagp-flap**

Configuring Layer 3 EtherChannels: Examples

This example shows how to configure a Layer 3 EtherChannel. It assigns two ports to channel 5 with the LACP mode **active**:

```

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end

```

This example shows how to configure a cross-stack Layer 3 EtherChannel. It assigns two ports on stack member 2 and one port on stack member 3 to channel 7 using LACP active mode:

```

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 7 mode active
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# no ip address
Device(config-if)# no switchport
Device(config-if)# channel-group 7 mode active
Device(config-if)# exit

```

Configuring LACP Hot-Standby Ports: Example

This example shows how to configure an Etherchannel (port channel 2) that will be active when there are at least three active ports, will comprise up to seven active ports and the remaining ports (up to nine) as hot-standby ports :

```
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# port-channel min-links 3
Device(config-if)# lacp max-bundle 7
```

This example shows how to disable the standalone EtherChannel member port state on port channel 42:

```
Device(config)# interface port-channel channel-group
Device(config-if)# port-channel standalone-disable
```

This example shows how to verify the configuration:

```
Device# show etherchannel 42 port-channel | include Standalone
Standalone Disable = enabled
Device# show etherchannel 42 detail | include Standalone
Standalone Disable = enabled
```

Configuring Auto LAG: Examples

This example shows how to configure Auto-LAG on a switch

```
device> enable
device# configure terminal
device (config)# port-channel auto
device (config-if)# end
device# show etherchannel auto
```

The following example shows the summary of EtherChannel that was created automatically.

```
device# show etherchannel auto
Flags: D - down          P - bundled in port-channel
       I - stand-alone  s - suspended
       H - Hot-standby (LACP only)
       R - Layer3       S - Layer2
       U - in use       f - failed to allocate aggregator
       M - not in use, minimum links not met
       u - unsuitable for bundling
       w - waiting to be aggregated
       d - default port
       A - formed by Auto LAG
```

```
Number of channel-groups in use: 1
```

```

Number of aggregators:          1

Group  Port-channel  Protocol  Ports
-----+-----+-----+-----
1      Po1(SUA)        LACP      Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)

```

The following example shows the summary of auto EtherChannel after executing the **port-channel 1 persistent** command.

```

device# port-channel 1 persistent

device# show etherchannel summary
Switch# show etherchannel summary
Flags: D - down          P - bundled in port-channel
       I - stand-alone  s - suspended
       H - Hot-standby (LACP only)
       R - Layer3       S - Layer2
       U - in use       f - failed to allocate aggregator
       M - not in use, minimum links not met
       u - unsuitable for bundling
       w - waiting to be aggregated
       d - default port
       A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators:          1

Group  Port-channel  Protocol  Ports
-----+-----+-----+-----
1      Po1(SU)        LACP      Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)

```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another device.
- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.
- You can configure UDLD in interface configuration mode and the configuration is accepted by the device; however, this configuration is not displayed in the running configuration, nor is it saved.

Caution

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.

Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

Modes of Operation

UDLD supports two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

Related Topics

[Enabling UDLD Globally \(CLI\)](#), on page 493

[Enabling UDLD on an Interface \(CLI\)](#), on page 494

Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
- One of the fiber strands in the cable is disconnected.

In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heart beat whose presence guarantees the health of the link. Conversely, the loss of the heart beat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

Note Udd is enabled with `udd aggressive mode` globally. When Rx cable or Tx is cable from switch1 , then the switch1 and switch2 ports will go into **Not connected** state. They do not go to **error disabled** state. Also the port does not show any light if you check the physical connection.

Switch1 (Tx)_____ (Rx) Switch2

Switch1 (Rx)_____ (Tx) Switch2

Related Topics

[Enabling UDLD Globally \(CLI\)](#), on page 493

[Enabling UDLD on an Interface \(CLI\)](#), on page 494

Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

Related Topics

[Enabling UDLD Globally \(CLI\)](#), on page 493

[Enabling UDLD on an Interface \(CLI\)](#), on page 494

Neighbor Database Maintenance

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the device receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the device receives a new hello message before an older cache entry ages, the device replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the device is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

Event-Driven Detection and Echoing

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

Related Topics

[Enabling UDLD on an Interface \(CLI\)](#), on page 494

UDLD Reset Options

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The **udld reset** interface configuration command.
- The **shutdown** interface configuration command followed by the **no shutdown** interface configuration command restarts the disabled port.
- The **no udld {aggressive | enable}** global configuration command followed by the **udld {aggressive | enable}** global configuration command reenables the disabled ports.
- The **no udld port** interface configuration command followed by the **udld port [aggressive]** interface configuration command reenables the disabled fiber-optic port.
- The **errdisable recovery cause udld** global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the **errdisable recovery interval interval** global configuration command specifies the time to recover from the UDLD error-disabled state.

How to Configure UDLD

Enabling UDLD Globally (CLI)

Follow these steps to enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic ports on the device.

SUMMARY STEPS

1. **configure terminal**
2. **udld {aggressive | enable | message time *message-timer-interval*}**
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	udld {aggressive enable message time <i>message-timer-interval</i>} Example: Device(config)# udld enable message time 10	Specifies the UDLD mode of operation: <ul style="list-style-type: none"> • aggressive—Enables UDLD in aggressive mode on all fiber-optic ports. • enable—Enables UDLD in normal mode on all fiber-optic ports on the device. UDLD is disabled by default. An individual interface configuration overrides the setting of the udld enable global configuration command. • message time <i>message-timer-interval</i>—Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are detected to be bidirectional. The range is from 1 to 90 seconds; the default value is 15. <p>Note This command affects fiber-optic ports only. Use the udld interface configuration command to enable UDLD on other port types.</p>

	Command or Action	Purpose
		Use the no form of this command, to disable UDLD.
Step 3	end Example: Device(config) # end	Returns to privileged EXEC mode.

Enabling UDLD on an Interface (CLI)

Follow these steps either to enable UDLD in the aggressive or normal mode or to disable UDLD on a port.

SUMMARY STEPS

1. **configure terminal**
2. **interface *interface-id***
3. **udld port [aggressive]**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device(config) # interface gigabitethernet 1/0/1	Specifies the port to be enabled for UDLD, and enters interface configuration mode.
Step 3	udld port [aggressive] Example:	UDLD is disabled by default.

	Command or Action	Purpose
	Device(config-if)# udld port aggressive	<ul style="list-style-type: none"> • udld port—Enables UDLD in normal mode on the specified port. • udld port aggressive—(Optional) Enables UDLD in aggressive mode on the specified port. <p>Note Use the no udld port interface configuration command to disable UDLD on a specified fiber-optic port.</p>
Step 4	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring the Device for Access Point Discovery

Caution You should connect APs directly to the Cisco Catalyst 3850 switch ports to use its wireless functionality.

- Ensure that the Control and Provisioning of Wireless Access Points (CAPWAP) UDP ports 5246 and 5247 (similar to the Lightweight Access Point Protocol (LWAPP) UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the device.
- If access control lists (ACLs) are in the control path between the device and its access points, you must open new protocol ports to prevent access points from being stranded.

- If an access point is in the UP state and its IP address changes, the access point tears down the existing CAPWAP tunnel and rejoins the device.
- Access points must be discovered by a device before they can become an active part of the network. The lightweight access points support the following device discovery processes:
 - Layer 3 CAPWAP discovery—You can enable this feature on different subnets from the access point. This feature uses IP addresses and UDP packets rather than the MAC addresses used by Layer 2 discovery.
 - Locally stored device IP address discovery—If the access point was previously associated to a device, the IP addresses of the primary, secondary, and tertiary devices are stored in the access point's nonvolatile memory. This process of storing device IP addresses on an access point for later deployment is called *priming the access point*.
 - DHCP server discovery—This feature uses DHCP option 43 to provide device IP addresses to the access points. Cisco switches support a DHCP server option that is typically used for this capability.
 - DNS discovery—The access point can discover devices through your domain name server (DNS). You must configure your DNS to return device IP addresses in response to CISCO-CAPWAP-CONTROLLER.localdomain, where localdomain is the access point domain name. When an access point receives an IP address and DNS information from a DHCP server, it contacts the DNS to resolve CISCO-CAPWAP-CONTROLLER.localdomain. When the DNS sends a list of device IP addresses, the access point sends discovery requests to the devices.

Restrictions for Configuring the Device for Access Point Discovery

- Ensure that the devices are configured with the correct date and time. If the date and time configured on the device precedes the creation and installation date of certificates on the access points, the access point fails to join the device.
- During the discovery process, access points that are supported by the Cisco device, such as the 1140, 1260, 3500, 1040, 1600, 2600, or 3600 query only for Cisco devices.
- Do not configure same VLAN for both wireless management and wireless clients.

Information About Configuring the Device for Access Point Discovery

In a CAPWAP environment, a lightweight access point discovers a device by using CAPWAP discovery mechanisms and then sends a CAPWAP join request to the device. The device sends a CAPWAP join response to the access point that allows the access point to join the device. When the access point joins the device, the device manages its configuration, firmware, control transactions, and data transactions.

Access Point Communication Protocols

Cisco lightweight access points use the IETF standard CAPWAP to communicate with the device and other lightweight access points on the network.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a device to manage a collection of wireless access points. CAPWAP is implemented in device for these reasons:

- To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP
- To manage RFID readers and similar devices
- To enable devices to interoperate with third-party access points in the future

Viewing Access Point Join Information

Join statistics for an access point that sends a CAPWAP discovery request to the device at least once are maintained on the device even if the access point is rebooted or disconnected. These statistics are removed only when the device is rebooted or when you choose to clear the statistics.

Troubleshooting the Access Point Join Process

Access points can fail to join a device for many reasons such as a RADIUS authorization is pending, self-signed certificates are not enabled on the device, the access point and device's regulatory domains do not match, and so on.

You can configure the access points to send all CAPWAP-related errors to a syslog server. You do not need to enable any debug commands on the device because all of the CAPWAP error messages can be viewed from the syslog server itself.

The state of the access point is not maintained on the device until it receives a CAPWAP join request from the access point, so it can be difficult to determine why the CAPWAP discovery request from a certain access point was rejected. In order to troubleshoot such joining issues without enabling CAPWAP debug commands on the device, the device collects information for all access points that send a discovery message to this device and maintains information for any access points that have successfully joined this device.

The device collects all join-related information for each access point that sends a CAPWAP discovery request to the device. Collection begins when the first discovery message is received from the access point and ends when the last configuration payload is sent from the device to the access point.

When the device is maintaining join-related information for the maximum number of access points, it does not collect information for any more access points.

You can also configure a DHCP server to return a syslog server IP address to the access point using option 7 on the server. The access point then starts sending all syslog messages to this IP address.

You can configure the syslog server IP address through the access point CLI, if the access point is not connected to the device by entering the **capwap ap log-server *syslog_server_IP_address*** command.

When the access point joins a device for the first time, the device pushes the global syslog server IP address (the default is 255.255.255.255) to the access point. After that, the access point sends all syslog messages to this IP address, until it is overridden by one of the following scenarios:

- The access point is still connected to the same device, and you changed the global syslog server IP address configuration on the device by using the **ap syslog host** *Syslog_Server_IP_Address* command. In this case, the device pushes the new global syslog server IP address to the access point.
- The access point is still connected to the same device, and you configured a specific syslog server IP address for the access point on the device by using the **ap name** *Cisco_AP* **syslog host** *Syslog_Host_IP_Address* command. In this case, the device pushes the new specific syslog server IP address to the access point.
- The access point gets disconnected from the device, and you configured the syslog server IP address from the access point CLI by using the **capwap ap log-server** *syslog_server_IP_address* command. This command works only if the access point is not connected to any device.
- The access point gets disconnected from the device and joins another device. In this case, the new device pushes its global syslog server IP address to the access point.

Whenever a new syslog server IP address overrides the existing syslog server IP address, the old address is erased from persistent storage, and the new address is stored in its place. The access point also starts sending all syslog messages to the new IP address, if the access point can reach the syslog server IP address.

How to Configure Access Point Discovery

Configuring the Syslog Server for Access Points (GUI)

-
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.
- The **All APs** page is displayed showing a list of access points that are associated with the device and their current settings.
- Step 2** From the **Show** drop-down list, choose **Quick Filter**.
- The filter options (text boxes) appear in each of the column header in the table.
- Step 3** Enter a keyword in the corresponding text boxes to specify the filter criteria based on which you want to search, and click the **Filter** icon.
-

Configuring the Syslog Server for Access Points (CLI)

SUMMARY STEPS

1. **show ap config global**
2. **show ap name** *Cisco_AP* **config general**

DETAILED STEPS

	Command or Action	Purpose
Step 1	show ap config global Example: Device# show ap config global	Displays the global syslog server settings for all access points that join the device.
Step 2	show ap name Cisco_AP config general Example: Device# show ap name AP03 config general	Displays the syslog server settings for a specific access point.

Monitoring Access Point Join Information (CLI)

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. enable
2. show ap join stats summary
3. show ap mac-address *mac_address* join stats summary
4. show ap mac-address *mac_address* join stats detailed
5. clear ap join statistics

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	show ap join stats summary Example: Device# show ap join stats summary	Displays the MAC addresses of all the access points that are joined to the device or that have tried to join.
Step 3	show ap mac-address <i>mac_address</i> join stats summary Example: Device# show ap mac-address 000.2000.0400 join stats summary	Displays all the statistics for the AP including the last join error detail.
Step 4	show ap mac-address <i>mac_address</i> join stats detailed Example:	Displays all join-related statistics collected for a specific access point.

	Command or Action	Purpose
	Device# show ap mac-address 000.2000.0400 join stats detailed	
Step 5	clear ap join statistics Example: Device# clear ap join statistics	Clears the join statistics for all access points. Note To clear the join statistics that correspond to specific access points, enter the clear ap mac-address mac_address join statistics command.

Related Topics

[Displaying the MAC Addresses of all Access Points: Example](#), on page 505

[DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example](#), on page 506

Searching for Access Point Radios (GUI)

Step 1 Choose **Monitor > Wireless > Access Points** and click **802.11a/n/ac Statistics** or **802.11b/g/n Statistics**.

The 802.11 Radio pages are displayed. These pages show all of the 802.11a/n/ac or 802.11b/g/n access point radios that are associated with the device and their current settings.

Note In a Cisco converged access environment, the 802.11a/n/ac and 802.11b/g/n radios should not be differentiated based on their Base Radio MAC addresses, because they might have the same addresses. Instead, the radios should be differentiated based on their physical addresses.

Step 2 From the **Show** drop-down list, choose **Quick Filter**.

The filter options (text boxes) appear in each of the column header in the table.

Step 3 Enter a keyword in the corresponding text boxes to specify the filter criteria based on which you want to search, and click the **Filter** icon.

Monitoring the Interface Details (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed showing a list of access points that are associated with the device.

Step 2 Click the access point name.

The **AP > Edit** page is displayed.

Step 3 Click the **Interface** tab.

The interface details are displayed.

Configuration Examples for Configuring the Device for Access Point Discovery

Displaying the MAC Addresses of all Access Points: Example

This example shows how to display MAC addresses of all the access points that are joined to the device:

```
Device# show ap join stats summary
Number of APs..... 4

Base Mac           EthernetMac       AP Name IP Address      Status
-----
00:0b:85:57:bc:c0 00:0b:85:57:bc:c0 AP1130 10.10.163.217    Joined
00:1c:0f:81:db:80 00:1c:63:23:ac:a0 AP1140 10.10.163.216    Not joined
00:1c:0f:81:fc:20 00:1b:d5:9f:7d:b2 AP1     10.10.163.215    Joined
00:21:1b:ea:36:60 00:0c:d4:8a:6b:c1 AP2     10.10.163.214    Not joined
```

This example shows how to display the last join error details for a specific access point:

```
Device# show ap mac-address 000.2000.0400 join stats summary
Is the AP currently connected to controller..... Yes
Time at which the AP joined this
controller last time..... Aug 21 12:50:36.061
Type of error
that occurred last..... AP got or has been disconnected
Reason for error
that occurred last..... The AP has been reset by the controller
Time at which the last join error occurred..... Aug 21 12:50:34.374
```

This example shows how to display all join-related statistics collected for a specific access point:

```
Device# show ap mac-address 000.2000.0400 join stats detailed
Discovery phase statistics
- Discovery requests received..... 2
- Successful discovery responses sent..... 2
- Unsuccessful discovery request processing..... 0
- Reason for last unsuccessful discovery attempt.... Not applicable
- Time at last successful discovery attempt..... Aug 21 12:50:23.335
- Time at last unsuccessful discovery attempt..... Not applicable

Join phase statistics
- Join requests received..... 1
- Successful join responses sent..... 1
- Unsuccessful join request processing..... 1
- Reason for last unsuccessful join attempt..... RADIUS authorization
is pending
for the AP
- Time at last successful join attempt..... Aug 21 12:50:34.481
- Time at last unsuccessful join attempt..... Aug 21 12:50:34.374

Configuration phase statistics
- Configuration requests received..... 1
- Successful configuration responses sent..... 1
- Unsuccessful configuration request processing..... 0
- Reason for last unsuccessful configuration attempt.. Not applicable
- Time at last successful configuration attempt..... Aug 21 12:50:34.374
- Time at last unsuccessful configuration attempt..... Not applicable

Last AP message decryption failure details
```

```

- Reason for last message decryption failure..... Not applicable

Last AP disconnect details
- Reason for last AP connection failure..... The AP has been reset by
the controller

Last join error summary
- Type of error that occurred last..... AP got or has been
disconnected
- Reason for error that occurred last..... The AP has been reset
by the controller
- Time at which the last join error occurred..... Aug 21 12:50:34.374

```

DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example

For more information about the AP join process, see *DHCP OPTION 43 for Lightweight Cisco Aironet Access Points Configuration Example*.

Configuring AP Pass Through

Information About AP Pass Through

AP pass through allows all the access points connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join another controller on the network.

Prior to this release, all access points connected Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches would be terminated on the device when the wireless management vlan is turned on. Unsupported access points connected to the device were unable join a controller on a different vlan. AP pass through allows the connected AP to join another wireless controller on the network by assigning different vlan.

The advantages of AP pass through are:

- Allows partial deployment of Cisco New Generation Wireless Controllers where some APs are connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches but other APs continue to join other controllers on the network.
- The APs that are not supported on the Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches are allowed to join other controllers on the network.
- The wireless LAN controller is used to provide access to both wired and wireless guests. AP Pass through allows the AP to pass through Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join any other controller when wired guest accessing is turned on.

Configuring AP Pass Through

All access points on VLANs other than the one with supported access points will be put into the AP pass-through mode and will not terminate on the Device.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless management interface vlan <i>vlan_id</i> Example: Device(config)# wireless management interface vlan10	Configures the ports that are connected to the supported access points with the wireless management VLAN
Step 3	interface GigabitEthernet1/0/1 Example: Device(config)# interface TenGigabitEthernet1/0/1	Sets the 10-Gigabit Ethernet interface. The command prompt changes from (config)# to (config-if)#.
Step 4	description Supported AP switchport access <i>vlan_id</i> Example: Device(config-if)# switchport access vlan10	Specifies the VLAN for which this access port will carry traffic
Step 5	description Unsupported AP switchport access <i>vlan_id</i> Example: Device(config-if)# switchport access vlan20	Configures the ports that are connected to the unsupported access points with a vlan other than the wireless management VLAN.

CHAPTER 30

Configuring Data Encryption

- [Finding Feature Information, on page 509](#)
- [Prerequisites for Configuring Data Encryption, on page 509](#)
- [Restrictions for Configuring Data Encryption, on page 509](#)
- [Information About Data Encryption, on page 510](#)
- [How to Configure Data Encryption, on page 510](#)
- [Configuration Examples for Configuring Data Encryption, on page 511](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Data Encryption

- Cisco 1260, 3500, 3600, 801, 1140, 1310, and 1520 series access points support Datagram Transport Layer Security (DTLS) data encryption.
- You can use the device to enable or disable DTLS data encryption for a specific access point or for all access points.
- Non-Russian customers who use the Cisco device do not need a data DTLS license.

Restrictions for Configuring Data Encryption

- Encryption limits throughput at both the device and the access point, and maximum throughput is desired for most enterprise networks.
- If your device does not have a data DTLS license and if the access point associated with the device has DTLS enabled, the data path will be unencrypted.

- In images that do not have a DTLS license, the DTLS commands are not available.

Information About Data Encryption

The device enables you to encrypt Control and Provisioning of Wireless Access Points (CAPWAP) control packets (and optionally, CAPWAP data packets) that are sent between the access point and the device using DTLS. DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS. CAPWAP control packets are management packets exchanged between a device and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data). If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

How to Configure Data Encryption

Configuring Data Encryption (CLI)

SUMMARY STEPS

1. **configure terminal**
2. **ap link-encryption**
3. **end**
4. **show ap link-encryption**
5. **show wireless dtls connections**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap link-encryption Example: Device(config)# ap link-encryption	Enables data encryption for all access points or a specific access point by entering this command. The default value is disabled. Changing the data encryption mode requires the access points to rejoin the device.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 4	show ap link-encryption Example:	Displays the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity

	Command or Action	Purpose
	Device# show ap link-encryption	check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet.
Step 5	show wireless dtls connections Example: Device# show wireless dtls connections	Displays a summary of all active DTLS connections. Note If you experience any problems with DTLS data encryption, enter the debug dtls ap {all event trace} command to debug all DTLS messages, events, or traces.

Related Topics

[Displaying Data Encryption States for all Access Points: Examples](#), on page 511

Configuring Data Encryption (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > All APs**.

The All APs page is displayed.

Step 2 Click the name of the access point for which you want to enable data encryption.

The **AP > Edit** page is displayed.

Step 3 Click the **Advanced** tab.

Step 4 Select or unselect the **Data Encryption** check box.

Note Changing the data encryption mode requires the access points to reassociate with the device.

Step 5 Click **Apply**.

Step 6 Click **Save Configuration**.

Configuration Examples for Configuring Data Encryption

Displaying Data Encryption States for all Access Points: Examples

This example shows how to display the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet:

```
Device# show ap link-encryption
          Encryption  Dnstream  Upstream  Last
AP Name      State      Count     Count     Update
-----
3602a        Enabled      0         0         Never
```

This example shows how to display a summary of all active DTLS connections:

```
Device# show wireless dtls connections
AP Name          Local Port  Peer IP      Peer Port  Ciphersuite
-----
3602a            Capwap_Ctrl 10.10.21.213 46075      TLS_RSA_WITH_AES_128_CBC_SHA
3602a            Capwap_Data 10.10.21.213 46075      TLS_RSA_WITH_AES_128_CBC_SHA
```

CHAPTER 31

Configuring Retransmission Interval and Retry Count

- [Finding Feature Information, on page 513](#)
- [Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count, on page 513](#)
- [Information About Retransmission Interval and Retry Count, on page 514](#)
- [How to Configure Access Point Retransmission Interval and Retry Count, on page 514](#)
- [Viewing CAPWAP Maximum Transmission Unit Information \(CLI\), on page 516](#)
- [Viewing CAPWAP Maximum Transmission Unit Information \(GUI\), on page 517](#)
- [Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count, on page 517](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count

- You can configure the retransmission intervals and retry count both at a global and a specific access point level. A global configuration applies these configuration parameters to all the access points. Alternatively, when you configure the retransmission level and retry count at a specific access point level, the values are applied to that particular access point. The access point specific configuration has a higher precedence than the global configuration.

Information About Retransmission Interval and Retry Count

The device and the access points exchange packets using the Control and Provisioning of Wireless Access Points (CAPWAP) reliable transport protocol. For each request, a response is defined. This response is used to acknowledge the receipt of the request message. Response messages are not explicitly acknowledged; therefore, if a response message is not received, the original request message is retransmitted after the retransmit interval. If the request is not acknowledged after a maximum number of retransmissions, the session is closed and the access points reassociate with another device.

How to Configure Access Point Retransmission Interval and Retry Count

Configuring the Access Point Retransmission Interval and Retry Count (CLI)

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap capwap retransmit interval interval_time`
4. `ap capwap retransmit count count_value`
5. `end`
6. `ap name Cisco_AP capwap retransmit interval interval_time`
7. `ap name Cisco_AP capwap retransmit count count_value`
8. `show ap capwap retransmit`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# <code>enable</code>	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	ap capwap retransmit interval <i>interval_time</i> Example: Device(config)# <code>ap capwap retransmit interval 2</code>	Configures the control packet retransmit interval for all access points globally. Note The range for the interval parameter is from 2 to 5.

	Command or Action	Purpose
Step 4	ap capwap retransmit count <i>count_value</i> Example: Device(config)# ap capwap retransmit count 3	Configures the control packet retry count for all access points globally. Note The range for the count is from 3 to 8.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 6	ap name <i>Cisco_AP</i> capwap retransmit interval <i>interval_time</i> Example: Device# ap name AP02 capwap retransmit interval 2	Configures the control packet retransmit interval for the individual access point that you specify. Note The range for the interval is from 2 to 5. Note You must be in privileged EXEC mode to use the ap name commands.
Step 7	ap name <i>Cisco_AP</i> capwap retransmit count <i>count_value</i> Example: Device# ap name AP02 capwap retransmit count 3	Configures the control packet retry count for the individual access point that you specify. Note The range for the retry count is from 3 to 8.
Step 8	show ap capwap retransmit Example: Device# show ap capwap retransmit	Displays the CAPWAP retransmit details.

Configuring the Access Point Retransmission Interval and Retry Count (GUI)

Procedure

- Global configuration applicable to all APs:
 - a) Choose **Configuration > Wireless > Access Points > Global AP Configuration**.
The **Global Configuration** page is displayed.
 - b) In the **AP Retransmit Config Parameters** area, enter the values for the following parameters:
 - **AP Retransmit Count**—Number of times you want the access point to retransmit the request to the device. The valid range is between 3 and 8.
 - **AP Retransmit Interval**—Duration between the retransmission of requests. The valid range is between 2 and 5.
 - c) Click **Apply**.
 - d) Click **Save Configuration**.
- Configuration that is applicable to a specific AP:
 - a) Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed with a list of access points.

- b) Click the access point name.

The **AP > Edit** page is displayed.

- c) Click the **Advanced** tab.
 d) In the **AP Retransmit Config Parameters** area, enter the values for the following **AP Retransmit Count** and **AP Retransmit Interval** parameters:

- **AP Retransmit Count**—Number of times you want the access point to retransmit the request to the device. The valid range is between 3 and 8.
- **AP Retransmit Interval**—Duration between the retransmission of requests. The valid range is between 2 and 5.

- e) Click **Apply**.
 f) Click **Save Configuration**.

Viewing CAPWAP Maximum Transmission Unit Information (CLI)

SUMMARY STEPS

1. `enable`
2. `show ap name Cisco_AP config general`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	show ap name Cisco_AP config general Example: Device# show ap name Maria-1250 config general include MTU	Displays the maximum transmission unit (MTU) for the CAPWAP path on the device. The MTU specifies the maximum size of any packet (in bytes) in a transmission.

Related Topics

[Viewing the CAPWAP Retransmission Details: Example](#), on page 517

[Viewing Maximum Transmission Unit Information: Example](#), on page 517

Viewing CAPWAP Maximum Transmission Unit Information (GUI)

-
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.
The **All APs** page is displayed.
- Step 2** Click the AP name.
The **AP > Edit** page is displayed.
- Step 3** Click the **Advanced** tab.
The **CAPWAP MTU** field shows the CAPWAP maximum retransmission unit information.
-

Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count

Viewing the CAPWAP Retransmission Details: Example

Enter the following command:

```
Device# show ap capwap retransmit
Global control packet retransmit interval : 3
Global control packet retransmit count : 5
```

AP Name	Retransmit Interval	Retransmit Count
-----	-----	-----
3602a	5	3

Viewing Maximum Transmission Unit Information: Example

This example shows how to view the maximum transmission unit (MTU) for the CAPWAP path on the device. The MTU specifies the maximum size of any packet (in bytes) in a transmission:

```
Device# show ap name cisco-ap-name config general | include MTU
CAPWAP Path MTU..... 1500
```

CHAPTER 32

Configuring Adaptive Wireless Intrusion Prevention System

- [Finding Feature Information, on page 519](#)
- [Prerequisites for Configuring wIPS, on page 519](#)
- [How to Configure wIPS on Access Points, on page 519](#)
- [Monitoring wIPS Information, on page 521](#)
- [Configuration Examples for Configuring wIPS on Access Points, on page 522](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring wIPS

- The regular local mode access point has been extended with a subset of Wireless Intrusion Prevention System (wIPS) capabilities. This feature enables you to deploy your access points to provide protection without needing a separate overlay network.

How to Configure wIPS on Access Points

Configuring wIPS on an Access Point (CLI)

SUMMARY STEPS

1. `ap name Cisco_AP mode local`
2. `ap name Cisco_AP dot11 5ghz shutdown`

3. `ap name Cisco_AP dot11 24ghz shutdown`
4. `ap name Cisco_AP mode monitor submode wips`
5. `ap name Cisco_AP monitor-mode wips-optimized`
6. `show ap dot11 24ghz monitor`
7. `ap name Cisco_AP no dot11 5ghz shutdown`
8. `ap name Cisco_AP no dot11 24ghz shutdown`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>ap name Cisco_AP mode local</code></p> <p>Example:</p> <pre>Device# ap name AP01 mode local</pre>	<p>Configures an access point for monitor mode.</p> <p>A message appears that indicates that changing the AP's mode causes the access point to reboot. This message also displays a prompt that enables you to specify whether or not you want to continue with changing the AP mode. Enter y at the prompt to continue.</p>
Step 2	<p><code>ap name Cisco_AP dot11 5ghz shutdown</code></p> <p>Example:</p> <pre>Device# ap name AP01 dot11 5ghz shutdown</pre>	<p>Disables the 802.11a radio on the access point.</p>
Step 3	<p><code>ap name Cisco_AP dot11 24ghz shutdown</code></p> <p>Example:</p> <pre>Device# ap name AP02 dot11 24ghz shutdown</pre>	<p>Disables the 802.11b radio on the access point.</p>
Step 4	<p><code>ap name Cisco_AP mode monitor submode wips</code></p> <p>Example:</p> <pre>Device# ap name AP01 mode monitor submode wips</pre>	<p>Configures the wIPS submode on the access point.</p> <p>Note To disable wIPS on the access point, enter the <code>ap name Cisco_AP modemonitor submode none</code> command.</p>
Step 5	<p><code>ap name Cisco_AP monitor-mode wips-optimized</code></p> <p>Example:</p> <pre>Device# ap name AP01 monitor-mode wips-optimized</pre>	<p>Enables wIPS optimized channel scanning for the access point.</p> <p>The access point scans each channel for 250 milliseconds. It derives the list of channels to be scanned from the monitor configuration. You can choose the following options:</p> <ul style="list-style-type: none"> • All—All channels supported by the access point's radio. • Country—Only the channels supported by the access point's country of operation. • DCA—Only the channel set used by the dynamic channel assignment (DCA) algorithm, which by default includes all of the nonoverlapping channels allowed in the access point's country of operation.

	Command or Action	Purpose
Step 6	show ap dot11 24ghz monitor Example: Device# show ap dot11 24ghz monitor	Displays the monitor configuration channel set. Note The 802.11b Monitor Channels value in the output of the command indicates the monitor configuration channel set.
Step 7	ap name Cisco_AP no dot11 5ghz shutdown Example: Device# ap name AP01 no dot11 5ghz shutdown	Enables the 802.11a radio on the access point.
Step 8	ap name Cisco_AP no dot11 24ghz shutdown Example: Device# ap name AP01 no dot11 24ghz shutdown	Enables the 802.11b radio on the access point.

Configuring WIPS on an Access Point (GUI)

- Step 1** Choose **Configuration > Wireless > Access Points > All APs**
The **All APs** page is displayed.
- Step 2** Click the access point name.
The **AP > Edit** page is displayed.
- Step 3** From the **AP Mode** drop-down list, choose one of the following options to configure the AP mode parameters:
- **Local**
 - **Monitor**
- Step 4** From the **AP Sub Mode** drop-down list, choose **WIPS**.
- Step 5** Click **Apply**.
- Step 6** Click **Save Configuration**.

Monitoring WIPS Information

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. **show ap name Cisco_AP config general**

2. `show ap monitor-mode summary`
3. `show wireless wps wips summary`
4. `show wireless wps wips statistics`
5. `clear wireless wips statistics`

DETAILED STEPS

	Command or Action	Purpose
Step 1	show ap name <i>Cisco_AP</i> config general Example: Device# show ap name AP01 config general	Displays information on the WPS submode on the access point.
Step 2	show ap monitor-mode summary Example: Device# show ap monitor-mode summary	Displays the WPS optimized channel scanning configuration on the access point.
Step 3	show wireless wps wips summary Example: Device# show wireless wps wips summary	Displays the WPS configuration forwarded by NCS or Prime to the device.
Step 4	show wireless wps wips statistics Example: Device# show wireless wps wips statistics	Displays the current state of WPS operation on the device.
Step 5	clear wireless wps statistics Example: Device# clear wireless wps statistics	Clears the WPS statistics on the device.

Configuration Examples for Configuring WPS on Access Points

Displaying the Monitor Configuration Channel Set: Example

This example shows how to display the monitor configuration channel set:

```
Device# show ap dot11 24ghz monitor
Default 802.11b AP monitoring
802.11b Monitor Mode..... enable
802.11b Monitor Channels..... Country channels
802.11b AP Coverage Interval..... 180 seconds
802.11b AP Load Interval..... 60 seconds
802.11b AP Noise Interval..... 180 seconds
802.11b AP Signal Strength Interval..... 60 seconds
```

Displaying wIPS Information: Examples

This example shows how to display information on the wIPS submode on the access point:

```
Device# show ap name AP01 config general
Cisco AP Identifier..... 3
Cisco AP Name..... AP1131:46f2.98ac
...
AP Mode ..... Monitor
Public Safety ..... Disabled Disabled
AP SubMode ..... WIPS
```

This example shows how to display the wIPS optimized channel scanning configuration on the access point:

```
Device# show ap monitor-mode summary
AP Name      Ethernet MAC   Status   Scanning
              Channel
              List
-----
AP1131:4f2.9a 00:16:4:f2:9:a WIPS     1, 6, NA, NA
```

This example shows how to display the wIPS configuration forwarded by WCS to the device:

```
Device# show wireless wps wips summary
Policy Name..... Default
Policy Version..... 3
```

This example shows how to display the current state of wIPS operation on the device:

```
Device# show wireless wps wips statistics

CHAPTER 33

Configuring Authentication for Access Points

- [Finding Feature Information, on page 525](#)
- [Prerequisites for Configuring Authentication for Access Points, on page 525](#)
- [Restrictions for Configuring Authentication for Access Points, on page 526](#)
- [Information about Configuring Authentication for Access Points, on page 526](#)
- [How to Configure Authentication for Access Points, on page 526](#)
- [Configuration Examples for Configuring Authentication for Access Points, on page 534](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Authentication for Access Points

- You can set a global username, password, and enable password for all access points that are currently joined to the device and any that join in the future inherit as they join the device. If desired, you can override the global credentials and assign a unique username, password, and enable password for a specific access point.
- After an access point joins the device, the access point enables console port security, and you are prompted for your username and password whenever you log into the access point's console port. When you log in, you are in nonprivileged mode, and you must enter the enable password in order to use the privileged mode.
- The global credentials that you configure on the device are retained across device and access point reboots. They are overwritten only if the access point joins a new device that is configured with a global username and password. If the new device is not configured with global credentials, the access point retains the global username and password configured for the first device.
- You must track the credentials used by the access points. Otherwise, you might not be able to log into an access point's console port. If you need to return the access points to the default *Cisco/Cisco* username

and password, you must clear the device's configuration and the access point's configuration to return them to factory-default settings. To reset the default access point configuration, enter the **ap name Cisco_AP mgmtuser username Cisco password Cisco** command. Entering the command does not clear the static IP address of the access point. Once the access point rejoins a device, it adopts the default *Cisco/Cisco* username and password.

- You can configure global authentication settings for all access points that are currently joined to the device and any that join in the future. If desired, you can override the global authentication settings and assign unique authentication settings for a specific access point.
- This feature is supported on the following hardware:
 - All Cisco switches that support authentication.
 - Cisco Aironet 1140, 1260, 1310, 1520, 1600, 2600, 3500, and 3600 access points

Restrictions for Configuring Authentication for Access Points

- The device name in the AP configuration is case sensitive. Therefore, make sure to configure the exact system name on the AP configuration. Failure to do this results in the AP fallback not working.

Information about Configuring Authentication for Access Points

Cisco IOS access points are shipped from the factory with *Cisco* as the default enable password. This password allows users to log into the nonprivileged mode and enter the **show** and **debug** commands that pose a security threat to your network. You must change the default enable password to prevent unauthorized access and to enable users to enter configuration commands from the access point's console port.

You can configure 802.1X authentication between a lightweight access point and a Cisco switch. The access point acts as an 802.1X supplicant and is authenticated by the switch where it uses EAP-FAST with anonymous PAC provisioning.

How to Configure Authentication for Access Points

Configuring Global Credentials for Access Points (CLI)

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap mgmtuser username *user_name* password 0 *password* secret 0 *secret_value***
4. **end**
5. **ap name *Cisco_AP* mgmtuser username *user_name* password *password* secret *secret***
6. **show ap summary**
7. **show ap name *Cisco_AP* config general**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	ap mgmtuser username user_name password 0 password secret 0 secret_value Example: Device(config)# ap mgmtuser apusr1 password appass 0 secret 0 appass1	Configures the global username and password and enables the password for all access points that are currently joined to the device and any access points that join the device in the future. In the command, the parameter 0 specifies that an unencrypted password will follow and 8 specifies that an AES encrypted password will follow.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 5	ap name Cisco_AP mgmtuser username user_name password password secret secret Example: Device(config)# ap name TSIM_AP-2 mgmtuser apusr1 password appass secret secret	<p>Overrides the global credentials for a specific access point and assigns a unique username and password and enables password to this access point.</p> <p>The credentials that you enter in this command are retained across device and access point reboots and if the access point joins a new device.</p> <p>Note If you want to force this access point to use the device's global credentials, enter the ap name Cisco_AP no mgmtuser command. The following message appears after you execute this command: "AP reverted to global username configuration."</p>
Step 6	show ap summary Example: Device# show ap summary	Displays a summary of all connected Cisco APs.
Step 7	show ap name Cisco_AP config general Example: Device# show ap name AP02 config general	<p>Displays the global credentials configuration for a specific access point.</p> <p>Note If this access point is configured for global credentials, the AP User Mode text boxes shows "Automatic." If the global credentials have been overwritten for this access point, the AP User Mode text box shows "Customized."</p>

Configuring Global Credentials for Access Points (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > Global AP Configuration**.

The **Global Configuration** page is displayed.

Step 2 In the **Login Credentials** area, enter the following parameters:

- **User Name**
- **Password**
- **Confirm Password**
- **Secret Password**
- **Confirm Secret Password**

The password should contain characters from at least three of the following classes: lowercase letters, uppercase letters, digits, and special characters. No character in the password can be repeated more than three times consecutively. The password should not contain the management username or the reverse of the username. The password should not contain words like Cisco, oscic, admin, nimda or any variant obtained by changing the capitalization of letters by substituting 1, |, or ! or substituting 0 for o or substituting \$ for s.

Step 3 Click **Apply**.

The global username and password are applied to all the access points that are associated with the devices

Step 4 Click **Save Configuration**.

Step 5 (Optional) You can override the global credentials for a specific access point and assign a unique username and password by following these steps:

a) Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed.

b) Click the name of an access point.

The **AP > Edit** page is displayed.

c) Click the **Credentials** tab.

d) In the **Login Credentials** area, select the **Over-ride Global Credentials** check box.

e) Enter the values for the following parameters:

- **Username**
- **Password**
- **Enable Password**

f) Click **Apply**.

g) Click **Save Configuration**.

Configuring Authentication for Access Points (CLI)

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap dot1x username user_name_value password 0 password_value`
4. `end`
5. `ap name Cisco_AP dot1x-user username username_value password password_value`
6. `configure terminal`
7. `no ap dot1x username user_name_value password 0 password_value`
8. `end`
9. `show ap summary`
10. `show ap name Cisco_AP config general`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device# enable</pre>	Enters privileged EXEC mode.
Step 2	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	<p><code>ap dot1x username <i>user_name_value</i> password 0 <i>password_value</i></code></p> <p>Example:</p> <pre>Device(config)# ap dot1x username AP3 password 0 password</pre>	<p>Configures the global authentication username and password for all access points that are currently joined to the device and any access points that join the device in the future. This command contains the following keywords and arguments:</p> <ul style="list-style-type: none"> • username—Specifies an 802.1X username for all access points. • <i>user-id</i>—Username. • password—Specifies an 802.1X password for all access points. • 0—Specifies an unencrypted password. • 8—Specifies an AES encrypted password. • <i>passwd</i>—Password.

	Command or Action	Purpose
		<p>Note You must enter a strong password for the password parameter. Strong passwords are at least eight characters long, contain a combination of uppercase and lowercase letters, numbers, and symbols, and are not a word in any language.</p>
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 5	<p>ap name <i>Cisco_AP</i> dot1x-user username <i>username_value</i> password <i>password_value</i></p> <p>Example:</p> <pre>Device# ap name AP03 dot1x-user username apuser1 password appass</pre>	<p>Overrides the global authentication settings and assigns a unique username and password to a specific access point. This command contains the following keywords and arguments:</p> <ul style="list-style-type: none"> • username—Specifies to add a username. • <i>user-id</i>—Username. • password—Specifies to add a password. • 0—Specifies an unencrypted password. • 8—Specifies an AES encrypted password. • <i>passwd</i>—Password. <p>Note You must enter a strong password for the password parameter. See the note in Step 2 for the characteristics of strong passwords.</p> <p>The authentication settings that you enter in this command are retained across device and access point reboots and whenever the access point joins a new device.</p>
Step 6	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 7	<p>no ap dot1x username <i>user_name_value</i> password 0 <i>password_value</i></p> <p>Example:</p> <pre>Device(config)# no ap dot1x username dot1xusr password 0 dot1xpass</pre>	<p>Disables 802.1X authentication for all access points or for a specific access point.</p> <p>The following message appears after you execute this command: “AP reverted to global username configuration.”</p> <p>Note You can disable 802.1X authentication for a specific access point only if global 802.1X authentication is not enabled. If global 802.1X authentication is enabled, you can disable 802.1X for all access points only.</p>

	Command or Action	Purpose
Step 8	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 9	show ap summary Example: Device# show ap summary	Displays the authentication settings for all access points that join the device. Note If global authentication settings are not configured, the Global AP Dot1x User Name text box shows “Not Configured.”
Step 10	show ap name Cisco_AP config general Example: Device# show ap name AP02 config general	Displays the authentication settings for a specific access point. Note If this access point is configured for global authentication, the AP Dot1x User Mode text boxes shows “Automatic.” If the global authentication settings have been overwritten for this access point, the AP Dot1x User Mode text box shows “Customized.”

Related Topics

[Displaying the Authentication Settings for Access Points: Examples](#), on page 534

Configuring Authentication for Access Points (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > Global AP Configuration**.

The **Global Configuration** page is displayed.

Step 2 In the **802.1x Supplicant Credentials** area, select the **Credentials Required** check box.

Step 3 Enter the username and password details.

Note You must enter a strong password in these text boxes. Strong passwords have the following characteristics:

- They are at least eight characters long
- They contain a combination of uppercase and lowercase letters, numbers, and symbols
- They are not a word in any language

Step 4 Click **Apply**.

Step 5 Click **Save Configuration**.

Step 6 (Optional) You can override the global configuration and assign a unique username and password to a specific access point by following these steps:

a) Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed.

- Step 7** Click the name of an access point.
The **AP > Edit** is displayed.
- Step 8** Click the **Credentials** tab.
- Step 9** In the **802.1x Supplicant Credentials** area, select the **Over-ride Global Credentials** check box.
- Step 10** Enter the username and password details.
- Step 11** Click **Apply**.
- Step 12** Click **Save Configuration**.

Configuring the Switch for Authentication (CLI)

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **dot1x system-auth-control**
4. **aaa new-model**
5. **aaa authentication dot1x default group radius**
6. **radius-server host *host_ip_adress* acct-port *port_number* auth-port *port_number* key 0 *unencrypted_server_key***
7. **interface TenGigabitEthernet1/0/1**
8. **switch mode access**
9. **dot1x pae authenticator**
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	dot1x system-auth-control Example: Device(config)# dot1x system-auth-control	Enables system authentication control.

	Command or Action	Purpose
Step 4	aaa new-model Example: Device(config)# aaa new-model	Enables new access control commands and functions.
Step 5	aaa authentication dot1x default group radius Example: Device(config)# aaa authentication dot1x default group radius	Sets the default authentications lists for IEEE 802.1X by using all the radius hosts in a server group.
Step 6	radius-server host <i>host_ip_adress</i> acct-port <i>port_number</i> auth-port <i>port_number</i> key 0 unencrypted_server_key Example: Device(config)# radius-server host 10.1.1.1 acct-port 1813 auth-port 6225 key 0 encryptkey	Sets a clear text encryption key for the RADIUS authentication server.
Step 7	interface TenGigabitEthernet1/0/1 Example: Device(config)# interface TenGigabitEthernet1/0/1	Sets the 10-Gigbit Ethernet interface. The command prompt changes from Controller(config)# to Controller(config-if)#.
Step 8	switch mode access Example: Device(config-if)# switch mode access	Sets the unconditional trunking mode access to the interface.
Step 9	dot1x pae authenticator Example: Device(config-if)# dot1x pae authenticator	Sets the 802.1X interface PAE type as the authenticator.
Step 10	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

- [Configuration Examples for Converting Autonomous Access Points to Lightweight Mode, on page 545](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Converting Autonomous Access Points to Lightweight Mode

- Access points that are converted to lightweight mode do not support Wireless Domain Services (WDS). Converted access points communicate only with Cisco wireless LAN devices and cannot communicate with WDS devices. However, the device provides functionality that is equivalent to WDS when the access point associates to it.

- All Cisco lightweight access points support 16 Basic Service Set Identifiers (BSSIDs) per radio and a total of 16 wireless LANs per access point. When a converted access point associates to a device, only wireless LANs with IDs 1 through 16 are pushed to the access point unless the access point is a member of an access point group.
- Access points that are converted to lightweight mode must get an IP address and discover the device using DHCP, DNS, or IP subnet broadcast.

Information About Autonomous Access Points Converted to Lightweight Mode

You can convert autonomous Cisco Aironet access points to lightweight mode. When you upgrade the access points to lightweight mode, the access point communicates with the device and receives a configuration and software image from the device.

Reverting from Lightweight Mode to Autonomous Mode

After you convert an autonomous access point to lightweight mode, you can convert the access point from a lightweight unit back to an autonomous unit by loading a Cisco IOS release that supports autonomous mode (Cisco IOS Release 12.3(7)JA or earlier releases). If the access point is associated with a device, you can use the device to load the Cisco IOS release. If the access point is not associated to a device, you can load the Cisco IOS release using TFTP. In either method, the access point must be able to access a TFTP server that contains the Cisco IOS release to be loaded.

Using DHCP Option 43 and DHCP Option 60

Cisco Aironet access points use the type-length-value (TLV) format for DHCP option 43. You must program the DHCP servers to return the option based on the access point's DHCP Vendor Class Identifier (VCI) string (DHCP option 60).

See the product documentation for your DHCP server for instructions on configuring DHCP option 43. The *Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode* document contains example steps for configuring option 43 on a DHCP server.

If the access point is ordered with the Service Provider Option - AIR-OPT60-DHCP selected, the VCI string for that access point will be different than those strings listed in the previous table. The VCI string has the following suffix: ServiceProvider. For example, a 1260 with this option returns this VCI string: Cisco AP c1260-ServiceProvider.

Note

The device IP address that you obtain from the DHCP server should be a unicast IP address. Do not configure the device IP address as a multicast address when configuring DHCP option 43.

How Converted Access Points Send Crash Information to the Device

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the device. If the unit rebooted because of a crash, the device pulls up the crash file using existing CAPWAP messages and stores it in the device flash memory. The crash information copy is removed from the access point flash memory when the device pulls it from the access point.

Uploading Memory Core Dumps from Converted Access Points

By default, access points converted to lightweight mode do not send memory core dumps to the device. This section provides instructions to upload access point core dumps using the device GUI or CLI.

Displaying MAC Addresses for Converted Access Points

There are some differences in the way that controllers display the MAC addresses of converted access points on information pages in the controller GUI:

- On the AP Summary page, the controller lists the Ethernet MAC addresses of converted access points.
- On the AP Detail page, the controller lists the BSS MAC addresses and Ethernet MAC addresses of converted access points.
- On the Radio Summary page, the device lists converted access points by the radio MAC address.

Configuring a Static IP Address for a Lightweight Access Point

If you want to specify an IP address for an access point rather than having one assigned automatically by a DHCP server, you can use the controller GUI or CLI to configure a static IP address for the access point. Static IP addresses are generally used only for deployments with a limited number of APs.

An access point cannot discover the device using domain name system (DNS) resolution if a static IP address is configured for the access point, unless you specify a DNS server and the domain to which the access point belongs. You can configure these parameters using either the device CLI or the GUI.

Note If you configure an access point to use a static IP address that is not on the same subnet on which the access point's previous DHCP address was, the access point falls back to a DHCP address after the access point reboots. If the access point falls back to a DHCP address, enter the **show ap config general Cisco_AP** CLI command to show that the access point is using a fallback IP address. However, the GUI shows both the static IP address and the DHCP address, but it does not identify the DHCP address as a fallback address.

How to Convert a Lightweight Access Point Back to an Autonomous Access Point

Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)

SUMMARY STEPS

1. `enable`
2. `ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device# enable</pre>	Enters privileged EXEC mode.
Step 2	<p><code>ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename</code></p> <p>Example:</p> <pre>Device# ap name AP02 tftp-downgrade 10.0.0.1 tsrvname</pre>	<p>Converts the lightweight access point back to autonomous mode.</p> <p>Note After entering this command, you must wait until the access point reboots and then reconfigure the access point using the CLI or GUI.</p>

Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)

- Step 1** Configure the PC on which your TFTP server software runs with a static IP address in the range of 10.0.0.2 to 10.0.0.30.
- Step 2** Make sure that the PC contains the access point image file (such as `c1140-k9w7-tar.123-7.JA.tar` for a 1140 series access point) in the TFTP server folder and that the TFTP server is activated.
- Step 3** Rename the access point image file in the TFTP server folder to `c1140-k9w7-tar.default` for a 1140 series access point.
- Step 4** Connect the PC to the access point using a Category 5 (CAT5) Ethernet cable.
- Step 5** Disconnect power from the access point.
- Step 6** Press and hold the **MODE** button while you reconnect power to the access point.

Note The **MODE** button on the access point must be enabled.
- Step 7** Hold the **MODE** button until the status LED turns red (approximately 20 to 30 seconds), and release the **MODE** button.
- Step 8** Wait until the access point reboots as indicated by all LEDs turning green followed by the Status LED blinking green.

Step 9 After the access point reboots, reconfigure the access point using the GUI or the CLI.

Authorizing Access Points (CLI)

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap auth-list ap-policy authorize-ap**
4. **username *user_name* mac aaa attribute list *list_name***
5. **aaa new-model**
6. **aaa authorization credential-download *auth_list* local**
7. **aaa attribute list *list***
8. **aaa session-id common**
9. **aaa local authentication default authorization default**
10. **show ap name *Cisco_AP* config general**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	ap auth-list ap-policy authorize-ap Example: Device(config)# ap auth-list ap-policy authorize-ap	Configures an access point authorization policy.
Step 4	username <i>user_name</i> mac aaa attribute list <i>list_name</i> Example: Device(config)# username aaa.bbb.ccc mac aaa attribute list attrlist	Configures the MAC address of an access point locally.
Step 5	aaa new-model Example: Device(config)# aaa new-model	Enables new access control commands and functions.

	Command or Action	Purpose
Step 6	aaa authorization credential-download <i>auth_list</i> local Example: Device(config)# aaa authorization credential-download auth_download local	Downloads EAP credentials from the local server.
Step 7	aaa attribute list <i>list</i> Example: Device(config)# aaa attribute list alist	Configures AAA attribute list definitions.
Step 8	aaa session-id common Example: Device(config)# aaa session-id common	Configures the AAA common session ID.
Step 9	aaa local authentication default authorization default Example: Device(config)# aaa local authentication default authorization default	Configures the local authentication method list.
Step 10	show ap name <i>Cisco_AP</i> config general Example: Device(config)# show ap name AP01 config general	Displays the configuration information that corresponds to a specific access point.

Authorizing Access Points (GUI)

Step 1 Choose **Configuration > Security > AAA > AP Policy**.

The **AP Policy** page is displayed.

Step 2 In the Policy Configuration area, enable or disable the following parameters:

- **Authorize LSC APs against Auth-List**
- **AP with Self-Signed Certificate**
- **Authorize MIC APs against AAA**
- **AP with Manufacturing Installed Certificate**

Step 3 Click **Apply**.

Step 4 Click **Save Configuration**.

Disabling the Reset Button on Converted Access Points (CLI)

You can enable or disable the Reset button on access points that are converted to lightweight mode. The Reset button is labeled MODE on the outside of the access point.

Note The procedure to perform this task using the controller GUI is not currently available.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no ap reset-button**
4. **end**
5. **ap name *Cisco_AP* reset-button**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	no ap reset-button Example: Device(config)# no ap reset-button	Disables the Reset buttons on all converted access points that are associated to the device. Note To enable the Reset buttons on all converted access points that are associated to the device, enter the ap reset-button command.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 5	ap name <i>Cisco_AP</i> reset-button Example: Device# ap name AP02 reset-button	Enables the Reset button on the converted access point that you specify.

Monitoring the AP Crash Log Information

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. enable
2. show ap crash-file

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	show ap crash-file Example: Device# show ap crash-file	Verifies whether the crash file is downloaded to the device.

How to Configure a Static IP Address on an Access Point

Configuring a Static IP Address on an Access Point (CLI)

SUMMARY STEPS

1. enable
2. ap name *Cisco_AP* static-ip ip-address *static_ap_address* netmask *static_ip_netmask* gateway *static_ip_gateway*
3. enable
4. configure terminal
5. ap static-ip name-server *nameserver_ip_address*
6. ap static-ip domain *static_ip_domain*
7. end
8. show ap name *Cisco_AP* config general

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>Cisco_AP</i> static-ip ip-address <i>static_ap_address</i> netmask <i>static_ip_netmask</i> gateway <i>static_ip_gateway</i> Example: Device# ap name AP03 static-ip ip-address 9.9.9.16 netmask 255.255.0.0 gateway 9.9.9.2	Configures a static IP address on the access point. This command contains the following keywords and arguments: <ul style="list-style-type: none"> • ip-address— Specifies the Cisco access point static IP address. • <i>ip-address</i>— Cisco access point static IP address. • netmask— Specifies the Cisco access point static IP netmask. • <i>netmask</i>— Cisco access point static IP netmask. • gateway— Specifies the Cisco access point gateway. • <i>gateway</i>— IP address of the Cisco access point gateway. <p>The access point reboots and rejoins the device, and the static IP address that you specify is pushed to the access point. After the static IP address has been sent to the access point, you can configure the DNS server IP address and domain name. You must perform Steps 3 and 4 after the access points reboot.</p>
Step 3	enable Example: Device# enable	Enters privileged EXEC mode.
Step 4	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 5	ap static-ip name-server <i>nameserver_ip_address</i> Example: Device(config)# ap static-ip name-server 10.10.10.205	Configures a DNS server so that a specific access point or all access points can discover the device using DNS resolution. <p>Note To undo the DNS server configuration, enter the no ap static-ip name-server <i>nameserver_ip_address</i> command.</p>
Step 6	ap static-ip domain <i>static_ip_domain</i> Example:	Configures the domain to which a specific access point or all access points belong.

	Command or Action	Purpose
	Device(config)# ap static-ip domain domain1	Note To undo the domain name configuration, enter the no ap static-ip domain static_ip_domain command.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 8	show ap name Cisco_AP config general Example: Device# show ap name AP03 config general	Displays the IP address configuration for the access point.

Configuring a Static IP Address on an Access Point (GUI)

-
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.
The **All APs** page is displayed.
- Step 2** Click the name of the access point.
The **AP > Edit** page is displayed.
- Step 3** In the **General** tab, in the **IP Config** area, select the **Static IP** check box if you want to assign a static IP address to the access point.
- Step 4** Enter the following details:
- **Static IP**
 - **Netmask**
 - **Gateway**
- Step 5** Click **Apply**.
The access point reboots and rejoins the device, and the static IP address that you specified is sent to the access point.
- Step 6** After the static IP address has been sent to the access point, configure the **DNS IP Address** and **Domain Name**.
- Step 7** Click **Apply**.
- Step 8** Click **Save Configuration**.
-

Recovering the Access Point Using the TFTP Recovery Procedure

-
- Step 1** Download the required recovery image from Cisco.com (ap3g2-k9w8-tar.152-2.JA.tar) and install it in the root directory of your TFTP server.
- Step 2** Connect the TFTP server to the same subnet as the target access point and power-cycle the access point. The access point boots from the TFTP image and then joins the device to download the oversized access point image and complete the upgrade procedure.
- Step 3** After the access point has been recovered, you can remove the TFTP server.
-

Configuration Examples for Converting Autonomous Access Points to Lightweight Mode

Displaying the IP Address Configuration for Access Points: Example

This example shows how to display the IP address configuration for the access point:

```
Device# show ap name AP03 dot11 24ghz config general
Cisco AP Identifier..... 4
Cisco AP Name..... AP6
IP Address Configuration..... Static IP assigned
IP Address..... 10.10.10.118
IP NetMask..... 255.255.255.0
Gateway IP Addr..... 10.10.10.1
Domain..... Domain1
Name Server..... 10.10.10.205
...
```

Displaying Access Point Crash File Information: Example

This example shows how to display access point crash file information. Using this command, you can verify whether the file is downloaded to the device:

```
Device# show ap crash-file
Local Core Files:
lrad_AP1130.rdump0 (156)
```

The number in parentheses indicates the size of the file. The size should be greater than zero if a core dump file is available.

CHAPTER 35

Using Cisco Workgroup Bridges

- [Finding Feature Information, on page 547](#)
- [Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges, on page 547](#)
- [Monitoring the Status of Workgroup Bridges, on page 548](#)
- [Debugging WGB Issues \(CLI\), on page 548](#)
- [Configuration Examples for Configuring Workgroup Bridges, on page 550](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges

A WGB is a mode that can be configured on an autonomous Cisco IOS access point to provide wireless connectivity to a lightweight access point on behalf of clients that are connected by Ethernet to the WGB access point. A WGB connects a wired network over a single wireless segment by learning the MAC addresses of its wired clients on the Ethernet interface and reporting them to the lightweight access point using Internet Access Point Protocol (IAPP) messaging. The WGB provides wireless access connectivity to wired clients by establishing a single wireless connection to the lightweight access point.

When a Cisco WGB is used, the WGB informs the access points of all the clients that it is associated with. The device is aware of the clients that are associated with the access point. When non-Cisco WGBs are used, the device has no information about the IP address of the clients on the wired segment behind the WGB. Without this information, the device drops the following types of messages:

- ARP REQ from the distribution system for the WGB client.
- ARP RPLY from the WGB client.
- DHCP REQ from the WGB client.

- DHCP RPLY for the WGB client.

Monitoring the Status of Workgroup Bridges

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. `enable`
2. `show wireless wgb summary`
3. `show wireless wgb mac-address wgb_mac_address detail`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	show wireless wgb summary Example: Device# show wireless wgb summary	Displays the WGBs on your network.
Step 3	show wireless wgb mac-address wgb_mac_address detail Example: Device# show wireless wgb mac-address 00:0d:ed:dd:25:82 detail	Displays the details of any wired clients that are connected to a particular WGB.

Debugging WGB Issues (CLI)

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. `enable`
2. `debug iapp all`
3. `debug iapp error`
4. `debug iapp packet`

5. `debug mobility handoff [switch switch_number]`
6. `debug dhcp`
7. `debug dot11 mobile`
8. `debug dot11 state`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	debug iapp all Example: Device# debug iapp all	Enables debugging for IAPP messages.
Step 3	debug iapp error Example: Device# debug iapp error	Enables debugging for IAPP error events.
Step 4	debug iapp packet Example: Device# debug iapp packet	Enables debugging for IAPP packets.
Step 5	debug mobility handoff [switch switch_number] Example: Device# debug mobility handoff	Enables debugging for any roaming issues.
Step 6	debug dhcp Example: Device# debug dhcp	Debug an IP assignment issue when DHCP is used.
Step 7	debug dot11 mobile Example: Device# debug dot11 mobile	Enables dot11/mobile debugging. Debug an IP assignment issue when static IP is used.
Step 8	debug dot11 state Example: Device# debug dot11 state	Enables dot11/state debugging. Debug an IP assignment issue when static IP is used.

Configuration Examples for Configuring Workgroup Bridges

WGB Configuration: Example

This example shows how to configure a WGB access point using static WEP with a 40-bit WEP key:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# dot11 ssid WGB_with_static_WEP
Device(config-ssid)# authentication open
Device(config-ssid)# guest-mode
Device(config-ssid)# exit
Device(config)# interface dot11Radio 0
Device(config)# station-role workgroup-bridge
Device(config-if)# encry mode wep 40
Device(config-if)# encry key 1 size 40 0 1234567890
Device(config-if)# ssid WGB_with_static_WEP
Device(config-if)# end
```

Verify that the WGB is associated to an access point by entering this command on the WGB:

show dot11 association

Information similar to the following appears:

```
Device# show dot11 associations
802.11 Client Stations on Dot11Radio0:
SSID [FCVTESTING] :
MAC Address      IP address      Device          Name            Parent          State
000b.8581.6aee  10.11.12.1     WGB-client     map1            -               Assoc
ap#
```

CHAPTER 36

Configuring Probe Request Forwarding

- [Finding Feature Information, on page 551](#)
- [Information About Configuring Probe Request Forwarding, on page 551](#)
- [How to Configure Probe Request Forwarding \(CLI\), on page 551](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring Probe Request Forwarding

Probe requests are 802.11 management frames that are sent by clients to request information about the capabilities of Service Set Identifiers (SSIDs). By default, access points forward acknowledged probe requests to the device for processing. Acknowledged probe requests are probe requests for SSIDs that are supported by the access point. If desired, you can configure access points to forward both acknowledged and unacknowledged probe requests to the device. The device can use the information from unacknowledged probe requests to improve the location accuracy.

How to Configure Probe Request Forwarding (CLI)

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. **configure terminal**
2. **wireless probe filter**
3. **wireless probe filter *num_probes interval***

4. `end`
5. `show wireless probe`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless probe filter Example: Device(config)# <code>wireless probe filter</code>	Enables or disables the filtering of probe requests forwarded from an access point to the device. Note If you enable probe filtering, the default filter setting, the access point forwards only acknowledged probe requests to the device. If you disable probe filtering, the access point forwards both acknowledged and unacknowledged probe requests to the device.
Step 3	wireless probe filter <i>num_probes interval</i> Example: Device(config)# <code>wireless probe filter 5 5</code>	Limits the number of probe requests sent to the device per client per access point radio in a given interval. You must specify the following arguments with this command: <ul style="list-style-type: none"> • <i>num_probes</i>—Number of probe requests forwarded to the device per client per access point radio in a given interval. The range is from 1 to 100. • <i>interval</i>—Probe limit interval in milliseconds. The range is from 100 to 10000.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 5	show wireless probe Example: Device# <code>show wireless probe</code>	Displays the advanced probe request configuration.

CHAPTER 37

Optimizing RFID Tracking

- [Finding Feature Information, on page 553](#)
- [Optimizing RFID Tracking on Access Points, on page 553](#)
- [How to Optimize RFID Tracking on Access Points, on page 553](#)
- [Configuration Examples for Optimizing RFID Tracking, on page 555](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Optimizing RFID Tracking on Access Points

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

How to Optimize RFID Tracking on Access Points

Optimizing RFID Tracking on Access Points (CLI)

SUMMARY STEPS

1. `ap name Cisco_AP mode monitor submode none`
2. `ap name Cisco_AP dot11 24ghz shutdown`
3. `ap name Cisco_AP monitor-mode tracking-opt`
4. `ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]}`

5. `ap name Cisco_AP no dot11 24ghz shutdown`
6. `show ap monitor-mode summary`

DETAILED STEPS

	Command or Action	Purpose
Step 1	ap name Cisco_AP mode monitor submode none Example: <pre>Device# ap name 3602a mode monitor submode none</pre>	Specifies the monitor submode for the access point as none. Note A warning message indicates that changing the access point's mode will cause the access point to reboot and prompts you to specify whether you want to continue by entering Y . After you enter Y , the access point reboots.
Step 2	ap name Cisco_AP dot11 24ghz shutdown Example: <pre>Device# ap name AP01 dot11 24ghz shutdown</pre>	Disables the access point radio.
Step 3	ap name Cisco_AP monitor-mode tracking-opt Example: <pre>Device# ap name TSIM_AP1 monitor-mode tracking-opt</pre>	Configures the access point to scan only the Dynamic Channel Assignment (DCA) channels supported by its country of operation. Note To disable tracking optimization for an access point, enter the ap name Cisco_AP monitor-mode tracking-opt no-optimization command.
Step 4	ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]} Example: <pre>Device# ap name AP01 monitor-mode dot11b fast-channel 1 2 3 4</pre>	Chooses up to four specific 802.11b channels to be scanned by the access point. Note In the United States, you can assign any value from 1 to 11 (inclusive) to the channel variable. Other countries support additional channels. You must assign at least one channel.
Step 5	ap name Cisco_AP no dot11 24ghz shutdown Example: <pre>Device# ap name AP01 no dot11 24ghz shutdown</pre>	Enables the access point radio.
Step 6	show ap monitor-mode summary Example: <pre>Device# show ap monitor-mode summary</pre>	Displays all the access points in monitor mode.

Configuration Examples for Optimizing RFID Tracking

Displaying all the Access Points in Monitor Mode: Example

This example shows how to display all the access points in monitor mode:

```
Device# show ap monitor-mode summary
```

AP Name	Ethernet MAC	Status	Scanning Channel List
-----	-----	-----	-----
AP1131:4f2.9a	00:16:4:f2:9:a	Tracking	1,6,NA,NA

CHAPTER 38

Configuring Country Codes

- [Finding Feature Information, on page 557](#)
- [Prerequisites for Configuring Country Codes, on page 557](#)
- [Information About Configuring Country Codes, on page 558](#)
- [How to Configure Country Codes \(CLI\), on page 558](#)
- [Configuration Examples for Configuring Country Codes, on page 561](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Country Codes

- Generally, you configure one country code per device; you configure one code that matches the physical location of the device and its access points. You can configure up to 20 country codes per device. This multiple-country support enables you to manage access points in various countries from a single device.
- When the multiple-country feature is used, all devices that are going to join the same RF group must be configured with the same set of countries, configured in the same order.
- Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.
- The country list configured on the RF group leader determines which channels the members would operate on. This list is independent of which countries have been configured on the RF group members.
- For devices in the Japan regulatory domain, you must have had one or more Japan country codes (JP, J2, or J3) configured on your device at the time you last booted your device.
- For devices in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your device.

Information About Configuring Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio's broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- JP—Allows only -J radios to join the controller
- J2—Allows only -P radios to join the controller
- J3—Uses the -U frequencies but allows -U, -P and -Q (other than 1550/1600/2600/3600) radios to join the WLC
- J4—Allows 2.4G JPQU and 5G PQU to join the controller.

Note The 1550, 1600, 2600, and 3600 APs require J4.

See the *Channels and Maximum Power Settings for Cisco Aironet Lightweight Access Points* document for the list of channels and power levels supported by access points in the Japanese regulatory domains.

How to Configure Country Codes (CLI)

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. `enable`
2. `show wireless country supported`
3. `configure terminal`
4. `ap dot11 24ghz shutdown`
5. `ap dot11 5ghz shutdown`
6. `ap country country_code`
7. `end`
8. `show wireless country channels`
9. `configure terminal`
10. `no ap dot11 5ghz shutdown`

11. `no ap dot11 24ghz shutdown`
12. `end`
13. `ap name Cisco_AP shutdown`
14. `configure terminal`
15. `ap country country_code`
16. `end`
17. `ap name Cisco_AP no shutdown`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	show wireless country supported Example: Device# show wireless country supported	Displays a list of all available country codes.
Step 3	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 4	ap dot11 24ghz shutdown Example: Device(config)# ap dot11 5ghz shutdown	Disables the 802.11a network.
Step 5	ap dot11 5ghz shutdown Example: Device(config)# ap dot11 24ghz shutdown	Disables the 802.11b/g network.
Step 6	ap country country_code Example: Device(config)# ap country IN	Assigns access points to a specific country. Note Make sure that the country code you choose is compatible with the regulatory domain of at least one of the access point's radios.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 8	show wireless country channels Example: Device# show wireless country channels	Displays the list of available channels for the country codes configured on your device. Note Perform Steps 9 through 17 only if you have configured multiple country codes in Step 6.

	Command or Action	Purpose
Step 9	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 10	no ap dot11 5ghz shutdown Example: Device(config)# <code>no ap dot11 5ghz shutdown</code>	Enables the 802.11a network.
Step 11	no ap dot11 24ghz shutdown Example: Device(config)# <code>no ap dot11 24ghz shutdown</code>	Enables the 802.11b/g network.
Step 12	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 13	ap name Cisco_AP shutdown Example: Device# <code>ap name AP02 shutdown</code>	Disables the access point. Note Ensure that you disable only the access point for which you are configuring country codes.
Step 14	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 15	ap country country_code Example: Device# <code>ap country IN</code>	Assigns an access point to a specific country. Note Ensure that the country code that you choose is compatible with the regulatory domain of at least one of the access point's radios. Note If you enabled the networks and disabled some access points and then enter the ap country country_code command, the specified country code is configured on only the disabled access points. All other access points are ignored.
Step 16	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 17	ap name Cisco_AP no shutdown Example: Device# <code>ap name AP02 no shutdown</code>	Enables the access point.

Configuration Examples for Configuring Country Codes

Displaying Channel List for Country Codes: Example

This example shows how to display the list of available channels for the country codes configured on your device:

```
Device# show wireless country channels

Configured Country.....: US - United States
KEY: * = Channel is legal in this country and may be configured manually.
A = Channel is the Auto-RF default in this country.
. = Channel is not legal in this country.
C = Channel has been configured for use by Auto-RF.
x = Channel is available to be configured for use by Auto-RF.
(-,-) = (indoor, outdoor) regulatory domain allowed by this country.

- [How to Configure TCP MSS, on page 568](#)
- [Performing a Link Test \(CLI\), on page 569](#)
- [Configuration Examples for Configuring Link Latency, on page 570](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Link Latency

- The device displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the device is up or can be cleared and allowed to restart.
- You can configure link latency for a specific access point using the device GUI or CLI or for all access points joined to the device using the CLI.

Restrictions for Configuring Link Latency

- Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the device. It does not measure network latency or ping responses.

Information About Configuring Link Latency

You can configure link latency on the device to measure the link between an access point and the device. You can use this feature with all access points that are joined to the device where the link can be a slow or unreliable WAN connection.

TCP MSS

If the client's maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the device or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the *ping link test*, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the *CCX link test*, the device can also test the link quality in the access point-to-client direction. The device issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and device. Not only can the access point or device initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or device.

The device shows the link-quality metrics for CCX link tests in both directions (out—the access point to the client; in—the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)
- Total number of packets that are retried
- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet

The controller shows this metric regardless of direction:

- Link test request/reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCXv4 or v5, the controller performs a ping link test on the client. If a client supports CCXv4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

How to Configure Link Latency

Configuring Link Latency (CLI)

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap link-latency`
4. `ap tcp-adjust-mss size size`
5. `show ap name Cisco_AP config general`
6. `ap name Cisco_AP link-latency [reset]`
7. `show ap name Cisco_AP config general`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Device# <code>enable</code>	Enters privileged EXEC mode.
Step 2	<code>configure terminal</code> Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	<code>ap link-latency</code> Example: Device(config)# <code>ap link-latency</code>	Enables link latency for all access points that are currently associated with the device. Note To disable link latency for all the access points that are associated with the device, use the no ap link-latency command.

	Command or Action	Purpose
		<p>Note These commands enable or disable link latency only for access points that are currently joined to the device. You have to enable or disable link latency for the access points that join in the future.</p> <p>Note To enable or disable link latency for specific access points that are associated with the device, enter the following commands in Privileged EXEC mode:</p> <ul style="list-style-type: none"> • ap name <i>Cisco_AP</i> link-latency—Enables link latency. • ap name <i>Cisco_AP</i> no link-latency—Disables link latency.
Step 4	<p>ap tcp-adjust-mss size <i>size</i></p> <p>Example:</p> <pre>Device(config)# ap tcp-adjust-mss size 537</pre>	Configures TCP MSS adjust size for all access points. The range is from 536 to 1363.
Step 5	<p>show ap name <i>Cisco_AP</i> config general</p> <p>Example:</p> <pre>Device(config)# show ap name AP02 config general</pre>	<p>Displays the general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.</p> <p>The output of this command contains the following link latency results:</p> <ul style="list-style-type: none"> • Current Delay—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back. • Maximum Delay—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back. • Minimum Delay—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.
Step 6	<p>ap name <i>Cisco_AP</i> link-latency [reset]</p> <p>Example:</p> <pre>Device(config)# ap name AP02 link-latency reset</pre>	Clears the current, minimum, and maximum link latency statistics on the device for a specific access point.

	Command or Action	Purpose
Step 7	show ap name <i>Cisco_AP</i> config general Example: Device(config)# show ap name AP02 config general	Displays the general configuration details of the access point. Use this command to see the result of the reset operation.

Configuring Link Latency (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page appears with a list of access points.

Step 2 Click the name of the access point.

The **AP > Edit** page appears.

Step 3 Click the **Advanced** tab.

Step 4 In the **Link Latency** area, select or unselect the **Enable Link Latency** check box.

Note You can select the **Enable Link Latency** check box to enable link latency for this access point or unselect it to prevent the access point from sending the round-trip time to the device after every echo response is received. The default state is unselected.

Step 5 Click **Apply**.

Step 6 When a message box appears that indicates that AP Parameters are modified successfully, click **OK**.

Step 7 When the **All APs** page is displayed, click the access point that you have modified earlier.

The **AP > Edit** page appears.

Step 8 Click the **Advanced** tab.

In the **Link Latency** area, the following link latency and data latency results are displayed:

- **Current(mSec)**—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the device and back.
- **Minimum(mSec)**—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the device and back.
- **Maximum(mSec)**—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the device and back.

Step 9 Click **Reset Link Latency** to clear the current, minimum, and maximum link latency and data latency statistics on the device for this access point.

Note After the page refreshes and the **All APs** page is displayed again, click the **Advanced** tab. The updated statistics appear in the **Minimum** and **Maximum** text boxes.

How to Configure TCP MSS

Configuring TCP MSS (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap tcp-adjust-mss size size_value`
3. `reload`
4. `show ap tcp-adjust-mss`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap tcp-adjust-mss size size_value Example: Device(config)# <code>ap tcp-adjust-mss size 537</code>	Enables the TCP MSS on the particular access point that you specify. Note To enable TCP MSS on all the access points that are associated with the device, enter the ap tcp-adjust-mss size size_value command, where the size parameter is from 536 to 1363 bytes. The default value varies for different clients.
Step 3	reload Example: Device# <code>reload</code>	Reboots the device in order for your change to take effect.
Step 4	show ap tcp-adjust-mss Example: Device# <code>show ap tcp-adjust-mss</code>	Displays the current TCP MSS setting for all the access points that are associated with the device. Note To display the TCP MSS settings that correspond to a specific access point, enter the show ap name Cisco_AP tcp-adjust-mss command.

Configuring TCP MSS (GUI)

Step 1 Choose **Configuration > Wireless > Access Points > Global AP Configuration**.

The **Global Configuration** page is displayed.

- Step 2** In the **TCP MSS** area, select the **Global TCP Adjust MSS** check box and set the MSS for all access points that are associated with the device. The valid range is from 536 to 1363 bytes.
- Step 3** Click **Apply**.
- Step 4** Click **Save Configuration**.

Performing a Link Test (CLI)

Note The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. `test wireless linktest mac_address`
2. `configure terminal`
3. `wireless linktest frame-size frame_size`
4. `wireless linktest number-of-frames number_of_frames`
5. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	test wireless linktest mac_address Example: Device# test wireless linktest 00:0d:88:c5:8a:d1	Runs a link test.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	wireless linktest frame-size frame_size Example: Device(config)# wireless linktest frame-size 41	Configures the link test frame size for each packet.
Step 4	wireless linktest number-of-frames number_of_frames Example: Device(config)# wireless linktest number-of-frames 50	Configures the number of frames to send for the link test.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuration Examples for Configuring Link Latency

Running a Link Test: Example

This example shows how to run a link test:

```
Device# test wireless linktest 6470.0227.ca55
Device# show wireless linktest statistic

Link Test to 64700227CA55 with 500 frame-size.
Client MAC Address           : 6470.0227.ca55
AP Mac Address               : 44e4.d901.19c0
Link Test Packets Sent       : 20
Link Test Packets Received   : 20
Link Test Pkts Lost(Total/AP->Clnt/Clnt->AP) : 0/0/0
Link Test Pkts round trip time (min/max/avg) : 9ms/31ms/14ms
RSSI at AP (min/max/average) : -53dBm/-51dBm/-52dBm
RSSI at Client (min/max/average) : -48dBm/-40dBm/-44dBm
```

Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

```
Device# show ap name AP01 config general

Cisco AP Name                : AP01

```

Displaying TCP MSS Settings: Example

This example shows how to display the current TCP MSS setting for all the access points that are associated with the device:

```
Device# show ap tcp-adjust-mss
```

AP Name	TCP State	MSS Size
AP01	Disabled	6146
AP02	Disabled	536
AP03	Disabled	6146
AP04	Disabled	6146
AP05	Disabled	6146

CHAPTER 40

Configuring Power over Ethernet

- [Finding Feature Information, on page 573](#)
- [Information About Configuring Power over Ethernet, on page 573](#)
- [How to Configure Power over Ethernet, on page 573](#)
- [Configuration Examples for Configuring Power over Ethernet, on page 576](#)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring Power over Ethernet

When an access point that has been converted to lightweight mode (such as an AP1262) access point is powered by a power injector that is connected to a Cisco pre-Intelligent Power Management (pre-IPM) switch, you must configure Power over Ethernet (PoE), which is also known as *inline power*.

How to Configure Power over Ethernet

Configuring Power over Ethernet (CLI)

SUMMARY STEPS

1. `ap name Cisco_AP power injector installed`
2. `ap name Cisco_AP power injector override`
3. `ap name Cisco_AP power injector switch-mac-address switch_mac_address`
4. `show ap name Cisco_AP config general`

DETAILED STEPS

	Command or Action	Purpose
Step 1	ap name <i>Cisco_AP</i> power injector installed Example: Device# ap name AP02 power injector installed	Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified. Note Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail.
Step 2	ap name <i>Cisco_AP</i> power injector override Example: Device# ap name AP02 power injector override	Removes the safety checks and allows the access point to be connected to any switch port. You can use this command if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The access point assumes that a power injector is always connected. If you relocate the access point, it continues to assume that a power injector is present.
Step 3	ap name <i>Cisco_AP</i> power injector switch-mac-address <i>switch_mac_address</i> Example: Device# ap name AP02 power injector switch-mac-address 10a.2d.5c.3d	Sets the MAC address of the switch port that has a power injector. Note Enter this command if you know the MAC address of the connected switch port and do not want to automatically detect it using the installed option.
Step 4	show ap name <i>Cisco_AP</i> config general Example: Device# show ap name AP02 config general	Displays common information that includes the PoE settings for a specific access point. Note The Power Type/Mode text box shows “degraded mode” if the access point is not operating at full power.

Configuring Power over Ethernet (GUI)

- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.
The **All APs** page appears with a list of access points that are associated with the device.
- Step 2** Click the name of the access point.
The **AP > Edit** page appears.
- Step 3** Click the **Advanced** tab.

Step 4 In the **Power Over Ethernet Settings** area, select the **Pre-Standard 802.3af Switches** check box.

Select this check box if the access point is being powered by a high-power 802.3af Cisco switch. This switch provides more than the traditional 6 Watts of power but does not support the intelligent power management (IPM) feature.

Note Unselect the **Pre-standard 802.3af Switches** check box if power is being provided by a power injector. This is the default value.

Step 5 Select the **Power Injector State** check box.

Select this check box if the attached switch does not support IPM and a power injector is being used. If the attached switch supports IPM, you do not need to select this check box.

The **Power Injector Selection** drop-down list is displayed that contains parameters that enable you to protect your switch port from an accidental overload if the power injector is inadvertently bypassed.

Step 6 From the **Power Injector Selection** drop-down list, choose an option to specify the desired level of protection.

You can choose any one of the following three options:

- **Installed**—Examines and remembers the MAC address of the currently connected switch port and assumes that a power injector is connected. Choose this option if your network contains older Cisco 6-Watt switches and you want to avoid possible overloads by forcing a double-check of any relocated access points.

If you want to configure the switch MAC address, enter the MAC address in the **Injector Switch MAC Address** text box. If you want the access point to find the switch MAC address, leave the **Injector Switch MAC Address** text box blank.

Note Each time that an access point is relocated, the MAC address of the new switch port fails to match the remembered MAC address, and the access point remains in low-power mode. You must then physically verify the existence of a power injector and reselect this option to cause the new MAC address to be remembered.

- **Override**—Allows the access point to operate in high-power mode without first verifying a matching MAC address. You can use this option if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The advantage of this option is that if you relocate the access point, it continues to operate in high-power mode without any further configuration. The disadvantage of this option is that if the access point is connected directly to a 6-W switch, an overload occurs.

Step 7 Click **Apply**.

Step 8 Click **Save Configuration**.

What to do next

Manually reset the access point in order for the change to take effect.

Configuration Examples for Configuring Power over Ethernet

Displaying Power over Ethernet Information: Example

This example shows how to display common information that includes the PoE settings for a specific access point:

```
Device# show ap name AP01 config general

Cisco AP Identifier..... 1
Cisco AP Name..... AP1
...
PoE Pre-Standard Switch..... Enabled
PoE Power Injector MAC Addr..... Disabled
Power Type/Mode..... PoE/Low Power (degraded mode)
...
```

- [Mobility Control Protocols, on page 589](#)
- [Configuring Mobility, on page 597](#)

CHAPTER 41

Information About Mobility

- [Overview, on page 579](#)
- [Wired and Wireless Mobility, on page 580](#)
- [Features of Mobility, on page 580](#)
- [Sticky Anchoring for Low Latency Roaming, on page 582](#)
- [Bridge Domain ID and L2/L3 Roaming, on page 582](#)
- [Link Down Behavior, on page 582](#)
- [Platform Specific Scale Requirement for the Mobility Controller, on page 583](#)

Overview

The delivers more services at access layer other than merely providing increased speeds and feeds. Wireless services is now integrated with the switch, which ensures that the access layer switch terminates the wireless users data plane, thereby delivering on the promise of Cisco's unified architecture. Unification implies that mobility services are provided to both wireless and wired stations.

The provides seamless roaming, which requires transparency of the network configuration and deployment options to the client.

From the end user's perspective, any mobility event must not change its IP address, its default router or DHCP server. This means that as stations roam, they must be able to

- Send an ARP to their default router, or
- Transmit a DHCP request to the server that had previously assigned their address.

From the infrastructure's perspective, as mobility events occur, the station's traffic must follow its current point of attachment, which can either be a mobility agent (MA) or mobility controller (MC). This must be true regardless of whether the station has moved to a network that is configured for a different subnet. The period from which the station is not receiving traffic following its mobility event must be as short as possible, even below 40 ms whenever possible, which includes any authentication procedures that are required.

From the infrastructure's perspective, the mobility management solution must have four main components, and all of these functions must be performed within the constraints of roaming:

- Initial Association—This function is used to identify the user's new point of attachment in the network.
- Context Transfer—This function is used to transfer state information associated with the station. This ensures that the station's static and real-time policies, including security and application ACLs, and services, remain the same across handoffs.

- Handoff—This function is used to signal that the station's point of attachment has changed, and control of the station should be relinquished by the previous access .
- Data Plane—This function is typically tied to the handoff process, and ensures that the station's traffic continues to be delivered and received from the station without any noticeable performance degradation.

**Caution**

If you have configured virtual routing and forwarding (VRF) on wireless management interface VLAN, the mobility feature may not work expected.

**Note**

You must enable PIM, IP ROUTING and IP MULTICAST Routing for wireless mobility multicast to work.

Wired and Wireless Mobility

One of the key features of the Converged access solution (applicable to both the Cisco Catalyst 3850 Switch and Cisco WLC 5700 Series Controller) is its ability to provide a device with an IP address and maintain its session persistence, across mobility events from ethernet connections to wireless and vice-versa. This feature allows users to remain on an ethernet network when possible, and make use of the freedom of mobility associated with wireless when necessary.

This feature leverages support from both the client and the infrastructure and uses the two factor authentication-device and user. The device authentication credentials is cached in the mobility controller (MC). When a device transitions across link layers, the device credentials is validated, and if a match is found, the MC ensures that the same IP address is assigned to the new interface.

Features of Mobility

- Mobility Controller (MC)—The controller provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and policy based control protocols, such as RADIUS. This eliminates the need for the infrastructure servers to maintain a user's location as it transitions throughout the network. The MC sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members. A sub-domain is synonymous to the MC that forms it. Each sub-domain consists of an MC and zero or more access switches that have AP's associated to them.
- Mobility Agents (MA)— A mobility agent is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. A mobility agent is the wireless component that maintains client mobility state machine for a mobile client that is connected via an AP to the device that the MA is running on.
- Mobility Sub Domain— It is an autonomous portion of the mobility domain network. A mobility sub-domain comprises of a single mobility controller and its associated mobility agents (MAs).

Note Even when more than one mobility controller is present, only one MC can be active at any given time.

A mobility sub-domain is the set of devices managed by the active mobility controller. A mobility sub-domain comprises of a set of mobility agents and associated access points.

- **Mobility Group**— A collection of mobility controllers (MCs) across which fast roaming is supported. The concept of mobility group is the same as a collection of buildings in a campus across which frequent roaming is expected.
- **Mobility Domain**— A collection of mobility sub-domains across which mobility is supported. The term mobility domain may be the same as a campus network.
- **Mobility Oracle (MO)**—The mobility oracle acts as the point of contact for mobility events that occur across mobility sub-domains. It also maintains a local database of each station in the entire mobility domain, their home and current sub-domain. A mobility domain includes one or more mobility oracle, though only one would be active at any given time.
- **Mobility Tunnel Endpoint (MTE)**— The mobility tunnel endpoint (MTE) provides data plane services for mobile devices through the use of tunneling. This minimizes the impact of roaming events on the network by keeping the user's point of presence on the network a constant.
- **Point of Attachment**— A station's point of attachment is where its data path is initially processed upon entry in the network. This could either be the access switch that is currently providing it service, or the wireless LAN controller.
- **Point of Presence**— A station's point of presence is the place in the network where the station is being advertised. For instance, if an access switch is advertising reachability to the station via a routing protocol, the interface on which the route is being advertised is considered the station's point of presence.
- **Switch Peer Group (SPG)**— A peer group is a statically created list of neighboring access switches between which fast mobility services is provided. A peer group limits the scope of interactions between switches during handoffs to only those that are geographically proximate.
- **Station**—A user's device that connects to and requests service from the network. The device may have a wired, wireless or both interfaces.
- **Switch in the same SPG**—A peer switch that is part of the peer group of the local switch.
- **Switch outside the SPG**—A peer access switch that is not part of the local switch's peer group.
- **Foreign Mobility Controller**— The mobility controller providing mobility management service for the station in a foreign mobility sub-domain. The foreign mobility controller acts as a liaison between access switches in the foreign sub-domain and the mobility controller in the home domain.
- **Foreign Mobility Sub-Domain**— The mobility sub-domain, controlled by a mobility controller, supporting a station which is anchored in another mobility sub-domain
- **Foreign Switch**— The access switch in the foreign mobility sub-domain currently providing service to the station.
- **Anchor Mobility Controller**— The mobility controller providing a single point of control and mobility management service for stations in their home mobility sub-domain.

- Anchor Mobility Sub-Domain— The mobility sub-domain, controlled by a mobility controller, for a station where its IP address was assigned.
- Anchor Switch— The switch in the home mobility sub-domain that last provided service to a station.

Sticky Anchoring for Low Latency Roaming

Sticky Anchoring ensures low roaming latency from the client's point of presence is maintained at the switch where the client initially joins the network. It is expensive to apply client policies at a switch for a roaming client. There can be considerable delay as it involves contacting the AAA server for downloadable ACLs which is not acceptable for restoring time sensitive client traffic.

To manage this delay, when the client roams between APs connected to different switches, irrespective of whether it is an intra sub-domain roam or inter sub-domain roam, the client traffic is always tunneled to the switch where the client first associates. The client is anchored at its first point of attachment for its lifetime in the network.

This behavior is enabled by default. You can also disable this behavior to allow the client anchoring only for inter-subnet roams. This configuration is per WLAN config and is available under the WLAN config mode. The customer can configure different SSIDs for time sensitive and non time sensitive applications.

Bridge Domain ID and L2/L3 Roaming

Bridge domain ID provides the mobility nodes with information to decide on specific roam type, either as L2 or L3 roam. It also allows the network administrators to reuse the VLAN IDs across network distribution. When the VLAN IDs do not have the associated subnet configurations, they may require additional parameter to use in conjunction with VLAN ID. The network administrator ensures that the given VLAN under the same bridge domain ID are associated with the unique subnet. The mobility nodes will first check for the bridge domain ID for the given node and the VLAN ID associated with the client to identify the roam type. The bridge domain ID and the VLAN ID must be same to treat a roam as L2 roam.

The bridge domain ID is configured for each SPG when creating a SPG and later on the MC. The bridge domain ID could be same for more than one SPG and all the MAs under the SPG will share the same bridge domain ID. This information is pushed to the MAs as part of the configuration download when MA comes up initially. If the bridge domain ID is modified when the system is up, it will be pushed to all the MAs in the modified SPG and will take immediate effect for the future roams.

Link Down Behavior

This section provides information about data synchronization between MA-MC and MC-MO when MC or MO faces downtime in absence of redundancy manager. When Keepalive is configured between MA-MC or MC-MO the clients database is synchronized between the MO and the MCs and the MC and its MAs respectively.

Platform Specific Scale Requirement for the Mobility Controller

The Mobility Controller (MC) role is supported on a number of different platforms like, the Cisco WLC 5700 Series, CUWN and Catalyst 3850 Switches. The scale requirements on these three platforms are summarized in the table below:

Scalability	Catalyst 3850 as MC	Catalyst 3650 as MC	Cisco WLC 5700 as MC	CUWN 5508 as MC	WiSM2 as MC
Max number of MC in Mobility Domain	8	8	72	72	72
Max number of MC in Mobility Group	8	8	24	24	24
Max number of MAs in Sub-domain (per MC)	16	16	350	350	350
Max number of SPGs in Sub-domain (per MC)	8	8	24	24	24
Max number of MAs in a SPG	16	16	64	64	64

CHAPTER 42

Mobility Network Elements

- [Mobility Agent, on page 585](#)
- [Mobility Controller, on page 586](#)
- [Mobility Oracle, on page 587](#)
- [Guest Controller, on page 587](#)

Mobility Agent

A Mobility Controller resides on the switch. It is both, control path and data path entity and is responsible for:

- Handling the mobility events on the switch
- Configuring the datapath elements on the switch for mobility, and
- Communicating with the mobility controller

As MA, the device performs the datapath functions by terminating the CAPWAP tunnels that encapsulate 802.11 traffic sourced by wireless stations.

This allows the device to apply features to wired and wireless traffic in a uniform fashion. As far as device is concerned, 802.11 is just another access medium.

The MA performs the following functions:

- Support the mobility protocol – The MA is responsible for responding in a timely manner, ensuring the device is capable of achieving its roaming budget.
- Point of presence – If the wireless subnets are not available at the MC, the MA assumes the point of presence if the wireless client VLAN is not available at the new point of attachment and tunnel the client traffic accordingly.
- ARP Server – When the network is configured in a layer 2 mode, the MA is responsible for advertising reachability for the stations connected to it. If tunneling is employed, the ARP request is transmitted on behalf of the station through the tunnel, which the point of presence (anchor switch) would bridge onto its uplink interface.
- Proxy IGMP – The MA on the device is responsible for subscribing to multicast groups on behalf of a station after a roaming event has occurred. This information is passed as part of the context to the new device. This ensures the multicast flows follow the user as it roams.
- Routing – When the device is connected to a layer 3 access network, the MA is responsible for injecting routes for the stations that are associated with it for which tunneling is not provided.

- 802.1X Authenticator – The authenticator function is included in the MA, and handles both wired and wireless stations.
- Secure PMK Sharing – When a station successfully authenticates to the network, the MA forwards the PMK to the MC. The MC is responsible for flooding the PMK to all the MAs under its sub-domain and to the peer MCs in the mobility group.

The MA also performs the following datapath functions:

- Mobility tunnel – If tunneling is used, the MA encapsulates and decapsulates packets from the mobility tunnel to the MC, and to other MA in the peer group, if the access switches are serving as points of presence. The MA supports the tunneling of client data traffic between the point of attachment and the point of attachment. The packet format used for other switches is CAPWAP with an 802.3 payload. The MA also supports reassembly and fragmentation for mobility tunnels.
- Encryption – The mobility control traffic between the mobility nodes is DTLS encrypted. The MA also encrypts the CAPWAP control and data (optional) at the point of attachment.
- CAPWAP – The device supports the CAPWAP control and data planes. The device forwarding logic is responsible for terminating the CAPWAP tunnels with 802.11 as well as 802.3 payloads. Since support for large frames (greater than 1500bytes) is not universally available, the device supports CAPWAP fragmentation and reassembly.

Note Mobility tunnel path via an L3 interface on the 4500 or the L3 interface on the uplink port is not supported. It is not possible to have an L3 wireless management interface. Even if the tunnel comes up, packet forwarding is not possible as it is not supported. 4510 drops DHCP packets from wireless clients if SSID is anchored to a different Cisco WLC.

Mobility Controller

The main function of mobility controller is to coordinate the client roaming beyond a switch peer group. The other features of the mobility controller are:

- Station Database—The Mobility Controller maintains a database of all the clients that are connected within the local mobility sub-domain.
- Mobility Protocol—The MC supports the mobility protocol which ensures the target roaming point responds in a timely manner and achieves the 150ms roaming budget
- Interface to Mobility Oracle—The Mobility Controller acts as a gateway between the and the Mobility Oracle. When the Mobility Controller does not find a match in its local database, it suggests a match for a wireless client entry (in its database) and forwards the request to the Mobility Oracle, which manages the Mobility Domain.

Note Mobility Oracle function can be enabled on an MC only if it is supported by the platform.

- ARP Server—When tunneling is employed for a station, its point of presence on the network is the Mobility Tunnel Endpoint (MTE). The Mobility Controller responds to any ARP requests received for the stations it is responsible for.
- Routing—When the Mobility Controller is connected to a layer three network, the Mobility Controller is responsible for injecting routes for the stations it supports into the network.
- Configures MTE—The Mobility Controller is the control point for the for all mobility management related requests. When a change in a station's point of attachment occurs, the Mobility Controller is responsible for configuring the forwarding policy on the MTE.
- NTP Server—The Mobility Controller acts as an NTP server to the and supports all the nodes to have their clocks synchronized with it.

Note The Cisco 5700 series WLC and other controller platforms that have the Mobility Controller function enabled by default should not be added to a switch peer group (SPG).

Mobility Oracle

The Mobility Oracle coordinates the client roams beyond the subdomain on a need basis and consists of the following features:

- Station Database—The Mobility Oracle maintains a database of all stations that are serviced within the mobility domain. This database is populated during the Mobility Oracle's interactions with all the Mobility Controllers, in all of the mobility sub-domains it supports.
- Interface to Mobility Controller—When the Mobility Oracle receives a request from a Mobility Controller, it performs a station lookup, and forwards, whenever needed, the request to the proper Mobility Controller.
- NTP Server—The Mobility Oracle acts as an NTP server to the Mobility Controllers and synchronizes all the clocks within the mobility domain.

Guest Controller

The guest access feature provides guest access to wireless clients. The guest tunnels use the same format as the mobility tunnels. Using the guest access feature, there is no need to configure guest VLANs on the access switch. Traffic from the wired and wireless clients terminates on Guest Controller. Since the guest VLAN is not present on the access switch, the traffic is tunneled to the MTE over the existing mobility tunnel, and then via a guest tunnel to the Guest Controller.

The advantage of this approach is that all guest traffic passes through the MTE before it is tunneled to the Guest Controller. The Guest Controller only needs to support tunnels between itself and all the MTEs.

The disadvantage is that the traffic from the guest client is tunneled twice - once to the MTE and then again to the Guest Controller.

Clients cannot roam to Guest Controllers because roaming is not supported on Guest Controllers. This restriction is applicable only for the IOS-XE guest anchor, and not for AireOS.

CHAPTER 43

Mobility Control Protocols

- [About Mobility Control Protocols, on page 589](#)
- [Initial Association and Roaming, on page 589](#)
- [Initial Association, on page 590](#)
- [Intra Switch Handoff, on page 591](#)
- [Intra Switch Peer Group Handoff, on page 591](#)
- [Inter Switch Peer Group Handoff, on page 592](#)
- [Inter Sub Domain Handoff, on page 593](#)
- [Inter Mobility Group Handoff, on page 595](#)

About Mobility Control Protocols

The mobility control protocol is used regardless of whether tunneled or routed. The mobility control protocol is used for mobility events between the MO, MC and MA.

The mobility architecture uses both,

- Distributed approach, using the direct communication with the switches in their respective SPG, as well as
- Centralized approach, using the MC and MO.

The goal is to reduce the overhead on the centralized MC, while limiting the interactions between switches to help scale the overall system.

Initial Association and Roaming

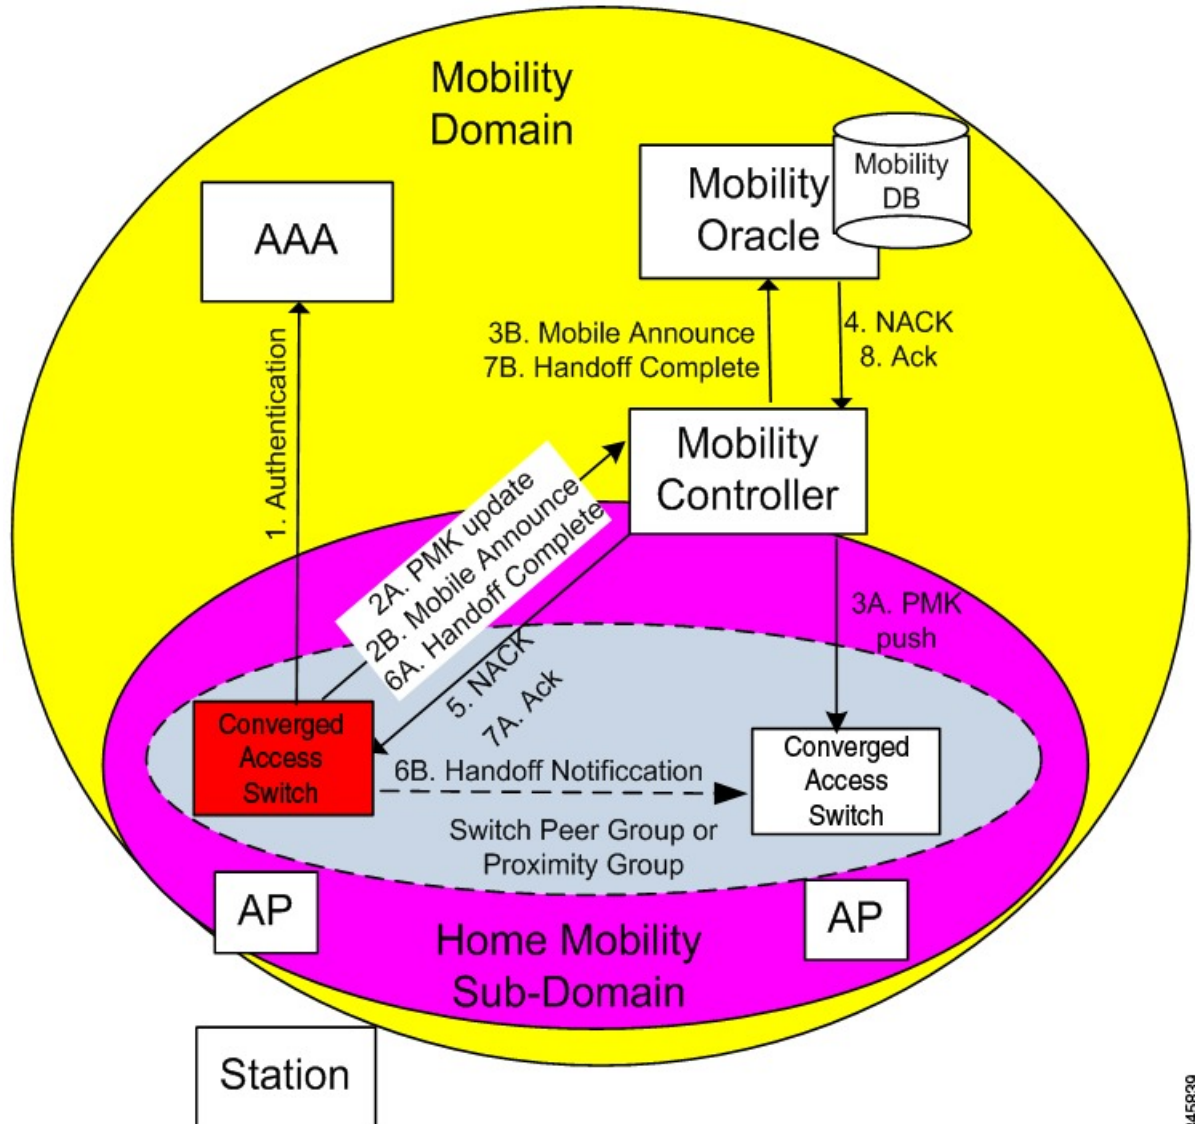

The following scenarios are applicable to the mobility management protocol:

- Initial Association
- Intra Switch Roam
- Intra Switch Peer Group Roam
- Inter Switch Peer Group Roam
- Inter Sub-Domain Roam
- Inter Group Roam

Initial Association

The illustration below explains the initial association process followed by the device:

Figure 41: Initial Association

1. When a station initially associates with a mobility agent, the MA performs a lookup to determine whether keying information for key caching is locally available in the MA. If no keying information is available, which is the case when the station first appears in the network, the device prompts the device to authenticate itself to generate the Pairwise Master Key (PMK). The PMK is generated on the client and the RADIUS server side, and the RADIUS server forwards the PMK to the authenticator, the MA.
2. The MA sends the PMK to the MC.
3. After receiving the PMK from the MA, the MC transmits the PMK to all the MAs in its sub-domain, and to all the other MCs in its mobility group.

4. The mobility group is a single key domain. This ensures that 802.11r compliant stations recognize the key domain, and attempts to utilize the fast transition procedures defined in 802.11r.

Note The 802.11r protocol defines a key domain, which is a collection of access points that share keying information.

5. (Refer to step 2B in the illustration). Since the station is new to the mobility sub-domain, as indicated by the fact that the PMK is not in the MA local key cache, the MA transmits a mobile announce message to the MC.
6. The MC checks if the client exists in its database. As the client cannot be found, the MC in turn forwards it to the MO, if available.
7. (Refer to step 5 in the illustration). As the station is new to the network, the MO returns a negative response (NACK), which is forwarded by the MC to the device. If the Mobility Oracle is not available then the MC is responsible for not responding to the Mobile Announce.

Note In new mobility if there are many peers, the IOS controller will not react on a NACK message from the AirOS peer and sends two more probes. NACK is ignored if the client is not present it just drops it, in such a scenario AIREOS sends the NACK. So NACK from mobility controller is not processed.

8. The MA on the device informs the MC about the station's new point of attachment via the Handoff Complete message.
9. The MA then informs the other MAs in its switch peer group (SPG) about the station's new point of attachment via the Handoff Notification message. It is necessary to transmit this notification to the MAs in its SPG to allow local handoff without interacting with the MC. The Handoff Notification message sent to MAs in SPG need not carry all the information in Handoff Complete message sent to the MC.
10. (Refer to step 7B in the illustration). The MC updates its database and forwards the Handoff Complete message to the Mobility Oracle. This ensures that the Mobility Oracle's database is updated to record the station's current home mobility sub-domain.

To eliminate race conditions that could occur with devices moving quickly across device, regardless of whether they are within a mobility sub-domain or not, the messages between MA and MC/MO are time synchronized. This would allow the MC and MO to properly process requests, if they are received out of order.

The Handoff Notification sent to MAs in the SPG are not acknowledged.

Intra Switch Handoff

Mobility events within an MA are completely transparent to the SPG and the MC. When a station moves across APs on the same MA and attempts to perform a fast handoff, the PMK is present on the MA. The MA will complete the fast handoff without invoking any additional signal.

Intra Switch Peer Group Handoff

The switch peer group (SPG) is a group of MAs between which users may roam, and expect fast roaming services. Allowing the MA to handoff directly within a SPG reduces the overhead on the MC as it requires fewer messages to be exchanged.

After the initial association is complete the station moves to another MA belonging to its SPG. In an intra switch peer group roam, the initial association, the stations PMK was forwarded to all MAs in the mobility sub-domain.

Figure 42: Intra Switch Peer Group Handoff

The following process explains the intra switch peer group handoff:

1. In the initial association example, the Handoff Notification message is sent to all MAs in its SPG to know the station's current point of attachment.
2. The new MA sends a unicast Mobile Announce message to the previous MA to which the client is associated.
3. After the handoff completion, the new MA transmits a Handoff Complete message to the MC.
4. The new device sends a Handoff Notification to all MA in its own SPG to inform them about the clients new point of presence.

Inter Switch Peer Group Handoff

The Intra SPG roams do not cover all possible scenarios and there can be cases where it is possible for mobility events to occur between two MAs that are not in the same SPG.

When a MA does not have any information about a station's current point of attachment, because of the Handoff Notification message getting lost in the network, or because of the the station roaming to an MA that is not in the new SPG, the MA consults the MC. The MC provides information about the clients point of presence within the mobility sub-domain. This eliminates the need to consult all other MCs within the mobility sub-domain.

Figure 43: Inter Switch Peer Group Handoff

345841

The image above illustrates an example of a mobility event that occurs across MAs that are not in the same SPG, but within the same mobility sub-domain.

Note The MA color matches the circle representing its SPG.

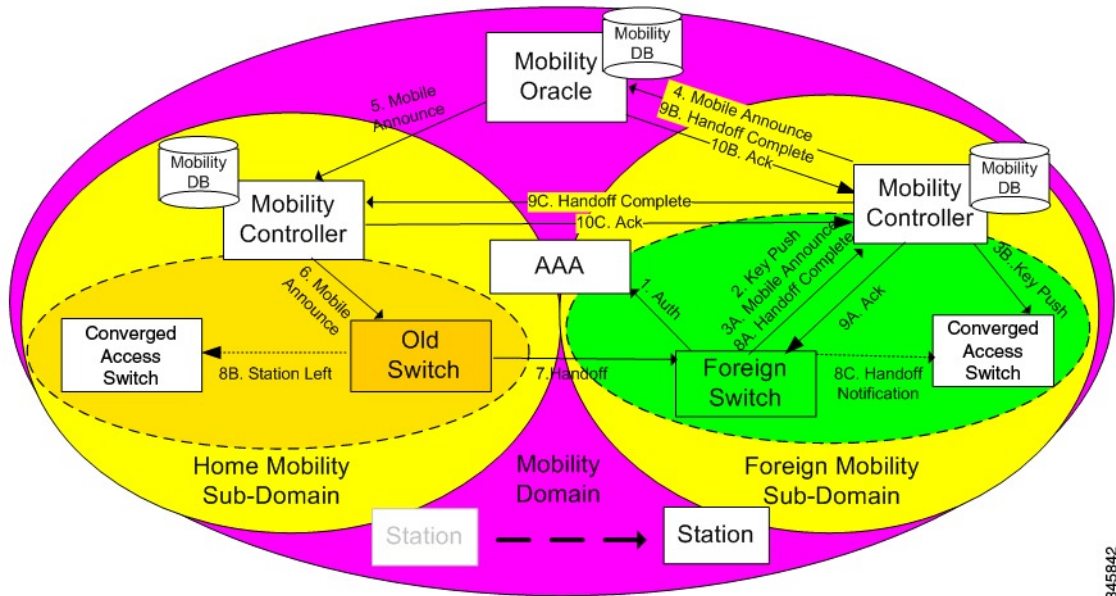

1. The new MA will have the PMK for the station, which was forwarded to each MA in the mobility sub-domain upon client initial authentication.
2. Since the MA had not been previously notified of the station's presence on a neighboring MA inside a different SPG transmits the mobile announce to the sub-domain's MC.
3. (Refer to step 2 in the illustration) On receiving the mobile announce message, the MC performs a lookup in its database, and forwards the request to the MA that was previously providing service to the station. This information is known to the MC through a previously received Handoff Complete message sent in a reliable fashion from the old MA.
4. (Refer to step 3 in the illustration) The old MA, shown in green above, transmits a Handoff message directly to the new MA.
5. The old MA needs to notify other MAs within its SPG of the fact that the station has left the group using a Station Left message. This ensures that if the station were to come back to one of the MA , they would be aware of the fact that the station is no longer being serviced by the old MA.
6. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the MC.
7. The new MA then transmits the Handoff Notification to the other MAs within its SPG.

Inter Sub Domain Handoff

A sub-domain is an ensemble formed by a mobility controller and the mobility agents it directly manages. An inter sub-domain mobility event implies communication between two mobility controllers. These 2 mobility controllers can be configured with the same mobility group value and recognize each other. They will appear in each other's mobility list, or they can be configured with different mobility group values, and still recognize each other.

When the roaming event occurs across sub-domains between MCs in the same mobility group, the 802.11r key domain advertised by the new APs are the same. Additionally, the client PMK is also transmitted to all MCs upon the client's initial authentication. The new MC does not need to force the client to reauthenticate, and the new MC also knows which previous MC was managing the wireless client mobility.

Figure 44: Inter Sub Domain Handoff

345842

The following steps are involved in the inter sub domain handoff, when mobility controllers belong to the same mobility group:

1. When a client's PMK was sent by the initial MA to all the MCs in the mobility group, the new MA already had already received the client PMK from its MC, and re-authentication is not required.
2. The new MA was not notified previously of the station's presence on a neighboring MA inside a different SPG it transmits the mobile announce to the sub-domain's MC.
3. On receiving the mobile announce message, the MC forwards the mobile announce to the MO, which performs a lookup in its database, and forwards the request to the MC that was previously providing service to the station.
4. The previous MC, in turn, forwards the request to the MA that was previously providing service to the station.
5. The old MA, shown in yellow color above, transmits a Handoff message directly to the new MA.
6. The old MA must notify the other MAs within its SPG of the fact that the station has left the SPG using a Station Left message. This ensures that if the station comes back to one of the MA, the MA is aware of the fact that the station is no longer serviced by the old MA.
7. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the new Mobility Controller.
8. The new MA then transmits the Handoff Notification to all other MAs.
9. The new MC then transmits the Handoff Complete to the old MC.

Inter Mobility Group Handoff

A mobility group is formed by MCs sharing the same mobility group name, and knowing each other.

Since the roaming event occurs across mobility groups, the 802.11r key domain advertised by the new APs differ. This forces the client to re-authenticate. They are propagated only within a mobility group, and roaming across mobility groups requires the stations to re-authenticate when they cross mobility group boundaries. When the authentication is complete, the PMK that is generated is pushed to the MAs and MCs within the same mobility group. The stations cache the PMK from the previous sub-domain because each PMK is associated to a given sub-domain (802.11y key domain). This ensures that you do not have to re-authenticate when the PMK roams back to the previous sub-domain within the pmk cache timeout interval. The remaining procedure follows the inter-sub-domain handoff steps, except that these steps relate to inter mobility group roaming.

CHAPTER 44

Configuring Mobility

- [Configuring Mobility Controller, on page 597](#)
- [Configuring Mobility Agent, on page 605](#)

Configuring Mobility Controller

Configuring Converged Access Controllers

Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)

Before you begin

- On the mobility agent, you can only configure the IP address of the mobility controller.
- On the mobility controller, you can define the peer group and the IP address of each peer group member.

SUMMARY STEPS

1. `wireless mobility controller`
2. `wireless mobility controller peer-group SPG1`
3. `wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr`
4. `wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr`
5. `wireless mobility controller peer-group SPG2`
6. `wireless mobility controller peer-group SPG2 member ip member-ip-addr public-ip public-ip-addr`
7. `wireless mobility controller peer-group SPG1 bridge-domain-id id`

DETAILED STEPS

	Command or Action	Purpose
Step 1	wireless mobility controller Example: Device(config)# <code>wireless mobility controller</code>	Enables the mobility controller functionality on the device. This command is applicable only to the switch. The controller is by default a mobility controller.

	Command or Action	Purpose
Step 2	wireless mobility controller peer-group <i>SPG1</i> Example: Device(config)# wireless mobility controller peer-group SPG1	Creates a peer group named SPG1.
Step 3	wireless mobility controller peer-group <i>SPG1</i> member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i> Example: Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip 10.10.20.2	Adds a mobility agent to the peer group. Note The 10.10.20.2 is the mobility agent's direct IP address. When NAT is used, use the optional public IP address to enter the mobility agent's NATed address. When NAT is not used, the public IP address is not used and the device displays the mobility agent's direct IP address.
Step 4	wireless mobility controller peer-group <i>SPG1</i> member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i> Example: Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.6 public-ip 10.10.20.6	Adds another member to the peer group SPG1.
Step 5	wireless mobility controller peer-group <i>SPG2</i> Example: Device(config)# wireless mobility controller peer-group SPG2	Creates another peer group SPG2.
Step 6	wireless mobility controller peer-group <i>SPG2</i> member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i> Example: Device(config)# wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip 10.10.10.20	Adds a member to peer group SPG2.
Step 7	wireless mobility controller peer-group <i>SPG1</i> bridge-domain-id <i>id</i> Example: Device(config)# wireless mobility controller peer-group SPG1 bridge-domain-id 54	(Optional) Adds a bridge domain to SPG1 used for defining the subnet-VLAN mapping with other SPGs.

Example

This example shows how to create peer group and add members to it:

```
Device(config)# wireless mobility controller
Device(config)# wireless mobility controller peer-group SPG1
Device(config)# wireless mobility controller peer-group SPG1
Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip
```

```
10.10.20.2
Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.6 public-ip
10.10.20.6
Device(config)# wireless mobility controller peer-group SPG2
Device(config)# wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip
10.10.10.20
Device(config)# wireless mobility controller peer-group SPG1 bridge-domain-id 54
```

Creating Peer Groups, Peer Group Member, and Bridge Domain ID (GUI)

Before you begin

- Ensure that the device is in mobility controller state.
- On the mobility agent, you can only configure the IP address of the mobility controller.
- On the mobility controller, you can define the peer group and the IP address of each peer group member.

Step 1 Choose **Controller > Mobility Management > Switch Peer Group**.

The **Mobility Switch Peer Groups** page is displayed.

Step 2 Click **New**.

Step 3 Enter the following details:

- a) **Switch Peer Group Name**
- b) **Bridge Domain ID**
- c) **Multicast IP Address**

Step 4 Click **Apply**.

Step 5 Click **Save Configuration**.

Configuring Local Mobility Group (CLI)

Configuration for wireless mobility groups and mobility group members where the mobility group is a group of MCs.

Before you begin

MCs can belong only to one mobility group, and can know MCs in several mobility groups.

SUMMARY STEPS

1. **wireless mobility group name** *group-name*
2. **wireless mobility group member ip** *member-ip-addr* **public-ip** *public-ip-addr*
3. **wireless mobility group keepalive interval** *time-in-seconds*
4. **wireless mobility group keepalive count** *count*

DETAILED STEPS

	Command or Action	Purpose
Step 1	wireless mobility group name <i>group-name</i> Example: Device(config)# wireless mobility group name Mygroup	Creates a mobility group named Mygroup .
Step 2	wireless mobility group member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i> Example: Device(config)# wireless mobility group member ip 10.10.34.10 public-ip 10.10.34.28	Adds a mobility controller to the Mygroup mobility group. Note When NAT is used, use the optional public IP address to enter the NATed IP address of the mobility controller.
Step 3	wireless mobility group keepalive interval <i>time-in-seconds</i> Example: Device(config)# wireless mobility group keepalive interval 5	Configures the interval between two keepalives sent to a mobility member.
Step 4	wireless mobility group keepalive count <i>count</i> Example: Device(config)# wireless mobility group keepalive count 3	Configures the keep alive retries before a member status is termed DOWN.

Example

```

Device(config)# wireless mobility group name Mygroup
Device(config)# wireless mobility group member ip 10.10.34.10 public-ip 10.10.34.28
Device(config)# wireless mobility group keepalive interval 5
Device(config)# wireless mobility group keepalive count 3

```

Configuring Local Mobility Group (GUI)**Before you begin**

Mobility controllers can belong to only one mobility group and can know mobility controllers in several mobility groups.

Step 1 Choose **Controller > Mobility Management > Mobility Global Config**.

The **Mobility Controller Configuration** page is displayed.

Step 2 Enter the following details:

- a) **Mobility Group Name**
- b) **Mobility Keepalive Interval**
- c) **Mobility Keepalive Count**

- d) **Multicast IP Address** if you want to enable multicast mode to send mobile announce messages to the mobility members.

Note If you do not enable multicast IP address, the device uses unicast mode to send mobile announce messages.

Step 3 Click **Apply**.

Step 4 Click **Save Configuration**.

Adding a Peer Mobility Group (CLI)

Before you begin

MCs belong to only one group, and can know MCs in several groups.

SUMMARY STEPS

1. `wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name</code></p> <p>Example:</p> <pre>Device(config)# wireless mobility group member ip 10.10.10.24 public-ip 10.10.10.25 group Group2</pre>	Adds the member as a peer MC in a different group than the Mygroup .

Adding a Peer Mobility Group (GUI)

Before you begin

Mobility controllers belong to only one group, and can know several mobility groups.

Step 1 Choose **Controller > Mobility Management > Mobility Peer**.

The **Mobility Peer** page is displayed.

Step 2 Click **New**.

Step 3 Enter the following details:

- a) **Mobility Member IP**
- b) **Mobility Member Public IP**
- c) **Mobility Member Group Name**
- d) **Multicast IP Address**

Step 4 Click **Apply**.

Step 5 Click **Save Configuration**.

Configuring Optional Parameters for Roaming Behavior

Use this configuration to disable the sticky anchor. This command can also be used, if required, between all MA's and MC's where roaming is expected for the target SSID.

SUMMARY STEPS

1. `wlan open21`
2. `no mobility anchor sticky`

DETAILED STEPS

	Command or Action	Purpose
Step 1	wlan open21 Example: Device(config)# wlan open20	Configures a WLAN.
Step 2	no mobility anchor sticky Example: Device(config-wlan)# no mobility anchor sticky	Disables the default sticky mobility anchor.

Example

```
Device(config)# wlan open20
Device(config-wlan)# no mobility anchor sticky
```

Pointing the Mobility Controller to a Mobility Oracle (CLI)

Before you begin

You can configure a mobility oracle on a known mobility controller.

SUMMARY STEPS

1. `wireless mobility group member ip member-ip-addr group group-name`
2. `wireless mobility oracle ip oracle-ip-addr`

DETAILED STEPS

	Command or Action	Purpose
Step 1	wireless mobility group member ip member-ip-addr group group-name Example: Device(config)# wireless mobility group member ip 10.10.10.10 group Group3	Creates and adds a MC to a mobility group.

	Command or Action	Purpose
Step 2	wireless mobility oracle ip <i>oracle-ip-addr</i> Example: Device(config)# wireless mobility oracle ip 10.10.10.10	Configures the mobility controller as mobility oracle.

Example

```
Device(config)# wireless mobility group member ip 10.10.10.10 group Group3
Device(config)# wireless mobility oracle ip 10.10.10.10
```

Pointing the Mobility Controller to a Mobility Oracle (GUI)

Before you begin

You can configure a mobility oracle on a known mobility controller.

Step 1 Choose **Controller > Mobility Management > Mobility Global Config**.

The **Mobility Controller Configuration** page is displayed.

Step 2 Enter the **Mobility Oracle IP Address**.

Note To make the mobility controller itself a mobility oracle, select the **Mobility Oracle Enabled** check box.

Step 3 Click **Apply**.

Step 4 Click **Save Configuration**.

Configuring Guest Controller

A guest controller is used when the client traffic is tunneled to a guest anchor controller in the demilitarized zone (DMZ). The guest client goes through a web authentication process. The web authentication process is optional, and the guest is allowed to pass traffic without authentication too.

Enable the WLAN on the mobility agent on which the guest client connects with the mobility anchor address of the guest controller.

On the guest controller WLAN, which can be Cisco 5500 Series WLC, Cisco WiSM2, or Cisco 5700 Series WLC, configure the IP address of the mobility anchor as its own IP address. This allows the traffic to be tunneled to the guest controller from the mobility agent.

Note With Cisco 5700 Series WLC as the guest anchor controller and Cisco 5500 Series WLC or Cisco WiSM2 as export foreign controller, the guest user role per user is not supported on the Cisco 5700 Series WLC.

SUMMARY STEPS

1. `wlan wlan-id`
2. `mobility anchor guest-anchor-ip-addr`
3. `client vlan vlan-name`
4. `security open`

DETAILED STEPS

	Command or Action	Purpose
Step 1	wlan <i>wlan-id</i> Example: Device(config)# wlan Mywlan1	Creates a WLAN for the client.
Step 2	mobility anchor <i>guest-anchor-ip-addr</i> Example: Device(config-wlan)# mobility anchor 10.10.10.2	Enables the guest anchors (GA) IP address on the MA. Note To enable guest anchor on the mobility controller, you need not enter the IP address. Enter the mobility anchor command in the WLAN configuration mode to enable GA on the mobility controller.
Step 3	client vlan <i>vlan-name</i> Example: Device(config-wlan)# client vlan gc_ga_vlan1	Assigns a VLAN to the client's WLAN.
Step 4	security open Example: Device(config-wlan)# security open	Assigns a security type to the WLAN.

Example

```
Device(config)# wlan Mywlan1
Device(config-wlan)# mobility anchor 10.10.10.2
Device(config-wlan)# client vlan gc_ga_vlan1
Device(config-wlan)# security open
```

Configuring Guest Anchor

SUMMARY STEPS

1. `wlan Mywlan1`
2. `mobility anchor <guest-anchors-own-ip-address>`
3. `client vlan<vlan-name>`
4. `security open`

DETAILED STEPS

	Command or Action	Purpose
Step 1	wlan Mywlan1 Example: Device(config)# wlan Mywlan1	Creates a wlan for the client.
Step 2	mobility anchor <guest-anchors-own-ip-address> Example: Device(config-wlan)# mobility anchor 10.10.10.2	Enables the guest anchors IP address on the guest anchor (GA). The GA assigns its own address on itself.
Step 3	client vlan<vlan-name> Example: Device(config-wlan)# client vlan gc_ga_vlan1	Assigns a vlan to the clients wlan.
Step 4	security open Example: Device(config-wlan)# security open	Assigns a security type to the wlan.

Example

```
Device(config)# wlan Mywlan1
Device(config-wlan)# mobility anchor 10.10.10.2
Device(config-wlan)# client vlan gc_ga_vlan1
Device(config-wlan)# security open
```

Configuring Mobility Agent

Configuring Mobility Agent by Pointing to Mobility Controller (CLI)

Before you begin

- By default, the switches are configured as mobility agents.
- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.
- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

SUMMARY STEPS

1. configure terminal

2. wireless management interface v`lan 21`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless management interface v<code>lan 21</code> Example: Device (config)# <code>wireless management interface v<code>lan 21</code></code>	Enables the wireless functionality on the device and activates the mobility agent function. This ensures the APs have a place to terminate the CAPWAP tunnel.

Example

This example shows how to add a mobility agent into the mobility group by pointing it to a mobility controller:

```
Device(config)# wireless management interface vlan 21
```

Configuring Mobility Agent by Pointing to Mobility Controller (GUI)

Before you begin

- By default, the switches are configured as mobility agents.
- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.
- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

Step 1 Choose **Configuration > Controller > Mobility Management > Mobility Global Config**

The **Mobility Controller Configuration** page is displayed.

Step 2 From the **Mobility Role** drop-down list, choose **Mobility Agent**.

Step 3 In the **Mobility Controller IP Address**, enter the IP address of the mobility controller.

Step 4 Click **Apply**.

Step 5 Click **Save Configuration**.

Step 6 Reboot the device.

Configuring the Mobility Controller for the Mobility Agent (CLI)

SUMMARY STEPS

1. wireless mobility controller
2. wireless mobility controller ip *ip-addr*

DETAILED STEPS

	Command or Action	Purpose
Step 1	wireless mobility controller Example: Device (config)# wireless mobility controller Mobility role changed to Mobility Controller. Please save config and reboot the whole stack.	Enables the mobility function on the device. Note After you enter this command, save the configuration and reboot the device for the mobility controller function to take effect.
Step 2	wireless mobility controller ip <i>ip-addr</i> Example: Device (config)# wireless mobility controller ip 10.10.21.3	Specifies the mobility controller to which the mobility agent relates. Note If a mobility agent is configured and the mobility controller exists on a different device, configure the SPG on the mobility controller to ensure the mobility agent functions properly.

What to do next

After you add a mobility controller role to the mobility agent, you can configure optional parameters on the mobility agent.

Adding a Mobility Controller Role to the Mobility Agent

SUMMARY STEPS

1. wireless mobility controller ip 10.10.21.3

DETAILED STEPS

	Command or Action	Purpose
Step 1	wireless mobility controller ip 10.10.21.3 Example: Device(config)# wireless mobility controller ip 10.10.21.3	Converts the mobility agent to a mobility controller.

Example

This example shows how to add the mobility controller role to a mobility agent:

```
Device(config)# wireless mobility controller ip 10.10.21.3
Mobility role changed to Mobility Controller.
Please save config and reboot the whole stack.
```

Configuring Optional Parameters on a Mobility Agent (CLI)

This section shows how to configure load-balancing on a device.

- By default, the load-balancing is enabled and it cannot be disabled.
- The device supports a maximum of 2000 clients and the default threshold value is fifty percent of client max load.
- When the device reaches its threshold, it redistributes the new clients load to other mobility agents in the same SPG, if their client load is lower.

SUMMARY STEPS

1. **wireless mobility load-balance threshold** *threshold-value*

DETAILED STEPS

	Command or Action	Purpose
Step 1	wireless mobility load-balance threshold <i>threshold-value</i> Example: Device(config)# wireless mobility load-balance threshold 150	Configures the threshold that triggers load-balancing.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.
- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured device.
- All devices configured with the **cns config partial** global configuration command must access the event bus. The DeviceID, as originated on the device, must match the DeviceID of the corresponding device definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

Related Topics

- [Cisco Networking Services IDs and Device Hostnames, on page 614](#)
- [DeviceID, on page 614](#)

Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured devices can share the same value for ConfigID.
- Within the scope of a single instance of the event bus, no two configured devices can share the same value for DeviceID.

[Cisco Networking Services IDs and Device Hostnames](#), on page 614

Information About Configuring the Configuration Engine

Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (devices and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
 - Web server
 - File manager
 - Namespace mapping server
- Event service (event gateway)
- Data service directory (data models and schema)

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.

Figure 45: Cisco Configuration Engine Architectural Overview

Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the device. The Configuration Service delivers device and service configurations to the device for initial configuration and mass reconfiguration by logical groups. Devices receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the device and facilitates the communication between the device and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.

Related Topics

[Enabling the CNS Event Agent](#), on page 618

NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, `cisco.cns.config.load`. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured device. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term *ConfigID* is the unique identifier for a device. Within the scope of the event bus namespace, the term *DeviceID* is the CNS unique identifier for a device.

Related Topics

[Prerequisites for Configuring the Configuration Engine](#), on page 611

[Restrictions for Configuring the Configuration Engine](#), on page 612

ConfigID

Each configured device has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of device CLI attributes. The ConfigID defined on the device must match the ConfigID for the corresponding device definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the device hostname is reconfigured.

DeviceID

Each configured device participating on the event bus has a unique DeviceID, which is analogous to the device source address so that the device can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the device. However, the DeviceID variable and its usage reside within the event gateway adjacent to the device.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the device. The event gateway represents the device and its corresponding DeviceID to the event bus.

The device declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the device.

Related Topics

[Prerequisites for Configuring the Configuration Engine](#), on page 611

Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the device hostname is reconfigured.

When changing the device hostname on the device, the only way to refresh the DeviceID is to break the connection between the device and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the device sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

Caution

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the device acquires *after*, not *before*, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

Related Topics

[Refreshing DeviceIDs](#), on page 626

Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a device, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the `cn=<value>` of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the device.

These and other associated attributes (tag value pairs) are set when you run **Setup** on the Cisco Configuration Engine.

Cisco IOS CNS Agents

The CNS event agent feature allows the device to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the device Cisco IOS software, allow the device to be connected and automatically configured.

Related Topics

[Enabling the Cisco IOS CNS Agent](#), on page 619

Initial Configuration

When the device first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution

device acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new device and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the device.

The device automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the device loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the device.

The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

Figure 46: Initial Configuration

Related Topics

[Enabling an Initial Configuration for Cisco IOS CNS Agent](#), on page 621

[Monitoring CNS Configurations](#), on page 629

Incremental (Partial) Configuration

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the device. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the device to initiate a pull operation.

The device can check the syntax of the configuration before applying it. If the syntax is correct, the device applies the incremental configuration and publishes an event that signals success to the configuration server. If the device does not apply the incremental configuration, it publishes an event showing an error status. When the device has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

Related Topics

[Enabling a Partial Configuration for Cisco IOS CNS Agent](#), on page 628

[Monitoring CNS Configurations](#), on page 629

Synchronized Configuration

When the device receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the device not to save the updated configuration into its NVRAM. The device uses the updated configuration as its running configuration. This ensures that the device configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

Automated CNS Configuration

To enable automated CNS configuration of the device, you must first complete the prerequisites listed in this topic. When you complete them, power on the device. At the **setup** prompt, do nothing; the device begins the initial configuration. When the full configuration file is loaded on your device, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

Table 48: Prerequisites for Enabling Automatic Configuration

Device	Required Configuration
Access device	Factory default (no configuration file)
Distribution device	<ul style="list-style-type: none"> • IP helper address • Enable DHCP relay agent³ • IP routing (if used as default gateway)
DHCP server	<ul style="list-style-type: none"> • IP address assignment • TFTP server IP address • Path to bootstrap configuration file on the TFTP server • Default gateway IP address
TFTP server	<ul style="list-style-type: none"> • A bootstrap configuration file that includes the CNS configuration commands that enable the device to communicate with the Configuration Engine • The device configured to use either the device MAC address or the serial number (instead of the default hostname) to generate the ConfigID and EventID • The CNS event agent configured to push the configuration file to the device
CNS Configuration Engine	One or more templates for each type of device, with the ConfigID of the device mapped to the template.

³ A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.

How to Configure the Configuration Engine

Enabling the CNS Event Agent

Note You must enable the CNS event agent on the device before you enable the CNS configuration agent.

Follow these steps to enable the CNS event agent on the device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cns event** *{hostname | ip-address}* [*port-number*] [[**keepalive seconds** *retry-count*] [**failover-time seconds**]] [**reconnect-time time**] | **backup**]
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	cns event <i>{hostname ip-address}</i> [<i>port-number</i>] [[keepalive seconds <i>retry-count</i>] [failover-time seconds]] [reconnect-time time] backup] Example: Device(config)# cns event 10.180.1.27 keepalive 120 10	Enables the event agent, and enters the gateway parameters. <ul style="list-style-type: none"> • For <i>{hostname ip-address}</i>, enter either the hostname or the IP address of the event gateway. • (Optional) For <i>port number</i>, enter the port number for the event gateway. The default port number is 11011. • (Optional) For keepalive seconds, enter how often the device sends keepalive messages. For <i>retry-count</i>, enter the number of unanswered keepalive messages that the device sends before the connection is terminated. The default for each is 0.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • (Optional) For failover-time <i>seconds</i>, enter how long the device waits for the primary gateway route after the route to the backup gateway is established. • (Optional) For reconnect-time <i>time</i>, enter the maximum time interval that the device waits before trying to reconnect to the event gateway. • (Optional) Enter backup to show that this is the backup gateway. (If omitted, this is the primary gateway.) <p>Note Though visible in the command-line help string, the encrypt and the clock-timeout <i>time</i> keywords are not supported.</p>
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show running-config Example: Device# show running-config	Verifies your entries.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

To verify information about the event agent, use the **show cns event connections** command in privileged EXEC mode.

To disable the CNS event agent, use the **no cns event** { *ip-address* | *hostname* } global configuration command.

Related Topics

[Event Service](#), on page 613

Enabling the Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent on the device.

Before you begin

You must enable the CNS event agent on the device before you enable this agent.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cns config initial** *{hostname | ip-address}* [*port-number*]
4. **cns config partial** *{hostname | ip-address}* [*port-number*]
5. **end**
6. **show running-config**
7. **copy running-config startup-config**
8. Start the Cisco IOS CNS agent on the device.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	cns config initial <i>{hostname ip-address}</i> [<i>port-number</i>] Example: <pre>Device(config)# cns config initial 10.180.1.27 10</pre>	Enables the Cisco IOS CNS agent, and enters the configuration server parameters. <ul style="list-style-type: none"> • For <i>{hostname ip-address}</i>, enter either the hostname or the IP address of the configuration server. • (Optional) For <i>port number</i>, enter the port number for the configuration server. This command enables the Cisco IOS CNS agent and initiates an initial configuration on the device.
Step 4	cns config partial <i>{hostname ip-address}</i> [<i>port-number</i>] Example: <pre>Device(config)# cns config partial 10.180.1.27 10</pre>	Enables the Cisco IOS CNS agent, and enters the configuration server parameters. <ul style="list-style-type: none"> • For <i>{hostname ip-address}</i>, enter either the hostname or the IP address of the configuration server. • (Optional) For <i>port number</i>, enter the port number for the configuration server.

	Command or Action	Purpose
		Enables the Cisco IOS CNS agent and initiates a partial configuration on the device.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# show running-config	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.
Step 8	Start the Cisco IOS CNS agent on the device.	

What to do next

You can now use the Cisco Configuration Engine to remotely send incremental configurations to the device.

Related Topics

[Cisco IOS CNS Agents](#), on page 615

Enabling an Initial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the CNS configuration agent and initiate an initial configuration on the device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cns template connect** *name*
4. **cli** *config-text*
5. Repeat Steps 3 to 4 to configure another CNS connect template.
6. **exit**
7. **cns connect** *name* [**retries** *number*] [**retry-interval** *seconds*] [**sleep** *seconds*] [**timeout** *seconds*]
8. **discover** {**controller** *controller-type* | **dlci** [**subinterface** *subinterface-number*] | **interface** [*interface-type*] | **line** *line-type*}
9. **template** *name* [... *name*]
10. Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile.

11. **exit**
12. **hostname** *name*
13. **ip route** *network-number*
14. **cns id** *interface num* {**dns-reverse** | **ipaddress** | **mac-address**} [**event**] [**image**]
15. **cns id** {**hardware-serial** | **hostname** | **string string** | **udi**} [**event**] [**image**]
16. **cns config initial** {*hostname* | *ip-address*} [*port-number*] [**event**] [**no-persist**] [**page page**] [**source ip-address**] [**syntax-check**]
17. **end**
18. **show running-config**
19. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	cns template connect <i>name</i> Example: Device (config)# cns template connect template-dhcp	Enters CNS template connect configuration mode, and specifies the name of the CNS connect template.
Step 4	cli <i>config-text</i> Example: Device (config-tmpl-conn)# cli ip address dhcp	Enters a command line for the CNS connect template. Repeat this step for each command line in the template.
Step 5	Repeat Steps 3 to 4 to configure another CNS connect template.	
Step 6	exit Example: Device (config)# exit	Returns to global configuration mode.
Step 7	cns connect <i>name</i> [retries number] [retry-interval seconds] [sleep seconds] [timeout seconds] Example:	Enters CNS connect configuration mode, specifies the name of the CNS connect profile, and defines the profile parameters. The device uses the CNS connect profile to connect to the Configuration Engine.

	Command or Action	Purpose
	<pre>Device(config)# cns connect dhcp</pre>	<ul style="list-style-type: none"> • Enter the <i>name</i> of the CNS connect profile. • (Optional) For retries number, enter the number of connection retries. The range is 1 to 30. The default is 3. • (Optional) For retry-interval seconds, enter the interval between successive connection attempts to the Configuration Engine. The range is 1 to 40 seconds. The default is 10 seconds. • (Optional) For sleep seconds, enter the amount of time before which the first connection attempt occurs. The range is 0 to 250 seconds. The default is 0. • (Optional) For timeout seconds, enter the amount of time after which the connection attempts end. The range is 10 to 2000 seconds. The default is 120.
Step 8	<p>discover {controller <i>controller-type</i> dlci [subinterface <i>subinterface-number</i>] interface [<i>interface-type</i>] line <i>line-type</i>}</p> <p>Example:</p> <pre>Device(config-cns-conn)# discover interface gigabitethernet</pre>	<p>Specifies the interface parameters in the CNS connect profile.</p> <ul style="list-style-type: none"> • For controller <i>controller-type</i>, enter the controller type. • For dlci, enter the active data-link connection identifiers (DLCIs). <p>(Optional) For subinterface <i>subinterface-number</i>, specify the point-to-point subinterface number that is used to search for active DLCIs.</p> <ul style="list-style-type: none"> • For interface [<i>interface-type</i>], enter the type of interface. • For line <i>line-type</i>, enter the line type.
Step 9	<p>template <i>name</i> [... <i>name</i>]</p> <p>Example:</p> <pre>Device(config-cns-conn)# template template-dhcp</pre>	<p>Specifies the list of CNS connect templates in the CNS connect profile to be applied to the device configuration. You can specify more than one template.</p>
Step 10	Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile.	
Step 11	<p>exit</p> <p>Example:</p> <pre>Device(config-cns-conn)# exit</pre>	Returns to global configuration mode.
Step 12	<p>hostname <i>name</i></p> <p>Example:</p>	Enters the hostname for the device.

	Command or Action	Purpose
	Device(config)# hostname device1	
Step 13	ip route network-number Example: RemoteDevice(config)# ip route 172.28.129.22 255.255.255.255 11.11.11.1	(Optional) Establishes a static route to the Configuration Engine whose IP address is <i>network-number</i> .
Step 14	cns id interface num {dns-reverse ipaddress mac-address} [event] [image] Example: RemoteDevice(config)# cns id GigabitEthernet1/0/1 ipaddress	(Optional) Sets the unique EventID or ConfigID used by the Configuration Engine. If you enter this command, do not enter the cns id {hardware-serial hostname string string udi} [event] [image] command. <ul style="list-style-type: none"> • For <i>interface num</i>, enter the type of interface. For example, ethernet, group-async, loopback, or virtual-template. This setting specifies from which interface the IP or MAC address should be retrieved to define the unique ID. • For {dns-reverse ipaddress mac-address}, enter dns-reverse to retrieve the hostname and assign it as the unique ID, enter ipaddress to use the IP address, or enter mac-address to use the MAC address as the unique ID. • (Optional) Enter event to set the ID to be the event-id value used to identify the device. • (Optional) Enter image to set the ID to be the image-id value used to identify the device. <p>Note If both the event and image keywords are omitted, the image-id value is used to identify the device.</p>
Step 15	cns id {hardware-serial hostname string string udi} [event] [image] Example: RemoteDevice(config)# cns id hostname	(Optional) Sets the unique EventID or ConfigID used by the Configuration Engine. If you enter this command, do not enter the cns id interface num {dns-reverse ipaddress mac-address} [event] [image] command. <ul style="list-style-type: none"> • For { hardware-serial hostname string string udi }, enter hardware-serial to set the device serial number as the unique ID, enter hostname (the default) to select the device hostname as the unique ID, enter an arbitrary text string for string string as the unique ID, or enter udi to set the unique device identifier (UDI) as the unique ID.
Step 16	cns config initial {hostname ip-address} [port-number] [event] [no-persist] [page page] [source ip-address] [syntax-check]	Enables the Cisco IOS agent, and initiates an initial configuration.

	Command or Action	Purpose
	<p>Example:</p> <pre>RemoteDevice(config)# cns config initial 10.1.1.1 no-persist</pre>	<ul style="list-style-type: none"> • For <i>{hostname ip-address}</i>, enter the hostname or the IP address of the configuration server. • (Optional) For <i>port-number</i>, enter the port number of the configuration server. The default port number is 80. • (Optional) Enable event for configuration success, failure, or warning messages when the configuration is finished. • (Optional) Enable no-persist to suppress the automatic writing to NVRAM of the configuration pulled as a result of entering the cns config initial global configuration command. If the no-persist keyword is not entered, using the cns config initial command causes the resultant configuration to be automatically written to NVRAM. • (Optional) For page page, enter the web page of the initial configuration. The default is <i>/Config/config/asp</i>. • (Optional) Enter source ip-address to use for source IP address. • (Optional) Enable syntax-check to check the syntax when this parameter is entered. <p>Note Though visible in the command-line help string, the encrypt, status url, and inventory keywords are not supported.</p>
Step 17	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.
Step 18	<p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre>	Verifies your entries.
Step 19	<p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

What to do next

To verify information about the configuration agent, use the **show cns config connections** command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the **no cns config initial** { *ip-address* | *hostname* } global configuration command.

Refreshing DeviceIDs

Follow these steps to refresh a DeviceID when changing the hostname on the device.

SUMMARY STEPS

1. **enable**
2. **show cns config connections**
3. Make sure that the CNS event agent is properly connected to the event gateway.
4. **show cns event connections**
5. Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.
6. **configure terminal**
7. **no cns event** *ip-address port-number*
8. **cns event** *ip-address port-number*
9. **end**
10. Make sure that you have reestablished the connection between the device and the event connection by examining the output from **show cns event connections**.
11. **show running-config**
12. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	show cns config connections Example: Device# show cns config connections	Displays whether the CNS event agent is connecting to the gateway, connected, or active, and the gateway used by the event agent, its IP address and port number.
Step 3	Make sure that the CNS event agent is properly connected to the event gateway.	Examine the output of show cns config connections for the following:

	Command or Action	Purpose
		<ul style="list-style-type: none"> • Connection is active. • Connection is using the currently configured device hostname. The DeviceID will be refreshed to correspond to the new hostname configuration using these instructions.
Step 4	show cns event connections Example: Device# <code>show cns event connections</code>	Displays the event connection information for your device.
Step 5	Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.	
Step 6	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 7	no cns event ip-address port-number Example: Device(config)# <code>no cns event 172.28.129.22 2012</code>	Specifies the IP address and port number that you recorded in Step 5 in this command. This command breaks the connection between the device and the event gateway. It is necessary to first break, then reestablish, this connection to refresh the DeviceID.
Step 8	cns event ip-address port-number Example: Device(config)# <code>cns event 172.28.129.22 2012</code>	Specifies the IP address and port number that you recorded in Step 5 in this command. This command reestablishes the connection between the device and the event gateway.
Step 9	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 10	Make sure that you have reestablished the connection between the device and the event connection by examining the output from show cns event connections .	
Step 11	show running-config Example: Device# <code>show running-config</code>	Verifies your entries.

	Command or Action	Purpose
Step 12	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Enabling a Partial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent and to initiate a partial configuration on the device.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `cns config partial {ip-address | hostname} [port-number] [source ip-address]`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	cns config partial {ip-address hostname} [port-number] [source ip-address] Example: Device(config)# <code>cns config partial 172.28.129.22 2013</code>	Enables the configuration agent, and initiates a partial configuration. <ul style="list-style-type: none"> • For <code>{ip-address hostname}</code>, enter the IP address or the hostname of the configuration server. • (Optional) For <code>port-number</code>, enter the port number of the configuration server. The default port number is 80.

	Command or Action	Purpose
		<ul style="list-style-type: none"> (Optional) Enter source <i>ip-address</i> to use for the source IP address. <p>Note Though visible in the command-line help string, the encrypt keyword is not supported.</p>
Step 4	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.
Step 5	show running-config Example: <pre>Device# show running-config</pre>	Verifies your entries.
Step 6	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

What to do next

To verify information about the configuration agent, use either the **show cns config stats** or the **show cns config outstanding** command in privileged EXEC mode.

To disable the Cisco IOS agent, use the **no cns config partial** { *ip-address* | *hostname* } global configuration command. To cancel a partial configuration, use the **cns config cancel** global configuration command.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About CDP

CDP Overview

CDP is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With CDP, network management applications can learn the device type and the Simple Network Management Protocol (SNMP) agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

CDP runs on all media that support Subnetwork Access Protocol (SNAP). Because CDP runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each CDP-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information,

which is the length of time a receiving device holds CDP information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.

On the device, CDP enables Network Assistant to display a graphical view of the network. The device uses CDP to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command device by default.

Related Topics

[Configuring CDP Characteristics](#), on page 634

[Monitoring and Maintaining CDP](#), on page 642

CDP and Stacks

A device stack appears as a single device in the network. Therefore, CDP discovers the device stack, not the individual stack members. The device stack sends CDP messages to neighboring network devices when there are changes to the device stack membership, such as stack members being added or removed.

Default CDP Configuration

This table shows the default CDP configuration.

Feature	Default Setting
CDP global state	Enabled
CDP interface state	Enabled
CDP timer (packet update frequency)	60 seconds
CDP holdtime (before discarding)	180 seconds
CDP Version-2 advertisements	Enabled

Related Topics

[Enabling CDP](#), on page 637

How to Configure CDP

Configuring CDP Characteristics

You can configure these CDP characteristics:

- Frequency of CDP updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version-2 advertisements

Note Steps 3 through 5 are all optional and can be performed in any order.

Follow these steps to configure the CDP characteristics.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cdp timer** *seconds*
4. **cdp holdtime** *seconds*
5. **cdp advertise-v2**
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	cdp timer <i>seconds</i> Example: Device(config)# cdp timer 20	(Optional) Sets the transmission frequency of CDP updates in seconds. The range is 5 to 254; the default is 60 seconds.
Step 4	cdp holdtime <i>seconds</i> Example: Device(config)# cdp holdtime 60	(Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it. The range is 10 to 255 seconds; the default is 180 seconds.
Step 5	cdp advertise-v2 Example: Device(config)# cdp advertise-v2	(Optional) Configures CDP to send Version-2 advertisements. This is the default state.

	Command or Action	Purpose
Step 6	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 7	show running-config Example: Device# show running-config	Verifies your entries.
Step 8	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

Use the **no** form of the CDP commands to return to the default settings.

Related Topics

[Monitoring and Maintaining CDP](#), on page 642

Disabling CDP

CDP is enabled by default.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to disable the CDP device discovery capability.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no cdp run**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	no cdp run Example: Device(config)# no cdp run	Disables CDP.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show running-config Example: Device# show running-config	Verifies your entries.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

You must reenabling CDP to use it.

Related Topics

[Default CDP Configuration](#), on page 634

Enabling CDP

CDP is enabled by default.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to enable CDP when it has been disabled.

Before you begin

CDP must be disabled, or it cannot be enabled.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cdp run**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	cdp run Example: Device(config)# cdp run	Enables CDP if it has been disabled.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show running-config Example:	Verifies your entries.

	Command or Action	Purpose
	Device# <code>show running-config</code>	
Step 6	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

What to do next

Use the `show run all` command to show that CDP has been enabled. If you enter only `show run`, the enabling of CDP may not be displayed.

Related Topics

[Default CDP Configuration](#), on page 634

[Disabling CDP](#), on page 636

Disabling CDP on an Interface

CDP is enabled by default on all supported interfaces to send and to receive CDP information.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to disable CDP on a port.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `no cdp enable`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet1/0/1</code>	Specifies the interface on which you are disabling CDP, and enters interface configuration mode.
Step 4	no cdp enable Example: Device(config-if)# <code>no cdp enable</code>	Disables CDP on the interface specified in Step 3.
Step 5	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# <code>show running-config</code>	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Related Topics

[Default CDP Configuration](#), on page 634

Enabling CDP on an Interface

CDP is enabled by default on all supported interfaces to send and to receive CDP information.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to enable CDP on a port on which it has been disabled.

Before you begin

CDP must be disabled on the port that you are trying to CDP enable on, or it cannot be enabled.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **cdp enable**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1	Specifies the interface on which you are enabling CDP, and enters interface configuration mode.
Step 4	cdp enable Example: Device(config-if)# cdp enable	Enables CDP on a disabled interface.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# show running-config	Verifies your entries.

	Command or Action	Purpose
Step 7	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Monitoring and Maintaining CDP

Table 50: Commands for Displaying CDP Information

Command	Description
<code>clear cdp counters</code>	Resets the traffic counters to zero.
<code>clear cdp table</code>	Deletes the CDP table of information about neighbors.
<code>show cdp</code>	Displays global information, such as frequency of transmissions and the holdtime for packets being sent.
<code>show cdp entry <i>entry-name</i> [<i>version</i>] [<i>protocol</i>]</code>	<p>Displays information about a specific neighbor.</p> <p>You can enter an asterisk (*) to display all CDP neighbors, or you can enter the name of the neighbor about which you want information.</p> <p>You can also limit the display to information about the protocols enabled on the specified neighbor or information about the version of software running on the device.</p>
<code>show cdp interface [<i>interface-id</i>]</code>	<p>Displays information about interfaces where CDP is enabled.</p> <p>You can limit the display to the interface about which you want information.</p>
<code>show cdp neighbors [<i>interface-id</i>] [<i>detail</i>]</code>	<p>Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, platform, and port ID.</p> <p>You can limit the display to neighbors of a specific interface or expand the display to provide more detailed information.</p>
<code>show cdp traffic</code>	Displays CDP counters, including the number of packets sent and received and checksum errors.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for SNMP

Supported SNMP Versions

This software release supports the following SNMP versions:

- SNMPv1—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- SNMPv2C replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:

- SNMPv2—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.
- SNMPv2C—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- SNMPv3—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
 - Message integrity—Ensures that a packet was not tampered with in transit.
 - Authentication—Determines that the message is from a valid source.
 - Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

Note To select encryption, enter the **priv** keyword.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent's MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

Table 51: SNMP Security Models and Levels

Model	Level	Authentication	Encryption	Result
SNMPv1	noAuthNoPriv	Community string	No	Uses a community string match for authentication.
SNMPv2C	noAuthNoPriv	Community string	No	Uses a community string match for authentication.
SNMPv3	noAuthNoPriv	Username	No	Uses a username match for authentication.

Model	Level	Authentication	Encryption	Result
SNMPv3	authNoPriv	Message Digest 5 (MD5) or Secure Hash Algorithm (SHA)	No	Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.
SNMPv3	authPriv	MD5 or SHA	Data Encryption Standard (DES) or Advanced Encryption Standard (AES)	<p>Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.</p> <p>Allows specifying the User-based Security Model (USM) with these encryption algorithms:</p> <ul style="list-style-type: none"> • DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard. • 3DES 168-bit encryption • AES 128-bit, 192-bit, or 256-bit encryption

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.

Restrictions for SNMP

Version Restrictions

- SNMPv1 does not support informs.

Information About SNMP

SNMP Overview

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime Infrastructure. The agent and MIB reside on the device. To configure SNMP on the device, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager's requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

Table 52: SNMP Operations

Operation	Description
get-request	Retrieves a value from a specific variable.
get-next-request	Retrieves a value from a variable within a table. ⁴
get-bulk-request ⁵	Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data.
get-response	Replies to a get-request, get-next-request, and set-request sent by an NMS.
set-request	Stores a value in a specific variable.
trap	An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.

⁴ With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

⁵ The get-bulk command only works with SNMPv2 or later.

SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- Get a MIB variable—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.

- Set a MIB variable—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

Related Topics

SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the device, the community string definitions on the NMS must match at least one of the three community string definitions on the device.

A community string can have one of the following attributes:

- Read-only (RO)—Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.
- Read-write (RW)—Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.
- When a cluster is created, the command device manages the exchange of messages among member devices and the SNMP application. The Network Assistant software appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device and propagates them to the member devices.

Related Topics

[Configuring Community Strings](#), on page 653

SNMP MIB Variables Access

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure 2.0 software uses the device MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in *get-request*, *get-next-request*, and *set-request* format.

Figure 47: SNMP Network

SNMP Notifications

SNMP allows the device to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps or informs, or both. Use the **snmp-server host** command to specify whether to send SNMP notifications as traps or informs.

Note SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the device and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the device is a concern and notification is not required, use traps.

SNMP ifIndex MIB Object Values

The SNMP agent's IF-MIB module comes up shortly after reboot. As various physical interface drivers are initialized they register with the IF-MIB module, essentially saying "Give me an ifIndex number". The IF-MIB module assigns the next available ifIndex number on a first-come-first-served basis. That is, minor differences in driver initialization order from one reboot to another can result in the same physical interface getting a different ifIndex number than it had before the reboot (unless ifIndex persistency is enabled of course).

Default SNMP Configuration

Feature	Default Setting
SNMP agent	Disabled ⁶ .
SNMP trap receiver	None configured.
SNMP traps	None enabled except the trap for TCP connections (tty).
SNMP version	If no version keyword is present, the default is Version 1.
SNMPv3 authentication	If no keyword is entered, the default is the noauth (noAuthNoPriv) security level.
SNMP notification type	If no type is specified, all notifications are sent.

- ⁶ This is the default when the device starts and the startup configuration does not have any **snmp-server** global configuration commands.

SNMP Configuration Guidelines

If the device starts and the device startup configuration has at least one **snmp-server** global configuration command, the SNMP agent is enabled.

An SNMP *group* is a table that maps SNMP users to SNMP views. An SNMP *user* is a member of an SNMP group. An SNMP *host* is the recipient of an SNMP trap operation. An SNMP *engine ID* is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The **snmp-server host** global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.
- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the **snmp-server engineID** global configuration command with the **remote** option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.
- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.
- If a local user is not associated with a remote host, the device does not send informs for the **auth** (authNoPriv) and the **priv** (authPriv) authentication levels.
- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the **snmp-server user username** global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

How to Configure SNMP

Disabling the SNMP Agent

The **no snmp-server** global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenables all versions of the SNMP agent by the first

snmp-server global configuration command that you enter. There is no Cisco IOS command specifically designated for enabling SNMP.

Follow these steps to disable the SNMP agent.

Before you begin

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first **snmp-server** global configuration command entered on the device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no snmp-server**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	no snmp-server Example: Device(config)# no snmp-server	Disables the SNMP agent operation.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show running-config Example: Device# show running-config	Verifies your entries.

	Command or Action	Purpose
Step 6	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the device. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

Follow these steps to configure a community string on the device.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `snmp-server community string [view view-name] [ro | rw] [access-list-number]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example:	Enters the global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 3	<p><code>snmp-server community string [view view-name] [ro rw] [access-list-number]</code></p> <p>Example:</p> <pre>Device(config)# snmp-server community comaccess ro 4</pre>	<p>Configures the community string.</p> <p>Note The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <ul style="list-style-type: none"> • For <i>string</i>, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings of any length. • (Optional) For view, specify the view record accessible to the community. • (Optional) Specify either read-only (ro) if you want authorized management stations to retrieve MIB objects, or specify read-write (rw) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects. • (Optional) For <i>access-list-number</i>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.
Step 4	<p><code>access-list access-list-number {deny permit} source [source-wildcard]</code></p> <p>Example:</p> <pre>Device(config)# access-list 4 deny any</pre>	<p>(Optional) If you specified an IP standard access list number in Step 3, then create the list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number specified in Step 3. • The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. • For <i>source</i>, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p>
Step 5	<p><code>end</code></p> <p>Example:</p>	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config)# end	
Step 6	show running-config Example: Device# show running-config	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the **no snmp-server** community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Related Topics

[SNMP Community Strings](#), on page 649

Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Follow these steps to configure SNMP groups and users on the device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server engineID** { **local** *engineid-string* | **remote** *ip-address* [**udp-port** *port-number*] *engineid-string* }
4. **snmp-server group** *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*]
5. **snmp-server user** *username* *group-name* { **remote** *host* [**udp-port** *port*] } { **v1** [**access** *access-list*] | **v2c** [**access** *access-list*] | **v3** [**encrypted**] [**access** *access-list*] [**auth** { **md5** | **sha** } *auth-password*] } [**priv** { **des** | **3des** | **aes** { **128** | **192** | **256** } } *priv-password*]

6. `end`
7. `show running-config`
8. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	<p><code>snmp-server engineID {local <i>engineid-string</i> remote <i>ip-address</i> [<i>udp-port port-number</i>] <i>engineid-string</i>}</code></p> <p>Example:</p> <pre>Device(config)# snmp-server engineID local 1234</pre>	<p>Configures a name for either the local or remote copy of SNMP.</p> <ul style="list-style-type: none"> The <i>engineid-string</i> is a 24-character ID string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. The Step Example configures an engine ID of 123400000000000000000000. If you select remote, specify the <i>ip-address</i> of the device that contains the remote copy of SNMP and the optional User Datagram Protocol (UDP) port on the remote device. The default is 162.
Step 4	<p><code>snmp-server group <i>group-name</i> {v1 v2c v3 {auth noauth priv}} [<i>read readview</i>] [<i>write writeview</i>] [<i>notify notifyview</i>] [<i>access access-list</i>]</code></p> <p>Example:</p> <pre>Device(config)# snmp-server group public v2c access 1mnop</pre>	<p>Configures a new SNMP group on the remote device.</p> <p>For <i>group-name</i>, specify the name of the group.</p> <p>Specify one of the following security models:</p> <ul style="list-style-type: none"> v1 is the least secure of the possible security models. v2c is the second least secure model. It allows transmission of informs and integers twice the normal width. v3, the most secure, requires you to select one of the following authentication levels: <ul style="list-style-type: none"> auth—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.

	Command or Action	Purpose
		<p>noauth—Enables the noAuthNoPriv security level. This is the default if no keyword is specified.</p> <p>priv—Enables Data Encryption Standard (DES) packet encryption (also called privacy).</p> <p>(Optional) Enter read <i>readview</i> with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.</p> <p>(Optional) Enter write <i>writeview</i> with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.</p> <p>(Optional) Enter notify <i>notifyview</i> with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.</p> <p>(Optional) Enter access <i>access-list</i> with a string (not to exceed 64 characters) that is the name of the access list.</p>
<p>Step 5</p>	<p>snmp-server user <i>username group-name</i> { remote <i>host</i> [udp-port <i>port</i>] } { v1 [access <i>access-list</i>] v2c [access <i>access-list</i>] v3 [encrypted] [access <i>access-list</i>] [auth { md5 sha } <i>auth-password</i>] } [priv { des 3des aes { 128 192 256 } } <i>priv-password</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server user Pat public v2c</pre>	<p>Adds a new user for an SNMP group.</p> <p>The <i>username</i> is the name of the user on the host that connects to the agent.</p> <p>The <i>group-name</i> is the name of the group to which the user is associated.</p> <p>Enter remote to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.</p> <p>Enter the SNMP version number (v1, v2c, or v3). If you enter v3, you have these additional options:</p> <ul style="list-style-type: none"> • encrypted specifies that the password appears in encrypted format. This keyword is available only when the v3 keyword is specified. • auth is an authentication level setting session that can be either the HMAC-MD5-96 (md5) or the HMAC-SHA-96 (sha) authentication level and requires a password string <i>auth-password</i> (not to exceed 64 characters). <p>If you enter v3 you can also configure a private (priv) encryption algorithm and password string <i>priv-password</i> using the following keywords (not to exceed 64 characters):</p> <ul style="list-style-type: none"> • priv specifies the User-based Security Model (USM). • des specifies the use of the 56-bit DES algorithm. • 3des specifies the use of the 168-bit DES algorithm.

	Command or Action	Purpose
		<ul style="list-style-type: none"> aes specifies the use of the DES algorithm. You must select either 128-bit, 192-bit, or 256-bit encryption. (Optional) Enter access <i>access-list</i> with a string (not to exceed 64 characters) that is the name of the access list.
Step 6	end Example: Device(config) # end	Returns to privileged EXEC mode.
Step 7	show running-config Example: Device# show running-config	Verifies your entries.
Step 8	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the device generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Devices running this Cisco IOS release can have an unlimited number of trap managers.

Note Many commands use the word **traps** in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword **traps** refers to traps, informs, or both. Use the **snmp-server host** global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the **snmp-server host** global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

Table 53: Device Notification Types

Notification Type Keyword	Description
bridge	Generates STP bridge MIB traps.

Notification Type Keyword	Description
cluster	Generates a trap when the cluster configuration changes.
config	Generates a trap for SNMP configuration changes.
copy-config	Generates a trap for SNMP copy configuration changes.
cpu threshold	Allow CPU-related traps.
entity	Generates a trap for SNMP entity changes.
envmon	Generates environmental monitor traps. You can enable any or all of these environmental traps: fan, shutdown, status, supply, temperature.
flash	Generates SNMP FLASH notifications. In a device stack, you can optionally enable notification for flash insertion or removal, which would cause a trap to be issued whenever a device in the stack is removed or inserted (physical removal, power cycle, or reload).
fru-ctrl	Generates entity field-replaceable unit (FRU) control traps. In the device stack, this trap refers to the insertion or removal of a device in the stack.
hsrp	Generates a trap for Hot Standby Router Protocol (HSRP) changes.
ipmulticast	Generates a trap for IP multicast routing changes.
mac-notification	Generates a trap for MAC address notifications.
ospf	Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes.
pim	Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes.
port-security	<p>Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.</p> <p>Note When you configure a trap by using the notification type port-security, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> snmp-server enable traps port-security snmp-server enable traps port-security trap-rate <i>rate</i>
snmp	Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down.
storm-control	Generates a trap for SNMP storm-control. You can also set a maximum trap rate per minute. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence).
stpx	Generates SNMP STP Extended MIB traps.

Notification Type Keyword	Description
syslog	Generates SNMP syslog traps.
tty	Generates a trap for TCP connections. This trap is enabled by default.
vlan-membership	Generates a trap for SNMP VLAN membership changes.
vlancreate	Generates SNMP VLAN created traps.
vlandelete	Generates SNMP VLAN deleted traps.
vtp	Generates a trap for VLAN Trunking Protocol (VTP) changes.

Follow these steps to configure the device to send traps or informs to a host.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server engineID remote ip-address engineid-string**
4. **snmp-server user username group-name { remote host [udp-port port] } { v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth { md5 | sha } auth-password] }**
5. **snmp-server group group-name { v1 | v2c | v3 { auth | noauth | priv } } [read readview] [write writeview] [notify notifyview] [access access-list]**
6. **snmp-server host host-addr [informs | traps] [version { 1 | 2c | 3 { auth | noauth | priv } }] community-string [notification-type]**
7. **snmp-server enable traps notification-types**
8. **snmp-server trap-source interface-id**
9. **snmp-server queue-length length**
10. **snmp-server trap-timeout seconds**
11. **end**
12. **show running-config**
13. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.

	Command or Action	Purpose
Step 3	<p>snmp-server engineID remote <i>ip-address engineid-string</i></p> <p>Example:</p> <pre>Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b</pre>	Specifies the engine ID for the remote host.
Step 4	<p>snmp-server user <i>username group-name</i> { remote host [udp-port <i>port</i>] } { v1 [access <i>access-list</i>] v2c [access <i>access-list</i>] v3 [encrypted] [access <i>access-list</i>] } [auth { md5 sha } <i>auth-password</i>] }</p> <p>Example:</p> <pre>Device(config)# snmp-server user Pat public v2c</pre>	<p>Configures an SNMP user to be associated with the remote host created in Step 3.</p> <p>Note You cannot configure a remote user for an address without first configuring the engine ID for the remote host. Otherwise, you receive an error message, and the command is not executed.</p>
Step 5	<p>snmp-server group <i>group-name</i> { v1 v2c v3 { auth noauth priv } } [read <i>readview</i>] [write <i>writeview</i>] [notify <i>notifyview</i>] [access <i>access-list</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server group public v2c access lmnop</pre>	Configures an SNMP group.
Step 6	<p>snmp-server host <i>host-addr</i> [informs traps] [version { 1 2c 3 { auth noauth priv } }] <i>community-string</i> [<i>notification-type</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server host 203.0.113.1 comaccess snmp</pre>	<p>Specifies the recipient of an SNMP trap operation.</p> <p>For <i>host-addr</i>, specify the name or Internet address of the host (the targeted recipient).</p> <p>(Optional) Specify traps (the default) to send SNMP traps to the host.</p> <p>(Optional) Specify informs to send SNMP informs to the host.</p> <p>(Optional) Specify the SNMP version (1, 2c, or 3). SNMPv1 does not support informs.</p> <p>(Optional) For Version 3, select authentication level auth, noauth, or priv.</p> <p>Note The priv keyword is available only when the cryptographic software image is installed.</p> <p>For <i>community-string</i>, when version 1 or version 2c is specified, enter the password-like community string sent with the notification operation. When version 3 is specified, enter the SNMPv3 username.</p> <p>The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <p>(Optional) For <i>notification-type</i>, use the keywords listed in the table above. If no type is specified, all notifications are sent.</p>

	Command or Action	Purpose
		<p>Note In case of SNMP version 3, SNMPv3 user should be configured prior SNMPv3 host configuration, otherwise SNMP traps will not be sent.</p>
Step 7	<p>snmp-server enable traps <i>notification-types</i></p> <p>Example:</p> <pre>Device(config)# snmp-server enable traps snmp</pre>	<p>Enables the device to send traps or informs and specifies the type of notifications to be sent. For a list of notification types, see the table above, or enter snmp-server enable traps ?</p> <p>To enable multiple types of traps, you must enter a separate snmp-server enable traps command for each trap type.</p> <p>Note When you configure a trap by using the notification type port-security, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> a. snmp-server enable traps port-security b. snmp-server enable traps port-security trap-rate rate
Step 8	<p>snmp-server trap-source <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# snmp-server trap-source gigabitethernet 1/0/1</pre>	<p>(Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs.</p>
Step 9	<p>snmp-server queue-length <i>length</i></p> <p>Example:</p> <pre>Device(config)# snmp-server queue-length 20</pre>	<p>(Optional) Establishes the message queue length for each trap host. The range is 1 to 5000; the default is 10.</p>
Step 10	<p>snmp-server trap-timeout <i>seconds</i></p> <p>Example:</p> <pre>Device(config)# snmp-server trap-timeout 60</pre>	<p>(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.</p>
Step 11	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode.</p>
Step 12	<p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre>	<p>Verifies your entries.</p>

	Command or Action	Purpose
Step 13	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

What to do next

The **snmp-server host** command specifies which hosts receive the notifications. The **snmp-server enable traps** command globally enables the method for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an **snmp-server host informs** command for the host and globally enable informs by using the **snmp-server enable traps** command.

To remove the specified host from receiving traps, use the **no snmp-server host** *host* global configuration command. The **no snmp-server host** command with no keywords disables traps, but not informs, to the host. To disable informs, use the **no snmp-server host informs** global configuration command. To disable a specific trap type, use the **no snmp-server enable traps** *notification-types* global configuration command.

Setting the Agent Contact and Location Information

Follow these steps to set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server contact** *text*
4. **snmp-server location** *text*
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	snmp-server contact <i>text</i> Example: Device(config)# <code>snmp-server contact Dial System Operator at beeper 21555</code>	Sets the system contact string.
Step 4	snmp-server location <i>text</i> Example: Device(config)# <code>snmp-server location Building 3/Room 222</code>	Sets the system location string.
Step 5	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# <code>show running-config</code>	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Limiting TFTP Servers Used Through SNMP

Follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `snmp-server tftp-server-list access-list-number`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`

7. copy running-config startup-config

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	snmp-server tftp-server-list access-list-number Example: Device(config)# snmp-server tftp-server-list 44	Limits the TFTP servers used for configuration file copies through SNMP to the servers in the access list. For <i>access-list-number</i> , enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.
Step 4	access-list access-list-number {deny permit} source [source-wildcard] Example: Device(config)# access-list 44 permit 10.1.1.2	Creates a standard access list, repeating the command as many times as necessary. For <i>access-list-number</i> , enter the access list number specified in Step 3. The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. For <i>source</i> , enter the IP address of the TFTP servers that can access the device. (Optional) For <i>source-wildcard</i> , enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore. The access list is always terminated by an implicit deny statement for everything.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# show running-config	Verifies your entries.

	Command or Action	Purpose
Step 7	<p><code>copy running-config startup-config</code></p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring Trap Flags for SNMP

SUMMARY STEPS

1. `configure terminal`
2. `trapflags ap { interfaceup | register }`
3. `trapflags client { dot11 | excluded }`
4. `trapflags dot11-security { ids-sig-attack | wep-decrypt-error }`
5. `trapflags mesh`
6. `trapflags rogueap`
7. `trapflags rrm-params { channels | tx-power }`
8. `trapflags rrm-profile { coverage | interference | load | noise }`
9. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 2	<p><code>trapflags ap { interfaceup register }</code></p> <p>Example:</p> <pre>Device(config)# trapflags ap interfaceup</pre>	<p>Enables sending AP-related traps. Use the no form of the command to disable the trap flags.</p> <ul style="list-style-type: none"> • interfaceup– Enables trap when a Cisco AP interface (A or B) comes up. • register– Enables trap when a Cisco AP registers with a Cisco device.
Step 3	<p><code>trapflags client { dot11 excluded }</code></p> <p>Example:</p> <pre>Device(config)# trapflags client excluded</pre>	<p>Enables sending client-related dot11 traps. Use the no form of the command to disable the trap flags.</p> <ul style="list-style-type: none"> • dot11– Enables Dot11 traps for clients. • excluded– Enables excluded traps for clients.

	Command or Action	Purpose
Step 4	<p>trapflags dot11-security {ids-sig-attack wep-decrypt-error}</p> <p>Example:</p> <pre>Device(config)# trapflags dot11-security wep-decrypt-error</pre>	<p>Enables sending 802.11 security-related traps. Use the no form of the command to disable the trap flags.</p> <ul style="list-style-type: none"> • ids-sig-attack– Enables IDS signature attack traps. • wep-decrypt-error– Enables traps for WEP decrypt error for clients.
Step 5	<p>trapflags mesh</p> <p>Example:</p> <pre>Device(config)# trapflags mesh</pre>	<p>Enables trap for the mesh. Use the no form of the command to disable the trap flags.</p>
Step 6	<p>trapflags rogueap</p> <p>Example:</p> <pre>Device(config)# trapflags rogueap</pre>	<p>Enables trap for rogue AP detection. Use the no form of the command to disable the trap flags.</p>
Step 7	<p>trapflags rrm-params {channels tx-power}</p> <p>Example:</p> <pre>Device(config)# trapflags rrm-params tx-power</pre>	<p>Enables sending RRM-parameter update-related traps. Use the no form of the command to disable the trap flags.</p> <ul style="list-style-type: none"> • channels– Enables trap when RF Manager automatically changes a channel number for the Cisco AP interface. • tx-power– Enables the trap when RF Manager automatically changes Tx-Power level for the Cisco AP interface.
Step 8	<p>trapflags rrm-profile {coverage interference load noise}</p> <p>Example:</p> <pre>Device(config)# trapflags rrm-profile interference</pre>	<p>Enables sending RRM-profile-related traps. Use the no form of the command to disable the trap flags.</p> <ul style="list-style-type: none"> • coverage– Enables the trap when the coverage profile maintained by RF Manager fails. • interference– Enables the trap when the interference profile maintained by RF Manager fails. • load– Enables trap when the load profile maintained by RF Manager fails. • noise– Enables trap when the noise profile maintained by RF Manager fails.
Step 9	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode.</p>

Enabling SNMP Wireless Trap Notification

SUMMARY STEPS

1. `configure terminal`
2. `snmp-server enable traps wireless [AP | RRM | bsn80211SecurityTrap | bsnAPPParamUpdate | bsnAPPProfile | bsnAccessPoint | bsnMobileStation | bsnRogue | client | mfp | rogue]`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>configure terminal</code></p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 2	<p><code>snmp-server enable traps wireless [AP RRM bsn80211SecurityTrap bsnAPPParamUpdate bsnAPPProfile bsnAccessPoint bsnMobileStation bsnRogue client mfp rogue]</code></p> <p>Example:</p> <pre>Device(config)# snmp-server enable traps wireless AP</pre>	<p>Enables SNMP wireless trap notification.</p> <ul style="list-style-type: none"> • AP– Enables access point traps. • RRM– Enables RRM traps. • bsn80211SecurityTrap– Enables the security-related trap. • bsnAPPParamUpdate– Enables the trap for AP parameters that get updated. • bsnAPPProfile– Enables BSN AP profile traps. • bsnAccessPoint– Enables BSN access point traps. • bsnMobileStation– Controls wireless client traps. • bsnRogue– Enables BSN rogue-related traps. • client– Enables client traps. • mfp– Enables MFP traps. • rogue– Enables rogue-related traps.
Step 3	<p><code>end</code></p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

Monitoring SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the **show snmp** privileged EXEC command. You also can use the other privileged EXEC commands listed in the table to display SNMP information.

Table 54: Commands for Displaying SNMP Information

Command	Purpose
show snmp	Displays SNMP statistics.
show snmp engineID	Displays information on the local SNMP engine and all remote engines that have been configured on the device.
show snmp group	Displays information on each SNMP group on the network.
show snmp pending	Displays information on pending SNMP requests.
show snmp sessions	Displays information on the current SNMP sessions.
show snmp user	<p>Displays information on each SNMP user name in the SNMP users table.</p> <p>Note You must use this command to display SNMPv3 configuration information for auth noauth priv mode. This information is not displayed in the show running-config output.</p>

SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*. This configuration does not cause the device to send any traps.

```
Device(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string *public*. The device also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33

using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string *public* is sent with the traps.

```
Device(config)# snmp-server community public
Device(config)# snmp-server enable traps vtp
Device(config)# snmp-server host 192.180.1.27 version 2c public
Device(config)# snmp-server host 192.180.1.111 version 1 public
Device(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the *comaccess* community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host *cisco.com* using the community string *public*.

```
Device(config)# snmp-server community comaccess ro 4
Device(config)# snmp-server enable traps snmp authentication
Device(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host *cisco.com*. The community string is restricted. The first line enables the device to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous **snmp-server** host commands for the host *cisco.com*.

```
Device(config)# snmp-server enable traps entity
Device(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the device to send all traps to the host *myhost.cisco.com* using the community string *public*:

```
Device(config)# snmp-server enable traps
Device(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send **auth** (authNoPriv) authentication-level informs when the user enters global configuration mode:

```
Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Device(config)# snmp-server group authgroup v3 auth
Device(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Device(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Device(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Device(config)# snmp-server enable traps
Device(config)# snmp-server inform retries 0
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions on SLAs

This section lists the restrictions on SLAs.

The following are restrictions on IP SLAs network performance measurement:

- The device does not support VoIP service levels using the gatekeeper registration delay operations measurements.
- Only a Cisco IOS device can be a source for a destination IP SLAs responder.
- You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

Information About SLAs

Cisco IOS IP Service Level Agreements (SLAs)

Cisco IOS IP SLAs send data across the network to measure performance between multiple network locations or across multiple network paths. They simulate network data and IP services and collect network performance information in real time. Cisco IOS IP SLAs generate and analyze traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLA operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLA operations, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLA packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs are Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs support the use of Cisco Mediatrace and Cisco Performance Monitor to collect and analyze the following performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Additionally, the device also supports Cisco Medianet to enable intelligent services in the network infrastructure for a wide variety of video applications. Cisco Medianet supports the auto-provisioning of endpoints offering video conferencing services and of IP Surveillance cameras through Auto Smartports.

Cisco Mediatrace and Cisco Performance Monitor can be used on devices running the IP Base image or the IP Services image.

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like Cisco Prime Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products.

Using IP SLAs can provide the following benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring
 - Measurement of jitter, latency, or packet loss in the network.
 - Continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Network operation troubleshooting by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.
- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the device supports MPLS).

Network Performance Measurement with Cisco IOS IP SLAs

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices.

Figure 48: Cisco IOS IP SLAs Operation

The following figure shows how IP SLAs begin when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

Related Topics

[Implementing IP SLA Network Performance Measurement](#), on page 681

[Restrictions on SLAs](#), on page 673

IP SLA Responder and IP SLA Control Protocol

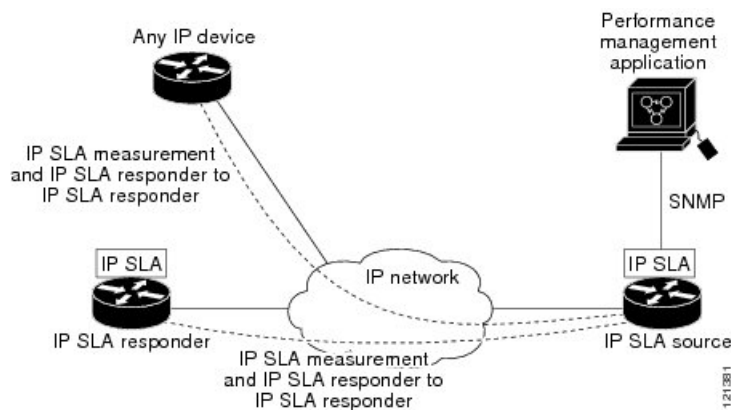

The IP SLA responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLA request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLA Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond.

Note The IP SLA responder can be a Cisco IOS Layer 2, responder-configurable device. The responder does not need to support full IP SLA functionality.

The following figure shows where the Cisco IOS IP SLA responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLA operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLA packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

Figure 49: Cisco IOS IP SLAs Operation

You do not need to enable the responder on the destination device for all IP SLA operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP).

Related Topics

[Restrictions on SLAs](#), on page 673

Response Time Computation for IP SLAs

Switches, controllers, and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimize these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLA test packets use time stamping to minimize the processing delays.

When the IP SLA responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

Figure 50: Cisco IOS IP SLA Responder Time Stamping

The following figure demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt

level to allow for greater accuracy. RTT (Round-trip time) = $T4$ (Time stamp 4) - $T1$ (Time stamp 1) - Δ

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

IP SLAs Operation Scheduling

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the *pending* option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLA operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLA multi-operations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the *Cisco IOS IP SLAs Configuration Guide*.

IP SLA Operation Threshold Monitoring

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as the following:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold
- One-way packet loss

- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency

An IP SLA threshold violation can also trigger another IP SLA operation for further analysis. For example, the frequency could be increased or an Internet Control Message Protocol (ICMP) path echo or ICMP path jitter operation could be initiated for troubleshooting.

ICMP Echo

The ICMP echo operation measures the end-to-end response time between a Cisco device and any other device that uses IP. The response time is computed by measuring the time it takes to send an ICMP echo request message to a destination and receive an ICMP echo reply. Many customers use IP SLA ICMP-based operations, in-house ping testing, or ping-based dedicated probes to measure this response time. The IP SLA ICMP echo operation conforms to the same specifications as ICMP ping testing, and both methods result in the same response times.

UDP Jitter

Jitter is a simple term that describes interpacket delay variance. When multiple packets are sent consecutively at an interval of 10 ms from source to destination, the destination should receive them 10 ms apart (if the network is behaving correctly). However, if there are delays in the network (such as queuing, arriving through alternate routes, and so on), the time interval between packet arrivals might be more or less than 10 ms. A positive jitter value indicates that the packets arrived more than 10 ms apart. A negative jitter value indicates that the packets arrived less than 10 ms apart. If the packets arrive 12 ms apart, the positive jitter is 2 ms; if the packets arrive 8 ms apart, the negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLA UDP jitter operation can be used as a multipurpose data gathering operation. The packets generated by IP SLAs carry sequence information and time stamps from the source and operational target that include packet sending and receiving data. Based on this data, UDP jitter operations measure the following:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), you can use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

To provide accurate one-way delay (latency) measurements, time synchronization (as provided by NTP) is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

How to Configure IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the *Cisco IOS IP SLAs Configuration Guide*. It does include several operations as examples, including configuring the responder, configuring a UDP jitter operation, which requires a responder, and configuring an ICMP echo operation, which does not require a responder. For details about configuring other operations, see the *Cisco IOS IP SLAs Configuration Guide*.

Default Configuration

No IP SLAs operations are configured.

Configuration Guidelines

For information on the IP SLA commands, see the *Cisco IOS IP SLAs Command Reference, Release 12.4T* command reference.

For detailed descriptions and configuration procedures, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4TL*.

Not all of the IP SLA commands or operations described in the referenced guide are supported on the device. The device supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the **show ip sla application** privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

```
Device# show ip sla application

      IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

Supported Operation Types:
      icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
      dns, udpJitter, dhcp, ftp, udpApp, wspApp

Supported Features:
      IPSLAs Event Publisher

IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389
```

```

Estimated number of configurable operations: 24389
Number of Entries configured      : 0
Number of active Entries         : 0
Number of pending Entries        : 0
Number of inactive Entries       : 0
Time of last change in whole IP SLAs: *13:04:37.668 UTC Wed Dec 19 2012

```

Configuring the IP SLA Responder

The IP SLA responder is available only on Cisco IOS software-based devices, including some Layer 2 devices that do not support full IP SLA functionality.

Follow these steps to configure the IP SLA responder on the target device (the operational target):

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sla responder {tcp-connect | udp-echo} ipaddress *ip-address* port *port-number***
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	ip sla responder {tcp-connect udp-echo} ipaddress <i>ip-address</i> port <i>port-number</i> Example: Device(config)# ip sla responder udp-echo 172.29.139.134 5000	Configures the device as an IP SLA responder. The keywords have these meanings: <ul style="list-style-type: none"> • tcp-connect—Enables the responder for TCP connect operations. • udp-echo—Enables the responder for User Datagram Protocol (UDP) echo or jitter operations. • ipaddress <i>ip-address</i>—Enter the destination IP address. • port <i>port-number</i>—Enter the destination port number.

	Command or Action	Purpose
		Note The IP address and port number must match those configured on the source device for the IP SLA operation.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show running-config Example: Device# show running-config	Verifies your entries.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Implementing IP SLA Network Performance Measurement

Follow these steps to implement IP SLA network performance measurement on your device:

Before you begin

Use the **show ip sla application** privileged EXEC command to verify that the desired operation type is supported on your software image.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sla operation-number**
4. **udp-jitter** {destination-ip-address | destination-hostname} destination-port [source-ip {ip-address | hostname}] [source-port port-number] [control {enable | disable}] [num-packets number-of-packets] [interval interpacket-interval]
5. **frequency** seconds
6. **threshold** milliseconds
7. **exit**
8. **ip sla schedule** operation-number [life {forever | seconds}] [start-time {hh:mm[:ss] [month day | day month]} | pending | now | after hh:mm:ss] [ageout seconds] [recurring]
9. **end**
10. **show running-config**

11. copy running-config startup-config

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	ip sla operation-number Example: Device(config)# ip sla 10	Creates an IP SLA operation, and enters IP SLA configuration mode.
Step 4	udp-jitter { <i>destination-ip-address</i> <i>destination-hostname</i> } <i>destination-port</i> [source-ip { <i>ip-address</i> <i>hostname</i> }] [source-port <i>port-number</i>] [control { enable disable }] [num-packets <i>number-of-packets</i>] [interval <i>interpacket-interval</i>] Example: Device(config-ip-sla)# udp-jitter 172.29.139.134 5000	Configures the IP SLA operation as the operation type of your choice (a UDP jitter operation is used in the example), and enters its configuration mode (UDP jitter configuration mode is used in the example). <ul style="list-style-type: none"> • <i>destination-ip-address</i> <i>destination-hostname</i>—Specifies the destination IP address or hostname. • <i>destination-port</i>—Specifies the destination port number in the range from 1 to 65535. • (Optional) source-ip {<i>ip-address</i> <i>hostname</i>}—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination • (Optional) source-port <i>port-number</i>—Specifies the source port number in the range from 1 to 65535. When a port number is not specified, IP SLA chooses an available port. • (Optional) control—Enables or disables sending of IP SLA control messages to the IP SLA responder. By default, IP SLA control messages are sent to the destination device to establish a connection with the IP SLA responder

	Command or Action	Purpose
		<ul style="list-style-type: none"> • (Optional) num-packets <i>number-of-packets</i>—Enters the number of packets to be generated. The range is 1 to 6000; the default is 10. • (Optional) interval <i>inter-packet-interval</i>—Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.
Step 5	frequency <i>seconds</i> Example: Device(config-ip-sla-jitter)# frequency 45	(Optional) Configures options for the SLA operation. This example sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.
Step 6	threshold <i>milliseconds</i> Example: Device(config-ip-sla-jitter)# threshold 200	(Optional) Configures threshold conditions. This example sets the threshold of the specified IP SLA operation to 200. The range is from 0 to 60000 milliseconds.
Step 7	exit Example: Device(config-ip-sla-jitter)# exit	Exits the SLA operation configuration mode (UDP jitter configuration mode in this example), and returns to global configuration mode.
Step 8	ip sla schedule <i>operation-number</i> [life { forever <i>seconds</i> }] [start-time { <i>hh:mm</i> [: <i>ss</i>] [<i>month day</i> <i>day month</i>] pending now after <i>hh:mm:ss</i> }] [ageout <i>seconds</i>] [recurring] Example: Device(config)# ip sla schedule 10 start-time now life forever	Configures the scheduling parameters for an individual IP SLA operation. <ul style="list-style-type: none"> • <i>operation-number</i>—Enter the RTR entry number. • (Optional) life—Sets the operation to run indefinitely (forever) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour). • (Optional) start-time—Enters the time for the operation to begin collecting information: To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month. Enter pending to select no information collection until a start time is selected. Enter now to start the operation immediately. Enter after <i>hh:mm:ss</i> to show that the operation should start after the entered time has elapsed.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • (Optional) ageout seconds—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out). • (Optional) recurring—Set the operation to automatically run every day.
Step 9	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 10	show running-config Example: Device# show running-config	Verifies your entries.
Step 11	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

UDP Jitter Configuration

This example shows how to configure a UDP jitter IP SLA operation:

```

Device(config)# ip sla 10
Device(config-ip-sla)# udp-jitter 172.29.139.134 5000
Device(config-ip-sla-jitter)# frequency 30
Device(config-ip-sla-jitter)# exit
Device(config)# ip sla schedule 5 start-time now life forever
Device(config)# end
Device# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Analyzing IP Service Levels by Using the UDP Jitter Operation

Follow these steps to configure a UDP jitter operation on the source device:

Before you begin

You must enable the IP SLA responder on the target device (the operational target) to configure a UDP jitter operation on the source device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sla operation-number**
4. **udp-jitter** {*destination-ip-address* | *destination-hostname*} *destination-port* [**source-ip** {*ip-address* | *hostname*}] [**source-port** *port-number*] [**control** {**enable** | **disable**}] [**num-packets** *number-of-packets*] [**interval** *interpacket-interval*]
5. **frequency** *seconds*
6. **exit**
7. **ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]
8. **end**
9. **show running-config**
10. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	ip sla operation-number Example: Device (config)# ip sla 10	Creates an IP SLA operation, and enters IP SLA configuration mode.
Step 4	udp-jitter { <i>destination-ip-address</i> <i>destination-hostname</i> } <i>destination-port</i> [source-ip { <i>ip-address</i> <i>hostname</i> }] [source-port <i>port-number</i>] [control { enable disable }] [num-packets <i>number-of-packets</i>] [interval <i>interpacket-interval</i>] Example: Device (config-ip-sla)# udp-jitter 172.29.139.134 5000	Configures the IP SLA operation as a UDP jitter operation, and enters UDP jitter configuration mode. <ul style="list-style-type: none"> • <i>destination-ip-address</i> <i>destination-hostname</i>—Specifies the destination IP address or hostname. • <i>destination-port</i>—Specifies the destination port number in the range from 1 to 65535. • (Optional) source-ip {<i>ip-address</i> <i>hostname</i>}—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination. • (Optional) source-port <i>port-number</i>—Specifies the source port number in the range from 1 to 65535. Monitoring IP SLA Operations

The following table describes the commands used to display IP SLA operation configurations and results:

Table 55: Monitoring IP SLA Operations

show ip sla application	Displays global information about Cisco IOS IP SLAs.
show ip sla authentication	Displays IP SLA authentication information.
show ip sla configuration [<i>entry-number</i>]	Displays configuration values including all defaults for all IP SLA operations or a specific operation.
show ip sla enhanced-history { collection-statistics distribution statistics } [<i>entry-number</i>]	Displays enhanced history statistics for collected history buckets or distribution statistics for all IP SLA operations or a specific operation.
show ip sla ethernet-monitor configuration [<i>entry-number</i>]	Displays IP SLA automatic Ethernet configuration.
show ip sla group schedule [<i>schedule-entry-number</i>]	Displays IP SLA group scheduling configuration and details.
show ip sla history [<i>entry-number</i> full tabular]	Displays history collected for all IP SLA operations.
show ip sla mpls-lsp-monitor { collection-statistics configuration ldp operational-state scan-queue summary [<i>entry-number</i>] neighbors }	Displays MPLS label switched path (LSP) Health Monitor operations.
show ip sla reaction-configuration [<i>entry-number</i>]	Displays the configured proactive threshold monitoring settings for all IP SLA operations or a specific operation.

show ip sla reaction-trigger [<i>entry-number</i>]	Displays the reaction trigger information for all IP SLA operations or a specific operation.
show ip sla responder	Displays information about the IP SLA responder.
show ip sla statistics [<i>entry-number</i> aggregated details]	Displays current or aggregated operational status and statistics.

Monitoring IP SLA Operation Examples

The following example shows all IP SLAs by application:

```
Device# show ip sla application

      IP Service Level Agreements

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Configuring Local Policies

- The policy map attributes supported on the device are QoS, VLAN, session timeout, and ACL.
- Apple iPhone 6s will get classified as "workstation" after HTTP profiling.

Information About Configuring Local Policies

Local policies can profile devices based on HTTP and DHCP to identify the end devices on the network. Users can configure device-based policies and enforce the policies per user or per device policy on the network.

Local policies allow profiling of mobile devices and basic onboarding of the profiled devices to a specific VLAN. They also assign ACL and QoS or configure session timeouts.

You can configure local policies as two separate components:

- Defining policy attributes as service templates specific to clients joining the network and applying policy match criteria.
- Applying match criteria to the policy.

The following policy match attributes are used for configuring local policies:

- Device—Defines the type of device. Windows-based computer, Smart phone, Apple devices such as iPad and iPhone.
- Username—Defines the username of the user.
- User role—Defines the user type or the user group the user belongs to, such as a student or employee.
- MAC—Defines the mac-address of the end point.
- MAC OUI—Defines the mac-address OUI.

Once the device has a match corresponding to these parameters per end point, the policy can be added. Policy enforcement allows basic device on-boarding of mobile devices based on the following session attributes:

- VLAN
- QoS
- ACL
- Session timeout

You can configure these policies and enforce end points with specified policies. The wireless clients are profiled based on MAC OUI, DHCP, and HTTP user agent (valid Internet is required for successful HTTP profiling)MAC OUI and DHCP. The device uses these attributes and predefined classification profiles to identify devices.

Replacing Default Profile Text File

If a new device is not classified, contact the Cisco support team with the device MAC address. The Cisco support team will provide a new **dc_default_profile.txt** file with the MAC address included in the file. You need to replace the **dc_default_profile.txt** file with the earlier file. Follow these steps to change the **dc_default_profile.txt** file:

1. Stop device classifier by entering this command:
`device(config)# no device classifier`
2. Copy the file by entering this command:

device# **device classifier profile location** *filepath*

3. Start the device classifier by entering this command:

device(config)# **device classifier**

Disabling session monitor on trunk ports

On uplink trunk ports, you should not create any session monitoring. By default, session monitoring is enabled. You should disable session monitoring.

1. Enter into global configuration mode by entering this command:

device# **configure terminal**

2. Enter into interface configuration mode by entering this command:

device(config)# **interface** *interface-id*

3. Disable session monitoring by entering this command:

device(config-if)# **no access-session monitor**

How to Configure Local Policies

Configuring Local Policies (CLI)

To configure local policies, complete these procedures:

1. Create a service template.
2. Create an interface template.
3. Create a parameter map.
4. Create a policy map.
5. Apply a local policy on a WLAN.

Creating a Service Template (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	service-template <i>service-template-name</i> Example: Device(config)# service-template cisco-phone-template Device(config-service-template)#	Enters service template configuration mode.
Step 3	access-group <i>acl_list</i> Example: Device(config-service-template)# access-group foo-acl	Specifies the access list to be applied.
Step 4	vlan <i>vlan_id</i> Example: Device(config-service-template)# vlan 100	Specifies VLAN ID. You can specify a value from 1 to 4094.
Step 5	absolute-timer <i>seconds</i> Example: Device(config-service-template)# absolute-timer 20	Specifies session timeout value for service template. You can specify a value from 1 to 65535.
Step 6	service-policy qos {input output} Example: Device(config-service-template)# service-policy qos input foo-qos	Configures QoS policies for the client.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Creating an Interface Template (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	template <i>interface-template-name</i> Example: Device(config)# <code>template cisco-phone-template</code> Device(config-template)#	Enters interface template configuration mode.
Step 3	switchport mode access Example: Device(config-template)# <code>switchport mode access</code>	Sets the interface as a nontrunking nontagged single-VLAN Ethernet interface. An access port can carry traffic in one VLAN only. By default, an access port carries traffic for VLAN1.
Step 4	switchport voice vlan <i>vlan_id</i> Example: Device(config-template)# <code>switchport voice vlan 20</code>	Specifies to forward all voice traffic through the specified VLAN. You can specify a value from 1 to 4094.
Step 5	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Creating a Parameter Map (CLI)

Parameter map is preferred to use than class map.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	parameter-map type subscriber attribute-to-service <i>parameter-map-name</i> Example: Device(config) # parameter-map type subscriber attribute-to-service Aironet-Policy-para	Specifies the parameter map type and name.
Step 3	map-index map { device-type mac-address oui user-role username } {eq not-eq regex <i>filter-name</i> } Example: Device(config-parameter-map-filter) # 10 map device-type eq "WindowsXP-Workstation"	Specifies parameter map attribute filter criteria.
Step 4	service-template <i>service-template-name</i> Example: Device(config-parameter-map-filter-submode) # service-template cisco-phone-template Device(config-parameter-map-filter-submode) #	Enters service template configuration mode.
Step 5	interface-template <i>interface-template-name</i> Example: Device(config-parameter-map-filter-submode) # interface-template cisco-phone-template Device(config-parameter-map-filter-submode) #	Enters service template configuration mode.
Step 6	end Example: Device(config) # end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Local Policies (GUI)

To configure local policies, complete these procedures:

1. Create a service template.
2. Create a policy map.
3. Apply a local policy that you have created to a WLAN.

Creating a Service Template (GUI)

Step 1 Choose **Configuration > Security > Local Policies > Service Template** to open the **Service Template** page.

Step 2 Create a new template as follows:

- a) Click **New** to open the **Service Template > New** page.
- b) In the Service Template name text box, enter the new service template name.
- c) In the VLAN ID text box, enter the VLAN identifier that has to be associated with the policy. The value ranges from 1 to 4094.
- d) In the Session timeout text box, enter the maximum amount of time, in seconds, after which a client is forced to reauthenticate. The value ranges from 1 to 65535 seconds.
- e) From the Access control list drop-down list, choose the access control list to be mapped to the policy.
- f) From the Ingress QoS drop-down list, choose the ingress QoS policy to be applied.
- g) From the Egress QoS drop-down list, choose the egress QoS policy to be applied.
- h) Click **Apply** to save the configuration.

Step 3 Edit a service template as follows:

- a) From the **Service Template** page, click the service template to open the **Service Template > Edit** page.
- b) In the VLAN ID text box, enter the VLAN identifier that has to be associated with the policy. The value ranges from 1 to 4094.
- c) In the Session timeout text box, enter the maximum amount of time, in seconds, after which a client is forced to reauthenticate. The value ranges from 1 to 65535 seconds.
- d) From the Access control list drop-down list, choose the access control list to be mapped to the policy.
- e) From the Ingress QoS drop-down list, choose the ingress QoS policy to be applied.
- f) From the Egress QoS drop-down list, choose the egress QoS policy to be applied.
- g) Click **Apply** to save the configuration.

Step 4 Remove a service template as follows:

- a) From the **Service Template** page, select the service template.
- b) Click **Remove**.
- c) Click **Apply** to save the configuration.

Related Topics

[Restrictions for Configuring Local Policies](#), on page 697

[Monitoring Local Policies](#), on page 708

[Examples: Local Policies Configuration](#), on page 709

Creating a Policy Map (GUI)

Step 1 Choose **Configuration > Security > Local Policies > Policy Map** to open the **Policy Map** page.

Step 2 Create a new policy map as follows:

- a) Click **New** to open the **Policy Map > New** page.
- b) In the Policy Map name text box, enter the new policy map name.
- c) Click **Add** to open the Match Criteria area.

- d) From the Device Type drop-down list, choose the device type. The match criteria for the device type can be eq, not-eq, or regex with respect to the device type you are choosing.
- e) From the User Role drop-down list, select the match criteria as eq, not-eq, or regex and enter the user type or user group of the user, for example, student, teacher, and so on.
- f) From the Service Template drop-down list, choose the service template to be mapped to the policy.
- g) Click **Add**. The match criteria is added to the Match Criteria Lists.
- h) In the Match Criteria Lists area, click **Add** to add the match criteria to the policy.
- i) Click **Apply** to save the configuration.

Step 3 Edit a policy map as follows:

- a) In the **Policy Map** page, select the policy map that you want to edit, and click **Edit** to open the **Policy Map > Edit** page.
- b) In the Match Criteria area, choose the device type from the Device Type drop-down list. The match criteria for the device type can be eq, not-eq, or regex with respect to the device type you are choosing.
- c) In the Match Criteria area, choose the user role from the User Role drop-down list. Select the match criteria as eq, not-eq, or regex and enter the user type or user group of the user
- d) From the Service Template drop-down list, choose the service template to be mapped to the policy.
- e) Click **Ok** to save the configuration or **Cancel** to discard the configuration.
- f) Click **Add** to add more match criteria based on device type, user role, and service template to the policy.
- g) In the Match Criteria Lists area, select the match criteria and click **Move to** to move the match criteria with respect to a value entered in the row text box.
- h) Select the match criteria and click **Move up** to move the match criteria up in the list.
- i) Select the match criteria and click **Move down** to move the match criteria down in the list.
- j) Select the match criteria and click **Remove** to remove the match criteria from the policy map list.
- k) Click **Apply** to save the configuration.

Step 4 Remove a policy map as follows:

- a) From the **Policy Map** page, select the policy map.
- b) Click **Remove**.
- c) Click **Apply** to save the configuration.

Monitoring Local Policies

The following commands can be used to monitor local policies configured on the device.

Table 56: Monitoring Local Policies Command

Command	Purpose
show access-session	Displays the summary of access session with authorization status, method and domain for each client or MAC address displayed.
show access-session cache	Displays the latest classification for the client.
show device classifier attached detail	Displays the latest classification for the client based on parameters such as Mac, DHCP, or HTTP.
show access-session mac mac-address details	<p>Displays the policy mapped, service template used, and attributes for the client.</p> <p>Note If the show access-session detail command output is not displaying session timeout details, you should enable client profiling with session timeout in client access session and then run the show access-session mac mac-address details command to see the session timeout details.</p>
show access-session mac mac-address policy	<p>Displays the policy mapped, service template used, and attributes for the client.</p> <p>In addition, you can view the Resultant Policy that displays the following information:</p> <ul style="list-style-type: none"> • The final attributes applied to the session when the session has locally configured attributes. • Attributes applied from the server.

- [Creating a Service Template \(GUI\), on page 706](#)
- [Creating a Policy Map \(GUI\), on page 706](#)
- [Applying Local Policies to WLAN \(GUI\), on page 707](#)

Examples: Local Policies Configuration

This example shows how to create service template:

```
Device(config)# service-template test3
Device(config-service-template)# access-group josephacl
Device(config-service-template)# vlan 137
Device(config-service-template)# absolute-timer 500
Device(config-service-template)# service-policy qos input qosingress
Device(config-service-template)# end
```

This example shows how to create parameter map:

```
Device(config)# parameter-map type subscriber attribute-to-service apple-tsim-param
Device(config-parameter-map)# 1 map device-type eq "Apple-Device"
Device(config-parameter-map)# 1 service-template test1
Device(config-parameter-map)# 2 map device-type eq "Apple-Ipad"
Device(config-parameter-map)# 1 service-template test2
Device(config-parameter-map)# 3 map device-type eq "Android"
Device(config-parameter-map)# 1 service-template test3
Device(config-parameter-map)# end
```

Note At the end of each configuration command line, enter CTRL Z to execute the command and proceed to the next line.

This example shows how to create interface template:

```
Device# configure terminal
Device(config)# template cisco-phone-template
Device(config-template)# switchport mode access
Device(config-template)# switchport voice vlan 20
Device(config-template)# end
```

This example shows how to create parameter map:

```
Device# configure terminal
Device(config)# parameter-map type subscriber attribute-to-service param-wired
Device(config-parameter-map-filter)# 10 map device-type regex Cisco-IP-Phone
Device(config-parameter-map-filter-submode)# 10 interface-template cisco-phone-template
Device(config-parameter-map)# end
```

This example shows how to create policy map:

```
Device(config)# policy-map type control subscriber apple-tsim
Device(config-policy-map)# event identity-update match-all
Device(config-policy-map)# 1 class always do-until-failure
```

```
Device(config-policy-map)# 1 map attribute-to-service table apple-tsim-param
Device(config-policy-map)# end
```

This example shows how to apply policy to a device on a WLAN:

```
Device(config)# wlan wlan1
Device(config-wlan)# client vlan VLAN0054
Device(config-wlan)# profiling local http
Device(config-wlan)# service-policy type control subscriber apple-tsim
Device(config-wlan)# no shutdown
Device# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for SPAN and RSPAN

SPAN

- You can limit SPAN traffic to specific VLANs by using the **filter vlan** keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

RSPAN

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.

Restrictions for SPAN and RSPAN

SPAN

The restrictions for SPAN are as follows:

- On each device, you can configure 66 sessions. A maximum of source sessions can be configured and the remaining sessions can be configured as RSPAN destination sessions. A source session is either a local SPAN session or an RSPAN source session.
- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.
- The destination port cannot be a source port; a source port cannot be a destination port.
- You cannot have two SPAN sessions using the same destination port.
- When you configure a device port as a SPAN destination port, it is no longer a normal device port; only monitored traffic passes through the SPAN destination port.
- Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the **no monitor session** *{session_number | all | local | remote}* global configuration command to delete configured SPAN parameters.
- For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the **encapsulation replicate** keywords are specified. If the keywords are not specified, the packets are sent in native form.
- You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.
- You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- Wireshark does not capture egress packets when egress span is active.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.

- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
 - An RSPAN source session cannot have a local destination port.
 - An RSPAN destination session cannot have a local source port.
 - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

RSPAN

The restrictions for RSPAN are as follows:

- RSPAN does not support BPDU packet monitoring or other Layer 2 device protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating devices.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the device does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the device.
-
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- To use RSPAN, the switch must be running the LAN Base image.

Information About SPAN and RSPAN

SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the device or on another device that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

Local SPAN

Local SPAN supports a SPAN session entirely within one device; all source ports or source VLANs and destination ports are in the same device or device stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

Figure 51: Example of Local SPAN Configuration on a Single Device

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port

Figure 52: Example of Local SPAN Configuration on a Device Stack

This is an example of a local SPAN in a device stack, where the source and destination ports reside on different stack members.

Remote SPAN

RSPAN supports source ports, source VLANs, and destination ports on different devices (or different device stacks), enabling remote monitoring of multiple devices across your network.

Figure 53: Example of RSPAN Configuration

The figure below shows source ports on Device A and Device B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating devices. The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source device must have either ports or VLANs as RSPAN sources. The destination is always a physical port,

as shown on Device C in the figure.

- [Monitored Traffic](#)
- [Source Ports](#)
- [Source VLANs](#)
- [VLAN Filtering](#)
- [Destination Port](#)
- [RSPAN VLAN](#)

SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination device.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

A single RSPAN session with multiple source and destination ports can be in the same session but more than one source session with the source being the same remote vlan is not allowed.

Traffic monitoring in a SPAN session has these restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.

- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
 - An RSPAN source session cannot have a local destination port.
 - An RSPAN destination session cannot have a local source port.
 - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

[Example: Configuring Local SPAN](#), on page 749

Monitored Traffic

SPAN sessions can monitor these traffic types:

- Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the device. A copy of each packet received by the source is sent to the destination port for that SPAN session.

Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

- Transmit (Tx) SPAN—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the device. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- Both—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

The default configuration for local SPAN session ports is to send all packets untagged. However, when you enter the **encapsulation replicate** keywords while configuring a destination port, these changes occur:

- Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.

- Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Device congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

- A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
- An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.
- An egress packet dropped because of device congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the device through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

Source Ports

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis. In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions. The device supports any number of source ports (up to the maximum number of available ports on the device) and any number of source VLANs (up to the maximum number of VLANs supported). However, the device supports a maximum of two sessions (local or RSPAN) with source ports or VLANs. You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.
- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.

Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same device or device stack as the source port. For an RSPAN session, it is located on the device containing the RSPAN destination session. There is no destination port on a device or device stack running only an RSPAN source session.
- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.

Note When QoS is configured on the SPAN destination port, QoS takes effect immediately.

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.

- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can be an EtherChannel group (**ON** mode only).
- It cannot be a VLAN.
- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).
- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- The maximum number of destination ports in a device or device stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

- For local SPAN, if the **encapsulation replicate** keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with **encapsulation replicate** enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.
- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the **remote-span** VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate devices.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

- **Routing**—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the device, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the device routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.
- **STP**—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.
- **CDP**—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.
Due to limitation in the ASIC, CDP packets are not dropped in RSPAN configured VLAN.
- **VTP**—You can use VTP to prune an RSPAN VLAN between devices.
- **VLAN and trunking**—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.
- **EtherChannel**—You can configure an EtherChannel group as a source port or a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored.

If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.

A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

- Multicast traffic can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.
- A private-VLAN port cannot be a SPAN destination port.
- A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

SPAN and RSPAN and Device Stacks

Because the stack of devices represents one logical device, local SPAN source ports and destination ports can be in different devices in the stack. Therefore, the addition or deletion of devices in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a device is removed from the stack or an inactive session can become active when a device is added to the stack.

Flow-Based SPAN

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session. The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.

You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL— Filters only IPv4 packets.
- IPv6 FSPAN ACL— Filters only IPv6 packets.
- MAC FSPAN ACL— Filters only non-IP packets.

If a VLAN-based FSPAN session configured on a stack cannot fit in the hardware memory on one or more devices, it is treated as unloaded on those devices, and traffic meant for the FSPAN ACL and sourcing on

that device is not copied to the SPAN destination ports. The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the devices where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

IPv4 and MAC FSPAN ACLs are supported on all feature sets. IPv6 FSPAN ACLs are supported only in the advanced IP Services feature set.

Default SPAN and RSPAN Configuration

Table 57: Default SPAN and RSPAN Configuration

Feature	Default Setting
SPAN state (SPAN and RSPAN)	Disabled.
Source port traffic to monitor	Both received and sent traffic (both).
Encapsulation type (destination port)	Native form (untagged packets).
Ingress forwarding (destination port)	Disabled.
VLAN filtering	On a trunk interface used as a source port, all VLANs are monitored.
RSPAN VLANs	None configured.

Configuration Guidelines

SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session session_number source {interface interface-id | vlan vlan-id}** global configuration command or the **no monitor session session_number destination interface interface-id** global configuration command. For destination interfaces, the **encapsulation** options are ignored with the **no** form of the command.
- To monitor all VLANs on the trunk port, use the **no monitor session session_number filter** global configuration command.

Related Topics

[Creating a Local SPAN Session](#), on page 726

[Creating a Local SPAN Session and Configuring Incoming Traffic](#), on page 729

[Example: Configuring Local SPAN](#), on page 749

RSPAN Configuration Guidelines

- All the SPAN configuration guidelines apply to RSPAN.
- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.
- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source devices.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple devices in your network.
- Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.
- You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
 - The same RSPAN VLAN is used for an RSPAN session in all the devices.
 - All participating devices support RSPAN.

[Examples: Creating an RSPAN VLAN](#), on page 751

FSPAN and FRSPAN Configuration Guidelines

- When at least one FSPAN ACL is attached, FSPAN is enabled.
- When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

How to Configure SPAN and RSPAN

Creating a Local SPAN Session

Follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **no monitor session** {*session_number* | **all** | **local** | **remote**}
4. **monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session_number* **destination** {**interface** *interface-id* [, | -] [**encapsulation replicate**]}
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	<p>no monitor session {<i>session_number</i> all local remote}</p> <p>Example:</p> <pre>Device(config)# no monitor session all</pre>	<p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	<p>monitor session <i>session_number</i> source {interface <i>interface-id</i> vlan <i>vlan-id</i>} [, -] [both rx tx]</p> <p>Example:</p> <pre>Device(config)# monitor session 1 source interface gigabitethernet1/0/1</pre>	<p>Specifies the SPAN session and the source port (monitored port).</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specify the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). Valid port-channel numbers are 1 to 48. • For <i>vlan-id</i>, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). <p>Note A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</p>

	Command or Action	Purpose
		<ul style="list-style-type: none"> • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) both rx tx—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. <ul style="list-style-type: none"> • both—Monitors both received and sent traffic. • rx—Monitors received traffic. • tx—Monitors sent traffic. <p>Note You can use the monitor session session_number source command multiple times to configure multiple source ports.</p>
Step 5	<p>monitor session <i>session_number</i> destination {interface <i>interface-id</i> [, -] [encapsulation replicate]}</p> <p>Example:</p> <pre>Device(config)# monitor session 1 destination interface gigabitethernet1/0/2 encapsulation replicate</pre>	<p>Specifies the SPAN session and the destination port (monitoring port). The port LED changes to amber when the configuration changes take effect. The LED returns to its original state(green) only after removing the SPAN destination configuration.</p> <p>Note For local SPAN, you must use the same session number for the source and destination interfaces.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in step 4. • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. <p>(Optional) encapsulation replicate specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).</p> <p>Note You can use monitor session session_number destination command multiple times to configure multiple destination ports.</p>
Step 6	<p>end</p> <p>Example:</p>	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config)# end	
Step 7	show running-config Example: Device# show running-config	Verifies your entries.
Step 8	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Creating a Local SPAN Session and Configuring Incoming Traffic

Follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session_number* | **all** | **local** | **remote**}
4. **monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session_number* **destination** {**interface** *interface-id* [, | -] [**encapsulation replicate**] [**ingress** {**dot1q** **vlan** *vlan-id* | **untagged** **vlan** *vlan-id* | **vlan** *vlan-id*}}}
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	<p>no monitor session <i>{session_number all local remote}</i></p> <p>Example:</p> <pre>Device(config)# no monitor session all</pre>	<p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	<p>monitor session <i>session_number</i> source <i>{interface interface-id vlan vlan-id}</i> [, -] [both rx tx]</p> <p>Example:</p> <pre>Device(config)# monitor session 2 source gigabitethernet1/0/1 rx</pre>	Specifies the SPAN session and the source port (monitored port).
Step 5	<p>monitor session <i>session_number</i> destination <i>{interface interface-id [, -] [encapsulation replicate] [ingress {dot1q vlan vlan-id untagged vlan vlan-id vlan vlan-id}]}</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6</pre>	<p>Specifies the SPAN session, the destination port, the packet encapsulation, and the ingress VLAN and encapsulation.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -]—Specifies a series or range of interfaces. Enter a space before and after the comma or hyphen. • (Optional) encapsulation replicate specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). • ingress enables forwarding of incoming traffic on the destination port and to specify the encapsulation type: <ul style="list-style-type: none"> • dot1q vlan vlan-id—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN. • untagged vlan vlan-id or vlan vlan-id—Accepts incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.

	Command or Action	Purpose
Step 6	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 7	show running-config Example: Device# show running-config	Verifies your entries.
Step 8	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Specifying VLANs to Filter

Follow these steps to limit SPAN source traffic to specific VLANs.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session_number* | **all** | **local** | **remote**}
4. **monitor session** *session_number* **source interface** *interface-id*
5. **monitor session** *session_number* **filter vlan** *vlan-id* [, | -]
6. **monitor session** *session_number* **destination** {**interface** *interface-id* [, | -] [**encapsulation replicate**]}
7. **end**
8. **show running-config**
9. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	no monitor session { <i>session_number</i> all local remote } Example: Device(config)# no monitor session all	Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	monitor session <i>session_number</i> source interface <i>interface-id</i> Example: Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx	Specifies the characteristics of the source port (monitored port) and SPAN session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specify the source port to monitor. The interface specified must already be configured as a trunk port.
Step 5	monitor session <i>session_number</i> filter vlan <i>vlan-id</i> [, -] Example: Device(config)# monitor session 2 filter vlan 1 - 5 , 9	Limits the SPAN source traffic to specific VLANs. <ul style="list-style-type: none"> • For <i>session_number</i>, enter the session number specified in Step 4. • For <i>vlan-id</i>, the range is 1 to 4094. • (Optional) Use a comma (,) to specify a series of VLANs, or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.
Step 6	monitor session <i>session_number</i> destination { interface <i>interface-id</i> [, -] [encapsulation replicate]}	Specifies the SPAN session and the destination port (monitoring port). <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.

	Command or Action	Purpose
		<ul style="list-style-type: none"> (Optional) encapsulation replicate specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).
Step 7	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.
Step 8	show running-config Example: <pre>Device# show running-config</pre>	Verifies your entries.
Step 9	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring a VLAN as an RSPAN VLAN

Follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vlan *vlan-id***
4. **remote-span**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	vlan <i>vlan-id</i> Example: Device(config)# <code>vlan 100</code>	Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094. The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs).
Step 4	remote-span Example: Device(config-vlan)# <code>remote-span</code>	Configures the VLAN as an RSPAN VLAN.
Step 5	end Example: Device(config-vlan)# <code>end</code>	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# <code>show running-config</code>	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

What to do next

You must create the RSPAN VLAN in all devices that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one device, and VTP propagates it to the other devices in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination devices and any intermediate devices.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the **no remote-span** VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the **no monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} global configuration command. To remove the RSPAN VLAN from the session, use the **no monitor session** *session_number* **destination remote vlan** *vlan-id*.

Creating an RSPAN Source Session

Follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session_number* | **all** | **local** | **remote**}
4. **monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session_number* **destination remote vlan** *vlan-id*
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	no monitor session { <i>session_number</i> all local remote } Example: <pre>Device(config)# no monitor session 1</pre>	Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	monitor session <i>session_number</i> source { interface <i>interface-id</i> vlan <i>vlan-id</i> } [, -] [both rx tx] Example:	Specifies the RSPAN session and the source port (monitored port). <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66.

	Command or Action	Purpose
	<pre>Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx</pre>	<ul style="list-style-type: none"> Enter a source port or source VLAN for the RSPAN session: <ul style="list-style-type: none"> For <i>interface-id</i>, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). Valid port-channel numbers are 1 to 48. For <i>vlan-id</i>, specifies the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). <p>A single session can include multiple sources (ports or VLANs), defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</p> (Optional) [<i>,</i> <i>-</i>]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. (Optional) both rx tx—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. <ul style="list-style-type: none"> both—Monitors both received and sent traffic. rx—Monitors received traffic. tx—Monitors sent traffic.
Step 5	<pre>monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i></pre> <p>Example:</p> <pre>Device(config)# monitor session 1 destination remote vlan 100</pre>	<p>Specifies the RSPAN session, the destination RSPAN VLAN, and the destination-port group.</p> <ul style="list-style-type: none"> For <i>session_number</i>, enter the number defined in Step 4. For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor.
Step 6	<pre>end</pre> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode.</p>
Step 7	<pre>show running-config</pre> <p>Example:</p>	<p>Verifies your entries.</p>

	Command or Action	Purpose
	Device# <code>show running-config</code>	
Step 8	copy running-config startup-config Example: Device# <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Specifying VLANs to Filter

Follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source interface interface-id`
5. `monitor session session_number filter vlan vlan-id [, | -]`
6. `monitor session session_number destination remote vlan vlan-id`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	<code>no monitor session {session_number all local remote}</code>	Removes any existing SPAN configuration for the session.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config)# no monitor session 2</pre>	<ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	<p>monitor session <i>session_number</i> source interface <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx</pre>	<p>Specifies the characteristics of the source port (monitored port) and SPAN session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specify the source port to monitor. The interface specified must already be configured as a trunk port.
Step 5	<p>monitor session <i>session_number</i> filter vlan <i>vlan-id</i> [, -]</p> <p>Example:</p> <pre>Device(config)# monitor session 2 filter vlan 1 - 5 , 9</pre>	<p>Limits the SPAN source traffic to specific VLANs.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, enter the session number specified in step 4. • For <i>vlan-id</i>, the range is 1 to 4094. • (Optional) , - Use a comma (,) to specify a series of VLANs or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.
Step 6	<p>monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination remote vlan 902</pre>	<p>Specifies the RSPAN session and the destination remote VLAN (RSPAN VLAN).</p> <ul style="list-style-type: none"> • For <i>session_number</i>, enter the session number specified in Step 4. • For <i>vlan-id</i>, specify the RSPAN VLAN to carry the monitored traffic to the destination port.
Step 7	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode.</p>
Step 8	<p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre>	<p>Verifies your entries.</p>
Step 9	<p>copy running-config startup-config</p> <p>Example:</p>	<p>(Optional) Saves your entries in the configuration file.</p>

	Command or Action	Purpose
	Device# <code>copy running-config startup-config</code>	

Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different device or device stack; that is, not the device or device stack on which the source session was configured.

Follow these steps to define the RSPAN VLAN on that device, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `vlan vlan-id`
4. `remote-span`
5. `exit`
6. `no monitor session {session_number | all | local | remote}`
7. `monitor session session_number source remote vlan vlan-id`
8. `monitor session session_number destination interface interface-id`
9. `end`
10. `show running-config`
11. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<code>configure terminal</code> Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	<code>vlan <i>vlan-id</i></code> Example: Device(config)# <code>vlan 901</code>	Specifies the VLAN ID of the RSPAN VLAN created from the source device, and enters VLAN configuration mode. If both devices are participating in VTP and the RSPAN VLAN ID is from 2 to 1005, Steps 3 through 5 are not

	Command or Action	Purpose
		required because the RSPAN VLAN ID is propagated through the VTP network.
Step 4	remote-span Example: Device(config-vlan)# remote-span	Identifies the VLAN as the RSPAN VLAN.
Step 5	exit Example: Device(config-vlan)# exit	Returns to global configuration mode.
Step 6	no monitor session {session_number all local remote} Example: Device(config)# no monitor session 1	Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 7	monitor session session_number source remote vlan vlan-id Example: Device(config)# monitor session 1 source remote vlan 901	Specifies the RSPAN session and the source RSPAN VLAN. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor.
Step 8	monitor session session_number destination interface interface-id Example: Device(config)# monitor session 1 destination interface gigabitethernet2/0/1	Specifies the RSPAN session and the destination interface. <ul style="list-style-type: none"> • For <i>session_number</i>, enter the number defined in Step 7. • In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port. • For <i>interface-id</i>, specify the destination interface. The destination interface must be a physical interface. • Though visible in the command-line help string, encapsulation replicate is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged.
Step 9	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device (config)# end	
Step 10	show running-config Example: Device# show running-config	Verifies your entries.
Step 11	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Creating an RSPAN Destination Session and Configuring Incoming Traffic

Follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session_number* | **all** | **local** | **remote**}
4. **monitor session** *session_number* **source remote vlan** *vlan-id*
5. **monitor session** *session_number* **destination** {**interface** *interface-id* [, | -] [**ingress** {**dot1q vlan** *vlan-id* | **untagged vlan** *vlan-id* | **vlan** *vlan-id*}]}
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 3	<p>no monitor session <i>{session_number all local remote}</i></p> <p>Example:</p> <pre>Device(config)# no monitor session 2</pre>	<p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	<p>monitor session <i>session_number</i> source remote vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 source remote vlan 901</pre>	<p>Specifies the RSPAN session and the source RSPAN VLAN.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor.
Step 5	<p>monitor session <i>session_number</i> destination <i>{interface interface-id [, -] [ingress {dot1q vlan vlan-id untagged vlan vlan-id vlan vlan-id}]}</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6</pre>	<p>Specifies the SPAN session, the destination port, the packet encapsulation, and the incoming VLAN and encapsulation.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, enter the number defined in Step 5. • In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port. • For <i>interface-id</i>, specify the destination interface. The destination interface must be a physical interface. • Though visible in the command-line help string, encapsulation replicate is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • Enter ingress with additional keywords to enable forwarding of incoming traffic on the destination port and to specify the encapsulation type: <ul style="list-style-type: none"> • dot1q vlan vlan-id—Forwards incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • untagged vlan <i>vlan-id</i> or vlan <i>vlan-id</i>—Forwards incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.
Step 6	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.
Step 7	show running-config Example: <pre>Device# show running-config</pre>	Verifies your entries.
Step 8	copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

Configuring an FSPAN Session

Follow these steps to create a SPAN session, specify the source (monitored) ports or VLANs and the destination (monitoring) ports, and configure FSPAN for the session.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** *{session_number | all | local | remote}*
4. **monitor session** *session_number* **source** *{interface interface-id | vlan vlan-id}* [, | -] *[both | rx | tx]*
5. **monitor session** *session_number* **destination** *{interface interface-id [, | -] [encapsulation replicate]}*
6. **monitor session** *session_number* **filter** *{ip | ipv6 | mac}* **access-group** *{access-list-number | name}*
7. **end**
8. **show running-config**
9. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	no monitor session { <i>session_number</i> all local remote } Example: <pre>Device(config)# no monitor session 2</pre>	Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	monitor session <i>session_number</i> source { interface <i>interface-id</i> vlan <i>vlan-id</i> } [, -] [both rx tx] Example: <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/1</pre>	Specifies the SPAN session and the source port (monitored port). <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). Valid port-channel numbers are 1 to 48. • For <i>vlan-id</i>, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). <p>Note A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</p> <ul style="list-style-type: none"> • (Optional) [, -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) [both rx tx]—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • both—Monitors both sent and received traffic. This is the default. • rx—Monitors received traffic. • tx—Monitors sent traffic. <p>Note You can use the monitor session session_number source command multiple times to configure multiple source ports.</p>
<p>Step 5</p>	<p>monitor session <i>session_number</i> destination {interface <i>interface-id</i> [, -] [encapsulation replicate]}</p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate</pre>	<p>Specifies the SPAN session and the destination port (monitoring port).</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For destination, specify the following parameters: <ul style="list-style-type: none"> • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) encapsulation replicate specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). <p>Note For local SPAN, you must use the same session number for the source and destination interfaces.</p> <p>You can use monitor session session_number destination command multiple times to configure multiple destination ports.</p>
<p>Step 6</p>	<p>monitor session <i>session_number</i> filter {ip ipv6 mac} access-group {<i>access-list-number</i> <i>name</i>}</p> <p>Example:</p> <pre>Device(config)# monitor session 2 filter ipv6 access-group 4</pre>	<p>Specifies the SPAN session, the types of packets to filter, and the ACLs to use in an FSPAN session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For <i>access-list-number</i>, specify the ACL number that you want to use to filter traffic. • For <i>name</i>, specify the ACL name that you want to use to filter traffic.

	Command or Action	Purpose
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 8	show running-config Example: Device# show running-config	Verifies your entries.
Step 9	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring an FRSPAN Session

Follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session_number* | **all** | **local** | **remote**}
4. **monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session_number* **destination remote vlan** *vlan-id*
6. **vlan** *vlan-id*
7. **remote-span**
8. **exit**
9. **monitor session** *session_number* **filter** {**ip** | **ipv6** | **mac**} **access-group** {*access-list-number* | *name*}
10. **end**
11. **show running-config**
12. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>no monitor session {<i>session_number</i> all local remote}</p> <p>Example:</p> <pre>Device(config)# no monitor session 2</pre>	<p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions.
Step 4	<p>monitor session <i>session_number</i> source {interface <i>interface-id</i> vlan <i>vlan-id</i>} [, -] [both rx tx]</p> <p>Example:</p> <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/1</pre>	<p>Specifies the SPAN session and the source port (monitored port).</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). Valid port-channel numbers are 1 to 48. • For <i>vlan-id</i>, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). <p>Note A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</p> <ul style="list-style-type: none"> • (Optional) [, -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) [both rx tx]—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • both—Monitors both sent and received traffic. This is the default. • rx—Monitors received traffic. • tx—Monitors sent traffic. <p>Note You can use the monitor session <i>session_number</i> source command multiple times to configure multiple source ports.</p>
Step 5	<p>monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination remote vlan 5</pre>	<p>Specifies the RSPAN session and the destination RSPAN VLAN.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, enter the number defined in Step 4. • For <i>vlan-id</i>, specify the destination RSPAN VLAN to monitor.
Step 6	<p>vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config)# vlan 10</pre>	<p>Enters the VLAN configuration mode. For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor.</p>
Step 7	<p>remote-span</p> <p>Example:</p> <pre>Device(config-vlan)# remote-span</pre>	<p>Specifies that the VLAN you specified in Step 5 is part of the RSPAN VLAN.</p>
Step 8	<p>exit</p> <p>Example:</p> <pre>Device(config-vlan)# exit</pre>	<p>Returns to global configuration mode.</p>
Step 9	<p>monitor session <i>session_number</i> filter {ip ipv6 mac} access-group {<i>access-list-number</i> <i>name</i>}</p> <p>Example:</p> <pre>Device(config)# monitor session 2 filter ip access-group 7</pre>	<p>Specifies the RSPAN session, the types of packets to filter, and the ACLs to use in an FRSPAN session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For <i>access-list-number</i>, specify the ACL number that you want to use to filter traffic. • For <i>name</i>, specify the ACL name that you want to use to filter traffic.
Step 10	<p>end</p> <p>Example:</p>	<p>Returns to privileged EXEC mode.</p>

	Command or Action	Purpose
	Device(config)# end	
Step 11	show running-config Example: Device# show running-config	Verifies your entries.
Step 12	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Monitoring SPAN and RSPAN Operations

The following table describes the command used to display SPAN and RSPAN operations configuration and results to monitor operations:

Table 58: Monitoring SPAN and RSPAN Operations

Command	Purpose
show monitor	Displays the current SPAN, RSPAN, FSPAN, or FRSPAN configuration.

SPAN and RSPAN Configuration Examples

Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1
Device(config)# monitor session 1 destination interface gigabitethernet1/0/2
encapsulation replicate
Device(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1
Device(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source vlan 1 - 3 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2
Device(config)# monitor session 2 source vlan 10
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with IEEE 802.1Q encapsulation and VLAN 6 as the default ingress VLAN:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source gigabitethernet1/0/1 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation
  replicate ingress dot1q vlan 6
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination interface gigabitethernet1/0/1
Device(config)# end
```

Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# vlan 901
Device(config-vlan)# remote span
Device(config-vlan)# end
```

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Device(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 1 source interface port-channel 2
Device(config)# monitor session 1 destination remote vlan 901
Device(config)# end
```

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination remote vlan 902
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 1 source remote vlan 901
Device(config)# monitor session 1 destination interface gigabitethernet2/0/1
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 2 source remote vlan 901
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6
Device(config)# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Wireshark

- Wireshark is supported on Supervisor Engine 7-E, Supervisor Engine 7L-E, Catalyst 3850, Catalyst 3650, Wireless LAN Controller 5700 Series, Catalyst 4500X-16, and Catalyst 4500X-32.
- IP Base image or IP Services image is required for Embedded Wireshark.

Restrictions for Wireshark

- Starting in Cisco IOS Release XE 3.3.0(SE), global packet capture on Wireshark is not supported.

- Capture filters are not supported.
- The CLI for configuring Wireshark requires that the feature be executed only from EXEC mode. Actions that usually occur in configuration submode (such as defining capture points), are handled at the EXEC mode instead. All key commands are not NVGEN'd and are not synchronized to the standby supervisor in NSF and SSO scenarios.
- Packets captured in the output direction of an interface might not reflect the changes made by rewrite (includes TTL, VLAN tag, CoS, checksum, MAC addresses, DSCP, precedent, UP, etc.).
- Limiting circular file storage by file size is not supported.

Wireless Packet Capture

- The only form of wireless capture is a CAPWAP tunnel capture.
- When capturing CAPWAP tunnels, no other interface types can be used as attachment points on the same capture point.
- Capturing multiple CAPWAP tunnels is supported.
- Core filters are not applied and should be omitted when capturing a CAPWAP tunnel.
- To capture a CAPWAP data tunnel, each CAPWAP tunnel is mapped to a physical port and an appropriate ACL will be applied to filter the traffic.
- To capture a CAPWAP non-data tunnel, the switch is set to capture traffic on all ports and apply an appropriate ACL to filter the traffic.
- To capture a CAPWAP tunnel, no matter what kind, the controller will be told to capture the traffic on all physical ports and apply an appropriate ACL to filter the traffic.

Configuration Limitations

- Starting from Cisco IOS release 16.1, as many as 8 capture points can be defined, but only one can be active at a time. You must stop one before you can start the other.
- You cannot use VRFs, management ports, and private VLANs as attachment points.
- Only one ACL (IPv4, IPv6 or MAC) is allowed in a Wireshark class map.
- Wireshark cannot capture packets on a destination SPAN port.
- Wireshark stops capturing packets when one of the attachment points (interfaces) attached to a capture point stops working. For example, if the device that is associated with an attachment point is unplugged from the . To resume capturing packets, restart manually.
- CPU-injected packets are considered control plane packets and are not captured on an interface egress capture.
- MAC ACL is only used for non-IP packets such as ARP. It will not be supported on a Layer 3 port or SVI.
- IPv6-based ACLs are not supported in VACL.
- Layer 2 EtherChannels are not supported. Individual members like GigabitEthernet 1 and GigabitEthernet 2 are supported on Layer 3 EtherChannels.

- ACL logging and Wireshark are incompatible. After Wireshark is activated, it takes priority. All traffic, including traffic captured by ACL logging on ports, will be redirected to Wireshark. We recommend that you deactivate ACL logging before you start Wireshark. Otherwise, Wireshark traffic is contaminated by ACL logging traffic.
- Wireshark does not capture packets dropped by floodblock.
- If you capture both PACL and RACL on the same port, only one copy is sent to the CPU. If you capture a DTLS-encrypted CAPWAP interface, two copies are sent to Wireshark, one encrypted and the other decrypted. The same behavior will occur if we capture a Layer 2 interface carrying DTLS-encrypted CAPWAP traffic. The core filter is based on the outer CAPWAP header.
- Control plane packets are not rate limited and do not impact performance. Use filters to limit control plane packet capture.

Information About Wireshark

Wireshark Overview

Wireshark is a packet analyzer program, formerly known as Ethereal, that supports multiple protocols and presents information in a text-based user interface.

The ability to capture and analyze traffic provides data on network activity. Prior to Cisco IOS Release XE 3.3.0(SE), only two features addressed this need: SPAN and debug platform packet. Both have limitations. SPAN is ideal for capturing packets, but can only deliver them by forwarding them to some specified local or remote destination; it provides no local display or analysis support.

So the need exists for a traffic capture and analysis mechanism that is applicable to both hardware and software forwarded traffic and that provides strong packet capture, display, and analysis support, preferably using a well known interface.

Wireshark dumps packets to a file using a well known format called .pcap, and is applied or enabled on individual interfaces. You specify an interface in EXEC mode along with the filter and other parameters. The Wireshark application is applied only when you enter a **start** command, and is removed only when Wireshark stops capturing packets either automatically or manually.

Note The current version of Wireshark installed on the switch is 1.10.8.

Capture Points

A capture point is the central policy definition of the Wireshark feature. The capture point describes all of the characteristics associated with a given instance of Wireshark: which packets to capture, where to capture them from, what to do with the captured packets, and when to stop. Capture points can be modified after creation, and do not become active until explicitly activated with a **start** command. This process is termed activating the capture point or starting the capture point. Capture points are identified by name and can also be manually or automatically deactivated or stopped.

Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.

In case of stacked systems, the capture point is activated on the active member. A switchover will terminate any active packet capture session and it will have to be restarted.

- [Example: Simple Capture and Store of Packets in Egress Direction](#), on page 798

Attachment Points

An attachment point is a point in the logical packet process path associated with a capture point. An attachment point is an attribute of the capture point. Packets that impact an attachment point are tested against capture point filters; packets that match are copied and sent to the associated Wireshark instance of the capture point. A specific capture point can be associated with multiple attachment points, with limits on mixing attachment points of different types. Some restrictions apply when you specify attachment points of different types. Attachment points are directional (input or output or both) with the exception of the Layer 2 VLAN attachment point, which is always bidirectional.

In case of stacked systems, the attachment points on all stack members are valid. EPC captures the packets from all the defined attachment points. However these packets are processed only on the active member.

Filters

Filters are attributes of a capture point that identify and limit the subset of traffic traveling through the attachment point of a capture point, which is copied and passed to Wireshark. To be displayed by Wireshark, a packet must pass through an attachment point, as well as all of the filters associated with the capture point.

A capture point has the following types of filters:

- Core system filter—The core system filter is applied by hardware, and its match criteria is limited by hardware. This filter determines whether hardware-forwarded traffic is copied to software for Wireshark purposes.
- Display filter—The display filter is applied by Wireshark. Packets that fail the display filter are not displayed.

Core System Filter

You can specify core system filter match criteria by using the class map or ACL, or explicitly by using the CLI.

Note When specifying CAPWAP as an attachment point, the core system filter is not used.

In some installations, you need to obtain authorization to modify the configuration, which can lead to extended delays if the approval process is lengthy. This can limit the ability of network administrators to monitor and analyze traffic. To address this situation, Wireshark supports explicit specification of core system filter match criteria from the EXEC mode CLI. The disadvantage is that the match criteria that you can specify is a limited subset of what class map supports, such as MAC, IP source and destination addresses, ether-type, IP protocol, and TCP/UDP source and destination ports.

If you prefer to use configuration mode, you can define ACLs or have class maps refer capture points to them. Explicit and ACL-based match criteria are used internally to construct class maps and policy maps.

Note The ACL and class map configuration are part of the system and not aspects of the Wireshark feature.

Display Filter

With the display filter, you can direct Wireshark to further narrow the set of packets to display when decoding and displaying from a .pcap file.

Related Topics

[Additional References](#), on page 800

Actions

Wireshark can be invoked on live traffic or on a previously existing .pcap file. When invoked on live traffic, it can perform four types of actions on packets that pass its display filters:

- Captures to buffer in memory to decode and analyze and store
- Stores to a .pcap file
- Decodes and displays

- Stores and displays

When invoked on a .pcap file only, only the decode and display action is applicable.

Storage of Captured Packets to Buffer in Memory

Packets can be stored in the capture buffer in memory for subsequent decode, analysis, or storage to a .pcap file.

The capture buffer can be in linear or circular mode. In linear mode, new packets are discarded when the buffer is full. In circular mode, if the buffer is full, the oldest packets are discarded to accommodate the new packets. Although the buffer can also be cleared when needed, this mode is mainly used for debugging network traffic. However, it is not possible to only clear the contents of the buffer alone without deleting it. Stop the current captures and restart the capture again for this to take effect.

Note If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

Storage of Captured Packets to a .pcap File

Note When WireShark is used on switches in a stack, packet captures can be stored only on flash or USB flash devices connected to the active switch.

For example, if flash1 is connected to the active switch, and flash2 is connected to the secondary switch, only flash1 can be used to store packet captures.

Attempts to store packet captures on devices other than flash or USB flash devices connected to the active switch will probably result in errors.

Wireshark can store captured packets to a .pcap file. The capture file can be located on the following storage devices:

- on-board flash storage (flash:)
- USB drive (usbflash0:)

Note Attempts to store packet captures on unsupported devices or devices not connected to the active switch will probably result in errors.

When configuring a Wireshark capture point, you can associate a filename. When the capture point is activated, Wireshark creates a file with the specified name and writes packets to it. If the file already exists at the time of creation of the capture point, Wireshark queries you as to whether the file can be overwritten. If the file already exists at the time of activating the capture point, Wireshark will overwrite the existing file. Only one capture point may be associated with a given filename.

If the destination of the Wireshark writing process is full, Wireshark fails with partial data in the file. You must ensure that there is sufficient space in the file system before you start the capture session. With Cisco IOS Release IOS XE 3.3.0(SE), the file system full status is not detected for some storage devices.

You can reduce the required storage space by retaining only a segment, instead of the entire packet. Typically, you do not require details beyond the first 64 or 128 bytes. The default behavior is to store the entire packet.

To avoid possible packet drops when processing and writing to the file system, Wireshark can optionally use a memory buffer to temporarily hold packets as they arrive. Memory buffer size can be specified when the capture point is associated with a .pcap file.

Packet Decoding and Display

Wireshark can decode and display packets to the console. This functionality is possible for capture points applied to live traffic and for capture points applied to a previously existing .pcap file.

Note Decoding and displaying packets may be CPU intensive.

Wireshark can decode and display packet details for a wide variety of packet formats. The details are displayed by entering the **monitor capture name start** command with one of the following keyword options, which place you into a display and decode mode:

- **brief**—Displays one line per packet (the default).
- **detailed**—Decodes and displays all the fields of all the packets whose protocols are supported. Detailed modes require more CPU than the other two modes.
- **(hexadecimal) dump**—Displays one line per packet as a hexadecimal dump of the packet data and the printable characters of each packet.

When you enter the **capture** command with the decode and display option, the Wireshark output is returned to Cisco IOS and displayed on the console unchanged.

Live Traffic Display

Wireshark receives copies of packets from the core system. Wireshark applies its display filters to discard uninteresting packets, and then decodes and displays the remaining packets.

.pcap File Display

Wireshark can decode and display packets from a previously stored .pcap file and direct the display filter to selectively displayed packets.

Packet Storage and Display

Functionally, this mode is a combination of the previous two modes. Wireshark stores packets in the specified .pcap file and decodes and displays them to the console. Only the core filters are applicable here.

Wireshark Capture Point Activation and Deactivation

After a Wireshark capture point has been defined with its attachment points, filters, actions, and other options, it must be activated. Until the capture point is activated, it does not actually capture packets.

Before a capture point is activated, some functional checks are performed. A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.*

Note *When performing a wireless capture with a CAPWAP tunneling interface, the core system filter is not required and cannot be used.

The display filters are specified as needed.

After Wireshark capture points are activated, they can be deactivated in multiple ways. A capture point that is storing only packets to a .pcap file can be halted manually or configured with time or packet limits, after which the capture point halts automatically.

When a Wireshark capture point is activated, a fixed rate policer is applied automatically in the hardware so that the CPU is not flooded with Wireshark-directed packets. The disadvantage of the rate policer is that you cannot capture contiguous packets beyond the established rate even if more resources are available.

The set packet capture rate is 1000 packets per sec (pps). The 1000 pps limit is applied to the sum of all attachment points. For example, if we have a capture session with 3 attachment points, the rates of all 3 attachment points added together is policed to 1000 pps.

Note Policer is not supported for control-plane packet capture. When activating control-plane capture points, you need to be extra cautious, so that it does not flood the CPU.

Wireshark Features

This section describes how Wireshark features function in the environment:

- If port security and Wireshark are applied on an ingress capture, a packet that is dropped by port security will still be captured by Wireshark. If port security is applied on an ingress capture, and Wireshark is applied on an egress capture, a packet that is dropped by port security will not be captured by Wireshark.
- Packets dropped by Dynamic ARP Inspection (DAI) are not captured by Wireshark.
- If a port that is in STP blocked state is used as an attachment point and the core filter is matched, Wireshark will capture the packets that come into the port, even though the packets will be dropped by the switch.
- Classification-based security features—Packets that are dropped by input classification-based security features (such as ACLs and IPSG) are not caught by Wireshark capture points that are connected to attachment points at the same layer. In contrast, packets that are dropped by output classification-based security features are caught by Wireshark capture points that are connected to attachment points at the same layer. The logical model is that the Wireshark attachment point occurs after the security feature lookup on the input side, and symmetrically before the security feature lookup on the output side.

On ingress, a packet goes through a Layer 2 port, a VLAN, and a Layer 3 port/SVI. On egress, the packet goes through a Layer 3 port/SVI, a VLAN, and a Layer 2 port. If the attachment point is before the point where the packet is dropped, Wireshark will capture the packet. Otherwise, Wireshark will not capture the packet. For example, Wireshark capture policies connected to Layer 2 attachment points in the input direction capture packets dropped by Layer 3 classification-based security features. Symmetrically, Wireshark capture policies attached to Layer 3 attachment points in the output direction capture packets dropped by Layer 2 classification-based security features.

- Routed ports and switch virtual interfaces (SVIs)—Wireshark cannot capture the output of an SVI because the packets that go out of an SVI's output are generated by CPU. To capture these packets, include the control plane as an attachment point.
- VLANs—Starting with Cisco IOS Release 16.1, when a VLAN is used as a Wireshark attachment point, packet capture is supported on L2 and L3 in both input and output directions.
- Redirection features—In the input direction, features traffic redirected by Layer 3 (such as PBR and WCCP) are logically later than Layer 3 Wireshark attachment points. Wireshark captures these packets even though they might later be redirected out another Layer 3 interface. Symmetrically, output features redirected by Layer 3 (such as egress WCCP) are logically prior to Layer 3 Wireshark attachment points, and Wireshark will not capture them.
- SPAN—Wireshark cannot capture packets on interface configured as a SPAN destination.
- SPAN—Wireshark is able to capture packets on interfaces configured as a SPAN source in the ingress direction, and may be available for egress direction too.
- You can capture packets from a maximum of 1000 VLANs at a time, if no ACLs are applied. If ACLs are applied, the hardware will have less space for Wireshark to use. As a result, the maximum number of VLANs than can be used for packet capture at a time will be lower. Using more than 1000 VLANs tunnels at a time or extensive ACLs might have unpredictable results. For example, mobility may go down.

Note Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

Wireless Packet Capture in Wireshark

- Wireless traffic is encapsulated inside CAPWAP packets. However, capturing only a particular wireless client's traffic inside a CAPWAP tunnel is not supported when using the CAPWAP tunnel as an attachment point. To capture only a particular wireless client's traffic, use the client VLAN as an attachment point and formulate the core filter accordingly.
- Limited decoding of inner wireless traffic is supported. Decoding of inner wireless packets inside encrypted CAPWAP tunnels is not supported.
- No other interface type can be used with the CAPWAP tunneling interface on the same capture point. A CAPWAP tunneling interface and a Level 2 port cannot be attachment points on the same capture point.
- You cannot specify a core filter when capturing packets for Wireshark via the CAPWAP tunnel. However, you can use the Wireshark display filters for filtering wireless client traffic against a specific wireless client.

- You can capture packets from a maximum of 135 CAPWAP tunnels at a time if no ACLs are applied. If ACLs are applied, the hardware memory will have less space for Wireshark to use. As a result, the maximum number of CAPWAP tunnels that can be used for packet capture at a time will be lower. Using more than 135 CAPWAP tunnels at a time or using extensive ACLs might have unpredictable results. For example, mobility may go down.

Note Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

Guidelines for Wireshark

- During Wireshark packet capture, hardware forwarding happens concurrently.
- Before starting a Wireshark capture process, ensure that CPU usage is moderate and that sufficient memory (at least 200 MB) is available.
- If you plan to store packets to a storage file, ensure that sufficient space is available before beginning a Wireshark capture process.
- The CPU usage during Wireshark capture depends on how many packets match the specified conditions and on the intended actions for the matched packets (store, decode and display, or both).
- Where possible, keep the capture to the minimum (limit by packets, duration) to avoid high CPU usage and other undesirable conditions.
- Because packet forwarding typically occurs in hardware, packets are not copied to the CPU for software processing. For Wireshark packet capture, packets are copied and delivered to the CPU, which causes an increase in CPU usage.

To avoid high CPU usage, do the following:

- Attach only relevant ports.
 - Use a class map, and secondarily, an access list to express match conditions. If neither is viable, use an explicit, in-line filter.
 - Adhere closely to the filter rules. Restrict the traffic type (such as, IPv4 only) with a restrictive, rather than relaxed ACL, which elicits unwanted traffic.
- Always limit packet capture to either a shorter duration or a smaller packet number. The parameters of the capture command enable you to specify the following:
 - Capture duration
 - Number of packets captured
 - File size
 - Packet segment size
 - Run a capture session without limits if you know that very little traffic matches the core filter.

- You might experience high CPU (or memory) usage if:
 - You leave a capture session enabled and unattended for a long period of time, resulting in unanticipated bursts of traffic.
 - You launch a capture session with ring files or capture buffer and leave it unattended for a long time, resulting in performance or system health issues.
- During a capture session, watch for high CPU usage and memory consumption due to Wireshark that may impact performance or health. If these situations arise, stop the Wireshark session immediately.
- Avoid decoding and displaying packets from a .pcap file for a large file. Instead, transfer the .pcap file to a PC and run Wireshark on the PC.
- You can define up to eight Wireshark instances. An active **show** command that decodes and displays packets from a .pcap file or capture buffer counts as one instance. However, only one of the instances can be active.
- Whenever an ACL that is associated with a running capture is modified, you must restart the capture for the ACL modifications to take effect. If you do not restart the capture, it will continue to use the original ACL as if it had not been modified.
- To avoid packet loss, consider the following:
 - Use store-only (when you do not specify the display option) while capturing live packets rather than decode and display, which is a CPU-intensive operation (especially in detailed mode).
 - If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.
 - If you use the default buffer size and see that you are losing packets, you can increase the buffer size to avoid losing packets.
 - Writing to flash disk is a CPU-intensive operation, so if the capture rate is insufficient, you may want to use a buffer capture.
 - The Wireshark capture session always operates in streaming mode at the rate of 1000 pps.
- The streaming capture mode rate is 1000 pps.
- If you want to decode and display live packets in the console window, ensure that the Wireshark session is bounded by a short capture duration.

**Warning**

A Wireshark session with either a longer duration limit or no capture duration (using a terminal with no auto-more support using the **term len 0** command) may make the console or terminal unusable.

- When using Wireshark to capture live traffic that leads to high CPU, usage, consider applying a QoS policy temporarily to limit the actual traffic until the capture process concludes.
- All Wireshark-related commands are in EXEC mode; no configuration commands exist for Wireshark. If you need to use access list or class-map in the Wireshark CLI, you must define an access list and class map with configuration commands.

- No specific order applies when defining a capture point; you can define capture point parameters in any order, provided that CLI allows this. The Wireshark CLI allows as many parameters as possible on a single line. This limits the number of commands required to define a capture point.
- All parameters except attachment points take a single value. Generally, you can replace the value with a new one by reentering the command. After user confirmation, the system accepts the new value and overrides the older one. A **no** form of the command is unnecessary to provide a new value, but it is necessary to remove a parameter.
- Wireshark allows you to specify one or more attachment points. To add more than one attachment point, reenter the command with the new attachment point. To remove an attachment point, use the **no** form of the command. You can specify an interface range as an attachment point. For example, enter **monitor capture mycap interface GigabitEthernet1/0/1 in** where interface GigabitEthernet1/0/1 is an attachment point.

If you also need to attach interface GigabitEthernet1/0/2, specify it in another line as follows:

```
monitor capture mycap interface GigabitEthernet1/0/2 in
```

- You cannot make changes to a capture point when the capture is active.
- The action you want to perform determines which parameters are mandatory. The Wireshark CLI allows you to specify or modify any parameter prior to entering the **start** command. When you enter the **start** command, Wireshark will start only after determining that all mandatory parameters have been provided.
- If the file already exists at the time of creation of the capture point, Wireshark queries you as to whether the file can be overwritten. If the file already exists at the time of activating the capture point, Wireshark will overwrite the existing file.
- The core filter can be an explicit filter, access list, or class map. Specifying a newer filter of these types replaces the existing one.

Note A core filter is required except when using a CAPWAP tunnel interface as a capture point attachment point.

- You can terminate a Wireshark session with an explicit **stop** command or by entering **q** in automore mode. The session could terminate itself automatically when a stop condition such as duration or packet capture limit is met, or if an internal error occurs, or resource is full (specifically if disk is full in file mode).
- Dropped packets will not be shown at the end of the capture. However, only the count of dropped, oversized packets will be displayed.

Default Wireshark Configuration

The table below shows the default Wireshark configuration.

Feature	Default Setting
Duration	No limit
Packets	No limit

Feature	Default Setting
Packet-length	No limit (full packet)
File size	No limit
Ring file storage	No
Buffer storage mode	Linear

How to Configure Wireshark

To configure Wireshark, perform these basic steps.

1. Define a capture point.
2. (Optional) Add or modify the capture point's parameters.
3. Activate or deactivate a capture point.
4. Delete the capture point when you are no longer using it.

Defining a Capture Point

The example in this procedure defines a very simple capture point. If you choose, you can define a capture point and all of its parameters with one instance of the **monitor capture** command.

Note You must define an attachment point, direction of capture, and core filter to have a functional capture point.

An exception to needing to define a core filter is when you are defining a wireless capture point using a CAPWAP tunneling interface. In this case, you do not define your core filter. It cannot be used.

Follow these steps to define a capture point.

SUMMARY STEPS

1. `enable`
2. `show capwap summary`
3. `monitor capture {capture-name} {interface interface-type interface-id | control-plane} {in | out | both}`
4. `monitor capture {capture-name} [match {any | ipv4 any any | ipv6} any any]`
5. `show monitor capture {capture-name} [parameter]`
6. `show running-config`
7. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	<p><code>show capwap summary</code></p> <p>Example:</p> <pre>Device# show capwap summary</pre>	<p>Displays the CAPWAP tunnels available as attachment points for a wireless capture.</p> <p>Note Use this command only if you are using a CAPWAP tunnel as an attachment point to perform a wireless capture. See the CAPWAP example in the examples section.</p>
Step 3	<p><code>monitor capture {capture-name} {interface interface-type interface-id control-plane} {in out both}</code></p> <p>Example:</p> <pre>Device# monitor capture mycap interface GigabitEthernet1/0/1 in</pre>	<p>Defines the capture point, specifies the attachment point with which the capture point is associated, and specifies the direction of the capture.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> • <i>capture-name</i>—Specifies the name of the capture point to be defined (mycap is used in the example). Capture Name should be less than or equal to 8 characters. Only alphanumeric characters and underscore (_) is permitted • (Optional) interface <i>interface-type interface-id</i>—Specifies the attachment point with which the capture point is associated (GigabitEthernet1/0/1 is used in the example). <p>Note Optionally, you can define multiple attachment points and all of the parameters for this capture point with this one command instance. These parameters are discussed in the instructions for modifying capture point parameters. Range support is also available both for adding and removing attachment points.</p>

	Command or Action	Purpose
		<p>Use one of the following for <i>interface-type</i>:</p> <ul style="list-style-type: none"> • GigabitEthernet—Specifies the attachment point as GigabitEthernet. • vlan—Specifies the attachment point as a VLAN. <p>Note Only ingress capture (in) is allowed when using this interface as an attachment point.</p> <ul style="list-style-type: none"> • capwap—Specifies the attachment point as a CAPWAP tunnel. <p>Note When using this interface as an attachment point, a core filter cannot be used.</p> <ul style="list-style-type: none"> • (Optional) control-plane—Specifies the control plane as an attachment point. • in out both—Specifies the direction of capture.
<p>Step 4</p>	<p>monitor capture {<i>capture-name</i>} [match {any ipv4 any any ipv6 any any}]</p> <p>Example:</p> <pre>Device# monitor capture mycap interface GigabitEthernet1/0/1 in match any</pre>	<p>Defines the core system filter.</p> <p>Note When using the CAPWAP tunneling interface as an attachment point, do not perform this step because a core filter cannot be used.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> • <i>capture-name</i>—Specifies the name of the capture point to be defined (mycap is used in the example). • match—Specifies a filter. The first filter defined is the core filter. <p>Note A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.</p> <ul style="list-style-type: none"> • ipv4—Specifies an IP version 4 filter. • ipv6—Specifies an IP version 6 filter.
<p>Step 5</p>	<p>show monitor capture {<i>capture-name</i>} [parameter]</p> <p>Example:</p> <pre>Device# show monitor capture mycap parameter monitor capture mycap interface GigabitEthernet1/0/1 in monitor capture mycap match any</pre>	<p>Displays the capture point parameters that you defined in Step 2 and confirms that you defined a capture point.</p>

	Command or Action	Purpose
Step 6	show running-config Example: Device# show running-config	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Example

To define a capture point with a CAPWAP attachment point:

```
Device# show capwap summary
```

```
CAPWAP Tunnels General Statistics:
  Number of Capwap Data Tunnels      = 1
  Number of Capwap Mobility Tunnels   = 0
  Number of Capwap Multicast Tunnels  = 0
```

Name	APName	Type	PhyPortIf	Mode	McastIf
Ca0	AP442b.03a9.6715	data	Gi3/0/6	unicast	-

Name	SrcIP	SrcPort	DestIP	DstPort	DtlsEn	MTU	Xact
Ca0	10.10.14.32	5247	10.10.14.2	38514	No	1449	0

```
Device# monitor capture mycap interface capwap 0 both
Device# monitor capture mycap file location flash:mycap.pcap
Device# monitor capture mycap file buffer-size 1
Device# monitor capture mycap start
```

```
*Aug 20 11:02:21.983: %BUFCAP-6-ENABLE: Capture Point mycap enabled.on
```

```
Device# show monitor capture mycap parameter
  monitor capture mycap interface capwap 0 in
  monitor capture mycap interface capwap 0 out
  monitor capture mycap file location flash:mycap.pcap buffer-size 1
```

```
Device#
```

```
Device# show monitor capture mycap
```

```
Status Information for Capture mycap
```

```
Target Type:
Interface: CAPWAP,
  Ingress:
0
  Egress:
0
Status : Active

```

What to do next

You can add additional attachment points, modify the parameters of your capture point, then activate it, or if you want to use your capture point just as it is, you can now activate it.

Note You cannot change a capture point's parameters using the methods presented in this topic.

If the user enters an incorrect capture name, or an invalid/non existing attachment point, the switch will show errors like "*Capture Name should be less than or equal to 8 characters. Only alphanumeric characters and underscore (_) is permitted*" and "*% Invalid input detected at '^' marker*" respectively.

Adding or Modifying Capture Point Parameters

Although listed in sequence, the steps to specify values for the parameters can be executed in any order. You can also specify them in one, two, or several lines. Except for attachment points, which can be multiple, you can replace any value with a more recent value by redefining the same option. You will need to confirm interactively when certain parameters already specified are being modified.

Follow these steps to modify a capture point's parameters.

Before you begin

A capture point must be defined before you can use these instructions.

SUMMARY STEPS

1. **enable**
2. **monitor capture** {*capture-name*} **match** {**any** | **mac** *mac-match-string* | **ipv4** {**any** | **host** | **protocol**}{**any** | **host**} | **ipv6** {**any** | **host** | **protocol**}{**any** | **host**}}
3. **monitor capture** {*capture-name*} **limit** { [**duration** *seconds*] [**packet-length** *size*] [**packets** *num*] }
4. **monitor capture** {*capture-name*} **file** {**location** *filename*}
5. **monitor capture** {*capture-name*} **file** {**buffer-size** *size*}
6. **show monitor capture** {*capture-name*} [**parameter**]
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	monitor capture { <i>capture-name</i> } match { any mac <i>mac-match-string</i> ipv4 { any host protocol } { any host } ipv6 { any host protocol } { any host }} Example: Device# monitor capture mycap match ipv4 any any	Defines the core system filter (ipv4 any any), defined either explicitly, through ACL or through a class map. Note If you are defining a wireless capture point using a CAPWAP tunneling interface, this command will have no effect, so it should not be used.
Step 3	monitor capture { <i>capture-name</i> } limit {[duration <i>seconds</i>] [packet-length <i>size</i>] [packets <i>num</i>]} Example: Device# monitor capture mycap limit duration 60 packet-len 400	Specifies the session limit in seconds (60), packets captured, or the packet segment length to be retained by Wireshark (400).
Step 4	monitor capture { <i>capture-name</i> } file { location <i>filename</i> } Example: Device# monitor capture mycap file location flash:mycap.pcap	Specifies the file association, if the capture point intends to capture packets rather than only display them. Note If the file already exists, you have to confirm if it can be overwritten. Note File option does not exist on LAN base license.
Step 5	monitor capture { <i>capture-name</i> } file { buffer-size <i>size</i> } Example: Device# monitor capture mycap file buffer-size 100	Specifies the size of the memory buffer used by Wireshark to handle traffic bursts.
Step 6	show monitor capture { <i>capture-name</i> } [parameter] Example: Device# show monitor capture mycap parameter monitor capture mycap interface GigabitEthernet1/0/1 in monitor capture mycap match ipv4 any any monitor capture mycap limit duration 60 packet-len 400 monitor capture point mycap file location bootdisk:mycap.pcap monitor capture mycap file buffer-size 100	Displays the capture point parameters that you defined previously.
Step 7	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config)# end	

Examples

Modifying Parameters

Associating or Disassociating a Capture File

```
Device# monitor capture point mycap file location flash:mycap.pcap
Device# no monitor capture mycap file
```

Specifying a Memory Buffer Size for Packet Burst Handling

```
Device# monitor capture mycap buffer size 100
```

Defining an Explicit Core System Filter to Match Both IPv4 and IPv6

```
Device# monitor capture mycap match any
```

What to do next

if your capture point contains all of the parameters you want, activate it.

Deleting Capture Point Parameters

Although listed in sequence, the steps to delete parameters can be executed in any order. You can also delete them in one, two, or several lines. Except for attachment points, which can be multiple, you can delete any parameter.

Follow these steps to delete a capture point's parameters.

Before you begin

A capture point parameter must be defined before you can use these instructions to delete it.

SUMMARY STEPS

1. **enable**

2. **no monitor capture** {*capture-name*} **match**
3. **no monitor capture** {*capture-name*} **limit** [*duration*] [*packet-length*] [*packets*]
4. **no monitor capture** {*capture-name*} **file** [*location*] [*buffer-size*]
5. **show monitor capture** {*capture-name*} [*parameter*]
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	no monitor capture { <i>capture-name</i> } match Example: Device# no monitor capture mycap match	Deletes all filters defined on capture point (mycap).
Step 3	no monitor capture { <i>capture-name</i> } limit [<i>duration</i>] [<i>packet-length</i>] [<i>packets</i>] Example: Device# no monitor capture mycap limit duration packet-len Device# no monitor capture mycap limit	Deletes the session time limit and the packet segment length to be retained by Wireshark. It leaves other specified limits in place. Deletes all limits on Wireshark.
Step 4	no monitor capture { <i>capture-name</i> } file [<i>location</i>] [<i>buffer-size</i>] Example: Device# no monitor capture mycap file Device# no monitor capture mycap file location	Deletes the file association. The capture point will no longer capture packets. It will only display them. Deletes the file location association. The file location will no longer be associated with the capture point. However, other defined file association will be unaffected by this action.
Step 5	show monitor capture { <i>capture-name</i> } [<i>parameter</i>] Example: Device# show monitor capture mycap parameter monitor capture mycap interface GigabitEthernet1/0/1 in	Displays the capture point parameters that remain defined after your parameter deletion operations. This command can be run at any point in the procedure to see what parameters are associated with a capture point.
Step 6	end Example: Device(config)# end	Returns to privileged EXEC mode.

What to do next

If your capture point contains all of the parameters you want, activate it.

Note If the parameters are deleted when the capture point is active, the switch will show an error "*Capture is active*".

Deleting a Capture Point

Follow these steps to delete a capture point.

Before you begin

A capture point must be defined before you can use these instructions to delete it. You have to stop the capture point before you can delete it.

SUMMARY STEPS

1. **enable**
2. **no monitor capture** { *capture-name* }
3. **show monitor capture** { *capture-name* } [**parameter**]
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	no monitor capture { <i>capture-name</i> } Example: Device# no monitor capture mycap	Deletes the specified capture point (mycap).

	Command or Action	Purpose
Step 3	show monitor capture <i>{capture-name}</i> [parameter] Example: Device# show monitor capture mycap parameter Capture mycap does not exist	Displays a message indicating that the specified capture point does not exist because it has been deleted.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 5	show running-config Example: Device# show running-config	Verifies your entries.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

You can define a new capture point with the same name as the one you deleted. These instructions are usually performed when one wants to start over with defining a capture point.

[Example: Simple Capture and Store of Packets in Egress Direction](#), on page 798

Activating and Deactivating a Capture Point

Follow these steps to activate or deactivate a capture point.

Before you begin

A capture point can be activated even if an attachment point and a core system filter have been defined and the associated filename already exists. In such an instance, the existing file will be overwritten.

A capture point with no associated filename can only be activated to display. When the filename is not specified, the packets are captured into the buffer. Live display (display during capture) is available in both file and buffer modes.

If no display filters are specified, packets are not displayed live, and all the packets captured by the core system filter are displayed. The default display mode is brief.

Note When using a CAPWAP tunneling interface as an attachment point, core filters are not used, so there is no requirement to define them in this case.

SUMMARY STEPS

1. **enable**
2. **monitor capture** {*capture-name*} **start** [**display** [**display-filter** *filter-string*]] [**brief** | **detailed** | **dump**]
3. **monitor capture** {*capture-name*} **stop**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	monitor capture { <i>capture-name</i> } start [display [display-filter <i>filter-string</i>]] [brief detailed dump] Example: Device# monitor capture mycap start display display-filter "stp"	Activates a capture point and filters the display, so only packets containing "stp" are displayed.
Step 3	monitor capture { <i>capture-name</i> } stop Example: Device# monitor capture name stop	Deactivates a capture point.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 5	show running-config Example: Device# show running-config	Verifies your entries.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

While activating and deactivating a capture point, you could encounter a few errors. Here are examples of some of the possible errors.

Missing attachment point on activation

```
Switch#monitor capture mycap match any
Switch#monitor capture mycap start
No Target is attached to capture failed to disable provision featurefailed to remove
policyfailed to disable provision featurefailed to remove policyfailed to disable provision
featurefailed to remove policy
Capture statistics collected at software (Buffer):

Clearing the Capture Point Buffer

Follow these steps to clear the buffer contents or save them to an external file for storage.

Note If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss. Do not try to clear buffer on an active capture point.

Note Clearing buffer on an active capture point is supported only on Lan Base as this only clears the content. On all other licenses, it deletes the buffer itself, hence cannot be run during active capture.

SUMMARY STEPS

1. **enable**
2. **monitor capture** *{capture-name}* [**clear** | **export filename**]
3. **end**
4. **show running-config**
5. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	monitor capture <i>{capture-name}</i> [clear export filename] Example: Device# monitor capture mycap clear	Clear - Completely deletes the buffer. Note When the clear command is run, <ul style="list-style-type: none"> • On Lan base - the command clears the buffer contents without deleting the buffer • On all other licenses - the command deletes the buffer itself. Export - Saves the captured packets in the buffer as well as deletes the buffer.

	Command or Action	Purpose
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 4	show running-config Example: Device# show running-config	Verifies your entries.
Step 5	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Examples: Capture Point Buffer Handling

Exporting Capture to a File

```
Device# monitor capture mycap export flash:mycap.pcap
```

```
Storage configured as File for this capture
```

Clearing Capture Point Buffer

```
Device# monitor capture mycap clear
```

```
Capture configured with file options
```

What to do next

Note If you try to clear the capture point buffer on licenses other than LAN Base, the switch will show an error "*Failed to clear capture buffer : Capture Buffer BUSY*".

Monitoring Wireshark

The commands in this table are used to monitor Wireshark.

Command	Purpose
<code>show monitor capture [capture-name]</code>	Displays the capture point state so that you can see what capture points are defined, what their attributes are, and whether they are active. When capture point name is specified, it displays specific capture point's details.
<code>show monitor capture [capture-name parameter]</code>	Displays the capture point parameters.
<code>show capwap summary</code>	Displays all the CAPWAP tunnels on the . Use this command to determine which CAPWAP tunnels are available to use for a wireless capture.

Configuration Examples for Wireshark

Example: Displaying a Brief Output from a .pcap File

You can display the output from a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap brief
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x002e,

      [Length: 72]

Frame 2: 114 bytes on wire (912 bits), 114 bytes captured (912 bits) on interface 0
Interface id: 0

```

Example: Simple Capture and Display

This example shows how to monitor traffic in the Layer 3 interface Gigabit Ethernet 1/0/1:

Step 1: Define a capture point to match on the relevant traffic by entering:

```

Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 50
Device# monitor capture mycap buffer size 100

```

To avoid high CPU utilization, a low packet count and duration as limits has been set.

Step 2: Confirm that the capture point has been correctly defined by entering:

```

Device# show monitor capture mycap parameter
      monitor capture mycap interface GigabitEthernet1/0/3 in
      monitor capture mycap match ipv4 any any
      monitor capture mycap buffer size 100

```

```

monitor capture mycap limit packets 50 duration 60

Device# show monitor capture mycap
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
  Buffer Size (in MB): 100
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 50
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packet sampling rate: 0 (no sampling)

```

Step 3: Start the capture process and display the results.

```

Device# monitor capture mycap start display
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1  0.000000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030, seq=0/0,
    ttl=254
  2  0.003682  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=1/256, ttl=254
  3  0.006586  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=2/512, ttl=254
  4  0.008941  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=3/768, ttl=254
  5  0.011138  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=4/1024, ttl=254
  6  0.014099  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=5/1280, ttl=254
  7  0.016868  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=6/1536, ttl=254
  8  0.019210  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=7/1792, ttl=254
  9  0.024785  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
    seq=8/2048, ttl=254
--More--

```

Step 4: Delete the capture point by entering:

```
Device# no monitor capture mycap
```

Note A **stop** command is not required in this particular case since we have set a limit and the capture will automatically stop once that limit is reached.

For more information on syntax to be used for pcap statistics, refer the "*Additional References*" section.

Example: Simple Capture and Store

This example shows how to capture packets to a filter:

Step 1: Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 50
Device# monitor capture mycap file location flash:mycap.pcap
```

Step 2: Confirm that the capture point has been correctly defined by entering:

```
Device# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet1/0/3 in
monitor capture mycap match ipv4 any any
monitor capture mycap file location flash:mycap.pcap
monitor capture mycap limit packets 50 duration 60
```

```
Device# show monitor capture mycap
```

```
Status Information for Capture mycap
Target Type:
Interface: GigabitEthernet1/0/3, Direction: in
Status : Inactive
Filter Details:
IPv4
Source IP: any
Destination IP: any
Protocol: any
Buffer Details:
Buffer Type: LINEAR (default)
File Details:
Associated file name: flash:mycap.pcap
Limit Details:
Number of Packets to capture: 50
Packet Capture duration: 60
Packet Size to capture: 0 (no limit)
Packet sampling rate: 0 (no sampling)
```

Step 3: Launch packet capture by entering:

```
Device# monitor capture mycap start
```

Step 4: Display extended capture statistics during runtime by entering:

```

Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 15 seconds
  Packets received - 40
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 40
  Bytes received - 7280
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 4560

```

Step 5: After sufficient time has passed, stop the capture by entering:

```

Device# monitor capture mycap stop
Capture statistics collected at software (Buffer & Wireshark):
  Capture duration - 20 seconds
  Packets received - 50
  Packets dropped - 0
  Packets oversized - 0

```

Note Alternatively, you could allow the capture operation stop automatically after the time has elapsed or the packet count has been met.

The mycap.pcap file now contains the captured packets.

Step 6: Display extended capture statistics after stop by entering:

```

Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 20 seconds
  Packets received - 50
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 50
  Bytes received - 8190
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 5130

```

Step 7: Display the packets by entering:

```

Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,

Example: Using Buffer Capture

This example shows how to use buffer capture:

Step 1: Launch a capture session with the buffer capture option by entering:

```

Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap buffer circular size 1
Device# monitor capture mycap start

```

Step 2: Determine whether the capture is active by entering:

```

Device# show monitor capture mycap
Status Information for Capture mycap
Target Type:
Interface: GigabitEthernet1/0/3, Direction: in
Status : Active
Filter Details:
IPv4
Source IP: any

```

```

Destination IP: any
Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Maximum number of packets to capture per second: 1000
  Packet sampling rate: 0 (no sampling)

```

Step 3: Display extended capture statistics during runtime by entering:

```

Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 88 seconds
  Packets received - 1000
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 1000
  Bytes received - 182000
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 114000

```

Step 4: Stop the capture by entering:

```

Device# monitor capture mycap stop
Capture statistics collected at software (Buffer):
  Capture duration - 2185 seconds
  Packets received - 51500
  Packets dropped - 0
  Packets oversized - 0

```

Step 5: Display extended capture statistics after stop by entering:

```

Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 156 seconds
  Packets received - 2000
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 2000
  Bytes received - 364000
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 228000

```

Step 6: Determine whether the capture is active by entering:

```

Device# show monitor capture mycap
Status Information for Capture mycap
  Target Type:
    Interface: GigabitEthernet1/0/3, Direction: in
    Status : Inactive
  Filter Details:

```

```

IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated

seq=40059/31644, ttl=254
  4  0.000073  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40060/31900, ttl=254
  5  0.000094  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40061/32156, ttl=254
  6  0.000115  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40062/32412, ttl=254
  7  0.000137  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40063/32668, ttl=254
  8  0.000158  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40064/32924, ttl=254
  9  0.000179  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40065/33180, ttl=254
 10  0.000200  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40066/33436, ttl=254
 11  0.000221  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40067/33692, ttl=254
 12  0.000243  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40068/33948, ttl=254
--More--

```

Notice that the packets have been buffered.

Step 8: Display the packets in other display modes.

```

Device# show monitor capture mycap buffer detailed
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

Frame 1: 114 bytes on wire (912 bits), 114 bytes captured (912 bits) on interface 0
Interface id: 0
Encapsulation type: Ethernet (1)
Arrival Time: Nov  6, 2015 18:10:06.297972000 UTC
[Time shift for this packet: 0.000000000 seconds]
Epoch Time: 1446833406.297972000 seconds
[Time delta from previous captured frame: 0.000000000 seconds]
[Time delta from previous displayed frame: 0.000000000 seconds]
[Time since reference or first frame: 0.000000000 seconds]

```

Example: Using Buffer Capture

```

```

Step 9: Clear the buffer by entering:

```
Device# monitor capture mycap clear
```

Note NOTE - Clearing the buffer deletes the buffer along with the contents.

Note If you require the buffer contents to be displayed, run the clear commands after show commands.

Step 10: Restart the traffic, wait for 10 seconds, then display the buffer contents by entering:

Note We cannot run show from buffer during an active capture. Capture should be stopped before running show from buffer. We can however run a show on a pcap file during an active capture in both file and buffer mode. In file mode, we can display the packets in the current capture session's pcap file as well when the capture is active.

```
Device# monitor capture mycap start
Switch# show monitor capture mycap
```

```

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
  Status : Active
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)

```

Example: Using Buffer Capture

```

Packet Size to capture: 0 (no limit)
Maximum number of packets to capture per second: 1000
Packet sampling rate: 0 (no sampling)

```

Step 11: Stop the packet capture and display the buffer contents by entering:

```

Device# monitor capture mycap stop
Capture statistics collected at software (Buffer):
  Capture duration - 111 seconds
  Packets received - 5000
  Packets dropped - 0
  Packets oversized - 0

```

Step 12: Determine whether the capture is active by entering:

```

Device# show monitor capture mycap
Status Information for Capture mycap
  Target Type:
    Interface: GigabitEthernet1/0/3, Direction: in
  Status : Inactive
Filter Details:
  IPv4
    Source IP: any
    Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Maximum number of packets to capture per second: 1000
  Packet sampling rate: 0 (no sampling)

```

Step 13: Display the packets in the buffer by entering:

```

Device# show monitor capture mycap buffer brief
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=0/0, ttl=254
  2 0.000030000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=1/256, ttl=254
  3 0.000051000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=2/512, ttl=254
  4 0.000072000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=3/768, ttl=254
  5 0.000093000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=4/1024, ttl=254
  6 0.000114000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=5/1280, ttl=254
  7 0.000136000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=6/1536, ttl=254
  8 0.000157000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=7/1792, ttl=254
  9 0.000178000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=8/2048, ttl=254
 10 0.000199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=9/2304, ttl=254
 11 0.000220000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=10/2560, ttl=254

```

```

12 0.000241000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=11/2816, ttl=254
--More<

```

Step 14: Store the buffer contents to the mycap.pcap file in the internal flash: storage device by entering:

```

Device# monitor capture mycap export flash:mycap.pcap
Exported Successfully

```

Note The current implementation of export is such that when the command is run, export is "started" but not complete when it returns the prompt to the user. So we have to wait for a message display on the console from Wireshark before it can run a display of packets in the file.

Step 15: Display capture packets from the file by entering:

```

Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

 1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=0/0, ttl=254
 2 0.000030000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=1/256, ttl=254
 3 0.000051000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=2/512, ttl=254
 4 0.000072000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=3/768, ttl=254
 5 0.000093000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,

Example: Capture and Store in Lock-step Mode

This example captures live traffic and stores the packets in lock-step mode.

Note The capture rate might be slow for the first 15 seconds. If possible and necessary, start the traffic 15 seconds after the capture session starts.

Step 1: Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Device# monitor capture mycap interface GigabitEthernet1/0/1 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 100
Device# monitor capture mycap file location flash:mycap.pcap buffer-size 64
```

Step 2: Confirm that the capture point has been correctly defined by entering:

```
Device# show monitor capture mycap parameter
      monitor capture mycap interface GigabitEthernet1/0/1 in
      monitor capture mycap file location flash:mycap.pcap buffer-size 64
      monitor capture mycap limit packets 100 duration 60
```

```
Device# show monitor capture mycap
```

```
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: in
Status : Inactive
Filter Details:
  Filter not attached
Buffer Details:
  Buffer Type: LINEAR (default)
File Details:
  Associated file name: flash:mycap.pcap
  Size of buffer(in MB): 64
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packets per second: 0 (no limit)
  Packet sampling rate: 0 (no sampling)
```

Step 3: Launch packet capture by entering:

```
Device# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode
```

```
Device#
*Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.
```

Step 4: Display the packets by entering:

```
Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

0.000000  10.1.1.30 -> 20.1.1.2      UDP Source port: 20001  Destination port: 20002
1.000000  10.1.1.31 -> 20.1.1.2      UDP Source port: 20001  Destination port: 20002
2.000000  10.1.1.32 -> 20.1.1.2      UDP Source port: 20001  Destination port: 20002
3.000000  10.1.1.33 -> 20.1.1.2      UDP Source port: 20001  Destination port: 20002
4.000000  10.1.1.34 -> 20.1.1.2      UDP Source port: 20001  Destination port: 20002
5.000000  10.1.1.35 -> 20.1.1.2      UDP Source port: 20001  Destination port: 20002
```

```

6.000000    10.1.1.36 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
7.000000    10.1.1.37 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
8.000000    10.1.1.38 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
9.000000    10.1.1.39 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002

```

Step 5: Delete the capture point by entering:

```
Device# no monitor capture mycap
```

Example: Simple Capture and Store of Packets in Egress Direction

This example shows how to capture packets to a filter:

Step 1: Define a capture point to match on the relevant traffic and associate it to a file by entering:

```

Device# monitor capture mycap interface Gigabit 1/0/1 out match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 100
Device# monitor capture mycap file location flash:mycap.pcap buffer-size 90

```

Step 2: Confirm that the capture point has been correctly defined by entering:

```

Device# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 out
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location flash:mycap.pcap buffer-size 90
  monitor capture mycap limit packets 100 duration 60

```

```
Device# show monitor capture mycap
```

```

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: out
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
File Details:
  Associated file name: flash:mycap.pcap
  Size of buffer(in MB): 90
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60

```

```

Packet Size to capture: 0 (no limit)
Packets per second: 0 (no limit)
Packet sampling rate: 0 (no sampling)

```

Step 3: Launch packet capture by entering:

```

Device# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode

```

```

Device#
*Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.

```

Note Allow the capture operation stop automatically after the time has elapsed or the packet count has been met. When you see the following message in the output, will know that the capture operation has stopped:

```

*Oct 14 09:36:34.632: %BUFCAP-6-DISABLE_ASYNC: Capture Point mycap disabled. Reason : Wireshark Session Ended

```

The mycap.pcap file now contains the captured packets.

Step 4: Display the packets by entering:

```

Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

0.000000  10.1.1.30 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
1.000000  10.1.1.31 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
2.000000  10.1.1.32 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
3.000000  10.1.1.33 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
4.000000  10.1.1.34 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002

Feature History and Information for WireShark

Release	Modification
Cisco IOS XE 3.3SE	This feature was introduced.

Embedded Packet Capture

Embedded Packet Capture (EPC) is an onboard packet capture facility that allows network administrators to capture packets flowing to, through, and from the device and to analyze them locally or save and export them for offline analysis by using a tool such as Wireshark. This feature simplifies network operations by allowing devices to become active participants in the management and operation of the network. This feature facilitates troubleshooting by gathering information about the packet format. This feature also facilitates application analysis and security.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Embedded Packet Capture

The Embedded Packet Capture (EPC) software subsystem consumes CPU and memory resources during its operation. You must have adequate system resources for different types of operations. Some guidelines for using the system resources are provided in the table below.

Table 59: System Requirements for the EPC Subsystem

System Resources	Requirements
Hardware	CPU utilization requirements are platform dependent.
Memory	The packet buffer is stored in DRAM. The size of the packet buffer is user specified.
Diskspace	Packets can be exported to external devices. No intermediate storage on flash disk is required.

Restrictions for Embedded Packet Capture

- Embedded Packet Capture (EPC) captures multicast packets only on ingress and does not capture the replicated packets on egress.
- From Cisco IOS XE Release 3.7S, Embedded Packet Capture is only supported on Advance Enterprise Krypto (K9) images.
- From Cisco IOS XE Release 3.9S, Embedded Packet Capture is available on the following images:
 - IP Base Images
 - Special Services Images
 - Advance Security Images
 - Advance IP Services Images
 - Advance Enterprise Images
- From Cisco IOS XE Release 16.1, Embedded Packet Capture is supported on LAN Base.

Wireless Restrictions

Configuration Guidelines

Information About Embedded Packet Capture

Embedded Packet Capture Overview

Embedded Packet Capture (EPC) provides an embedded systems management facility that helps in tracing and troubleshooting packets. This feature allows network administrators to capture data packets flowing through, to, and from a Cisco device. The network administrator may define the capture buffer size and type (circular, or linear) and the maximum number of bytes of each packet to capture. The packet capture rate can be throttled using further administrative controls. For example, options allow for filtering the packets to be captured using an Access Control List and, optionally, further defined by specifying a maximum packet capture rate or by specifying a sampling interval.

Benefits of Embedded Packet Capture

- Ability to capture IPv4 and IPv6 packets in the device, and also capture non-IP packets with MAC filter or match any MAC address.
- Extensible infrastructure for enabling packet capture points. A capture point is a traffic transit point where a packet is captured and associated with a buffer.
- Facility to export the packet capture in packet capture file (PCAP) format suitable for analysis using any external tool.
- Methods to decode data packets captured with varying degrees of detail.

Packet Data Capture

Packet data capture is the capture of data packets that are then stored in a buffer. You can define packet data captures by providing unique names and parameters.

You can perform the following actions on the capture:

- Activate captures at any interface.
- Apply access control lists (ACLs) or class maps to capture points.

Note Network Based Application Recognition (NBAR) and MAC-style class map is not supported.

- Destroy captures.
- Specify buffer storage parameters such as size and type. The size ranges from 1 MB to 100 MB. The default buffer is linear;; the other option for the buffer is circular.
- Specify match criteria that includes information about the protocol, IP address or port address.

How to Implement Embedded Packet Capture

Managing Packet Data Capture

Note Export of an active capture point is only supported on LAN Base licence. On all other license we need to stop the capture first and only then export.

To manage Packet Data Capture in the buffer mode, perform the following steps:

SUMMARY STEPS

1. **enable**
2. **monitor capture** *capture-name* **access-list** *access-list-name*
3. **monitor capture** *capture-name* **limit duration** *seconds*
4. **monitor capture** *capture-name* **interface** *interface-name* **both**
5. **monitor capture** *capture-name* **buffer circular** *size bytes*
6. **monitor capture** *capture-name* **start**
7. **monitor capture** *capture-name* **stop**
8. **monitor capture** *capture-name* **export** *file-location/file-name*
9. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	monitor capture <i>capture-name</i> access-list <i>access-list-name</i> Example: Device# monitor capture mycap access-list v4acl	Configures a monitor capture specifying an access list as the core filter for the packet capture.
Step 3	monitor capture <i>capture-name</i> limit duration <i>seconds</i> Example: Device# monitor capture mycap limit duration 1000	Configures monitor capture limits.
Step 4	monitor capture <i>capture-name</i> interface <i>interface-name</i> both Example: Device# monitor capture mycap interface GigabitEthernet 0/0/1 both	Configures monitor capture specifying an attachment point and the packet flow direction.
Step 5	monitor capture <i>capture-name</i> buffer circular size <i>bytes</i> Example: Device# monitor capture mycap buffer circular size 10	Configures a buffer to capture packet data.
Step 6	monitor capture <i>capture-name</i> start Example: Device# monitor capture mycap start	Starts the capture of packet data at a traffic trace point into a buffer.
Step 7	monitor capture <i>capture-name</i> stop Example: Device# monitor capture mycap stop	Stops the capture of packet data at a traffic trace point.
Step 8	monitor capture <i>capture-name</i> export <i>file-location/file--name</i> Example: Device# monitor capture mycap export tftp://10.1.88.9/mycap.pcap	Exports captured data for analysis.

	Command or Action	Purpose
Step 9	end Example: Device# end	Returns to privileged EXEC mode.

What to do next

Note If you try to export an active capture point on licenses other than LAN Base, the switch will show an error "*Failed to Export : Capture Buffer BUSY*".

Monitoring and Maintaining Captured Data

Perform this task to monitor and maintain the packet data captured. Capture buffer details and capture point details are displayed.

SUMMARY STEPS

1. **enable**
2. **show monitor capture *capture-buffer-name* buffer dump**
3. **show monitor capture *capture-buffer-name* parameter**
4. **debug epc capture-point**
5. **debug epc provision**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	show monitor capture <i>capture-buffer-name</i> buffer dump Example: Device# show monitor capture mycap buffer dump	(Optional) Displays a hexadecimal dump of captured packet and its metadata.

	Command or Action	Purpose
Step 3	show monitor capture <i>capture-buffer-name</i> parameter Example: Device# <code>show monitor capture mycap parameter</code>	(Optional) Displays a list of commands that were used to specify the capture.
Step 4	debug epc capture-point Example: Device# <code>debug epc capture-point</code>	(Optional) Enables packet capture point debugging.
Step 5	debug epc provision Example: Device# <code>debug epc provision</code>	(Optional) Enables packet capture provisioning debugging.
Step 6	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.

Configuration Examples for Embedded Packet Capture

Example: Managing Packet Data Capture

The following example shows how to manage packet data capture:

```
Device> enable
Device# monitor capture mycap start
Device# monitor capture mycap access-list v4acl
Device# monitor capture mycap limit duration 1000
Device# monitor capture mycap interface GigabitEthernet 0/0/1 both
Device# monitor capture mycap buffer circular size 10
Device# monitor capture mycap start
Device# monitor capture mycap export tftp://10.1.88.9/mycap.pcap
Device# monitor capture mycap stop
Device# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information about COAP Proxy Server

The COAP protocol is designed for use with constrained devices. COAP works in the same way on constrained devices as HTTP works on servers in accessing information.

The comparison of COAP and HTTP is shown below:

- In the case of a webserver: **HTTP** is the protocol; **TCP** is the transport; and **HTML** is the most common information format transported.
- In case of a constrained device: **COAP** is the protocol; **UDP** is the transport; and **JSON/link-format/CBOR** is the popular information format.

COAP provides a means to access and control device using a similar **GET/POST** metaphor and restful API as in HTTP.

Supported Hardware for COAP Proxy Server

COAP Proxy Server is supported on the following Catalyst 3850 Switch Models:

Switch Model	Cisco IOS Image	Description
WS-C3850-24T-S	IP Base	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Base feature set
WS-C3850-48T-S	IP Base	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Base feature set
WS-C3850-24P-S	IP Base	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Base feature set
WS-C3850-48P-S	IP Base	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Base feature set
WS-C3850-48F-S	IP Base	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 1100-WAC power supply 1 RU, IP Base feature set
WS-C3850-24U-S	IP Base	Stackable 24 10/100/1000 Cisco UPOE ports, 1 network module slot, 1100 W power supply
WS-C3850-48U-S	IP Base	Stackable 48 10/100/1000 Cisco UPOE ports, 1 network module slot, 1100 W power supply
WS-C3850-12S-S	IP Base	Stackable 12 SFP module slots, 1 network module slot, 350-W power supply
WS-C3850-24S-S	IP Base	Stackable 24 SFP module slots, 1 network module slot, 350-W power supply
WS-C3850-12XS-S	IP Base	Catalyst 3850 12-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 350 W power supply
WS-C3850-16XS-S	IP Base	Catalyst 3850 16-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 350 W power supply. 16 ports are available when the C3850-NM-4-10G network module is plugged into the WS-C3850-12XS-S switch.
WS-C3850-24XS-S	IP Base	Catalyst 3850 24-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 715 W power supply.
WS-C3850-32XS-S	IP Base	Catalyst 3850 32-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 715 W power supply. 32 ports are available when the C3850-NM-8-10G network module is plugged into the WS-C3850-24XS-S switch.
WS-C3850-48XS-S	IP Base	Stackable, with SFP+ transceivers, 48 ports that support up to 10 G, and 4 ports that support up to 40 G. 750 W power supply.

Switch Model	Cisco IOS Image	Description
WS-C3850-48XS-F-S	IP Base	Stackable, with SFP+ transceivers, 48 ports that support up to 10 G, and 4 ports that support up to 40 G. 750 W power supply.
WS-C3850-24XU-S	IP Base	Stackable 24 100M/1G/2.5G/5G/10G UPoE ports, 1 network module slot, 1100-W power supply.
WS-C3850-24T-E	IP Services	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Services feature set
WS-C3850-48T-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Services feature set
WS-C3850-24P-E	IP Services	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Services feature set
WS-C3850-48P-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Services feature set
WS-C3850-48F-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 1100-WAC power supply 1 RU, IP Services feature set
WS-3850-24U-E	IP Services	Cisco Catalyst 3850 Stackable 24 10/100/1000 Cisco UPOE ports, 1 network module slot, 1100-W power supply
WS-3850-48U-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Cisco UPOE ports, 1 network module slot, 1100-W power supply
WS-C3850-12S-E	IP Services	Stackable, 2 SFP module slots, 1 network module slot, 350-W power supply
WS-C3850-24S-E	IP Services	Stackable, 24 SFP module slots, 1 network module slot, 350-W power supply
WS-C3850-12XS-E	IP Services	Catalyst 3850 12-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 350 -W power supply.
WS-C3850-16XS-E	IP Services	Catalyst 3850 16-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 350 W power supply. 16 ports are available when the C3850-NM-4-10G network module is plugged into the WS-C3850-12XS-E switch.
WS-C3850-24XS-E	IP Services	Catalyst 3850 24-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 715 W power supply.
WS-C3850-32XS-E	IP Services	Catalyst 3850 32-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 715 W power supply. 32 ports are available when the C3850-NM-8-10G network module is plugged into the WS-C3850-24XS-E switch.

Switch Model	Cisco IOS Image	Description
WS-C3850-48XS-E	IP Services	Stackable, SFP+ transceivers, 48 ports that support up to 10 G, and 4 ports that support up to 40 G. 750 W power supply.
WS-C3850-48XS-F-E	IP Services	Stackable, SFP+ transceivers, 48 ports that support up to 10 G, and 4 ports that support up to 40 G. 750 W power supply.
WS-C3850-24XU-E	IP Services	Stackable 24 100M/1G/2.5G/5G/10G UPoE ports, 1 network module slot, 1100-W power supply.

Configuring COAP Proxy Server

To configure the COAP proxy server, you can configure the COAP Proxy and COAP Endpoints in the Configuration mode.

The commands are: **coap [proxy | endpoints]**.

Configuring COAP Proxy

To start or stop the COAP proxy on the switch, perform the steps given below:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **coap proxy**
4. **security [none [[ipv4 | ipv6] {ip-address ip-mask/prefix} | list {ipv4-list name | ipv6-list-name}]] | dtls [id-trustpoint {identity-trustpoint label}] [verification-trustpoint {verification-trustpoint}] [ipv4 | ipv6 {ip-address ip-mask/prefix}] | list {ipv4-list name | ipv6-list-name}]]**
5. **max-endpoints {number}**
6. **port-unsecure {port-num}**
7. **port-dtls {port-num}**
8. **resource-directory [ipv4 | ipv6] {ip-address}]**
9. **list [ipv4 | ipv6] {list-name}**
10. **start**
11. **stop**
12. **exit**
13. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	coap proxy Example: Device(config)# coap proxy	Enters the COAP proxy sub mode. Note To stop the coap proxy and delete all configurations under coap proxy, use the no coap proxy command.
Step 4	security [none [[ipv4 ipv6] { <i>ip-address ip-mask/prefix</i> } list { <i>ipv4-list name</i> <i>ipv6-list-name</i> }] dtls [id-trustpoint { <i>identity-trustpoint label</i> }] [verification-trustpoint { <i>verification-trustpoint</i> } [ipv4 ipv6] { <i>ip-address ip-mask/prefix</i> }] list { <i>ipv4-list name</i> <i>ipv6-list-name</i> }]] Example: Device(config-coap-proxy)# security none ipv4 1.1.0.0 255.255.0.0	Takes the encryption type as argument. The two security modes supported are none and dtls <ul style="list-style-type: none"> • none - Indicates no security on that port. With security none, a maximum of 5 ipv4 and 5 ipv6 addresses can be associated. • dtls - The DTLS security takes RSA trustpoint and Verification trustpoint which are optional. Without Verification trustpoint it does the normal Public Key Exchange. With security dtls, a maximum of 5 ipv4 and 5 ipv6 addresses can be associated. Note To delete all security configurations under coap proxy, use the no security command.
Step 5	max-endpoints { <i>number</i> } Example: Device(config-coap-proxy)# max-endpoints 10	(Optional) Specifies the maximum number of endpoints that can be learnt on the switch. The default value is 10. The range is 1 to 500. Note To delete all max-endpoints configured under coap proxy, use the no max-endpoints command.
Step 6	port-unsecure { <i>port-num</i> } Example: Device(config-coap-proxy)# port-unsecure 5683	(Optional) Configures a port other than the default 5683. The range is 1 to 65000. Note To delete all port configurations under coap proxy, use the no port-unsecure command.
Step 7	port-dtls { <i>port-num</i> } Example:	(Optional) Configures a port other than the default 5684. Note To delete all dtls port configurations under coap proxy, use the no port-dtls command.

	Command or Action	Purpose
	Device (config-coap-proxy) # port-dtls 5864	
Step 8	resource-directory [ipv4 ipv6] { <i>ip-address</i> }] Example: Device (config-coap-proxy) # resource-directory ipv4 192.168.1.1	Configures a unicast upstream resource directory server to which the switch can act as a COAP client. With resource-directory , a maximum of 5 of ipv4 and 5 ipv6, ip addresses can be configured. Note To delete all resource directory configurations under coap proxy, use the no resource-directory command.
Step 9	list [ipv4 ipv6] { <i>list-name</i> } Example: Device (config-coap-proxy) # list ipv4 trial_list	(Optional) Restricts the IP address range where the lights and their resources can be learnt. Creates a named list of ip address/masks, to be used in the security [none dtls] command options above. With list , a maximum of 5 ip-lists can be configured, irrespective of ipv4 or ipv6. We can configure a max of 5 ip addresses per ip-list. Note To delete any ip list on the COAP proxy server, use the no list [ipv4 ipv6] { <i>list-name</i> } command.
Step 10	start Example: Device (config-coap-proxy) # start	Starts the COAP proxy on this switch.
Step 11	stop Example: Device (config-coap-proxy) # stop	Stops the COAP proxy on this switch.
Step 12	exit Example: Device (config-coap-proxy) # exit	Exits the COAP proxy sub mode.
Step 13	end Example: Device (config) # end	Returns to privileged EXEC mode.

Examples: [COAP Proxy Server](#), on page 821

Configuring COAP Endpoints

To configure the COAP Proxy to support multiple IPv4/IPv6 static-endpoints, perform the steps given below:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **coap endpoint [ipv4 | ipv6] {ip-address}**
4. **exit**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	coap endpoint [ipv4 ipv6] {ip-address} Example: Device(config)# coap endpoint ipv4 1.1.1.1 Device(config)# coap endpoint ipv6 2001::1	Configures the static endpoints on the switch. <ul style="list-style-type: none"> • ipv4 - Configures the IPv4 Static endpoints. • ipv6 - Configures the IPv6 Static endpoints. Note To stop the coap proxy on any endpoint, use the no coap endpoint [ipv4 ipv6] {ip-address} command.
Step 4	exit Example: Device(config-coap-endpoint)# exit	Exits the COAP endpoint sub mode.
Step 5	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device (config) # end	

Monitoring COAP Proxy Server

To display the COAP protocol details, use the commands in the following table:

Table 60: Commands to Display to COAP specific data

show coap version	Shows the IOS COAP version and the RFC information.
show coap resources	Shows the resources of the switch and those learnt by it.
show coap endpoints	Shows the endpoints which are discovered and learnt.
show coap globals	Shows the timer values and end point values.
show coap stats	Shows the message counts for endpoints, requests and external queries.
show coap dtls-endpoints	Shows the dtls endpoint status.

Table 61: Commands to Clear COAP Commands

clear coap database	Clears the COAP learnt on the switch, and the internal database of endpoint information.
----------------------------	--

To debug the COAP protocol, use the commands in the following table:

Table 62: Commands to Debug COAP protocol

debug coap database	Debugs the COAP database output.
debug coap errors	Debugs the COAP errors output.
debug coap events	Debugs the COAP events output.
debug coap packets	Debugs the COAP packets output.
debug coap trace	Debugs the COAP traces output.
debug coap warnings	Debugs the COAP warnings output.
debug coap all	Debugs all the COAP output.

Note If you wish to disable the debugs, prepend the command with a "no" keyword.

Examples: COAP Proxy Server

This example shows how you can configure the port number 5683 to support a maximum of 10 endpoints.

```
Device#coap proxy security none ipv4 2.2.2.2 255.255.255.0 port 5683 max-endpoints 10
```

This example shows how to configure COAP proxy on *ipv4 1.1.0.0 255.255.0.0* with **no** security settings.

```
Device(config-coap-proxy)# security ?
  dtls  dtls
  none  no security

Device(config-coap-proxy)#security none ?
  ipv4  IP address range on which to learn lights
  ipv6  IPv6 address range on which to learn lights
  list  IP address range on which to learn lights

Device(config-coap-proxy)#security none ipv4 ?
  A.B.C.D {/nn || A.B.C.D} IP address range on which to learn lights

Device(config-coap-proxy)#security none ipv4 1.1.0.0 255.255.0.0
```

This example shows how to configure COAP proxy on *ipv4 1.1.0.0 255.255.0.0* with **dtls id trustpoint** security settings.

```
Device(config-coap-proxy)#security dtls ?
  id-trustpoint DTLS RSA and X.509 Trustpoint Labels
  ipv4 IP address range on which to learn lights
  ipv6 IPv6 address range on which to learn lights
  list IP address range on which to learn lights

Device(config-coap-proxy)#security dtls id-trustpoint ?
  WORD Identity TrustPoint Label

Device(config-coap-proxy)#security dtls id-trustpoint RSA-TRUSTPOINT ?
  verification-trustpoint Certificate Verification Label
  <cr>

Device(config-coap-proxy)#security dtls id-trustpoint RSA-TRUSTPOINT

Device(config-coap-proxy)#security dtls ?
  id-trustpoint DTLS RSA and X.509 Trustpoint Labels
  ipv4 IP address range on which to learn lights
  ipv6 IPv6 address range on which to learn lights
  list IP address range on which to learn lights

Device(config-coap-proxy)# security dtls ipv4 1.1.0.0 255.255.0.0
```

Note For configuring **ipv4 / ipv6 / list**, the **id-trustpoint** and (optional) **verification-trustpoint**, should be pre-configured, else the system shows an error.

This example shows how to configure a Trustpoint. This is a pre-requisite for COAP **security dtls** with **id trustpoint** configurations.

```
ip domain-name myDomain
crypto key generate rsa general-keys exportable label MyLabel modulus 2048

Device(config)#crypto pki trustpoint MY_TRUSTPOINT
Device(ca-trustpoint)#rsakeypair MyLabel 2048
Device(ca-trustpoint)#enrollment selfsigned
Device(ca-trustpoint)#exit

Device(config)#crypto pki enroll MY_TRUSTPOINT
% Include the router serial number in the subject name? [yes/no]: no
% Include an IP address in the subject name? [no]: no
Generate Self Signed Router Certificate? [yes/no]: yes
```

This example shows how to configure COAP proxy on *ipv4 1.1.0.0 255.255.0.0* with **dtls verification trustpoint** (DTLS with certificates or verification trustpoints)

```
Device(config-coap-proxy)#security dtls ?
  id-trustpoint DTLS RSA and X.509 Trustpoint Labels
  ipv4 IP address range on which to learn lights
  ipv6 IPv6 address range on which to learn lights
  list IP address range on which to learn lights

Device(config-coap-proxy)#security dtls id-trustpoint ?
  WORD Identity TrustPoint Label

Device(config-coap-proxy)#security dtls id-trustpoint RSA-TRUSTPOINT ?
  verification-trustpoint Certificate Verification Label
  <cr>

Device(config-coap-proxy)#security dtls id-trustpoint RSA-TRUSTPOINT verification-trustpoint
?
  WORD Identity TrustPoint Label

Device(config-coap-proxy)#security dtls id-trustpoint RSA-TRUSTPOINT verification-trustpoint
CA-TRUSTPOINT ?
  <cr>
```

This example shows how to configure Verification Trustpoint. This is a pre-requisite for COAP **security dtls** with **verification trustpoint** configurations.

```
Device(config)#crypto pki import CA-TRUSTPOINT pkcs12 flash:hostA.p12 password cisco123
% Importing pkcs12...
Source filename [hostA.p12]?
Reading file from flash:hostA.p12
CRYPTO_PKI: Imported PKCS12 file successfully.
```

This example shows how to create a list named trial-list, to be used in the security [none | dtls] command options.

```

Device(config-coap-proxy)#list ipv4 trial_list
Device (config-coap-proxy-iplist)#1.1.0.0 255.255.255.0
Device (config-coap-proxy-iplist)#2.2.0.0 255.255.255.0
Device (config-coap-proxy-iplist)#3.3.0.0 255.255.255.0
Device (config-coap-proxy-iplist)#exit
Device (config-coap-proxy)#security none list trial_list

```

This example shows all the negation commands available in the coap-proxy sub mode.

```

Device(config-coap-proxy)#no ?
  ip-list           Configure IP-List
  max-endpoints     maximum number of endpoints supported
  port-unsecure     Specify a port number to use
  port-dtls         Specify a dtls-port number to use
  resource-discovery Resource Discovery Server
  security          CoAP Security features

```

This example shows how you can configure multiple IPv4/IPv6 static-endpoints on the coap proxy.

```

Device (config)# coap endpoint ipv4 1.1.1.1
Device (config)# coap endpoint ipv4 2.1.1.1
Device (config)# coap endpoint ipv6 2001::1

```

This example shows how you can display the COAP protocol details.

```

Device#show coap version
CoAP version 1.0.0
RFC 7252

```

```

Device#show coap resources
Link format data =
</>
</1.1.1.6/cisco/context>
</1.1.1.6/cisco/actuator>

Configuring Auto SmartPorts

- [Finding Feature Information, on page 825](#)
- [Information about Auto SmartPorts, on page 825](#)
- [Auto SmartPort Macros, on page 826](#)
- [Commands executed by CISCO_LIGHT_AUTO_SMARTPORT , on page 826](#)
- [Enabling Auto SmartPort, on page 827](#)
- [Configuring Mapping Between Event Triggers and Built-in Macros, on page 828](#)
- [Example: Enabling Auto SmartPorts, on page 830](#)
- [Example: Configuring Mapping Between Event Triggers and Built-in Macros, on page 830](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information about Auto SmartPorts

Auto SmartPort macros dynamically configure ports based on the device type detected on the port. When the switch detects a new device on a port, it applies the appropriate Auto SmartPorts macro. When a link-down event occurs on the port, the switch removes the macro. For example, when you connect a Cisco IP phone to a port, Auto SmartPorts automatically applies the Cisco IP phone macro. The Cisco IP phone macro enables quality of service (QoS), security features, and a dedicated voice VLAN to ensure proper treatment of delay-sensitive voice traffic.

Auto SmartPorts uses event triggers to map devices to macros. The most common event triggers are based on Cisco Discovery Protocol (CDP) messages received from connected devices. The detection of a device (Cisco IP phone, Cisco wireless access point, or Cisco router) invokes an event trigger for that device.

Note Although Auto SmartPort detects the Cisco switch it does not invoke the event trigger automatically. The event trigger needs to be manually invoked to map the switch to macros.

Link Layer Discovery Protocol (LLDP) is used to detect devices that do not support CDP. Other mechanisms used as event triggers include the 802.1X authentication result and MAC-address learned.

System built-in event triggers exist for various devices based mostly on CDP and LLDP messages and some MAC address. These triggers are enabled as long as Auto SmartPort is enabled.

You can configure user-defined trigger groups for profiles and devices. The name of the trigger group is used to associate a user-defined macro.

Auto SmartPort Macros

The Auto SmartPort macros are groups of CLI commands. Detection of devices on a port triggers the application of the macro for the device. System built-in macros exist for various devices, and, by default, system built-in triggers are mapped to the corresponding built-in macros. You can change the mapping of built-in triggers or macros as needed.

A macro basically applies or removes a set of CLIs on an interface based on the link status. In a macro, the link status is checked. If the link is up, then a set of CLIs is applied; if the link is down, the set is removed (the no format of the CLIs are applied). The part of the macro that applies the set of CLIs is termed macro. The part that removes the CLIs (the no format of the CLIs) are termed antimacro.

When a device is connected to an Auto SmartPort, if it gets classified as a lighting end point, it invokes the event trigger `CISCO_LIGHT_EVENT`, and the macro `CISCO_LIGHT_AUTO_SMARTPORT` is executed.

Related Topics

[Enabling Auto SmartPort](#), on page 827

[Example: Enabling Auto SmartPorts](#), on page 830

Commands executed by CISCO_LIGHT_AUTO_SMARTPORT

When the macro is executed, it runs a series of commands on the switch.

The commands that are executed by running the macro `CISCO_LIGHT_AUTO_SMARTPORT` are:

- switchport mode access
- switchport port-security violation restrict
- switchport port-security mac-address sticky
- switchport port-security
- power inline port poe-ha
- storm-control broadcast level 50.00
- storm-control multicast level 50.00
- storm-control unicast level 50.00

- spanning-tree portfast
- spanning-tree bpduguard enable

Enabling Auto SmartPort

Note Auto SmartPort is disabled by default.

To disable Auto SmartPorts macros on a specific port, use the **no macro auto global processing** interface command before enabling Auto SmartPort globally.

To enable Auto SmartPort globally, use the **macro auto global processing** global configuration command.

To enable Auto SmartPorts, perform this task:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **device classifier**
4. **macro auto global processing**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	device classifier Example: Device(config)# device classifier	Enables the device classifier. Use no device classifier command to disable the device classifier.
Step 4	macro auto global processing	Enables Auto SmartPorts on the switch globally.

	Command or Action	Purpose
	Example: Device(config)# macro auto global processing	Use no macro auto global processing command to disable Auto SmartPort globally.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 6	show running-config Example: Device# show running-config	Verifies your entries.
Step 7	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring Mapping Between Event Triggers and Built-in Macros

Note You need to perform this task when a Cisco switch is connected to the Auto SmartPort.

To map an event trigger to a built-in macros, perform this task:

Before you begin

You need to enable auto smartport macros globally.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **macro auto execute** *event trigger* **builtin** *built-in macro name*
4. **macro auto trigger** *event trigger*

5. `device device_ID`
6. `end`
7. `show shell triggers`
8. `show running-config`
9. `copy running-config startup-config`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <code>Switch> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <code>Switch# configure terminal</code>	Enters global configuration mode.
Step 3	macro auto execute event trigger builtin built-in macro name Example: <code>Switch(config)# macro auto execute CISCO_SWITCH_EVENT builtin CISCO_SWITCH_AUTO_SMARTPORT</code>	Specifies a user-defined event trigger and a macro name. This action configures mapping from an event trigger to a built-in Auto Smartports macro.
Step 4	macro auto trigger event trigger Example: <code>Switch(config)# macro auto trigger CISCO_SWITCH_EVENT</code>	Invokes the user-defined event trigger.
Step 5	device device_ID Example: <code>Switch(config)# device cisco WS-C3560CX-8PT-S</code>	Matches the event trigger to the device identifier.
Step 6	end Example: <code>Switch(config)# end</code>	Returns to privileged EXEC mode.
Step 7	show shell triggers Example: <code>Switch# show shell triggers</code>	Displays the event triggers on the switch.
Step 8	show running-config Example: <code>Switch# show running-config</code>	Verifies your entries.

	Command or Action	Purpose
Step 9	copy running-config startup-config Example: Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Example: Enabling Auto SmartPorts

This example shows how you can enable to Auto SmartPort.

```
Device> enable
Device# configure terminal
Device(config)# device classifier
Device(config)# macro auto global processing
Device(config)# end
```

Related Topics

Configuring 2-event Classification

- [Finding Feature Information, on page 831](#)
- [Information about 2-event Classification, on page 831](#)
- [Configuring 2-event Classification, on page 831](#)
- [Example: Configuring 2-Event Classification, on page 832](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information about 2-event Classification

When a class 4 device gets detected, IOS allocates 30W without any CDP or LLDP negotiation. This means that even before the link comes up the class 4 power device gets 30W.

Also, on the hardware level the PSE does a 2-event classification which allows a class 4 PD to detect PSE capability of providing 30W from hardware, register itself and it can move up to PoE+ level without waiting for any CDP/LLDP packet exchange.

Once 2-event is enabled on a port, you need to manually shut/un-shut the port or connect the PD again to start the IEEE detection again. Power budget allocation for a class-4 device will be 30W if 2-event classification is enabled on the port, else it will be 15.4W.

Configuring 2-event Classification

To configure the switch for a 2-event Classification, perform the steps given below:

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `power inline port 2-event`
5. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet2/0/1</code>	Specifies the physical port to be configured, and enters interface configuration mode.
Step 4	power inline port 2-event Example: Device(config-if)# <code>power inline port 2-event</code>	Configures 2-event classification on the switch.
Step 5	end Example: Device(config-if)# <code>end</code>	Returns to privileged EXEC mode.

CHAPTER 55

Configuring Perpetual and Fast POE

- [Restrictions for Perpetual and Fast PoE, on page 835](#)
- [Perpetual POE, on page 835](#)
- [Fast POE, on page 835](#)
- [Supported Hardware for Perpetual POE and Fast POE, on page 836](#)
- [Configuring Perpetual and Fast POE, on page 838](#)
- [Example: Configuring Perpetual and Fast POE, on page 839](#)

Restrictions for Perpetual and Fast PoE

The following restrictions apply to perpetual and fast PoE :

- When the switches are power-stacked, perpetual and fast PoE functionalities may not work as expected. This is due to power budget shortage.
- The CREE light PD may flap at regular intervals if not configured with IP assigned from the DHCP server.
- If the PD doesn't support LLDP user can configure with either static or 2-event to receive required power as per the PD specification.

Perpetual POE

The Perpetual POE provides uninterrupted power to connected PD device even when the PSE switch is booting.

Note

Power to the ports will be interrupted in case of MCU firmware upgrade and ports will be back up immediately after the upgrade.

Fast POE

This feature remembers the last power drawn from a particular PSE port and switches on power the moment AC power is plugged in (within 15 to 20 seconds of switching on power) without waiting for IOS to boot up.

When **poe-ha** is enabled on a particular port, the switch on a recovery after power failure, provides power to the connected endpoint devices within short duration before even the IOS forwarding starts up.

Note Fast POE is supported on Catalyst 3850 only.

Note In case of UPOE, even though Fast POE is available on the switch side, the PD endpoints may not be able to take advantage of the same, due to the reliance on LLDP to signal the UPOE power availability. This reliance on LLDP requires that the PD endpoint still needs to wait till the IOS comes up and LLDP packet exchanges can happen, signaling the availability of UPOE power.

Supported Hardware for Perpetual POE and Fast POE

Perpetual POE is supported on the following Catalyst 3850 Switch Models:

Switch Model	Cisco IOS Image	Description
WS-C3850-24T-S	IP Base	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Base feature set
WS-C3850-48T-S	IP Base	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Base feature set
WS-C3850-24P-S	IP Base	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Base feature set
WS-C3850-48P-S	IP Base	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Base feature set
WS-C3850-48F-S	IP Base	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 1100-WAC power supply 1 RU, IP Base feature set
WS-C3850-24U-S	IP Base	Stackable 24 10/100/1000 Cisco UPOE ports, 1 network module slot, 1100 W power supply
WS-C3850-48U-S	IP Base	Stackable 48 10/100/1000 Cisco UPOE ports, 1 network module slot, 1100 W power supply
WS-C3850-12S-S	IP Base	Stackable 12 SFP module slots, 1 network module slot, 350-W power supply
WS-C3850-24S-S	IP Base	Stackable 24 SFP module slots, 1 network module slot, 350-W power supply
WS-C3850-12XS-S	IP Base	Catalyst 3850 12-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 350 W power supply

Switch Model	Cisco IOS Image	Description
WS-C3850-16XS-S	IP Base	Catalyst 3850 16-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 350 W power supply. 16 ports are available when the C3850-NM-4-10G network module is plugged into the WS-C3850-12XS-S switch.
WS-C3850-24XS-S	IP Base	Catalyst 3850 24-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 715 W power supply.
WS-C3850-32XS-S	IP Base	Catalyst 3850 32-port SFP+ transceiver, 1 network module slot, support for up to 10 G SFP+, 715 W power supply. 32 ports are available when the C3850-NM-8-10G network module is plugged into the WS-C3850-24XS-S switch.
WS-C3850-48XS-S	IP Base	Stackable, with SFP+ transceivers, 48 ports that support up to 10 G, and 4 ports that support up to 40 G. 750 W power supply.
WSC3850-48XS-F-S	IP Base	Stackable, with SFP+ transceivers, 48 ports that support up to 10 G, and 4 ports that support up to 40 G. 750 W power supply.
WS-C3850-24XU-S	IP Base	Stackable 24 100M/1G/2.5G/5G/10G UPoE ports, 1 network module slot, 1100-W power supply.
WS-C3850-24T-E	IP Services	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Services feature set
WS-C3850-48T-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet ports, with 350-WAC power supply 1 RU, IP Services feature set
WS-C3850-24P-E	IP Services	Cisco Catalyst 3850 Stackable 24 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Services feature set
WS-C3850-48P-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 715-WAC power supply 1 RU, IP Services feature set
WS-C3850-48F-E	IP Services	Cisco Catalyst 3850 Stackable 48 10/100/1000 Ethernet PoE+ ports, with 1100-WAC power supply 1 RU, IP Services feature set

Configuring Perpetual and Fast POE

To configure perpetual and fast POE, perform the following steps:

Note

You will need to configure the **perpetual-poe-ha** command before connecting the PD, or you will need to manually shut/unshut the port after configuring **poe-ha**.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **power inline port perpetual poe-ha**
5. **power inline port poe-ha**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet2/0/1	Specifies the physical port to be configured, and enters interface configuration mode.
Step 4	power inline port perpetual poe-ha Example: Device(config-if)# power inline port perpetual poe-ha	Configures perpetual PoE. When you configure perpetual PoE on a port connected to a PD device, the PD device remains powered on during reload.
Step 5	power inline port poe-ha Example: Device(config-if)# power inline port poe-ha	Configures Fast PoE. When you configure Fast PoE, if switch is power cycled, PD device is powered on within 10-15 seconds of plugging into a power source without waiting for IOS to boot up. Note You should configure perpetual PoE using power inline port perpetual-poe-ha command before configuring Fast PoE using power inline port poe-ha command.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Example: Configuring Perpetual and Fast POE

This example shows how you can configure perpetual PoE on the switch.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet2/0/1
```

```
Device(config-if)# power inline port perpetual poe-ha
Device(config-if)# end
```

This example shows how you can configure fast PoE on the switch.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# power inline port perpetual poe-ha
Device(config-if)# power inline port poe-ha
Device(config-if)# end
```

This example shows what happens if you configure fast PoE before configuring perpetual PoE.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# power inline port poe-ha
Interface Gi2/0/1:INFO: Please execute "power inline port perpetual-poe-ha"
configuration command when "power inline port poe-ha" is configured on
the interface to enable fast poe
Device(config-if)# power inline port perpetual poe-ha
Device(config-if)# end
```

This example shows what happens when you disable perpetual PoE without disabling fast PoE on the interface.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# power inline port poe-ha
Interface Gi2/0/1:INFO: Please execute "power inline port perpetual-poe-ha"
configuration command when "power inline port poe-ha" is configured on
the interface to enable fast poe
Device(config-if)# power inline port perpetual poe-ha
Device(config-if)# no power inline port poe-ha
Device(config-if)# power inline port poe-ha
Device(config-if)# no power inline port perpetual poe-ha
Interface Gi2/0/1:INFO: Please execute "no power inline port poe-ha"
configuration command, as fast poe has no effect without "power inline
port perpetual-poe-ha" configuration on the interface
Device(config-if)# end
```

Frequently Asked Questions

- [Finding Feature Information, on page 841](#)
- [Frequently Asked Questions, on page 841](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Frequently Asked Questions

This section lists some frequently asked questions about Network Powered Lighting.

- **Question:**

What does "New Endpoint" in the "show coap stats" output mean? When does "New Endpoint" migrate to "Endpoint"?

Answer:

New endpoint means that an endpoint has been seen (Discovery packets received) but not yet registered by the CoAP proxy. The CoAP proxy will periodically look at the new endpoint and then send them a GET on “./well-known/core” to get more details, and once RSP is received, it is moved to “Endpoint”.

- **Question:**

Why can I not do a "CoAP start" unless there is a security configuration?

Answer:

We need to ensure that all configurations related to CoAP are done and then it can be explicitly enabled. This avoids any intermittent unstable states across configurations.

- **Question:**

Why do we need to enforce drop into the “coap proxy” configuration mode “coap proxy <cr>”? When I have completed the configuration, I have to exit twice to get back to the switch prompt. I do not find this very user friendly.

Answer:

We would alternatively have to type “coap proxy” as prefix for each configuration that we do. It is a better option to get into a sub-mode, as all the configurations under the sub-mode relating to coap-proxy can be done.

• **Question:**

Why am I not able to unconfigure security or other parameters without first stopping the coap process?

Answer:

We need to ensure that all configurations related to CoAP are done and then it can be explicitly enabled. This also avoids and controls the complexity where the user might configure settings on the fly, when CoAP is enabled.

• **Question:**

When I stop coap, all configurations associated with the CoAP process are not removed automatically (or return to defaults). Why does the CoAP remember previous configuration? This seems very hard for users to start fresh.

Answer:

The system has been intentionally designed this way and this is expected behavior. Sometimes we just want to make minor changes, like change max-endpoints and re-start the proxy. It is a better option to hold all other configurations in place, else the user has to configure everything all over again.

• **Question:**

How can I see what the security configurations have been set?

Answer:

The command “show run” shows all the configurations.

• **Question:**

How can I tune the timer values?

```
Example:
wtsao-3850#sho coap glo
Coap System Timer Values:
Discovery : 120 sec
Cache Exp : 5 sec
Keep Alive : 120 sec
Client DB : 5 sec
Query Queue : 500 ms
Ack delay : 500 ms
Timeout : 5 sec
Max Endpoints : 500
Resource Disc Mode : POST
```

Answer:

The timer values are fixed and are not tunable at the moment. The reason for this is to avoid inconsistency across systems.

- **Question:**

What are the commands “list” and “endpoint” used for?

Answer:

The “list” command is to make it easier to configure multiple ip-addresses and give a name to it. Then you can assign the name instead of a single ip, to represent multiple ip’s. The “endpoint” command is used to configure a static end point, in cases where the endpoints do not advertise themselves.

- **Question:**

How can I find the endpoint-to-port mapping by using the “show” command?

Answer:

We do not support that of now. However, other commands can be run to fetch this data. Currently, we can still get all the details mentioned using individual commands like “lldp neighbours”, “ip dhcp”, “power inlines” and so on.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for QoS

Before configuring standard QoS, you must have a thorough understanding of these items:

- Standard QoS concepts.
- Wireless concepts and network topologies.
- Classic Cisco IOS QoS.

- Modular QoS CLI (MQC).
- Understanding of QoS implementation.
- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?
- Bandwidth requirements and speed of the network.
- Location of congestion points in the network.

Related Topics

QoS Components

QoS consists of the following key components:

- **Classification**— Classification is the process of distinguishing one type of traffic from another based upon ACLs, Differentiated Services Code Point (DSCP), Class of Service (CoS), and other factors.
- **Marking and mutation**— Marking is used on traffic to convey specific information to a downstream device in the network, or to carry information from one interface in a to another. When traffic is marked, QoS operations on that traffic can be applied. This can be accomplished directly using the **set** command or through a table map, which takes input values and translates them directly to values on output.
- **Shaping and policing**— Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that downstream devices are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface. Policing is used to impose a maximum rate on a traffic class. If the rate is exceeded, then a specific action is taken as soon as the event occurs.
- **Queuing** — Queuing is used to prevent traffic congestion. Traffic is sent to specific queues for servicing and scheduling based upon bandwidth allocation. Traffic is then scheduled or sent out through the port.
- **Bandwidth**—Bandwidth allocation determines the available capacity for traffic that is subject to QoS policies.
- **Trust**— Trust enables traffic to pass through the , and the DSCP, precedence, or CoS values coming in from the end points are retained in the absence of any explicit policy configuration.

QoS Terminology

The following terms are used interchangeably in this QoS configuration guide:

- Upstream (direction towards the) is the same as ingress.
- Downstream (direction from the) is the same as egress.

Note Upstream is wireless to wired. Downstream is wired to wireless. Wireless to wireless has no specific term.

Information About QoS

QoS Overview

By configuring the quality of service (QoS), you can provide preferential treatment to specific types of traffic at the expense of other traffic types. Without QoS, the device offers best-effort service to each packet, regardless of the packet contents or size. The device sends the packets without any assurance of reliability, delay bounds, or throughput.

The following are specific features provided by QoS:

- Low latency
- Bandwidth guarantee
- Buffering capabilities and dropping disciplines
- Traffic policing
- Enables the changing of the attribute of the frame or packet header
- Relative services

Modular QoS Command-Line Interface

With the device, QoS features are enabled through the Modular QoS command-line interface (MQC). The MQC is a command-line interface (CLI) structure that allows you to create traffic policies and attach these policies to interfaces. A traffic policy contains a traffic class and one or more QoS features. A traffic class is used to classify traffic, while the QoS features in the traffic policy determine how to treat the classified traffic. One of the main goals of MQC is to provide a platform-independent interface for configuring QoS across Cisco platforms.

Wireless QoS Overview

Wireless QoS can be configured on the following wireless targets:

- Wireless ports, including all physical ports to which an access point can be associated.
- Radio
- SSID (applicable on a per-radio, per-AP, and per-SSID)
- Client

From Cisco IOS XE Release 3E, marking and policing actions for ingress SSID and client policies are applied at the access point. The SSID and client ingress policies that you configure in the are moved to the access point. The access point performs policing and marking actions for each packet. However, the selects the QoS policies. Marking and policing of egress SSID and client policies are applied at the .

The following table displays how policies are supported for the wireless targets.

Table 63: Wireless Targets Policies Support

Wireless Target	Policies on Wireless Targets Supported	Policies Supported Egress Direction	Policies Supported Ingress Direction
Wireless port	Yes	Yes - user configurable	No
Radio	Yes	Yes - but not configurable by user	No
SSID	Yes	Yes - user configurable	Yes - user configurable
Client	Yes	Yes - user configurable	Yes - user configurable

Note Additional polices that are user configured include multidestination policers and VLANs.

Wireless QoS supports the following features:

- Queuing in the egress direction.
- Policing of wireless traffic
- Marking of wireless traffic.
- Shaping of wireless traffic in the egress direction.
- Approximate Fair Drop (AFD) in the egress direction.
- Mobility support for QoS.
- Compatibility with precious metal QoS policies available on Cisco Unified Wireless Controllers.
- Combination of CLI/Traffic Class (TCLAS) and CLI/snooping.
- Application control (can drop or mark the data traffic) by configuring an AVC QoS client policy.
- Drop action for ingress policies.
- QoS statistics for client and SSID targets in the ingress direction.
- QoS attribute for local profiling policy.
- Hierarchical policies.

QoS and IPv6 for Wireless

The supports QoS for both IPv4 and IPv6 traffic, and client policies can now have IPv4 and IPv6 filters.

Supported QoS Features for Wired Access

The following table describes the supported QoS features for wired access.

Table 64: Supported QoS Features for Wired Access

Feature	Description
Supported targets	<ul style="list-style-type: none"> • Gigabit Ethernet • 10-Gigabit Ethernet • VLAN
Configuration sequence	QoS policy installed using the service-policy command.
Supported number of queues at port level	Up to 8 queues supported on a port. No Approximate Fair Dropping or Discard (AFD) support for wired targets.
Supported classification mechanism	<ul style="list-style-type: none"> • DSCP • IP precedence • CoS • QoS-group • ACL membership including: <ul style="list-style-type: none"> • IPv4 ACLs • IPv6 ACLS • MAC ACLs

Wired and Wireless Access Supported Features

The following table describes the supported features for both wired and wireless access.

Table 65: Supported QoS Features for Wired and Wireless Access

Feature	Wired	Wireless
Targets	<ul style="list-style-type: none"> • Gigabit Ethernet • 10 Gigabit Ethernet • VLAN 	<ul style="list-style-type: none"> • Wireless port (CAPWAP tunnel) • SSID • Client • Radio • CAPWAP multicast tunnel

Feature	Wired	Wireless
Configuration Sequence	QoS policy installed using the service-policy command.	<ul style="list-style-type: none"> • When an access point joins the switch, the switch installs a policy on the port. The port policy has a child policy called <code>port_child_policy</code>. • A policy is installed on the radio which has a shaper configured to the radio rate. The default radio policy (which cannot be modified) is attached to the radio. • The default client policies take effect when a WMM client associates, and if admission control is enabled on the radio. • User can modify the <code>port_child_policy</code> to add more classes. • User can attach a user-defined policy at the SSID level. • User can attach a user-defined policy at the client level. • User can configure a port policy. • User can configure an SSID policy. • These policies can then be modified. • The default radio policy (which cannot be modified) is attached to the radio. • Optionally, the user can attach a client policy as required. • The default client policies take effect when a WMM client associates, and if admission control is enabled on the radio.
Number of queues permitted at port level	Up to 8 queues supported on a port.	Only four queues supported.

Feature	Wired	Wireless
Classification mechanism	<ul style="list-style-type: none"> • DSCP • IP precedence • CoS • QoS-group • ACL membership including: <ul style="list-style-type: none"> • IPv4 ACLs • IPv6 ACLS • MAC ACLs 	<ul style="list-style-type: none"> • Port level <ul style="list-style-type: none"> • Ingress: QoS policies not supported on ingress in wireless ports. • Egress: Only DSCP based classification. • SSID level <ul style="list-style-type: none"> • Ingress: DSCP, UP • Egress: DSCP,COS, QoS group • Client level <ul style="list-style-type: none"> • Ingress: ACL, DSCP, UP • Egress: DSCP and COS

[Client Policies](#), on page 858

Port Policies

The device supports port-based policies. The port policies includes port shaper and a child policy (port_child_policy).

Note Port child policies only apply to wireless ports and not to wired ports on the switch. A wireless port is defined as a port to which APs join. A default port child policy is applied on the switch to the wireless ports at start up. The port shaper rate is limited to 1G

Port shaper specifies the traffic policy applicable between the device and the AP. This is the sum of the radio rates supported on the access point.

The child policy determines the mapping between packets and queues defined by the port-child policy. The child policy can be configured to include voice, video, class-default, and non-client-nrt classes where voice and video are based on DSCP value (which is the outer CAPWAP header DSCP value). The definition of class-default is known to the system as any value other than voice and video DSCP.

The DSCP value is assigned when the packet reaches the port. Before the packet arrives at the port, the SSID policies are applied on the packet. Port child policy also includes multicast percentage for a given port traffic. By default, the port child policy allocates up to 10 percent of the available rate.

Port Policy Format

This section describes the behavior of the port policies on a switch. The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suit the QoS configuration. The switch is pre configured with a default class map and a policy map.

Default class map:

```
Class Map match-any non-client-nrt-class
  Match non-client-nrt
```

The above port policy processes all network traffic to the Q3 queue. You can view the class map by executing the **show class-map** command.

Default policy map:

```
Policy Map port_child_policy
  Class non-client-nrt-class
    bandwidth remaining ratio 10
```

Note The class map and policy map listed are system-defined policies and cannot be changed.

The following is the system-defined policy map available on the ports on which wireless devices are associated. The format consists of a parent policy and a service child policy (**port_child_policy**). To customize the policies to suite your network needs, you must configure the port child policy.

```
Policy-map policy_map_name
  Class class-default
    Shape average average_rate
    Service-policy port_child_policy
```

Note The parent policy is system generated and cannot be changed. You must configure the *port_child_policy* policy to suit the QoS requirements on your network.

Depending on the type of traffic in your network, you can configure the port child policy. For example, in a typical wireless network deployment, you can assign specific priorities to voice and video traffic. Here is an example:

```
Policy-map port_child_policy
  Class voice-policy-name (match dscp ef)
    Priority level 1
    Police (multicast-policer-name-voice) Multicast Policer
  Class video-policy-name (match dscp af41)
    Priority level 2
    Police (multicast-policer-name-video) Multicast Policer
  Class non-client-nrt-class traffic(match non-client-nrt)
    Bandwidth remaining ratio (brr-value-nrt-q2)
  Class class-default (NRT Data)
    Bandwidth remaining ratio (brr-value-q3)
```

In the above port child policy:

- *voice-policy-name*— Refers to the name of the class that specifies rules for the traffic for voice packets. Here the DSCP value is mapped to a value of 46 (represented by the keyword **ef**). The voice traffic is assigned the highest priority of 1.
- *video-policy-name*— Refers to the name of the class that specifies rules for the traffic for video packets. The DSCP value is mapped to a value of 34 (represented by the keyword **af41**).
- *multicast-policer-name-voice*— If you need to configure multicast voice traffic, you can configure policing for the voice class map.
- *multicast-policer-name-video*— If you need to configure multicast video traffic, you can configure policing for the video class map.

In the above sample configuration, all voice and video traffic is directed to the Q0 and Q1 queues, respectively. These queues maintain a strict priority. The packets in Q0 and Q1 are processed in that order. The bandwidth remaining ratios *brr-value-nrt-q2* and *brr-value-q3* are directed to the Q2 and Q3 respectively specified by

the class maps and *class-default* and *non-client-nrt*. The processing of packets on Q2 and Q3 are based on a weighted round-robin approach. For example, if the *brr-value-nrtq2* has a value of 90 and *brr-value-nrtq3* is 10, the packets in queue 2 and queue 3 are processed in the ratio of 9:1.

The Cisco 5700 Series Wireless Controller does not contain a default port policy. Physical port policies must be configured for voice and video to function. Because a Cisco 5700 Series Wireless Controller contains six 10-gigabit ports, the policy map must be configured on all ports.

Note The policy must be configured on all of the six physical ports on the controller even if LAG (Link Aggregation/Etherchannel) is configured.

The following basic port policy must be configured on the physical ports. You can add further classification if required:

```
Policy-map <port-policy-name>
  Class voice
    Priority level 1
  class video
    Priority level 2
```

Radio Policies

The radio policies are system defined and are not user configurable. Radio wireless targets are only applicable in the egress direction.

Radio policies are applicable on a per-radio, per-access point basis. The rate limit on the radios is the practical limit of the AP radio rate. This value is equivalent to the sum of the radios supported by the access point.

The following radios are supported:

- 802.11 a/n
- 802.11 b/n
- 802.11 ac

Related Topics

- [Supported QoS Features on Wireless Targets, on page 853](#)

SSID Policies

You can create QoS policies on SSID BSSID (Basic Service Set Identification) in both the ingress and egress directions. By default, there is no SSID policy. All traffic is transmitted as best effort because the wireless traffic is untrusted. You can configure an SSID policy based on the SSID name. The policy is applicable on a per BSSID.

The types of policies you can create on SSID include marking by using table maps (table-maps), shape rate, and RT1 (Real Time 1) and RT2 (Real Time 2) policies. If traffic is ingress, you usually configure a marking and policing policy on the SSID. If traffic is downstream, you can configure marking and queuing.

There should be a one-to-one mapping between the policies configured on a port and an SSID. For example, if you configure class voice and class video on the port, you can have a similar policy on the SSID.

The policy on the port is mandatory if you want to preserve the voice and video behavior priority at the port level. Queuing policy is applicable in a downstream direction. When packets arrive from the AP, you can only configure policing and rate limiting.

SSID priorities can be specified by configuring bandwidth remaining ratio. Queuing SSID policies are applied in the egress direction.

[Examples: SSID Policy](#)

[Examples: Configuring Downstream SSID Policy](#), on page 964

Client Policies

Client policies are applicable in the ingress and egress direction. The wireless control module of the device applies the default client policies when admission control is enabled for WMM clients. When admission control is disabled, there is no default client policy. You can configure policing and marking policies on clients.

Note A client policy can have both IPv4 and IPv6 filters.

You can configure client policies in the following ways:

- Using AAA
- Using the Cisco IOS MQC CLI
 - You can use **service policy client** command in the WLAN configuration.
- Using the default configuration
- Using local policies (native profiling)

Use the **show wireless client mac address mac_address service-policy** command to display the source of the client policy (for example, local profiling policy, AAA, or CLI). The precedence order of client policies is AAA > local policy > WLAN service client policy CLI > default configuration.

Note If you configured AAA by configuring the unified wireless controller procedure, and using the MQC QoS commands, the policy configuration performed through the MQC QoS commands takes precedence.

Note When applying client policies on a WLAN, you must disable the WLAN before modifying the client policy. SSID policies can be modified even if the WLAN is enabled.

The default client policy is enabled only on Wi-Fi Multimedia (WMM) clients that are admission control (ACM)-enabled.

Policy Chaining

Every packet has a maximum of two applicable policies, first at the client target and second at the SSID target. The client policing action is applied to the packet before the marking action that is specified in the client policy. After the client policing and marking actions are applied to the packet, the SSID policy action is applied to the updated packet. If no custom policies are specified, the system trust configuration is applied to the packet. Egress trust is based on DSCP, and ingress trust is based on WLAN user priority.

Hierarchical QoS

The supports hierarchical QoS (HQoS). HQoS allows you to perform:

- Hierarchical classification—Traffic classification is based upon other classes.
- Hierarchical policing—The process of having the policing configuration at multiple levels in a hierarchical policy.
- Hierarchical shaping—Shaping can also be configured at multiple levels in the hierarchy.

Note Hierarchical shaping is only supported for the port shaper, where for the parent you only have a configuration for the class default, and the only action for the class default is shaping.

Related Topics

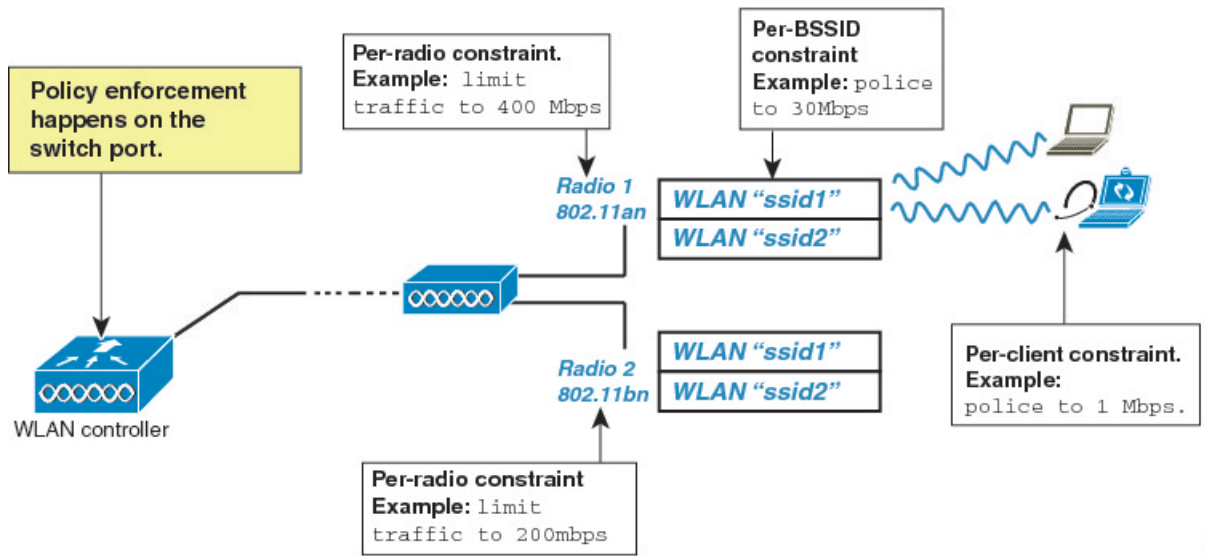

- [Examples: Hierarchical Classification](#), on page 961
- [Examples: Hierarchical Policy Configuration](#), on page 961

Hierarchical Wireless QoS

The device supports hierarchical QoS for wireless targets. Hierarchical QoS policies are applicable on port, radio, SSID, and client. QoS policies configured on the device (including marking, shaping, policing) can be applied across the targets. If the network contains non-realtime traffic, the non-realtime traffic is subject to approximate fair drop. Hierarchy refers to the process of application of the various QoS policies on the packets arriving to the device. You can configure policing in both the parent and child policies.

Note For hierarchical client and SSID policies, you only configure marking either in the parent or child policy.

352757

Wireless Packet Format

Figure 54: Wireless Packet Path in the Egress Direction during First Pass

This figure displays the wireless packet flow and encapsulation used in hierarchical wireless QoS. The incoming packet enters the device. The device encapsulates this incoming packet and adds the 802.11e and CAPWAP headers.

Hierarchical AFD

Approximate Fair Dropping (AFD) is a feature provided by the QoS infrastructure in Cisco IOS. For wireless targets, AFD can be configured on SSID (via shaping) and clients (via policing). AFD shaping rate is only applicable for downstream direction. Unicast real-time traffic is not subjected to AFD drops.

QoS Implementation

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (*class*) information. Classification can also be carried in the Layer 2 frame.

Figure 55: QoS Classification Layers in Frames and Packets

The special bits in the Layer 2 frame or a Layer 3 packet are shown in the following

Encapsulated Packet

Layer 2 ISL Frame

3 bits used for CoS

Layer 2 802.1Q and 802.1p Frame

3 bits used for CoS (user priority)

Layer 3 IPv4 Packet

IP precedence or DSCP

Layer 3 IPv6 Packet

IP precedence or DSCP

Related Topics

[Restrictions for QoS on Wired Targets](#), on page 889

[Restrictions for QoS on Wireless Targets](#), on page 892

Layer 2 Frame Prioritization Bits

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.

End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

Packet Classification

Packet classification is the process of identifying a packet as belonging to one of several classes in a defined policy, based on certain criteria. The Modular QoS CLI (MQC) is a policy-class based language. The policy class language is used to define the following:

- Class-map template with one or several match criteria
- Policy-map template with one or several classes associated to the policy map

The policy map template is then associated to one or several interfaces on the .

Packet classification is the process of identifying a packet as belonging to one of the classes defined in the policy map. The process of classification will exit when the packet being processed matches a specific filter in a class. This is referred to as first-match exit. If a packet matches multiple classes in a policy, irrespective of the order of classes in the policy map, it would still exit the classification process after matching the first class.

If a packet does not match any of the classes in the policy, it would be classified into the default class in the policy. Every policy map has a default class, which is a system-defined class to match packets that do not match any of the user-defined classes.

Packet classification can be categorized into the following types:

- Classification based on information that is propagated with the packet
- Classification based on information that is specific
- Hierarchical classification

Classification Based on Information That is Propagated with the Packet

Classification that is based on information that is part of the packet and propagated either end-to-end or between hops, typically includes the following:

- Classification based on Layer 3 or 4 headers
- Classification based on Layer 2 information

Classification Based on Layer 3 or Layer 4 Header

This is the most common deployment scenario. Numerous fields in the Layer 3 and Layer 4 headers can be used for packet classification.

At the most granular level, this classification methodology can be used to match an entire flow. For this deployment type, an access control list (ACLs) can be used. ACLs can also be used to match based on various subsets of the flow (for example, source IP address only, or destination IP address only, or a combination of both).

Classification can also be done based on the precedence or DSCP values in the IP header. The IP precedence field is used to indicate the relative priority with which a particular packet needs to be handled. It is made up of three bits in the IP header's type of service (ToS) byte.

The following table shows the different IP precedence bit values and their names.

Note IP precedence is not supported for wireless QoS.

Table 67: IP Precedence Values and Names

IP Precedence Value	IP Precedence Bits	IP Precedence Names
0	000	Routine
1	001	Priority
2	010	Immediate
3	011	Flash
4	100	Flash Override
5	101	Critical
6	110	Internetwork control
7	111	Network control

Note All routing control traffic in the network uses IP precedence value 6 by default. IP precedence value 7 also is reserved for network control traffic. Therefore, the use of IP precedence values 6 and 7 is not recommended for user traffic.

The DSCP field is made up of 6 bits in the IP header and is being standardized by the Internet Engineering Task Force (IETF) Differentiated Services Working Group. The original ToS byte contained the DSCP bits has been renamed the DSCP byte. The DSCP field is part of the IP header, similar to IP precedence. The

DSCP field is a super set of the IP precedence field. Therefore, the DSCP field is used and is set in ways similar to what was described with respect to IP precedence.

Note The DSCP field definition is backward-compatible with the IP precedence values.

Classification Based on Layer 2 Header

A variety of methods can be used to perform classification based on the Layer 2 header information. The most common methods include the following:

- MAC address-based classification (only for access groups)—Classification is based upon the source MAC address (for policies in the input direction) and destination MAC address (for policies in the output direction).
- Class-of-Service—Classification is based on the 3 bits in the Layer 2 header based on the IEEE 802.1p standard. This usually maps to the ToS byte in the IP header.
- VLAN ID—Classification is based on the VLAN ID of the packet.

Note Some of these fields in the Layer 2 header can also be set using a policy.

Classification Based on Information that is Device Specific (QoS Groups)

The also provides classification mechanisms that are available where classification is not based on information in the packet header or payload.

At times you might be required to aggregate traffic coming from multiple input interfaces into a specific class in the output interface. For example, multiple customer edge routers might be going into the same access on different interfaces. The service provider might want to police all the aggregate voice traffic going into the core to a specific rate. However, the voice traffic coming in from the different customers could have a different ToS settings. QoS group-based classification is a feature that is useful in these scenarios.

Policies configured on the input interfaces set the QoS group to a specific value, which can then be used to classify packets in the policy enabled on output interface.

The QoS group is a field in the packet data structure internal to the . It is important to note that a QoS group is an internal label to the and is not part of the packet header.

Hierarchical Classification

The permits you to perform a classification based on other classes. Typically, this action may be required when there is a need to combine the classification mechanisms (that is, filters) from two or more classes into a single class map.

QoS Wired Model

To implement QoS, the must perform the following tasks:

- Traffic classification—Distinguishes packets or flows from one another.

- Traffic marking and policing—Assigns a label to indicate the given quality of service as the packets move through the , and then make the packets comply with the configured resource usage limits.
- Queuing and scheduling—Provides different treatment in all situations where resource contention exists.
- Shaping—Ensures that traffic sent from the meets a specific traffic profile.

Ingress Port Activity

The following activities occur at the ingress port of the :

- Classification—Classifying a distinct path for a packet by associating it with a QoS label. For example, the maps the CoS or DSCP in the packet to a QoS label to distinguish one type of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.
- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).

Note Applying polices on the wireless ingress port is not supported on the .

Egress Port Activity

The following activities occur at the egress port of the :

- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).
- Queueing—Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, Weighted Tail Drop (WTD) differentiates traffic classes and subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.

Classification

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is enabled on the . By default, QoS is enabled on the .

During classification, the performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.

Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:

- If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.
- If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.

Note Deny action is supported in Cisco IOS Release 3.7.4E and later releases.

- If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the offers best-effort service to the packet.
- If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

Note When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate-limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the **access-list** global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the **mac access-list extended** global configuration command.

Class Maps

A class map is a mechanism that you use to name a specific traffic flow (or class) and isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

You create a class map by using the **class-map** global configuration command or the **class** policy-map configuration command. You should use the **class-map** command when the map is shared among many ports. When you enter the **class-map** command, the enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the **match** class-map configuration command.

You can create a default class by using the **class class-default** policy-map configuration command. The default class is system-defined and cannot be configured. Unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as default traffic.

Related Topics

[Creating a Traffic Class \(CLI\)](#), on page 895

[Examples: Classification by Access Control Lists](#), on page 959

Policy Maps

A policy map specifies which traffic class to act on. Actions can include the following:

- Setting a specific DSCP or IP precedence value in the traffic class
- Setting a CoS value in the traffic class
- Setting a QoS group
- Setting a wireless LAN (WLAN) value in the traffic class
- Specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile

Before a policy map can be effective, you must attach it to a port.

You create and name a policy map using the **policy-map** global configuration command. When you enter this command, the router enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the **class** or **set** policy-map configuration and policy-map class configuration commands.

The policy map can also be configured using the **police** and **bandwidth** policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded. In addition, the policy-map can further be configured using the **priority** policy-map class configuration command, to schedule priority for the class or the queuing policy-map class configuration commands, **queue-buffers** and **queue-limit**.

To enable the policy map, you attach it to a port by using the **service-policy** interface configuration command.

Note You cannot configure both **priority** and **set** for a policy map. If both these commands are configured for a policy map, and when the policy map is applied to an interface, error messages are displayed. The following example shows this restriction:

```
Switch# configure terminal
Switch(config)# class-map cmap
Switch(config-cmap)# exit
Switch(config)# class-map classmap1
Switch(config-cmap)# exit
Switch(config)# policy-map pmap
Switch(config-pmap)# class cmap
Switch(config-pmap-c)# priority
Switch(config-pmap-c)# exit
Switch(config-pmap)# class classmap1
Switch(config-pmap-c)# set
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet 0/1/1
Switch(config-if)# service-policy output pmap

Non-queuing action only is unsupported in a queuing policy!!!
%QOS-6-POLICY_INST_FAILED:
Service policy installation failed
```

- [Port Policy Format](#), on page 855

Policy Map on Physical Port

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions can include setting a specific DSCP or IP precedence value in the traffic class, specifying the traffic bandwidth limitations for each matched traffic class (policer), and taking action when the traffic is out of profile (marking).

A policy map also has these characteristics:

- A policy map can contain multiple class statements, each with different match criteria and policers.
- A policy map can contain a predefined default traffic class explicitly placed at the end of the map.

When you configure a default traffic class by using the **class class-default** policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (**class-default**).

- A separate policy-map class can exist for each type of traffic received through a port.

Related Topics

- [Attaching a Traffic Policy to an Interface \(CLI\)](#), on page 912

Policy Map on VLANs

The `service-policy` command supports a VLAN QoS feature that allows the user to perform QoS treatment at the VLAN level (classification and QoS actions) using the incoming frame's VLAN information. In VLAN-based QoS, a service policy is applied to an SVI interface. All physical interfaces belonging to a VLAN policy map then need to be programmed to refer to the VLAN-based policy maps instead of the port-based policy map.

Although the policy map is applied to the VLAN SVI, any policing (rate-limiting) action can only be performed on a per-port basis. You cannot configure the policer to take account of the sum of traffic from a number of physical ports. Each port needs to have a separate policer governing the traffic coming into that port.

Related Topics

[Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps \(CLI\)](#), on page 919

[Examples: Policer VLAN Configuration](#), on page 971

Wireless QoS Multicast

You can configure multicast policing rate at the port level.

There are two modes of a multicast configuration in the Cisco 5700 Series Wireless Controller:

- multicast-unicast mode—Multicast traffic is copied as unicast traffic to the APs. QoS on multicast traffic when multicast-unicast mode is not supported on the Cisco 5700 Series Wireless Controller.
- multicast-multicast mode—The controller sends the traffic to the multicast group. The APs in the multicast group then receive the multicast traffic.

Related Topics

[Configuring QoS Policies for Multicast Traffic \(CLI\)](#), on page 952

[Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic](#), on page 963

Policing

After a packet is classified and has a DSCP-based, CoS-based, or QoS-group label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP or CoS value of the packet and allowing the packet to pass through.

To avoid out-of-order packets, both conform and nonconforming traffic typically exit the same queue.

Note All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can only configure policing on a physical port.

After you configure the policy map and policing actions, attach the policy to an ingress port or SVI by using the **service-policy** interface configuration command.

Related Topics

[Configuring Police \(CLI\)](#), on page 939

[Examples: Policing Action Configuration](#), on page 970

Token-Bucket Algorithm

Policing uses a token-bucket algorithm. As each frame is received by the , a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).

How quickly the bucket fills is a function of the bucket depth (burst-byte), the rate at which the tokens are removed (rate-bps), and the duration of the burst above the average rate. The size of the bucket imposes an upper limit on the burst length and limits the number of frames that can be transmitted back-to-back. If the burst is short, the bucket does not overflow, and no action is taken against the traffic flow. However, if a burst is long and at a higher rate, the bucket overflows, and the policing actions are taken against the frames in that burst.

You configure the bucket depth (the maximum burst that is tolerated before the bucket overflows) by using the burst-byte option of the **police** policy-map class configuration command. You configure how fast (the average rate) that the tokens are removed from the bucket by using the rate option of the **police** policy-map class configuration command.

[Examples: Policing Units](#), on page 971

Marking

Marking is used to convey specific information to a downstream device in the network, or to carry information from one interface in a to another.

Marking can be used to set certain field/bits in the packet headers, or marking can also be used to set certain fields in the packet structure that is internal to the . Additionally, the marking feature can be used to define mapping between fields. The following marking methods are available for QoS:

- Packet header
- Device () specific information
- Table maps

Packet Header Marking

Marking on fields in the packet header can be classified into two general categories:

- IPv4/v6 header bit marking
- Layer 2 header bit marking

The marking feature at the IP level is used to set the precedence or the DSCP in the IP header to a specific value to get a specific per-hop behavior at the downstream device (switch or router), or it can also be used to aggregate traffic from different input interfaces into a single class in the output interface. The functionality is currently supported on both the IPv4 and IPv6 headers.

Marking in the Layer 2 headers is typically used to influence dropping behavior in the downstream devices (switch or router). It works in tandem with the match on the Layer 2 headers. The bits in the Layer 2 header that can be set using a policy map are class of service.

Switch Specific Information Marking

This form of marking includes marking of fields in the packet data structure that are not part of the packets header, so that the marking can be used later in the data path. This is not propagated between the switches. Marking of QoS-group falls into this category. This form of marking is only supported in policies that are enabled on the input interfaces. The corresponding matching mechanism can be enabled on the output interfaces on the same switch and an appropriate QoS action can be applied.

Table Map Marking

Table map marking enables the mapping and conversion from one field to another using a conversion table. This conversion table is called a table map.

Depending upon the table map attached to an interface, CoS, DSCP, and UP values (UP specific to wireless packets) of the packet are rewritten. The allows configuring both ingress table map policies and egress table map policies.

Note The stack supports a total of 14 table maps. Only one table map is supported per wired port, per direction.

As an example, a table map can be used to map the Layer 2 CoS setting to a precedence value in Layer 3. This feature enables combining multiple **set** commands into a single table, which indicates the method to perform the mapping. This table can be referenced in multiple policies, or multiple times in the same policy.

The following table shows the currently supported forms of mapping:

Table 68: Packet-Marking Types Used for Establishing a To-From Relationship

The To Packet-Marking Type	The From Packet-Marking Type
Precedence	CoS
Precedence	QoS Group
DSCP	CoS
DSCP	QoS Group
CoS	Precedence
CoS	DSCP
QoS Group	Precedence
QoS Group	DSCP

A table map-based policy supports the following capabilities:

- Mutation—You can have a table map that maps from one DSCP value set to another DSCP value set, and this can be attached to an egress port.

- Rewrite—Packets coming in are rewritten depending upon the configured table map.
- Mapping—Table map based policies can be used instead of set policies.

The following steps are required for table map marking:

1. Define the table map—Use the **table-map** global configuration command to map the values. The table does not know of the policies or classes within which it will be used. The default command in the table map is used to indicate the value to be copied into the to field when there is no matching from field.
2. Define the policy map—You must define the policy map where the table map will be used.
3. Associate the policy to an interface.

Note A table map policy on an input port changes the trust setting of that port to the from type of qos-marking.

[Examples: Table Map Marking Configuration](#), on page 973

Traffic Conditioning

To support QoS in a network, traffic entering the service provider network needs to be policed on the network boundary routers to ensure that the traffic rate stays within the service limit. Even if a few routers at the network boundary start sending more traffic than what the network core is provisioned to handle, the increased traffic load leads to network congestion. The degraded performance in the network makes it difficult to deliver QoS for all the network traffic.

Traffic policing functions (using the police feature) and shaping functions (using the traffic shaping feature) manage the traffic rate, but differ in how they treat traffic when tokens are exhausted. The concept of tokens comes from the token bucket scheme, a traffic metering function.

Note When running QoS tests on network traffic, you may see different results for the shaper and policing data. Network traffic data from shaping provides more accurate results.

This table compares the policing and shaping functions.

Table 69: Comparison Between Policing and Shaping Functions

Policing Function	Shaping Function
Sends conforming traffic up to the line rate and allows bursts.	Smooths traffic and sends it out at a constant rate.
When tokens are exhausted, action is taken immediately.	When tokens are exhausted, it buffers packets and sends them out later, when tokens are available. A class with shaping has a queue associated with it which will be used to buffer the packets.

Policing Function	Shaping Function
Policing has multiple units of configuration – in bits per second, packets per second and cells per second.	Shaping has only one unit of configuration - in bits per second.
Policing has multiple possible actions associated with an event, marking and dropping being example of such actions.	Shaping does not have the provision to mark packets that do not meet the profile.
Works for both input and output traffic.	Implemented for output traffic only.
Transmission Control Protocol (TCP) detects the line at line speed but adapts to the configured rate when a packet drop occurs by lowering its window size.	TCP can detect that it has a lower speed line and adapt its retransmission timer accordingly. This results in less scope of retransmissions and is TCP-friendly.

Policing

The QoS policing feature is used to impose a maximum rate on a traffic class. The QoS policing feature can also be used with the priority feature to restrict priority traffic. If the rate is exceeded, then a specific action is taken as soon as the event occurs. The rate (committed information rate [CIR] and peak information rate [PIR]) and the burst parameters (conformed burst size [B_c] and extended burst size [B_e]) are all configured in bytes per second.

The following policing forms or policers are supported for QoS:

- Single-rate two-color policing
- Dual-rate three-color policing

Note Single-rate three-color policing is not supported.

Single-Rate Two-Color Policing

Single-rate two-color policer is the mode in which you configure only a CIR and a B_c .

The B_c is an optional parameter, and if it is not specified it is computed by default. In this mode, when an incoming packet has enough tokens available, the packet is considered to be conforming. If at the time of packet arrival, enough tokens are not available within the bounds of B_c , the packet is considered to have exceeded the configured rate.

Note For information about the token-bucket algorithm, see [Token-Bucket Algorithm, on page 871](#).

Related Topics

[Configuring Police \(CLI\)](#), on page 939

[Examples: Single-Rate Two-Color Policing Configuration](#), on page 972

Dual-Rate Three-Color Policing

With the dual rate policer, the supports only color-blind mode. In this mode, you configure a committed information rate (CIR) and a peak information rate (PIR). As the name suggests, there are two token buckets in this case, one for the peak rate, and one for the conformed rate.

Note For information about the token-bucket algorithm, see [Token-Bucket Algorithm, on page 871](#).

In the color-blind mode, the incoming packet is first checked against the peak rate bucket. If there are not enough tokens available, the packet is said to violate the rate. If there are enough tokens available, then the tokens in the conformed rate buckets are checked to determine if there are enough tokens available. The tokens in the peak rate bucket are decremented by the size of the packet. If it does not have enough tokens available, the packet is said to have exceeded the configured rate. If there are enough tokens available, then the packet is said to conform, and the tokens in both the buckets are decremented by the size of the packet.

The rate at which tokens are replenished depends on the packet arrival. Assume that a packet comes in at time T1 and the next one comes in at time T2. The time interval between T1 and T2 determines the number of tokens that need to be added to the token bucket. This is calculated as:

Time interval between packets (T2-T1) * CIR/8 bytes

Shaping

Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that the downstream switches and routers are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface.

Shaping has a buffer associated with it that ensures that packets which do not have enough tokens are buffered as opposed to being immediately dropped. The number of buffers available to the subset of traffic being shaped is limited and is computed based on a variety of factors. The number of buffers available can also be tuned using specific QoS commands. Packets are buffered as buffers are available, beyond which they are dropped.

Class-Based Traffic Shaping

The uses class-based traffic shaping. This shaping feature is enabled on a class in a policy that is associated to an interface. A class that has shaping configured is allocated a number of buffers to hold the packets that do not have tokens. The buffered packets are sent out from the class using FIFO. In the most common form of usage, class-based shaping is used to impose a maximum rate for an physical interface or logical interface as a whole. The following shaping forms are supported in a class:

- Average rate shaping
- Hierarchical shaping

Shaping is implemented using a token bucket. The values of CIR, B_c and B_e determine the rate at which the packets are sent out and the rate at which the tokens are replenished.

Note For information about the token-bucket algorithm, see [Token-Bucket Algorithm, on page 871](#).

Average Rate Shaping

You use the **shape average** policy-map class command to configure average rate shaping.

This command configures a maximum bandwidth for a particular class. The queue bandwidth is restricted to this value even though the port has more bandwidth available. The `shape average` supports configuring shape average by either a percentage or by a target bit rate value.

Related Topics

[Configuring Shaping \(CLI\), on page 949](#)

[Examples: Average Rate Shaping Configuration, on page 968](#)

Hierarchical Shaping

Shaping can also be configured at multiple levels in a hierarchy. This is accomplished by creating a parent policy with shaping configured, and then attaching child policies with additional shaping configurations to the parent policy.

There are two supported types of hierarchical shaping:

- Port shaper
- User-configured shaping

The port shaper uses the class default and the only action permitted in the parent is shaping. The queuing action is in the child with the port shaper. With the user configured shaping, you cannot have queuing action in the child.

Related Topics

[Configuring Shaping \(CLI\), on page 949](#)

Queueing and Scheduling

The `shape average` uses both queueing and scheduling to help prevent traffic congestion. The `shape average` supports the following queueing and scheduling features:

- Bandwidth
- Weighted Tail Drop
- Priority queues
- Queue buffers

Bandwidth

The `shape average` supports the following bandwidth configurations:

- Bandwidth percent
- Bandwidth remaining ratio

Related Topics

[Configuring Bandwidth \(CLI\)](#), on page 935

Bandwidth Percent

You can use the **bandwidth percent** policy-map class command to allocate a minimum bandwidth to a particular class. The total sum cannot exceed 100 percent and in case the total sum is less than 100 percent, then the rest of the bandwidth is divided equally among all bandwidth queues.

Note A queue can oversubscribe bandwidth in case the other queues do not utilize the entire port bandwidth.

You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.

Bandwidth Remaining Ratio

You use the **bandwidth remaining ratio** policy-map class command to create a ratio for sharing unused bandwidth in specified queues. Any unused bandwidth will be used by these specific queues in the ratio that is specified by the configuration. Use this command when the **priority** command is also used for certain queues in the policy.

When you assign ratios, the queues will be assigned certain weights which are inline with these ratios.

You can specify ratios using a range from 0 to 100. For example, you can configure a bandwidth remaining ratio of 2 on one class, and another queue with a bandwidth remaining ratio of 4 on another class. The bandwidth remaining ratio of 4 will be scheduled twice as often as the bandwidth remaining ratio of 2.

The total bandwidth ratio allocation for the policy can exceed 100. For example, you can configure a queue with a bandwidth remaining ratio of 50, and another queue with a bandwidth remaining ratio of 100.

Weighted Tail Drop

The egress queues use an enhanced version of the tail-drop congestion-avoidance mechanism called weighted tail drop (WTD). WTD is implemented on queues to manage the queue lengths and to provide drop precedences for different traffic classifications.

As a frame is enqueued to a particular queue, WTD uses the frame's assigned QoS label to subject it to different thresholds. If the threshold is exceeded for that QoS label (the space available in the destination queue is less than the size of the frame), the drops the frame.

Each queue has three configurable threshold values. The QoS label determines which of the three threshold values is subjected to the frame.

Figure 56: WTD and Queue Operation

The following figure shows an example of WTD operating on a queue whose size is 1000 frames. Three drop percentages are configured: 40 percent (400 frames), 60 percent (600 frames), and 100 percent (1000 frames). These percentages indicate that up to 400 frames can be queued at the 40-percent threshold, up to 600 frames

at the 60-percent threshold, and up to 1000 frames at the 100-percent

threshold.

In the example, CoS value 6 has a greater importance than the other CoS values, and is assigned to the 100-percent drop threshold (queue-full state). CoS values 4 is assigned to the 60-percent threshold, and CoS values 3 is assigned to the 40-percent threshold. All of these threshold values are assigned using the **queue-limit cos** command.

Assuming the queue is already filled with 600 frames, and a new frame arrives. It contains CoS value 4 and is subjected to the 60-percent threshold. If this frame is added to the queue, the threshold will be exceeded, so the drops it.

Related Topics

[Configuring Queue Limits \(CLI\)](#), on page 946

[Examples: Queue-limit Configuration](#), on page 969

Weighted Tail Drop Default Values

The following are the Weighted Tail Drop (WTD) default values and the rules for configuring WTD threshold values.

- If you configure less than three queue-limit percentages for WTD, then WTD default values are assigned to these thresholds.

The following are the WTD threshold default values:

Table 70: WTD Threshold Default Values

Threshold	Default Value Percentage
0	80
1	90
2	400

- If 3 different WTD thresholds are configured, then the queues are programmed as configured.
- If 2 WTD thresholds are configured, then the maximum value percentage will be 400.
- If a WTD single threshold is configured as x, then the maximum value percentage will be 400.
 - If the value of x is less than 90, then threshold1=90 and threshold 0= x.
 - If the value of x equals 90, then threshold1=90, threshold 0=80.
 - If the value x is greater than 90, then threshold1=x, threshold 0=80.

Priority Queues

Each port supports eight egress queues, of which two can be given a priority.

You use the **priority level** policy class-map command to configure the priority for two classes. One of the classes has to be configured with a priority queue level 1, and the other class has to be configured with a priority queue level 2. Packets on these two queues are subjected to less latency with respect to other queues.

Note You can configure a priority only with a level.

Only one strict priority or a priority with levels is allowed in one policy map. Multiple priorities with the same priority levels without kbps/percent are allowed in a policy map only if all of them are configured with police.

Related Topics

[Configuring Priority \(CLI\)](#), on page 941

Queue Buffer

Each 1-gigabit port on the is allocated 168 buffers for a wireless port and 300 buffers for a wired port. Each 10-gigabit port is allocated 1800 buffers. At boot time, when there is no policy map enabled on the wired port, there are two queues created by default. Wired ports can have a maximum of 8 queues configured using MQC-based policies. The following table shows which packets go into which one of the queues:

Table 71: DSCP, Precedence, and CoS - Queue Threshold Mapping Table

DSCP, Precedence or CoS	Queue	Threshold
Control Packets	0	2
Rest of Packets	1	2

Note You can guarantee the availability of buffers, set drop thresholds, and configure the maximum memory allocation for a queue. You use the **queue-buffers** policy-map class command to configure the queue buffers. You use the **queue-limit** policy-map class command to configure the maximum thresholds.

There are two types of buffer allocations: hard buffers, which are explicitly reserved for the queue, and soft buffers, which are available for other ports when unused by a given port.

For the wireless port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 67 buffers are allocated for Queue 0 in the context of 1-gigabit ports. The soft maximum for this queue is set to 268 (calculated as $67 * 400/100$) for 1-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

For the wired port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 120 buffers are allocated for Queue 0 in the context of 1-gigabit ports, and 720 buffers in the context of 10-gigabit ports. The soft maximum for this queue is set to 480 (calculated as $120 * 400/100$) for 1-gigabit ports and 2880 for 10-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

Queue 1 does not have any hard buffers allocated. The default soft buffer limit is set to 400 (which is the maximum threshold). The threshold would determine the maximum number of soft buffers that can be borrowed from the common pool.

Queue Buffer Allocation

The buffer allocation to any queue can be tuned using the **queue-buffers ratio** policy-map class configuration command.

Related Topics

[Configuring Queue Buffers \(CLI\)](#), on page 944

[Examples: Queue Buffers Configuration](#), on page 970

Dynamic Threshold and Scaling

Traditionally, reserved buffers are statically allocated for each queue. No matter whether the queue is active or not, its buffers are held up by the queue. In addition, as the number of queues increases, the portion of the reserved buffers allocated for each queue can become smaller and smaller. Eventually, a situation may occur where there are not enough reserved buffers to support a jumbo frame for all queues.

The supports Dynamic Thresholding and Scaling (DTS), which is a feature that provides a fair and efficient allocation of buffer resources. When congestion occurs, this DTS mechanism provides an elastic buffer allocation for the incoming data based on the occupancy of the global/port resources. Conceptually, DTS scales down the queue buffer allocation gradually as the resources are used up to leave room for other queues, and vice versa. This flexible method allows the buffers to be more efficiently and fairly utilized.

As mentioned in the previous sections, there are two limits configured on a queue—a hard limit and a soft limit.

Hard limits are not part of DTS. These buffers are available only for that queue. The sum of the hard limits should be less than the globally set up hard maximum limit. The global hard limit configured for egress queuing is currently set to 5705. In the default scenario when there are no MQC policies configured, the 24 1-gigabit ports would take up $24 * 67 = 1608$, and the 4 10-gigabit ports would take up $4 * 720 = 2880$, for a total of 4488 buffers, allowing room for more hard buffers to be allocated based upon the configuration.

Soft limit buffers participate in the DTS process. Additionally, some of the soft buffer allocations can exceed the global soft limit allocation. The global soft limit allocation for egress queuing is currently set to 7607. The sum of the hard and soft limits add up to 13312, which in turn translates to 3.4 MB. Because the sum of the soft buffer allocations can exceed the global limit, it allows a specific queue to use a large number of buffers when the system is lightly loaded. The DTS process dynamically adjusts the per-queue allocation as the system becomes more heavily loaded.

Queuing in Wireless

Queuing in the wireless component is performed based on the port policy and is applicable only in the downstream direction. The wireless module supports the following four queues:

- **Voice**—This is a strict priority queue. Represented by Q0, this queue processes control traffic and multicast or unicast voice traffic. All control traffic (such as CAPWAP packets) is processed through the voice queue. The QoS module uses a different threshold within the voice queue to process control and voice packets to ensure that control packets get higher priority over other non-control packets.
- **Video**—This is a strict priority queue. Represented by Q1, this queue processes multicast or unicast video traffic.
- **Data NRT**—Represented by Q2, this queue processes all non-real-time unicast traffic.

- Multicast NRT—Represented by Q3, this queue processes Multicast NRT traffic. Any traffic that does not match the traffic in Q0, Q1, or Q2 is processed through Q3.

Note By default, the queues Q0 and Q1 are not enabled.

Note A weighted round-robin policy is applied for traffic in the queues Q2 and Q3.

For upstream direction only one queue is available. Port and radio policies are applicable only in the downstream direction.

Note The wired ports support eight queues.

Trust Behavior

Trust Behavior for Wired Ports

For wired ports that are connected to the (end points such as IP phones, laptops, cameras, telepresence units, or other devices), their DSCP, precedence, or CoS values coming in from these end points are trusted by the and therefore are retained in the absence of any explicit policy configuration.

The packets are enqueued to the appropriate queue per the default initial configuration.

In scenarios where the incoming packet type differs from the outgoing packet type, the trust behavior and the queuing behavior are explained in the following table. Note that the default trust mode for a wired port is DSCP based. The trust mode ‘falls back’ to CoS if the incoming packet is a pure Layer 2 packet. You can also change the trust setting from DSCP to CoS. This is accomplished by using an MQC policy that has a class default with a 'set cos cos table default default-cos' action, where default-cos is the name of the table map created (which only performs a default copy).

Table 72: Trust and Queuing Behavior

Incoming Packet	Outgoing Packet	Trust Behavior	Queuing Behavior
Layer 3	Layer 3	Preserve DSCP/Precedence	Based on DSCP
Layer 2	Layer 2	Not applicable	Based on CoS
Tagged	Tagged	Preserve DSCP and CoS	Based on DSCP (trust DSCP takes precedence)
Layer 3	Tagged	Preserve DSCP, CoS is set to 0	Based on DSCP

Trust Behavior for Wired and Wireless Ports

For wired or wireless ports that are connected to the (end points such as IP phones, laptops, cameras, telepresence units, or other devices), their DSCP, precedence, or CoS values coming in from these end points are trusted by the and therefore are retained in the absence of any explicit policy configuration.

This trust behavior is applicable to both upstream and downstream QoS.

The packets are enqueued to the appropriate queue per the default initial configuration. No priority queuing at the is done by default. This is true for unicast and multicast packets.

In scenarios where the incoming packet type differs from the outgoing packet type, the trust behavior and the queuing behavior are explained in the following table. Note that the default trust mode for a port is DSCP based. The trust mode 'falls back' to CoS if the incoming packet is a pure Layer 2 packet. You can also change the trust setting from DSCP to CoS. This setting change is accomplished by using an MQC policy that has a class default with a 'set cos cos table default default-cos' action, where default-cos is the name of the table map created (which only performs a default copy).

Table 73: Trust and Queuing Behavior

Incoming Packet	Outgoing Packet	Trust Behavior	Queuing Behavior
Layer 3	Layer 3	Preserve DSCP/Precedence	Based on DSCP
Layer 2	Layer 2	Not applicable	Based on CoS
Tagged	Tagged	Preserve DSCP and CoS	Based on DSCP (trust DSCP takes precedence)
Layer 3	Tagged	Preserve DSCP, CoS is set to 0	Based on DSCP

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired , all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

The default trust behavior in the case of wireless ports could be changed by using the **qos wireless default untrust** command.

Note

If you upgrade from Cisco IOS XE 3.2 SE Release to a later release, the default behavior of the wireless traffic is still untrusted. In this situation, you can use the **no qos wireless-default untrust** command to enable trust behavior for wireless traffic. However, if you install Cisco IOS XE 3.3 SE or a later release on the device, the default QoS behavior for wireless traffic is trust. Starting with Cisco IOS XE 3.3 SE Release and later, the packet markings are preserved in both egress and ingress directions for new installations (not upgrades) for wireless traffic.

[Example: Table Map Configuration to Retain CoS Markings](#), on page 974

Port Security on a Trusted Boundary for Cisco IP Phones

In a typical network, you connect a Cisco IP Phone to a port and cascade devices that generate data packets from the back of the telephone. The Cisco IP Phone guarantees the voice quality through a shared data link by marking the CoS level of the voice packets as high priority (CoS = 5) and by marking the data packets as low priority (CoS = 0). Traffic sent from the telephone to the is typically marked with a tag that uses the 802.1Q header. The header contains the VLAN information and the class of service (CoS) 3-bit field, which is the priority of the packet.

For most Cisco IP Phone configurations, the traffic sent from the telephone to the should be trusted to ensure that voice traffic is properly prioritized over other types of traffic in the network. By using the **trust device** interface configuration command, you configure the port to which the telephone is connected to trust the traffic received on that port.

Note The **trust device** *device_type* command available in interface configuration mode is a stand-alone command on the device. When using this command in an AutoQoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.

With the trusted setting, you also can use the trusted boundary feature to prevent misuse of a high-priority queue if a user bypasses the telephone and connects the PC directly to the . Without trusted boundary, the CoS labels generated by the PC are trusted by the (because of the trusted CoS setting). By contrast, trusted boundary uses CDP to detect the presence of a Cisco IP Phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the port and prevents misuse of a high-priority queue. Note that the trusted boundary feature is not effective if the PC and Cisco IP Phone are connected to a hub that is connected to the .

[Configuring Trust Behavior for the Device Type](#), on page 925

Wireless QoS Mobility

Wireless QoS mobility enables you to configure QoS policies so that the network provides the same service anywhere in the network. A wireless client can roam from one location to another and as a result the client can get associated to different access points associated with a different device. Wireless client roaming can be classified into two types:

- Intra-device roaming
- Inter-device roaming

Note The client policies must be available on all of the devices in the mobility group. The same SSID and port policy must be applied to all devices in the mobility group so that the clients get consistent treatment.

Inter-Device Roaming

When a client roams from one location to another, the client can get associated to access points either associated to the same device (anchor device) or a different device (foreign device). Inter-device roaming refers to the scenario where the client gets associated to an access point that is not associated to the same device before the client roamed. The host device is now foreign to the device to which the client was initially anchored.

In the case of inter-device roaming, the client QoS policy is always executed on the foreign controller. When a client roams from anchor device to foreign device, the QoS policy is uninstalled on the anchor device and installed on the foreign device. In the mobility handoff message, the anchor device passes the name of the policy to the foreign device. The foreign device should have a policy with the same name configured for the QoS policy to be applied correctly.

In the case of inter-device roaming, all of the QoS policies are moved from the anchor device to the foreign device. While the QoS policies are in transition from the anchor device to the foreign device, the traffic on the foreign device is provided the default treatment. This is comparable to a new policy installation on the client target.

Note If the foreign device is not configured with the user-defined physical port policy, the default port policy is applicable to all traffic is routed through the NRT queue, except the control traffic which goes through RT1 queue. The network administrator must configure the same physical port policy on both the anchor and foreign devices symmetrically.

During inter-device roaming, client and SSID policy statistics are collected only for the duration that the client is associated with the foreign device. Cumulative statistics for the whole roaming (anchor device and foreign device) are not collected.

Intra-Device Roaming

With intra-device roaming, the client gets associated to an access point that is associated to the same device before the client roamed, but this association to the device occurs through a different access point.

Note QoS policies remain intact in the case of intra-device roaming.

Precious Metal Policies for Wireless QoS

Wireless QoS is backward compatible with the precious metal policies offered by the unified wireless controller platforms. The precious metal policies are system-defined policies that are available on the controller.

The following policies are available:

- Platinum—Used for VoIP clients.
- Gold—Used for video clients.
- Silver— Used for traffic that can be considered best-effort.
- Bronze—Used for NRT traffic.

These policies (also known as profiles) can be applied to a WLAN based on the traffic. We recommend the configuration using the Cisco IOS MQC configuration. The policies are available in the system based on the precious metal policy required. You can configure precious metal policies only for SSID ingress and egress policies.

Based on the policies applied, the 802.1p, 802.11e (WMM), and DSCP fields in the packets are affected. These values are preconfigured and installed when the device is booted.

Note Unlike the precious metal policies that were applicable in the Cisco Unified Wireless controllers, the attributes rt-average-rate, nrt-average-rate, and peak rates are not applicable for the precious metal policies configured on this device platform.

Note The 802.1p protocol priority is applicable on the Cisco 5700 Series Wireless Controller.

Standard QoS Default Settings

Default Wired QoS Configuration

There are two queues configured by default on each wired interface on the . All control traffic traverses and is processed through queue 0. All other traffic traverses and is processed through queue 1.

DSCP Maps

Default CoS-to-DSCP Map

You use the CoS-to-DSCP map to map CoS values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default CoS-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

Table 74: Default CoS-to-DSCP Map

CoS Value	DSCP Value
0	0
1	8
2	16
3	24
4	32
5	40
6	48

CoS Value	DSCP Value
7	56

Default IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default IP-precedence-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

Table 75: Default IP-Precedence-to-DSCP Map

IP Precedence Value	DSCP Value
0	0
1	8
2	16
3	24
4	32
5	40
6	48
7	56

Default DSCP-to-CoS Map

You use the DSCP-to-CoS map to generate a CoS value, which is used to select one of the four egress queues. The following table shows the default DSCP-to-CoS map. If these values are not appropriate for your network, you need to modify them.

Table 76: Default DSCP-to-CoS Map

DSCP Value	CoS Value
0–7	0
8–15	1
16–23	2
24–31	3
32–39	4
40–47	5
48–55	6
56–63	7

Default Wireless QoS Configuration

The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suite the QoS configuration. The switch is preconfigured with a default class map and a policy map.

Configuring Auto QoS for Wireless

Information About Auto QoS for Wireless

Auto QoS for Wireless feature, introduced in Cisco IOS XE Release 3.7.0, is supported on the following platforms:

- Cisco 5760 Wireless Controller
- Catalyst 3850 Series Switches
- Catalyst 3650 Series Switches
- Cisco Catalyst 4500E Supervisor Engine 8-E

The following pre-defined global configuration templates/profiles are available:

- Enterprise
- Voice
- Guest

You can customize these templates to suit your needs. Auto QoS for Wireless can be configured using both CLI and GUI. Auto QoS for Wireless can be applied on a per-WLAN basis.

Precedence applicable:

1. AAA QoS
2. Native Profile QoS
3. Auto QoS/CLI-based QoS

Policy Names

P1	AutoQos-4.0-wlan-ET-Client-Input-Policy

Guidelines for Auto QoS for Wireless

- The Catalyst 3850 Switch uplink ports should not be configured along with Auto QoS for Wireless. This should be managed using Wired Auto QoS
- The Catalyst 3850 Switch AP Port Policy (port_child_policy) and Cisco 5760 WLC physical ports should be automatically configured for Enterprise and Voice templates.
- AP Control traffic must go through the P0 queue (should be given highest priority among all traffic).
- All the Auto QoS policies for Wireless applied through the GUI have the prefix 'AutoQos-4.0'. This enables you to recognize the policies that are applied through templates.
- On the CLI, it is not possible to create a policy name that starts with 'AutoQos-4.0' because this is reserved for policies generated through templates.

Configuring Auto QoS for Wireless (GUI)

- Step 1** Choose **Configuration > Wireless > WLAN**.
- Step 2** Click the WLAN ID.
- Step 3** Click the QoS tab.
- Step 4** In the **Auto QoS** section, choose the policy from the drop-down list.
- Note** By default, the Auto QoS policy applied for a WLAN is 'None'.
- Step 5** Save the configuration.
-

Configuring Auto QoS for Wireless (CLI)

```
Device(config-wlan)# auto qos {enterprise | guest | voice}
```

Guidelines for QoS Policies

Follow these guidelines to prevent clients from getting excluded due to malformed QoS policies:

- When a new QoS policy is added to the device, a QoS policy with the same name should be added to other device within the same roam or mobility domain.
- When a device is loaded with a software image of a later release, the new policy formats are supported. If you have upgraded the software image from an earlier release to a later release, you should save the configuration separately. When an earlier release image is loaded, some QoS policies might show as not supported, and you should restore those QoS policies to supported policy formats.

Restrictions for QoS on Wired Targets

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio policies are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the device to the wireless client. Upstream indicates that traffic is flowing from wireless client to the device.

The following are restrictions for applying QoS features on the device for the wired target:

- A maximum of 8 queuing classes are supported on the device port for the wired target.
- A maximum of 63 policers are supported per policy on the wired port for the wired target.
- In Cisco IOS XE Release 3.7.5E and later releases, by default all downlink ports are allocated 1 GB port buffer, even though the downlink port size is 10 GB. Prior to this change, all 1 GB downlink ports had 1 GB buffer and 10 GB downlink ports had 10 GB buffer.
- A maximum of 1600 policies are supported on the switch.

- No more than two levels are supported in a QoS hierarchy.
- In a hierarchical policy, overlapping actions between parent and child are not allowed, except when a policy has the port shaper in the parent and queuing features in the child policy.
- A QoS policy cannot be attached to any EtherChannel interface.
- Policing in both the parent and child is not supported in a QoS hierarchy.
- Marking in both the parent and child is not supported in a QoS hierarchy.
- A mixture of queue limit and queue buffer in the same policy is not supported.

Note The queue-limit percent is not supported on the device because the **queue-buffer** command handles this functionality. Queue limit is only supported with the DSCP and CoS extensions.

- With shaping, there is an IPG overhead of 20Bytes for every packet that is accounted internally in the hardware. Shaping accuracy will be effected by this, specially for packets of small size.
- The classification sequence for all wired queuing-based policies should be the same across all wired upstream ports (10-Gigabit Ethernet), and the same for all downstream wired ports (1-Gigabit Ethernet).
- Empty classes are not supported.
- Class-maps with empty actions are not supported. If there are two policies with the same order of class-maps and if there are class-maps with no action in one of the policies, there may be traffic drops. As a workaround, allocate minimal bandwidth for all the classes in PRIORITY_QUEUE.
- A maximum of 256 classes are supported per policy on the wired port for the wired target.
- The **match vlan** class-map configuration command supports either a match VLAN range or a single VLAN.
- The actions under a policer within a policy map have the following restrictions:
 - The conform action must be transmit.
 - The exceed/violate action for markdown type can only be cos2cos, prec2prec, dscp2dscp.
 - The markdown types must be the same within a policy.
- A port-level input marking policy takes precedence over an SVI policy; however, if no port policy is configured, the SVI policy takes precedence. For a port policy to take precedence, define a port-level policy; so that the SVI policy is overwritten.
- Classification counters have the following specific restrictions:
 - Classification counters count packets instead of bytes.
 - Filter-based classification counters are not supported
 - Only QoS configurations with marking or policing trigger the classification counter.
 - The classification counter is not port based. This means that the classification counter aggregates all packets belonging to the same class of the same policy which attach to different interfaces.

- As long as there is policing or marking action in the policy, the class-default will have classification counters.
- When there are multiple match statements in a class, then the classification counter only shows the traffic counter for one of the match statements.
- Table maps have the following specific restrictions:
 - Only one table map for policing exceeding the markdown and one table map for policing violating the markdown per direction per target is supported.
 - Table maps must be configured under the class-default; table maps are unsupported for a user-defined class.
- Hierarchical policies are required for the following:
 - Port-shapers
 - Aggregate policers
 - PV policy
 - Parent shaping and child marking/policing

Note Any "on-the-fly" change (modifying a policy while it is attached to a target) is not permitted for wired hierarchical policies.

- For ports with wired targets, these are the only supported hierarchical policies:
 - Police chaining in the same policy is unsupported, except for wireless client.
 - Hierarchical queueing is unsupported in the same policy (port shaper is the exception).
 - In a parent class, all filters must have the same type. The child filter type must match the parent filter type with the following exceptions:
 - If the parent class is configured to match IP, then the child class can be configured to match the ACL.
 - If the parent class is configured to match CoS, then the child class can be configured to match the ACL.
- Modification to a policy *name* on a wired port is not recommended. Please remove and reapply the policies if any unexpected behavior is seen.
- The **trust device** *device_type* command available in interface configuration mode is a stand-alone command on the device. When using this command in an AutoQoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.

The following are restrictions for applying QoS features on the VLAN to the wired target:

- For a flat or nonhierarchical policy, only marking or a table map is supported.

The following are restrictions and considerations for applying QoS features on EtherChannel and channel member interfaces:

- QoS is not supported on an EtherChannel interface.
- QoS is supported on EtherChannel member interfaces in both ingress and egression directions. All EtherChannel members must have the same QoS policy applied. If the QoS policy is not the same, each individual policy on the different link acts independently.
- On attaching a service policy to channel members, the following warning message appears to remind the user to make sure the same policy is attached to all ports in the EtherChannel: ' Warning: add service policy will cause inconsistency with port xxx in ether channel xxx. '.
- Auto QoS is not supported on EtherChannel members.

Note

On attaching a service policy to an EtherChannel, the following message appears on the console: ' Warning: add service policy will cause inconsistency with port xxx in ether channel xxx. '. This warning message should be expected. This warning message is a reminder to attach the same policy to other ports in the same EtherChannel. The same message will be seen during boot up. This message does not mean there is a discrepancy between the EtherChannel member ports.

Restrictions for QoS on Wireless Targets

General Restrictions

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio policies are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the device to the wireless client. Upstream indicates that traffic is flowing from wireless client to the device.

- Only port, SSID, and client (using AAA and Cisco IOS command-line interface) policies are user-configurable. Radio policies are set by the wireless control module and are not user-configurable.
- Port and radio policies are applicable only in the egress direction.
- SSID and client targets can be configured only with marking and policing policies.
- One policy per target per direction is supported.
- For the egress class-default SSID policy, you must configure the queue buffer ratio as 0 after you configure the average shape rate.
- Class maps in a policy map can have different types of filters. However, only one marking action (either table map, or set dscp, or set cos) is supported in a map in egress direction.

- For hierarchical client and SSID ingress policies, you cannot configure marking in both the parent and child policies. You can only configure marking either in the parent or child policy.
- You cannot configure multiple set actions in the same class.
- For both SSID and client ingress policies, supported set actions are only for DSCP, and CoS values.
- You cannot delete a group of WLANs or QoS policy.

Wireless QoS Restrictions on Ports

The following are restrictions for applying QoS features on a wireless port target:

- All wireless ports have similar parent policy with one class-default and one action shape under class-default. Shape rates are dependent on the 802.11a/b/g/ac bands.
- You can create a maximum of four classes in a child policy by modifying the `port_child_policy`.
- If there are four classes in the `port_child_policy` at the port level, one must be a non-client-nrt class and one must be class-default.
- No two classes can have the same priority level. Only priority level 1 (for voice traffic and control traffic) and 2 (for video) are supported.
- Priority is not supported in the multicast NRT class (non-client-nrt class) and `class-default`.
- If four classes are configured, two of them have to be priority classes. If only three classes are configured, at least one of them should be a priority class. If three classes are configured and there is no non-client-nrt class, both priority levels must be present.
- Only match DSCP is supported.
- The port policy applied by the wireless control module cannot be removed using the CLI.
- Both priority rate and police CIR (using MQC) in the same class is unsupported.
- Queue limit (which is used to configure Weighted Tail Drop) is unsupported.

Wireless QoS Restrictions on SSID

The following are restrictions for applying QoS features on SSID:

- One table map is supported at the ingress policy.
- Table maps are supported for the parent class-default only. Up to two table maps are supported in the egress direction and three table-maps can be configured when a QoS group is involved.

Note Table-maps are not supported at the client targets.

- If a wireless port has a default policy with only two queues (one for multicast-NRT, one for class-default), the policy at SSID level cannot have voice and video class in the egress direction.
- Policing without priority is not supported in the egress direction.
- Priority configuration at the SSID level is used only to configure the RT1 and RT2 policers (AFD for policer). Priority configuration does not include the shape rate. Therefore, priority is restricted for SSID policies without police.

- If **set** is not enabled in class-default, the classification at the SSID for voice or video must be a subset of the classification for the voice or video class at the port level.
- The mapping in the DSCP2DSCP and COS2COS table should be based on the classification function for the voice and video classes in the port level policy.
- No action is allowed under the class-default of a child policy.
- For SSID ingress policies, only UP and DSCP filters (match criteria) are supported. ACL and protocol match criteria are not supported.
- For a flat policy (non hierarchical), in the ingress direction, the policy configuration must be a set (table map) or policing or both.

Wireless QoS Restrictions on Clients

The following are restrictions for applying QoS policies on client targets:

- The default client policy is enabled only on WMM clients that are ACM-enabled.
- Queuing is not supported.
- Attaching, removing, or modifying client policies on a WLAN in the enabled state is not supported. You must shut down the WLAN to apply, remove, or modify a policy.
- Table-map configuration is not supported for client targets.
- Policing and set configured together in class-default is blocked in egress direction:

```
policy-map foo
class class-default
police X
set dscp Y
```

- Child policy is not supported under class-default if the parent policy contains other user-defined class maps in it.
- For flat egress client policy, policing in class-default and marking action in other classes are not supported.
- Only set marking actions are supported in the client policies.
- For client ingress policies, only ACL, UP, DSCP, and protocol filters (match criteria) are supported.
- All the filters in classes in a policy map for client policy must have the same attributes. Filters matching on protocol-specific attributes such as IPv4 or IPv6 addresses are considered as different attribute sets.
- For filters matching on ACLs, all ACEs (Access Control Entry) in the access list should have the same type and number of attributes.
- In client egress policies, all filters in the policy-map must match on the same marking attribute for filters matching on marking attributes. For example, If filter matches on DSCP, then all filters in the policy must match on DSCP.
- ACL matching on port ranges and subnet are only supported in ingress direction.

How to Configure QoS

Configuring Class, Policy, and Table Maps

Creating a Traffic Class (CLI)

To create a traffic class containing match criteria, use the **class-map** command to specify the traffic class name, and then use the following **match** commands in class-map configuration mode, as needed.

Before you begin

All match commands specified in this configuration task are considered optional, but you must configure at least one match criterion for a class.

SUMMARY STEPS

1. **configure terminal**
2. **class-map** { *class-map name* | **match-any** | **type** }
3. **match access-group** { *index number* | *name* }
4. **match class-map** *class-map name*
5. **match cos** *cos value*
6. **match dscp** *dscp value*
7. **match ip** { **dscp** *dscp value* | **precedence** *precedence value* }
8. **match non-client-nrt**
9. **match precedence** *precedence value*
10. **match qos-group** *qos group value*
11. **match vlan** *vlan value*
12. **match wlan user-priority** *wlan value*
13. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters the global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 2	<p>class-map {<i>class-map name</i> match-any type}</p> <p>Example:</p> <pre>Device(config)# class-map test_1000 Device(config-cmap)#</pre>	<p>Enters class map configuration mode.</p> <ul style="list-style-type: none"> Creates a class map to be used for matching packets to the class whose name you specify. If you specify match-any, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default. If you specify type, configures the CPL class map. Additional sub-command parameters include: <ul style="list-style-type: none"> control—This sub-command parameter configures the control policies. multicast-flows—This sub-command parameter configures multicast class-maps. <p>Note The type command option is not supported on the device</p>
Step 3	<p>match access-group {<i>index number</i> <i>name</i>}</p> <p>Example:</p> <pre>Device(config-cmap)# match access-group 100 Device(config-cmap)#</pre>	<p>The following parameters are available for this command:</p> <ul style="list-style-type: none"> access-group class-map cos dscp ip non-client-nrt precedence qos-group vlan wlan user priority <p>(Optional) For this example, enter the access-group ID:</p> <ul style="list-style-type: none"> Access list index (value from 1 to 2799) Named access list
Step 4	<p>match class-map <i>class-map name</i></p> <p>Example:</p>	<p>(Optional) Matches to another class-map name.</p>

	Command or Action	Purpose
	Device(config-cmap)# match class-map test_2000 Device(config-cmap)#	
Step 5	match cos <i>cos value</i> Example: Device(config-cmap)# match cos 2 3 4 5 Device(config-cmap)#	(Optional) Matches IEEE 802.1Q or ISL class of service (user) priority values. <ul style="list-style-type: none"> • Enters up to 4 CoS values separated by spaces (0 to 7).
Step 6	match dscp <i>dscp value</i> Example: Device(config-cmap)# match dscp af11 af12 Device(config-cmap)#	(Optional) Matches the DSCP values in IPv4 and IPv6 packets.
Step 7	match ip { <i>dscp dscp value</i> <i>precedence precedence value</i> } Example: Device(config-cmap)# match ip dscp af11 af12 Device(config-cmap)#	(Optional) Matches IP values including the following: <ul style="list-style-type: none"> • dscp—Matches IP DSCP (DiffServ codepoints). • precedence—Matches IP precedence (0 to 7). <p>Note Since CPU generated packets are not marked at egress, the packet will not match the configured class-map.</p>
Step 8	match non-client-nrt Example: Device(config-cmap)# match non-client-nrt Device(config-cmap)#	(Optional) Matches non-client NRT (Non-Real-Time).
Step 9	match precedence <i>precedence value</i> Example: Device(config-cmap)# match precedence 7 Device(config-cmap)#	(Optional) Matches precedence for IPv4 or IPv6 packets. Possible values include: <ul style="list-style-type: none"> • Critical—Match packets with critical precedence (5) • Flash—Match packets with flash precedence (3) • Flash-override—Match packets with flash override precedence (4) • Immediate—Match packets with immediate precedence (2) • Internet—Match packets with internetwork control precedence (6) • Network—Match packets with network control precedence (7)

	Command or Action	Purpose
		<ul style="list-style-type: none"> • Priority—Match packets with priority precedence (1) • Routine—Match packets with routine precedence (0)
Step 10	match qos-group <i>qos group value</i> Example: <pre>Device(config-cmap)# match qos-group 10 Device(config-cmap)#</pre>	(Optional) Matches QoS group value (from 0 to 31).
Step 11	match vlan <i>vlan value</i> Example: <pre>Device(config-cmap)# match vlan 210 Device(config-cmap)#</pre>	(Optional) Matches a VLAN ID (from 1 to 4095).
Step 12	match wlan user-priority <i>wlan value</i> Example: <pre>Device(config-cmap)# match wlan user priority 7 Device(config-cmap)#</pre>	(Optional) Matches 802.11e specific values. Enter the user priority 802.11e user priority (0 to 7).
Step 13	end Example: <pre>Device(config-cmap)# end</pre>	Saves the configuration changes.

What to do next

Configure the policy map.

Creating a Traffic Policy (CLI)

To create a traffic policy, use the **policy-map** global configuration command to specify the traffic policy name.

The traffic class is associated with the traffic policy when the **class** command is used. The **class** command must be entered after you enter the policy map configuration mode. After entering the **class** command, the is automatically in policy map class configuration mode, which is where the QoS policies for the traffic policy are defined.

The following policy map class-actions are supported:

- **admit**—Admits the request for Call Admission Control (CAC).
- **bandwidth**—Bandwidth configuration options.
- **exit**—Exits from the QoS class action configuration mode.
- **netflow-sampler**—NetFlow sampler configuration options.
- **no**—Negates or sets default values for the command.
- **police**—Policer configuration options.
- **priority**—Strict scheduling priority configuration options for this class.
- **queue-buffers**—Queue buffer configuration options.
- **queue-limit**—Queue maximum threshold for Weighted Tail Drop (WTD) configuration options.
- **service-policy**—Configures the QoS service policy.
- **set**—Sets QoS values using the following options:
 - CoS values
 - DSCP values
 - Precedence values
 - QoS group values
 - WLAN values
- **shape**—Traffic-shaping configuration options.

Before you begin

You should have first created a class map.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy-map name*
3. **class** {*class-name* | **class-default**}
4. **admit**
5. **bandwidth** {*kb/s kb/s value* | **percent** *percentage* | **remaining** {*percent* | *ratio*}}
6. **exit**
7. **netflow-sampler**
8. **no**
9. **police** {*target_bit_rate* | **cir** | **rate**}
10. **priority** {*kb/s* | **level** *level value* | **percent** *percentage value*}
11. **queue-buffers ratio** *ratio limit*
12. **queue-limit** {*packets* | **cos** | **dscp** | **percent**}
13. **service-policy** *policy-map name*

14. **set** { **cos** | **dscp** | **ip** | **precedence** | **qos-group** | **wlan** }
15. **shape average** { *target_bit_rate* | **percent** }
16. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	policy-map <i>policy-map name</i> Example: Device(config)# policy-map test_2000 Device(config-pmap)#	Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 3	class { <i>class-name</i> class-default } Example: Device(config-pmap)# class test_1000 Device(config-pmap-c)#	Specifies the name of the class whose policy you want to create or change. You can also create a system default class for unclassified packets.
Step 4	admit Example: Device(config-pmap-c)# admit cac wmm-tspeg Device(config-pmap-c)#	(Optional) Admits the request for Call Admission Control (CAC). For a more detailed example of this command and its usage, see Configuring Call Admission Control (CLI), on page 928 . Note This command only configures CAC for wireless QoS.
Step 5	bandwidth { kb/s <i>kb/s value</i> percent <i>percentage</i> remaining { <i>percent</i> <i>ratio</i> } } Example: Device(config-pmap-c)# bandwidth 50 Device(config-pmap-c)#	(Optional) Sets the bandwidth using one of the following: <ul style="list-style-type: none"> • kb/s—Kilobits per second, enter a value between 20000 and 10000000 for Kb/s. • percent—Enter the percentage of the total bandwidth to be used for this policy map. • remaining—Enter the percentage ratio of the remaining bandwidth. For a more detailed example of this command and its usage, see Configuring Bandwidth (CLI), on page 935 .
Step 6	exit Example:	(Optional) Exits from QoS class action configuration mode.

	Command or Action	Purpose
	Device(config-pmap-c) # exit Device(config-pmap-c) #	
Step 7	netflow-sampler Example: Device(config-pmap-c) # netflow-sampler Device(config-pmap-c) #	(Optional) Configures the Flexible NetFlow policy. Enter the name of the Flexible NetFlow sampler. For a more detailed example of this command and its usage, see Configuring NetFlow Sampler, on page 937 .
Step 8	no Example: Device(config-pmap-c) # no Device(config-pmap-c) #	(Optional) Negates the command.
Step 9	police { <i>target_bit_rate</i> cir rate } Example: Device(config-pmap-c) # police 100000 Device(config-pmap-c) #	(Optional) Configures the policer: <ul style="list-style-type: none"> • <i>target_bit_rate</i>—Enter the bit rate per second, enter a value between 8000 and 10000000000. • cir—Committed Information Rate • rate—Specify police rate, PCR for hierarchical policies or SCR for single-level ATM 4.0 policer policies. For a more detailed example of this command and its usage, see Configuring Police (CLI), on page 939 .
Step 10	priority { <i>kb/s</i> level <i>level value</i> percent <i>percentage value</i> } Example: Device(config-pmap-c) # priority percent 50 Device(config-pmap-c) #	(Optional) Sets the strict scheduling priority for this class. Command options include: <ul style="list-style-type: none"> • <i>kb/s</i>—Kilobits per second, enter a value between 1 and 2000000. • level—Establishes a multi-level priority queue. Enter a value (1 or 2). • percent—Enter a percent of the total bandwidth for this priority. For a more detailed example of this command and its usage, see Configuring Priority (CLI), on page 941 .
Step 11	queue-buffers ratio <i>ratio limit</i> Example: Device(config-pmap-c) # queue-buffers ratio 10 Device(config-pmap-c) #	(Optional) Configures the queue buffer for the class. Enter the queue buffers ratio limit (0 to 100). For a more detailed example of this command and its usage, see Configuring Queue Buffers (CLI), on page 944 .

	Command or Action	Purpose
Step 12	<p>queue-limit { <i>packets</i> <i>cos</i> <i>dscp</i> <i>percent</i> }</p> <p>Example:</p> <pre>Device(config-pmap-c)# queue-limit cos 7 percent 50 Device(config-pmap-c)#</pre>	<p>(Optional) Specifies the queue maximum threshold for the tail drop:</p> <ul style="list-style-type: none"> • <i>packets</i>—Packets by default, enter a value between 1 to 2000000. • <i>cos</i>—Enter the parameters for each COS value. • <i>dscp</i>—Enter the parameters for each DSCP value. • <i>percent</i>—Enter the percentage for the threshold. <p>For a more detailed example of this command and its usage, see Configuring Queue Limits (CLI), on page 946.</p>
Step 13	<p>service-policy <i>policy-map name</i></p> <p>Example:</p> <pre>Device(config-pmap-c)# service-policy test_2000 Device(config-pmap-c)#</pre>	<p>(Optional) Configures the QoS service policy.</p>
Step 14	<p>set { <i>cos</i> <i>dscp</i> <i>ip</i> <i>precedence</i> <i>qos-group</i> <i>wlan</i> }</p> <p>Example:</p> <pre>Device(config-pmap-c)# set cos 7 Device(config-pmap-c)#</pre>	<p>(Optional) Sets the QoS values. Possible QoS configuration values include:</p> <ul style="list-style-type: none"> • <i>cos</i>—Sets the IEEE 802.1Q/ISL class of service/user priority. • <i>dscp</i>—Sets DSCP in IP(v4) and IPv6 packets. • <i>ip</i>—Sets IP specific values. • <i>precedence</i>—Sets precedence in IP(v4) and IPv6 packet. • <i>qos-group</i>—Sets the QoS Group. • <i>wlan</i>—Sets the WLAN user-priority.
Step 15	<p>shape average { <i>target_bit_rate</i> <i>percent</i> }</p> <p>Example:</p> <pre>Device(config-pmap-c) #shape average percent 50 Device(config-pmap-c) #</pre>	<p>(Optional) Sets the traffic shaping. Command parameters include:</p> <ul style="list-style-type: none"> • <i>target_bit_rate</i>—Target bit rate. • <i>percent</i>—Percentage of interface bandwidth for Committed Information Rate. <p>For a more detailed example of this command and its usage, see Configuring Shaping (CLI), on page 949.</p>
Step 16	<p>end</p> <p>Example:</p> <pre>Device(config-pmap-c) #end</pre>	<p>Saves the configuration changes.</p>

Command or Action	Purpose
Device(config-pmap-c) #	

What to do next

Configure the interface.

Configuring Client Policies (GUI)

-
- Step 1** Choose **Configuration > Wireless**.
- Step 2** Expand the **QoS** node by clicking on the left pane and choose **QOS-Policy**.
The **QOS-Policy** page is displayed.
- Step 3** Click **Add New** to create a new QoS Policy.
The **Create QoS Policy** page is displayed.
- Step 4** Select **Client** from the **Policy Type** drop-down menu.
- Step 5** Select the direction into which the policy needs to be applied from the **Policy Direction** drop-down menu.
The available options are:
- **Ingress**
 - **Egress**
- Step 6** Specify a policy name in the **Policy Name** text box.
- Step 7** Provide a description to the policy in the **Description** text box.
- Step 8** (Optional) Configure the default voice or video configuration parameters by checking the **Enable Voice** or **Enable Video** checkbox.
The following options are available:
- **Trust**—Specify the classification type behavior on this policy. The options available are:
 - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
 - **User Priority**—This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7.
 - **COS**—This option is available when the **Policy Direction** is egress. Matches IEEE 802.1Q class of service. The range is from 0 to 7.
 - **Mark**—Specify the marking label for each packet. The following options are available:
 - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
 - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
 - **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.
 - **Police(kbps)**—Specify the policing rate in kbps.

Note The marking and policing options are optional.

Step 9 Specify the **Class-default** parameters.

The following options are available:

- **Mark**—Specify the marking label for each packet. The following options are available:
 - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
 - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
 - **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.
- **Police (kbps)**—This option is available when the **Policy Direction** is egress. This option Specify the policing rate in kbps.

Note You can choose either Mark or Police action for the class-default class when creating an egress client policy.

Step 10 (Optional) To configure the AVC class map for a client policy, check the **Enable Application Recognition** check box

Note For an egress client policy, when you enable Application Recognition, the Voice, Video, and User Defined check boxes are disabled.

The following options are available:

- **Trust**—Specify a classification type for this policy.
 - **Protocol**—Allows you to choose the protocols and configure the marking and policing of the packets.
 - **Category**—Allows you to choose the category of the application. For example, browsing.
 - **Subcategory**—Allows you to choose the subcategory of the application. For example, file-sharing.
 - **Application-Group**—Allows you to choose the application group. For example, ftp-group.
- **Protocol Choice**—Choose the protocols, category, subcategory, or application group from the **Available Protocols** list into the **Assigned Protocols** to apply the marking and policing of the packets.
- **Mark**—Specify the marking label for each packet. The following options are available:
 - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
 - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
 - **None**—Choose this option when you do not want to mark the packets.
- **Police (kbps)**—Specifies the policing rate in kbps. This option is available when the **Policy Direction** is egress.
- **Drop**—Drops the ingress packets that correspond to the chosen protocols.

Step 11 (Optional) To configure user defined classes, check the **User Defined Classes** checkbox.

The following options are available:

- **Trust**—Specify the classification type behavior on this policy.
 - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
 - **User Priority**—This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7.
 - **COS**—This option is available when the **Policy Direction** is egress. Matches IEEE 802.1Q class of service. The range is from 0 to 7.
- **Mark**—Specify the marking label for each packet. The following options are available:
 - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.

- **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
- **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.
- **Police (kbps)**—This option is available when the **Policy Direction** is egress. This option specifies the policing rate in kbps.

Note You can add a maximum of five user-defined classes for each client policy.

Step 12 Click **Add** to add the policy.

Configuring Class-Based Packet Marking (CLI)

This procedure explains how to configure the following class-based packet marking features on your :

- CoS value
- DSCP value
- IP value
- Precedence value
- QoS group value
- WLAN value

Before you begin

You should have created a class map and a policy map before beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **set cos** {*cos value* | **cos table** *table-map name* | **dscp table** *table-map name* | **precedence table** *table-map name* | **qos-group table** *table-map name* | **wlan user-priority table** *table-map name*}
5. **set dscp** {*dscp value* | **default** | **dscp table** *table-map name* | **ef** | **precedence table** *table-map name* | **qos-group table** *table-map name* | **wlan user-priority table** *table-map name*}
6. **set ip** {**dscp** | **precedence**}
7. **set precedence** {*precedence value* | **cos table** *table-map name* | **dscp table** *table-map name* | **precedence table** *table-map name* | **qos-group table** *table-map name*}
8. **set qos-group** {*qos-group value* | **dscp table** *table-map name* | **precedence table** *table-map name*}
9. **set wlan user-priority** {*wlan user-priority value* | **cos table** *table-map name* | **dscp table** *table-map name* | **qos-group table** *table-map name* | **wlan table** *table-map name*}
10. **end**
11. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.

	Command or Action	Purpose
Step 2	<p>policy-map <i>policy name</i></p> <p>Example:</p> <pre>Device(config)# policy-map policy1 Device(config-pmap)#</pre>	<p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>
Step 3	<p>class <i>class name</i></p> <p>Example:</p> <pre>Device(config-pmap)# class class1 Device(config-pmap-c)#</pre>	<p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change.</p> <p>Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> • admit—Admits the request for Call Admission Control (CAC). • bandwidth—Bandwidth configuration options. • exit—Exits from the QoS class action configuration mode. • netflow-sampler—NetFlow sampler configuration options. • no—Negates or sets default values for the command. • police—Policer configuration options. • priority—Strict scheduling priority configuration options for this class. • queue-buffers—Queue buffer configuration options. • queue-limit—Queue maximum threshold for Weighted Tail Drop (WTD) configuration options. • service-policy—Configures the QoS service policy. • set—Sets QoS values using the following options: <ul style="list-style-type: none"> • CoS values • DSCP values • Precedence values • QoS group values • WLAN values • shape—Traffic-shaping configuration options.

	Command or Action	Purpose
		<p>Note This procedure describes the available configurations using set command options. The other command options (admit, bandwidth, etc.) are described in other sections of this guide. Although this task lists all of the possible set commands, only one set command is supported per class.</p>
<p>Step 4</p>	<p>set cos {<i>cos value</i> cos table <i>table-map name</i> dscp table <i>table-map name</i> precedence table <i>table-map name</i> qos-group table <i>table-map name</i> wlan user-priority table <i>table-map name</i>}</p> <p>Example:</p> <pre>Device(config-pmap)# set cos 5 Device(config-pmap)#</pre>	<p>(Optional) Sets the specific IEEE 802.1Q Layer 2 CoS value of an outgoing packet. Values are from 0 to 7.</p> <p>You can also set the following values using the set cos command:</p> <ul style="list-style-type: none"> • cos table—Sets the CoS value based on a table map. • dscp table—Sets the code point value based on a table map. • precedence table—Sets the code point value based on a table map. • qos-group table—Sets the CoS value from QoS group based on a table map. • wlan user-priority table—Sets the CoS value from the WLAN user priority based on a table map.
<p>Step 5</p>	<p>set dscp {<i>dscp value</i> default dscp table <i>table-map name</i> ef precedence table <i>table-map name</i> qos-group table <i>table-map name</i> wlan user-priority table <i>table-map name</i>}</p> <p>Example:</p> <pre>Device(config-pmap)# set dscp af11 Device(config-pmap)#</pre>	<p>(Optional) Sets the DSCP value.</p> <p>In addition to setting specific DSCP values, you can also set the following using the set dscp command:</p> <ul style="list-style-type: none"> • default—Matches packets with default DSCP value (000000). • dscp table—Sets the packet DSCP value from DSCP based on a table map. • ef—Matches packets with EF DSCP value (101110). • precedence table—Sets the packet DSCP value from precedence based on a table map. • qos-group table—Sets the packet DSCP value from a QoS group based upon a table map. • wlan user-priority table—Sets the packet DSCP value based upon a WLAN user-priority based upon a table map.
<p>Step 6</p>	<p>set ip {<i>dscp</i> <i>precedence</i>}</p> <p>Example:</p>	<p>(Optional) Sets IP specific values. These values are either IP DSCP or IP precedence values.</p>

	Command or Action	Purpose
	<pre>Device(config-pmap) # set ip dscp c3 Device(config-pmap) #</pre>	<p>You can set the following values using the set ip dscp command:</p> <ul style="list-style-type: none"> • <i>dscp value</i>—Sets a specific DSCP value. • default—Matches packets with default DSCP value (000000). • dscp table—Sets the packet DSCP value from DSCP based on a table map. • ef—Matches packets with EF DSCP value (101110). • precedence table—Sets the packet DSCP value from precedence based on a table map. • qos-group table—Sets the packet DSCP value from a QoS group based upon a table map. • wlan user-priority table—Sets the packet DSCP value based upon a WLAN user-priority based upon a table map. <p>You can set the following values using the set ip precedence command:</p> <ul style="list-style-type: none"> • <i>precedence value</i>—Sets the precedence value (from 0 to 7) . • cos table—Sets the packet precedence value from Layer 2 CoS based on a table map. • dscp table—Sets the packet precedence from DSCP value based on a table map. • precedence table—Sets the precedence value from precedence based on a table map • qos-group table—Sets the precedence value from a QoS group based upon a table map.
<p>Step 7</p>	<pre>set precedence {precedence value cos table table-map name dscp table table-map name precedence table table-map name qos-group table table-map name}</pre> <p>Example:</p> <pre>Device(config-pmap) # set precedence 5 Device(config-pmap) #</pre>	<p>(Optional) Sets precedence values in IPv4 and IPv6 packets.</p> <p>You can set the following values using the set precedence command:</p> <ul style="list-style-type: none"> • <i>precedence value</i>—Sets the precedence value (from 0 to 7) . • cos table—Sets the packet precedence value from Layer 2 CoS on a table map. • dscp table—Sets the packet precedence from DSCP value on a table map.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • precedence table—Sets the precedence value from precedence based on a table map. • qos-group table—Sets the precedence value from a QoS group based upon a table map.
Step 8	<p>set qos-group {<i>qos-group value</i> dscp table <i>table-map name</i> precedence table <i>table-map name</i>}</p> <p>Example:</p> <pre>Device(config-pmap)# set qos-group 10 Device(config-pmap)#</pre>	<p>(Optional) Sets QoS group values. You can set the following values using this command:</p> <ul style="list-style-type: none"> • <i>qos-group value</i>—A number from 1 to 31. • dscp table—Sets the code point value from DSCP based on a table map. • precedence table—Sets the code point value from precedence based on a table map.
Step 9	<p>set wlan user-priority {<i>wlan user-priority value</i> cos table <i>table-map name</i> dscp table <i>table-map name</i> qos-group table <i>table-map name</i> wlan table <i>table-map name</i>}</p> <p>Example:</p> <pre>Device(config-pmap)# set wlan user-priority 1 Device(config-pmap)#</pre>	<p>(Optional) Sets the WLAN user priority value. You can set the following values using this command:</p> <ul style="list-style-type: none"> • <i>wlan user-priority value</i>—A value between 0 to 7. • cos table—Sets the WLAN user priority value from CoS based on a table map. • dscp table—Sets the WLAN user priority value from DSCP based on a table map. • qos-group table—Sets the WLAN user priority value from QoS group based on a table map. • wlan table—Sets the WLAN user priority value from the WLAN user priority based on a table map.
Step 10	<p>end</p> <p>Example:</p> <pre>Device(config-pmap)# end Device#</pre>	Saves configuration changes.
Step 11	<p>show policy-map</p> <p>Example:</p> <pre>Device# show policy-map</pre>	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Attach the traffic policy to an interface using the **service-policy** command.

Configuring Class Maps for Voice and Video (CLI)

To configure class maps for voice and video traffic, follow these steps:

SUMMARY STEPS

1. **configure terminal**
2. **class-map** *class-map-name*
3. **match dscp** *dscp-value-for-voice*
4. **end**
5. **configure terminal**
6. **class-map** *class-map-name*
7. **match dscp** *dscp-value-for-video*
8. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	class-map <i>class-map-name</i> Example: Device(config)# class-map voice	Creates a class map.
Step 3	match dscp <i>dscp-value-for-voice</i> Example: Device(config-cmap)# match dscp 46	Matches the DSCP value in the IPv4 and IPv6 packets. Set this value to 46.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 5	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 6	class-map <i>class-map-name</i> Example: Device(config)# class-map video	Configures a class map.
Step 7	match dscp <i>dscp-value-for-video</i> Example: Device(config-cmap)# match dscp 34	Matches the DSCP value in the IPv4 and IPv6 packets. Set this value to 34.

	Command or Action	Purpose
Step 8	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Attaching a Traffic Policy to an Interface (CLI)

After the traffic class and traffic policy are created, you must use the **service-policy** interface configuration command to attach a traffic policy to an interface, and to specify the direction in which the policy should be applied (either on packets coming into the interface or packets leaving the interface).

Before you begin

A traffic class and traffic policy must be created before attaching a traffic policy to an interface.

SUMMARY STEPS

1. **configure terminal**
2. **interface *type***
3. **service-policy {input *policy-map* | output *policy-map* type control subscriber }**
4. **end**
5. **show policy map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	interface <i>type</i> Example: Device(config)# interface GigabitEthernet1/0/1 Device(config-if)#	Enters interface configuration mode and configures an interface. Command parameters for the interface configuration include: <ul style="list-style-type: none"> • Auto Template— Auto-template interface • Capwap—CAPWAP tunnel interface • GigabitEthernet—Gigabit Ethernet IEEE 802 • GroupVI—Group virtual interface • Internal Interface— Internal interface • Loopback—Loopback interface • Null—Null interface

	Command or Action	Purpose
		<ul style="list-style-type: none"> • Port-channel—Ethernet Channel of interface • TenGigabitEthernet—10-Gigabit Ethernet • Tunnel—Tunnel interface • Vlan—Catalyst VLANs • Range—Interface range
Step 3	service-policy {input <i>policy-map</i> output <i>policy-map</i> type control subscriber } Example: <pre>Device(config-if) # service-policy output policy_map_01 Device(config-if) #</pre>	<p>Attaches a policy map to an input or output interface. This policy map is then used as the service policy for that interface.</p> <p>Note The type control subscriber command option is not supported on the device .</p> <p>In this example, the traffic policy evaluates all traffic leaving that interface.</p>
Step 4	end Example: <pre>Device(config-if) # end Device#</pre>	Saves configuration changes.
Step 5	show policy map Example: <pre>Device# show policy map</pre>	(Optional) Displays statistics for the policy on the specified interface.

What to do next

Proceed to attach any other traffic policy to an interface, and to specify the direction in which the policy should be applied.

Configuring SSID Policies (GUI)

Step 1 Choose **Configuration > Wireless**.

Step 2 Expand the **QoS** node by clicking on the left pane and choose **QOS-Policy**.

The **Create QoS Policy** page is displayed.

Step 3 Click **Add New** to create a new QoS Policy.

The **QoS Policy** page is displayed.

Step 4 Select **SSID** from the **Policy Type** drop-down menu.

Step 5 Select the direction into which the policy needs to be applied from the **Policy Direction** drop-down list.

The available options are:

- **Ingress**
- **Egress**

Note Voice and video configurations are available only in the egress direction.

Note When creating an egress SSID policy for voice and video classes, if the **port_child_policy** is already configured with voice and video classes having priority level, the existing **port_child_policy** is used. If a **port_child_policy** does not exist with voice and video classes, the switch will create voice and video classes with priority levels 1 and 2 under **port_child_policy** for voice and video traffic.

Step 6 Specify a policy name in the **Policy Name** text box.

Step 7 Provide a description to the policy in the **Description** text box.

Step 8 Select the trust parameter from the **Trust** drop-down list.

The following options are available:

- **DSCP**—Assigns a label to indicate the given quality of service as DSCP.
- **COS**—Matches IEEE 802.1Q class of service. This option is not available when the **Policy Direction** is ingress.
- **User Priority**—Enter the 802.11e user priority. This option is not available when the **Policy Direction** is egress.
- **None**—This option is available when the **Policy Direction** is egress. This option is available only for egress policies.

Step 9 If you chose **Egress** policy above, the following options are available:

- **Bandwidth**—Specifies the bandwidth rate. The following options are available:
 - **Rate**—Specifies the bandwidth in kbps. Enter a value in kbps in the **Value** field.
 - **Remaining Ratio**—Specifies the bandwidth in BRR (bandwidth remaining ratio). Enter the percentage in the **Percent** field.

Note If you choose the **Rate** option for the **Bandwidth** parameter, this value must be greater than the sum of the policing values for voice and video traffic.

- **Enable Voice**—Check the **Enable Voice** check box to enable voice traffic on this policy. Specify the following properties:

- **Priority**—Sets the priority for this policy for strict scheduling. The priority level is set to 1.
- **Police (kbps)**—Specifies the police rate in Kilobits per second.
- **CAC**—Enables or disables CAC. If CAC is enabled, you must specify the following options:
 - **User priority** This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7. By default, a value of 6 is assigned.
 - **Rate(kbps)**

Note The CAC rate must be less than the police rate.

- **Enable Video**—Check the **Enable Video** check box to enable video traffic on this policy. Specify the following properties:
- **Priority**—Sets the priority for this policy for strict scheduling.
- **Police (kbps)**—Specifies the police rate in kilobits per second.

Step 10 Click **Apply**.

Applying an SSID or Client Policy on a WLAN (CLI)

Before you begin

You must have a service-policy map configured before applying it on an SSID.

SUMMARY STEPS

1. **configure terminal**
2. **wlan *profile-name***
3. **service-policy [*input* | *output*] *policy-name***
4. **service-policy client [*input* | *output*] *policy-name***
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan <i>profile-name</i> Example: Device# wlan test4	Enters the WLAN configuration submode. The <i>profile-name</i> is the profile name of the configured WLAN.
Step 3	service-policy [<i>input</i> <i>output</i>] <i>policy-name</i> Example: Device(config-wlan)# service-policy input policy-map-ssid	Applies the policy. The following options are available: <ul style="list-style-type: none"> • input— Assigns the policy map to WLAN ingress traffic. • output— Assigns the policy map to WLAN egress traffic.

	Command or Action	Purpose
Step 4	service-policy client [input output] policy-name Example: Device(config-wlan) # service-policy client input policy-map-client	Applies the policy. The following options are available: <ul style="list-style-type: none"> • input— Assigns the client policy for ingress direction on the WLAN. • output— Assigns the client policy for egress direction on the WLAN.
Step 5	end Example: Device(config) # end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps (CLI)

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions supported are remarking and policing.

Before you begin

You should have already decided upon the classification, policing, and marking of your network traffic by policy maps prior to beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **class-map** { *class-map name* | **match-any** | **type** }
3. **match access-group** { *access list index* | *access list name* }
4. **policy-map** *policy-map-name*
5. **class** { *class-map-name* | **class-default** }
6. **set** { **cos** | **dscp** | **ip** | **precedence** | **qos-group** | **wlan user-priority** }
7. **police** { *target_bit_rate* | **cir** | **rate** }
8. **exit**
9. **exit**
10. **interface** *interface-id*
11. **service-policy input** *policy-map-name*
12. **end**
13. **show policy-map** [*policy-map-name* [**class** *class-map-name*]]
14. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 2	<p>class-map {<i>class-map name</i> match-any type}</p> <p>Example:</p> <pre>Device(config)# class-map ipclass1 Device(config-cmap)# exit Device(config)#</pre>	<p>Enters class map configuration mode.</p> <ul style="list-style-type: none"> • Creates a class map to be used for matching packets to the class whose name you specify. • If you specify match-any, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.
Step 3	<p>match access-group {<i>access list index</i> <i>access list name</i>}</p> <p>Example:</p> <pre>Device(config-cmap)# match access-group 1000 Device(config-cmap)# exit Device(config)#</pre>	<p>Specifies the classification criteria to match to the class map. You can match on the following criteria:</p> <ul style="list-style-type: none"> • access-group—Matches to access group. • class-map—Matches to another class map. • cos—Matches to a CoS value. • dscp—Matches to a DSCP value. • ip—Matches to a specific IP value. • non-client-nrt—Matches non-client NRT. • precedence—Matches precedence in IPv4 and IPv6 packets. • qos-group—Matches to a QoS group. • vlan—Matches to a VLAN. • wlan—Matches to a wireless LAN.
Step 4	<p>policy-map <i>policy-map-name</i></p> <p>Example:</p> <pre>Device(config)# policy-map flowit Device(config-pmap)#</pre>	<p>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</p> <p>By default, no policy maps are defined.</p>
Step 5	<p>class {<i>class-map-name</i> class-default}</p> <p>Example:</p> <pre>Device(config-pmap)# class ipclass1</pre>	<p>Defines a traffic classification, and enter policy-map class configuration mode.</p> <p>By default, no policy map class-maps are defined.</p>

	Command or Action	Purpose
	Device (config-pmap-c) #	<p>If a traffic class has already been defined by using the class-map global configuration command, specify its name for <i>class-map-name</i> in this command.</p> <p>A class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any included in the class-default class, all packets that have not already matched the other traffic classes will match class-default.</p>
Step 6	<p>set { cos dscp ip precedence qos-group wlan user-priority }</p> <p>Example:</p> <pre>Device (config-pmap-c) # set dscp 45 Device (config-pmap-c) #</pre>	<p>(Optional) Sets the QoS values. Possible QoS configuration values include:</p> <ul style="list-style-type: none"> • cos—Sets the IEEE 802.1Q/ISL class of service/user priority. • dscp—Sets DSCP in IP(v4) and IPv6 packets. • ip—Sets IP specific values. • precedence—Sets precedence in IP(v4) and IPv6 packet. • qos-group—Sets QoS group. • wlan user-priority—Sets WLAN user priority. <p>In this example, the set dscp command classifies the IP traffic by setting a new DSCP value in the packet.</p>
Step 7	<p>police { target_bit_rate cir rate }</p> <p>Example:</p> <pre>Device (config-pmap-c) # police 100000 conform-action transmit exceed-action drop Device (config-pmap-c) #</pre>	<p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> • target_bit_rate—Specifies the bit rate per second, enter a value between 8000 and 10000000000. • cir—Committed Information Rate. • rate—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies. <p>In this example, the police command adds a policer to the class where any traffic beyond the 100000 set target bit rate is dropped.</p>
Step 8	<p>exit</p> <p>Example:</p> <pre>Device (config-pmap-c) # exit</pre>	Returns to policy map configuration mode.
Step 9	<p>exit</p> <p>Example:</p>	Returns to global configuration mode.

	Command or Action	Purpose
	Device (config-pmap) # exit	
Step 10	interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 2/0/1	Specifies the port to attach to the policy map, and enters interface configuration mode. Valid interfaces include physical ports.
Step 11	service-policy input <i>policy-map-name</i> Example: Device (config-if) # service-policy input flowit	Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported.
Step 12	end Example: Device (config-if) # end	Returns to privileged EXEC mode.
Step 13	show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] Example: Device# show policy-map	(Optional) Verifies your entries.
Step 14	copy running-config startup-config Example: Device# copy-running-config startup-config	(Optional) Saves your entries in the configuration file.

What to do next

If applicable to your QoS configuration, configure classification, policing, and marking of traffic on SVIs by using policy maps.

Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps (CLI)

Before you begin

You should have already decided upon the classification, policing, and marking of your network traffic by using policy maps prior to beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **class-map** {*class-map name* | **match-any** | **type**}
3. **match vlan** *vlan number*
4. **policy-map** *policy-map-name*
5. **description** *description*
6. **class** {*class-map-name* | **class-default**}
7. **set** {**cos** | **dscp** | **ip** | **precedence** | **qos-group** | **wlan user-priority**}
8. **police** {*target_bit_rate* | **cir** | **rate**}
9. **exit**
10. **exit**
11. **interface** *interface-id*
12. **service-policy input** *policy-map-name*
13. **end**
14. **show policy-map** [*policy-map-name* [**class** *class-map-name*]]
15. **copy running-config startup-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	class-map { <i>class-map name</i> match-any type }	Enters class map configuration mode.
	Example: Device(config)# class-map class_vlan100	<ul style="list-style-type: none"> • Creates a class map to be used for matching packets to the class whose name you specify. • If you specify match-any, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.
Step 3	match vlan <i>vlan number</i> Example: Device(config-cmap)# match vlan 100 Device(config-cmap)# exit Device(config)#	Specifies the VLAN to match to the class map. Note The device installs the policy only if the lowest value in the VLAN range is configured on the device. For example, if the VLAN range is 100 to 200, VLAN with ID 100 must be configured on the device. If you have any of the other VLANs with ID starting from 101 to 200 configured on the device, the policy will not be installed on the device. This check is only performed when you install or reinstall a policy. You can delete all the VLANs after the policy is installed. The policy will continue to work.

	Command or Action	Purpose
Step 4	<p>policy-map <i>policy-map-name</i></p> <p>Example:</p> <pre>Device(config)# policy-map policy_vlan100 Device(config-pmap)#</pre>	<p>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</p> <p>By default, no policy maps are defined.</p>
Step 5	<p>description <i>description</i></p> <p>Example:</p> <pre>Device(config-pmap)# description vlan 100</pre>	<p>(Optional) Enters a description of the policy map.</p>
Step 6	<p>class {<i>class-map-name</i> class-default}</p> <p>Example:</p> <pre>Device(config-pmap)# class class_vlan100 Device(config-pmap-c)#</pre>	<p>Defines a traffic classification, and enters the policy-map class configuration mode.</p> <p>By default, no policy map class-maps are defined.</p> <p>If a traffic class has already been defined by using the class-map global configuration command, specify its name for <i>class-map-name</i> in this command.</p> <p>A class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any included in the class-default class, all packets that have not already matched the other traffic classes will match class-default.</p>
Step 7	<p>set {cos dscp ip precedence qos-group wlan user-priority}</p> <p>Example:</p> <pre>Device(config-pmap-c)# set dscp af23 Device(config-pmap-c)#</pre>	<p>(Optional) Sets the QoS values. Possible QoS configuration values include:</p> <ul style="list-style-type: none"> • cos—Sets the IEEE 802.1Q/ISL class of service/user priority. • dscp—Sets DSCP in IP(v4) and IPv6 packets. • ip—Sets IP specific values. • precedence—Sets precedence in IP(v4) and IPv6 packet. • qos-group—Sets QoS group. • wlan user-priority—Sets WLAN user-priority. <p>In this example, the set dscp command classifies the IP traffic by matching the packets with a DSCP value of AF23 (010010).</p>
Step 8	<p>police {<i>target_bit_rate</i> cir rate}</p> <p>Example:</p> <pre>Device(config-pmap-c)# police 200000</pre>	<p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> • <i>target_bit_rate</i>—Specifies the bit rate per second. Enter a value between 8000 and 10000000000. • cir—Committed Information Rate.

	Command or Action	Purpose
	<pre>conform-action transmit exceed-action drop Device (config-pmap-c) #</pre>	<ul style="list-style-type: none"> rate—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies. <p>In this example, the police command adds a policer to the class where any traffic beyond the 200000 set target bit rate is dropped.</p>
Step 9	<pre>exit Example: Device (config-pmap-c) # exit</pre>	Returns to policy map configuration mode.
Step 10	<pre>exit Example: Device (config-pmap) # exit</pre>	Returns to global configuration mode.
Step 11	<pre>interface interface-id Example: Device (config) # interface gigabitethernet 1/0/3</pre>	<p>Specifies the port to attach to the policy map, and enters interface configuration mode.</p> <p>Valid interfaces include physical ports.</p>
Step 12	<pre>service-policy input policy-map-name Example: Device (config-if) # service-policy input policy_vlan100</pre>	Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported.
Step 13	<pre>end Example: Device (config-if) # end</pre>	Returns to privileged EXEC mode.
Step 14	<pre>show policy-map [policy-map-name [class class-map-name]] Example: Device# show policy-map</pre>	(Optional) Verifies your entries.
Step 15	<pre>copy running-config startup-config Example:</pre>	(Optional) Saves your entries in the configuration file.

	Command or Action	Purpose
	Device# <code>copy-running-config startup-config</code>

Configuring Table Maps (CLI)

Table maps are a form of marking, and also enable the mapping and conversion of one field to another using a table. For example, a table map can be used to map and convert a Layer 2 CoS setting to a precedence value in Layer 3.

Note A table map can be referenced in multiple policies or multiple times in the same policy.

SUMMARY STEPS

1. **configure terminal**
2. **table-map** *name* {**default** {*default value* | **copy** | **ignore**} | **exit** | **map** {*from from value to to value* } | **no**}
3. **map** *from value to value*
4. **exit**
5. **exit**
6. **show table-map**
7. **configure terminal**
8. **policy-map**
9. **class class-default**
10. **set cos dscp table** *table map name*
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 2	table-map <i>name</i> { default { <i>default value</i> copy ignore } exit map { <i>from from value to to value</i> } no } Example:	Creates a table map and enters the table map configuration mode. In table map configuration mode, you can perform the following tasks:

	Command or Action	Purpose
	<pre>Device(config)# table-map table01 Device(config-tablemap)#</pre>	<ul style="list-style-type: none"> • default—Configures the table map default value, or sets the default behavior for a value not found in the table map to copy or ignore. • exit—Exits from the table map configuration mode. • map—Maps a <i>from</i> to a <i>to</i> value in the table map. • no—Negates or sets the default values of the command.
Step 3	<p>map from value to value</p> <p>Example:</p> <pre>Device(config-tablemap)# map from 0 to 2 Device(config-tablemap)# map from 1 to 4 Device(config-tablemap)# map from 24 to 3 Device(config-tablemap)# map from 40 to 6 Device(config-tablemap)# default 0 Device(config-tablemap)#</pre>	<p>In this step, packets with DSCP values 0 are marked to the CoS value 2, DSCP value 1 to the CoS value 4, DSCP value 24 to the CoS value 3, DSCP value 40 to the CoS value 6 and all others to the CoS value 0.</p> <p>Note The mapping from CoS values to DSCP values in this example is configured by using the set policy map class configuration command as described in a later step in this procedure.</p>
Step 4	<p>exit</p> <p>Example:</p> <pre>Device(config-tablemap)# exit Device(config)#</pre>	Returns to global configuration mode.
Step 5	<p>exit</p> <p>Example:</p> <pre>Device(config) exit Device#</pre>	Returns to privileged EXEC mode.
Step 6	<p>show table-map</p> <p>Example:</p> <pre>Device# show table-map Table Map table01 from 0 to 2 from 1 to 4 from 24 to 3 from 40 to 6 default 0</pre>	Displays the table map configuration.
Step 7	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
	Device(config)#	
Step 8	policy-map Example: Device(config)# policy-map table-policy Device(config-pmap)#	Configures the policy map for the table map.
Step 9	class class-default Example: Device(config-pmap)# class class-default Device(config-pmap-c)#	Matches the class to the system default.
Step 10	set cos dscp table table map name Example: Device(config-pmap-c)# set cos dscp table table01 Device(config-pmap-c)#	If this policy is applied on input port, that port will have trust DSCP enabled on that port and marking will take place depending upon the specified table map.
Step 11	end Example: Device(config-pmap-c)# end Device#	Returns to privileged EXEC mode.

What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

Configuring Trust

Configuring Trust Behavior for the Device Type

This procedure explains how to configure trust for one or more device classes within your network configuration.

Before you begin

There are two types of trust behavior supported on the :

- Trust QoS at the policy level—You can configure trust for individual packets by creating specific policy maps and applying them on an interface. If you do not configure a specific policy map, then the default is to trust DSCP.
- Trust devices at the interface level—You can configure trust for the device using the **trust device** interface configuration command.

Note The default mode on an interface is trusted and changes to untrusted only when an untrusted device is detected. In the untrusted mode, the DSCP, IP precedence, or CoS value is reset to 0.

SUMMARY STEPS

1. **configure terminal**
2. **interface type**
3. **trust device { cisco-phone | cts | ip-camera | media-player }**
4. **end**
5. **show interface status**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	interface type Example: Device(config)# interface GigabitEthernet1/0/1 Device(config-if)#	Enters interface configuration mode and configures an interface. Command parameters for the interface configuration include: <ul style="list-style-type: none"> • Auto Template— Auto-Template interface • Capwap—Capwap tunnel interface • GigabitEthernet—Gigabit Ethernet IEEE 802 • GroupVI—Group virtual interface • Internal Interface—Internal interface • Loopback—Loopback interface • Null—Null interface • Port-channel—Ethernet Channel of interface • TenGigabitEthernet—10-Gigabit Ethernet • Tunnel—Tunnel interface

	Command or Action	Purpose
		<ul style="list-style-type: none"> • Vlan—Catalyst VLANs • range—interface range
Step 3	trust device { cisco-phone cts ip-camera media-player } Example: <pre>Device(config-if)# trust device cisco-phone Device(config-if)#</pre>	Configures the trust value for the interface. You can configure trust for the following supported devices: <ul style="list-style-type: none"> • cisco-phone—Cisco IP Phone • cts—Cisco TelePresence system • ip-camera—IPVSC • media-player—DMP
Step 4	end Example: <pre>Device(config-if)# end Device#</pre>	Saves configuration changes.
Step 5	show interface status Example: <pre>Device# show interface status Device#</pre>	(Optional) Displays the configured interface's status.

What to do next

Connect the trusted device to the appropriately configured trusted port on the .

Configuring Trust Behavior for Wireless Traffic (CLI)

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired , all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

SUMMARY STEPS

1. **configure terminal**
2. **qos wireless-default-untrust**

3. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	qos wireless-default-untrust Example: Device (config)# qos wireless-default-untrust	Configures the behavior of the device to untrust wireless traffic. To configure the device to trust wireless traffic by default, use the no form of the command.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring QoS Features and Functionality

Configuring Call Admission Control (CLI)

This task explains how to configure class-based, unconditional packet marking features on your device for Call Admission Control (CAC).

SUMMARY STEPS

1. **configure terminal**
2. **class-map** *class name*
3. **match dscp** *dscp value*
4. **exit**
5. **class-map** *class name*
6. **match dscp** *dscp value*
7. **exit**
8. **table-map** *name*
9. **default copy**
10. **exit**
11. **table-map** *name*
12. **default copy**
13. **map from** *value to value*
14. **exit**
15. **policy-map** *policy name*
16. **class** *class-map-name*

17. **priority level** *level_value*
18. **police** [*target_bit_rate* | **cir** | **rate**]
19. **admit cac wmm-tspec**
20. **rate** *value*
21. **wlan-up** *value*
22. **exit**
23. **exit**
24. **class** *class name*
25. **priority level** *level_value*
26. **police** [*target_bit_rate* | **cir** | **rate**]
27. **admit cac wmm-tspec**
28. **rate** *value*
29. **wlan-up** *value*
30. **exit**
31. **exit**
32. **policy-map** *policy name*
33. **class** *class-map-name*
34. **set dscp dscp table** *table_map_name*
35. **set wlan user-priority dscp table** *table_map_name*
36. **shape average** {*target bit rate* | **percent** *percentage*}
37. **queue-buffers** {**ratio** *ratio value*}
38. **service-policy** *policy_map_name*
39. **end**
40. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	class-map <i>class name</i> Example: Device(config)# class-map voice Device(config-cmap)#	Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> • <i>word</i>—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 3	match dscp <i>dscp value</i> Example:	(Optional) Matches the DSCP values in IPv4 and IPv6 packets.

	Command or Action	Purpose
	Device(config-cmap)# match dscp 46	
Step 4	exit Example: Device(config-cmap)# exit Device(config)#	Returns to global configuration mode.
Step 5	class-map class name Example: Device(config)# class-map video Device(config-cmap)#	Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> • <i>word</i>—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 6	match dscp dscp value Example: Device(config-cmap)# match dscp 34	(Optional) Matches the DSCP values in IPv4 and IPv6 packets.
Step 7	exit Example: Device(config-cmap)# exit Device(config)#	Returns to global configuration mode.
Step 8	table-map name Example: Device(config)# table-map dscp2dscp Device(config-tablemap)#	Creates a table map and enters the table map configuration mode.
Step 9	default copy Example: Device(config-tablemap)# default copy	Sets the default behavior for value not found in the table map to copy. Note This is the default option. You can also do a mapping of values for DSCP to DSCP.
Step 10	exit Example: Device(config-tablemap)# exit	Returns to global configuration mode.

	Command or Action	Purpose
	Device(config)#	
Step 11	table-map <i>name</i> Example: Device(config)# table-map dscp2up Device(config-tablemap)#	Creates a new table map and enters the table map configuration mode.
Step 12	default copy Example: Device(config-tablemap)# default copy	Sets the default behavior for value not found in the table map to copy. Note This is the default option. You can also do a mapping of values for DSCP to UP.
Step 13	map from <i>value to value</i> Example: Device(config-tablemap)# map from 0 to 0 Device(config-tablemap)# map from 1 to 8 Device(config-tablemap)# map from 2 to 8 Device(config-tablemap)# map from 3 to 0 Device(config-tablemap)# map from 4 to 24 Device(config-tablemap)# map from 5 to 34 Device(config-tablemap)# map from 6 to 46 Device(config-tablemap)# map from 7 to 48 Device(config-tablemap)# default copy Device(config-tablemap)#	In this step, packets with DSCP values 0 are marked to the DSCP value 0, DSCP value 1 to the DSCP value 8, DSCP value 2 to the DSCP value 8, DSCP value 3 to the DSCP value 0, DSCP value 4 to DSCP value 24, DSCP value 5 to DSCP value 34, DSCP value 6 to DSCP value 46, DSCP value 7 to DSCP value 48, and all others to the default. Note The mapping from DSCP values to DSCP values in this example is configured by using the set policy map class configuration command as described in a later step in this procedure.
Step 14	exit Example: Device(config-tablemap)# exit Device(config)#	Returns to global configuration mode.
Step 15	policy-map <i>policy name</i> Example: Device(config)# policy-map ssid_child_cac Device(config-pmap)#	Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 16	class <i>class-map-name</i> Example: Device(config-pmap)# class voice	Defines an interface-level traffic classification, and enters policy-map configuration mode.

	Command or Action	Purpose
Step 17	<p>priority level <i>level_value</i></p> <p>Example:</p> <pre>Device(config-pmap-c) # priority level 1</pre>	<p>The priority command assigns a strict scheduling priority for the class.</p> <p>Note Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.</p>
Step 18	<p>police [<i>target_bit_rate</i> cir rate]</p> <p>Example:</p> <pre>Device(config-pmap-c) # police cir 10m</pre>	<p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> • <i>target_bit_rate</i>—Specifies the bit rate per second. Enter a value between 8000 and 10000000000. • cir—Committed Information Rate. • rate—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.
Step 19	<p>admit cac wmm-tspec</p> <p>Example:</p> <pre>Device(config-pmap-c) # admit cac wmm-tspec Device(config-pmap-cac-wmm) #</pre>	<p>Configures call admission control for the policy map.</p> <p>Note This command only configures CAC for wireless QoS.</p>
Step 20	<p>rate <i>value</i></p> <p>Example:</p> <pre>Device(config-pmap-admit-cac-wmm) # rate 5000</pre>	<p>Configures the target bit rate (Kilo Bits per second). Enter a value from 8 to 10000000.</p>
Step 21	<p>wlan-up <i>value</i></p> <p>Example:</p> <pre>Device(config-pmap-admit-cac-wmm) # wlan-up 6 7</pre>	<p>Configures the WLAN UP value. Enter a value from 0 to 7.</p>
Step 22	<p>exit</p> <p>Example:</p> <pre>Device(config-pmap-admit-cac-wmm) # exit Device(config-pmap-c) #</pre>	<p>Returns to policy map class configuration mode.</p>
Step 23	<p>exit</p> <p>Example:</p> <pre>Device(config-pmap-c) # exit</pre>	<p>Returns to policy map configuration mode.</p>

	Command or Action	Purpose
	Device(config-pmap)#	
Step 24	<p>class <i>class name</i></p> <p>Example:</p> <pre>Device(config-pmap)# class video Device(config-pmap-c)#</pre>	<p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> • <i>word</i>—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 25	<p>priority level <i>level_value</i></p> <p>Example:</p> <pre>Device(config-pmap-c)# priority level 2</pre>	<p>The priority command assigns a strict scheduling priority for the class.</p> <p>Note Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.</p>
Step 26	<p>police [<i>target_bit_rate</i> cir rate]</p> <p>Example:</p> <pre>Device(config-pmap-c)# police cir 20m</pre>	<p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> • <i>target_bit_rate</i>—Specifies the bit rate per second. Enter a value between 8000 and 1000000000. • cir—Committed Information Rate. • rate—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.
Step 27	<p>admit cac wmm-tspec</p> <p>Example:</p> <pre>Device(config-pmap-c)# admit cac wmm-tspec Device(config-pmap-admit-cac-wmm)#</pre>	<p>Configures call admission control for the policy map.</p> <p>Note This command only configures CAC for wireless QoS.</p>
Step 28	<p>rate <i>value</i></p> <p>Example:</p> <pre>Device(config-pmap-admit-cac-wmm)# rate 5000</pre>	<p>Configures the target bit rate (Kilo Bits per second). Enter a value from 8 to 10000000.</p>
Step 29	<p>wlan-up <i>value</i></p> <p>Example:</p> <pre>Device(config-pmap-admit-cac-wmm)# wlan-up 4 5</pre>	<p>Configures the WLAN UP value. Enter a value from 0 to 7.</p>
Step 30	exit	Returns to policy map configuration mode.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config-pmap-cac-wmm)# exit Device(config-pmap)#</pre>	
Step 31	<p>exit</p> <p>Example:</p> <pre>Device(config-pmap)# exit Device(config)#</pre>	Returns to global configuration mode.
Step 32	<p>policy-map <i>policy name</i></p> <p>Example:</p> <pre>Device(config)# policy-map ssid_cac Device(config-pmap)#</pre>	<p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>
Step 33	<p>class <i>class-map-name</i></p> <p>Example:</p> <pre>Device(config-pmap)# class default</pre>	<p>Defines an interface-level traffic classification, and enters policy-map configuration mode.</p> <p>In this example, the class map is set to default.</p>
Step 34	<p>set dscp dscp table <i>table_map_name</i></p> <p>Example:</p> <pre>Device(config-pmap-c)# set dscp dscp table dscp2dscp</pre>	(Optional) Sets the QoS values. In this example, the set dscp dscp table command creates a table map and sets its values.
Step 35	<p>set wlan user-priority dscp table <i>table_map_name</i></p> <p>Example:</p> <pre>Device(config-pmap-c)# set wlan user-priority dscp table dscp2up</pre>	(Optional) Sets the QoS values. In this example, the set wlan user-priority dscp table command sets the WLAN user priority.
Step 36	<p>shape average {<i>target bit rate</i> <i>percent percentage</i>}</p> <p>Example:</p> <pre>Device(config-pmap-c)# shape average 100000000</pre>	Configures the average shape rate. You can configure the average shape rate by target bit rates (bits per second) or by percentage of interface bandwidth for the Committed Information Rate (CIR).
Step 37	<p>queue-buffers {<i>ratio ratio value</i>}</p> <p>Example:</p>	Configures the relative buffer size for the queue.

	Command or Action	Purpose
	<pre>Device(config-pmap-c)# queue-buffers ratio 0</pre>	<p>Note The sum of all configured buffers in a policy must be less than or equal to 100 percent. Unallocated buffers are evenly distributed to all the remaining queues. Ensure sufficient buffers are allocated to all queues including the priority queues.</p> <p>Note Protocol Data Units (PDUs) for network control protocols such as spanning-tree and LACP utilize the priority queue or queue 0 (when a priority queue is not configured). Ensure sufficient buffers are allocated to these queues for the protocols to function.</p>
Step 38	<p>service-policy <i>policy_map_name</i></p> <p>Example:</p> <pre>Device(config-pmap-c)# service-policy ssid_child_cac</pre>	Specifies the policy map for the service policy.
Step 39	<p>end</p> <p>Example:</p> <pre>Device(config-pmap)# end Device#</pre>	Saves configuration changes.
Step 40	<p>show policy-map</p> <p>Example:</p> <pre>Device# show policy-map</pre>	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.

For additional information about CAC, refer to the *System Management Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*.

For additional information about CAC, refer to the *System Management Configuration Guide, Cisco IOS XE Release 3SE (Cisco WLC 5700 Series)*.

Configuring Bandwidth (CLI)

This procedure explains how to configure bandwidth on your .

Before you begin

You should have created a class map for bandwidth before beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **bandwidth** {*Kb/s* | **percent** *percentage* | **remaining** { **ratio** *ratio* }}
5. **end**
6. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	policy-map <i>policy name</i> Example: Device(config)# policy-map <i>policy_bandwidth01</i> Device(config-pmap)#	Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 3	class <i>class name</i> Example: Device(config-pmap)# class <i>class_bandwidth01</i> Device(config-pmap-c)#	Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> • word—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 4	bandwidth { <i>Kb/s</i> percent <i>percentage</i> remaining { ratio <i>ratio</i> }} Example: Device(config-pmap-c)# bandwidth 200000 Device(config-pmap-c)#	Configures the bandwidth for the policy map. The parameters include: <ul style="list-style-type: none"> • Kb/s—Configures a specific value in kilobits per second (from 20000 to 10000000). • percent—Allocates minimum bandwidth to a particular class based on a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • remaining— Allocates minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the priority command is used for certain queues in the policy. You can also assign ratios rather than percentages to each queue; the queues will be assigned certain weights which are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100. <p>Note You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.</p>
Step 5	end Example: <pre>Device(config-pmap-c) # end Device#</pre>	Saves configuration changes.
Step 6	show policy-map Example: <pre>Device# show policy-map</pre>	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Configure any additional policy maps for QoS for your network. After creating the policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

Configuring NetFlow Sampler

This task explains how to configure class-based, unconditional packet marking features on your device for Flexible NetFlow samplers.

Before you begin

You should have created a class map for the NetFlow sampler before beginning this procedure. You should also have created a NetFlow sampler before beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **sampler** *sampler name*
3. **policy-map** *policy name*
4. **class** *class name*
5. **netflow-sampler** *flow sampler name*
6. **end**
7. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal Device(config)#	Enters global configuration mode.
Step 2	sampler <i>sampler name</i> Example: Device(config)# sampler NFS01 Device(config-sampler)# exit	Defines a Cisco NetFlow sampler.
Step 3	policy-map <i>policy name</i> Example: Device(config)# policy-map policy_NFS01 Device(config-pmap)#	Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 4	class <i>class name</i> Example: Device(config-pmap)# class class_NFS01 Device(config-pmap-c)#	Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> • Word—Class map name • class-default—System default class matching any otherwise unclassified packets
Step 5	netflow-sampler <i>flow sampler name</i> Example: Device(config-pmap)# netflow-sampler NFS01 Device(config-sampler)#	Attaches a Flexible Netflow sampler to the policy map. After attaching a NetFlow sampler to the policy map, the following configuration options are available: <ul style="list-style-type: none"> • default—Sets the sampler to its default. • description—Provides a sampler description. • exit—Exits from sampler configuration mode.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • <code>mode</code>—Sampling mode selection (random or deterministic) • <code>no</code>—negates a command
Step 6	end Example: Device(config-sampler)# end Device#	Saves configuration changes.
Step 7	show policy-map Example: Device# show policy-map	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Proceed to configure any additional policy maps for your QoS network. After creating your policy maps, proceed to attach the traffic policy or polices to an interface using the **service-policy** command.

Configuring Police (CLI)

This procedure explains how to configure policing on your .

Before you begin

You should have created a class map for policing before beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **police** {*target_bit_rate* [*burst bytes* | **bc** | **conform-action** | **pir**] | **cir** {*target_bit_rate* | **percent** *percentage*} | **rate** {*target_bit_rate* | **percent** *percentage*} **conform-action** **transmit** **exceed-action** {**drop** [**violate** **action**] | **set-cos-transmit** | **set-dscp-transmit** | **set-prec-transmit** | **transmit** [**violate** **action**] } }
5. **end**
6. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.

	Command or Action	Purpose
Step 2	<p>policy-map <i>policy name</i></p> <p>Example:</p> <pre>Device(config)# policy-map policy_police01 Device(config-pmap)#</pre>	<p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>
Step 3	<p>class <i>class name</i></p> <p>Example:</p> <pre>Device(config-pmap)# class class_police01 Device(config-pmap-c)#</pre>	<p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> • word—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 4	<p>police {<i>target_bit_rate</i> [<i>burst bytes</i> bc conform-action pir] cir {<i>target_bit_rate</i> percent percentage} rate {<i>target_bit_rate</i> percent percentage} conform-action transmit exceed-action {drop [<i>violate action</i>] set-cos-transmit set-dscp-transmit set-prec-transmit transmit [<i>violate action</i>] } }</p> <p>Example:</p> <pre>Device(config-pmap-c)# police 8000 conform-action transmit exceed-action drop Device(config-pmap-c)#</pre>	<p>The following police subcommand options are available:</p> <ul style="list-style-type: none"> • target_bit_rate—Bits per second (from 8000 to 10000000000). • burst bytes—Enter a value from 1000 to 512000000. • bc—Conform burst. • conform-action—Action taken when rate is less than conform burst. • pir—Peak Information Rate. • cir—Committed Information Rate. <ul style="list-style-type: none"> • target_bit_rate—Target bit rate (8000 to 10000000000). • percent—Percentage of interface bandwidth for CIR. • rate—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies. <ul style="list-style-type: none"> • target_bit_rate—Target Bit Rate (8000 to 10000000000). • percent—Percentage of interface bandwidth for rate. <p>The following police conform-action transmit exceed-action subcommand options are available:</p> <ul style="list-style-type: none"> • drop—Drops the packet.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • set-cos-transmit—Sets the CoS value and sends it. • set-dscp-transmit—Sets the DSCP value and sends it. • set-prec-transmit—Rewrites the packet precedence and sends it. • transmit—Transmits the packet. <p>Note Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the .</p>
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-pmap-c) # end Device#</pre>	Saves configuration changes.
Step 6	<p>show policy-map</p> <p>Example:</p> <pre>Device# show policy-map</pre>	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

Configuring Priority (CLI)

This procedure explains how to configure priority on your .

The supports giving priority to specified queues. There are two priority levels available (1 and 2).

Note Queues supporting voice and video should be assigned a priority level of 1.

Before you begin

You should have created a class map for priority before beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **priority** [*Kb/s* [*burst_in_bytes*] | **level** *level_value* [*Kb/s* [*burst_in_bytes*] | **percent** *percentage* [*burst_in_bytes*]] | **percent** *percentage* [*burst_in_bytes*]]
5. **end**
6. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	policy-map <i>policy name</i> Example: Device(config)# policy-map <i>policy_priority01</i> Device(config-pmap)#	Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 3	class <i>class name</i> Example: Device(config-pmap)# class <i>class_priority01</i> Device(config-pmap-c)#	Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> • <i>word</i>—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 4	priority [<i>Kb/s</i> [<i>burst_in_bytes</i>] level <i>level_value</i> [<i>Kb/s</i> [<i>burst_in_bytes</i>] percent <i>percentage</i> [<i>burst_in_bytes</i>]] percent <i>percentage</i> [<i>burst_in_bytes</i>]] Example: Device(config-pmap-c)# priority <i>level 1</i>	(Optional) The priority command assigns a strict scheduling priority for the class. The command options include: <ul style="list-style-type: none"> • <i>Kb/s</i>—Specifies the kilobits per second (from 1 to 2000000).

	Command or Action	Purpose
	Device (config-pmap-c) #	<ul style="list-style-type: none"> • <i>burst_in_bytes</i>—Specifies the burst in bytes (from 32 to 2000000). • level <i>level_value</i>—Specifies the multilevel (1-2) priority queue. <ul style="list-style-type: none"> • <i>Kb/s</i>—Specifies the kilobits per second (from 1 to 2000000). <ul style="list-style-type: none"> • <i>burst_in_bytes</i>—Specifies the burst in bytes (from 32 to 2000000). • percent—Percentage of the total bandwidth. <ul style="list-style-type: none"> • <i>burst_in_bytes</i>—Specifies the burst in bytes (from 32 to 2000000). • percent—Percentage of the total bandwidth. <ul style="list-style-type: none"> • <i>burst_in_bytes</i>—Specifies the burst in bytes (32 to 2000000). <p>Note Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.</p>
Step 5	end Example: Device (config-pmap-c) # end Device#	Saves configuration changes.
Step 6	show policy-map Example: Device# show policy-map	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

[Priority Queues](#), on page 879

Configuring Queues and Shaping

Configuring Egress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you may need to perform all of the procedures in this section. You need to make decisions about these characteristics:

- Which packets are mapped by DSCP, CoS, or QoS group value to each queue and threshold ID?
- What drop percentage thresholds apply to the queues, and how much reserved and maximum memory is needed for the traffic type?
- How much of the fixed buffer space is allocated to the queues?
- Does the bandwidth of the port need to be rate limited?
- How often should the egress queues be serviced and which technique (shaped, shared, or both) should be used?

Note You can only configure the egress queues on the .

Configuring Queue Buffers (CLI)

The `queue-buffer` command allows you to allocate buffers to queues. If there is no allocation made to buffers, then they are divided equally for all queues. You can use the `queue-buffer` ratio to divide it in a particular ratio. Since by default DTS (Dynamic Threshold and Scaling) is active on all queues, these are soft buffers.

Before you begin

The following are prerequisites for this procedure:

- You should have created a class map for the queue buffer before beginning this procedure.
- You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue buffers.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **bandwidth** {*Kb/s* | **percent** *percentage* | **remaining** { **ratio** *ratio value* }}
5. **queue-buffers** {**ratio** *ratio value*}
6. **end**
7. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters the global configuration mode.
Step 2	<p>policy-map <i>policy name</i></p> <p>Example:</p> <pre>Device(config)# policy-map policy_queuebuffer01 Device(config-pmap)#</pre>	<p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>
Step 3	<p>class <i>class name</i></p> <p>Example:</p> <pre>Device(config-pmap)# class class_queuebuffer01 Device(config-pmap-c)#</pre>	<p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> • <i>word</i>—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 4	<p>bandwidth {<i>Kb/s</i> percent <i>percentage</i> remaining { <i>ratio</i> <i>value</i> } }</p> <p>Example:</p> <pre>Device(config-pmap-c)# bandwidth percent 80 Device(config-pmap-c)#</pre>	<p>Configures the bandwidth for the policy map. The command parameters include:</p> <ul style="list-style-type: none"> • <i>Kb/s</i>—Use this command to configure a specific value. The range is 20000 to 10000000. • percent—Allocates a minimum bandwidth to a particular class using a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues. • remaining—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the priority command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.

	Command or Action	Purpose
		Note You cannot mix bandwidth types on a policy map.
Step 5	queue-buffers {ratio ratio value} Example: <pre>Device(config-pmap-c)# queue-buffers ratio 10 Device(config-pmap-c)#</pre>	Configures the relative buffer size for the queue. Note The sum of all configured buffers in a policy must be less than or equal to 100 percent. Unallocated buffers are evenly distributed to all the remaining queues. Ensure sufficient buffers are allocated to all queues including the priority queues. Note Protocol Data Units(PDUs) for network control protocols such as spanning-tree and LACP utilize the priority queue or queue 0 (when a priority queue is not configured). Ensure sufficient buffers are allocated to these queues for the protocols to function.
Step 6	end Example: <pre>Device(config-pmap-c)# end Device#</pre>	Saves configuration changes.
Step 7	show policy-map Example: <pre>Device# show policy-map</pre>	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.

Configuring Queue Limits (CLI)

You use queue limits to configure Weighted Tail Drop (WTD). WTD ensures the configuration of more than one threshold per queue. Each class of service is dropped at a different threshold value to provide for QoS differentiation. With the , each queue has 3 explicit programmable threshold classes—0, 1, 2. Therefore, the enqueue/drop decision of each packet per queue is determined by the packet's threshold class assignment, which is determined by the DSCP, CoS, or QoS group field of the frame header.

WTD also uses a soft limit, and therefore you are allowed to configure the queue limit to up to 400 percent (maximum four times the reserved buffer from common pool). This soft limit prevents overrunning the common pool without impacting other features.

Note You can only configure queue limits on the egress queues on wired ports.

Before you begin

The following are prerequisites for this procedure:

- You should have created a class map for the queue limits before beginning this procedure.
- You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue limits.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **bandwidth** {*Kb/s* | **percent** *percentage* | **remaining** { **ratio** *ratio value* }}
5. **queue-limit** {*packets* **packets** | **cos** {*cos value* { *maximum threshold value* | **percent** *percentage* } | **values** {*cos value* | **percent** *percentage* } } | **dscp** {*dscp value* { *maximum threshold value* | **percent** *percentage* } | *match packet* { *maximum threshold value* | **percent** *percentage* } | **default** { *maximum threshold value* | **percent** *percentage* } | **ef** { *maximum threshold value* | **percent** *percentage* } | **dscp values** *dscp value* } | **percent** *percentage* } }
6. **end**
7. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	policy-map <i>policy name</i> Example: Device(config)# policy-map <i>policy_queue-limit01</i> Device(config-pmap)#	Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 3	class <i>class name</i> Example:	Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or

	Command or Action	Purpose
	<pre>Device(config-pmap) # class class_queuelimit01 Device(config-pmap-c) #</pre>	<p>change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> • word—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 4	<p>bandwidth {<i>Kb/s</i> percent <i>percentage</i> remaining { <i>ratio</i> <i>value</i> } }</p> <p>Example:</p> <pre>Device(config-pmap-c) # bandwidth 500000 Device(config-pmap-c) #</pre>	<p>Configures the bandwidth for the policy map. The parameters include:</p> <ul style="list-style-type: none"> • Kb/s—Use this command to configure a specific value. The range is 20000 to 10000000. • percent—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues. • remaining—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the priority command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100. <p>Note You cannot mix bandwidth types on a policy map.</p>
Step 5	<p>queue-limit {<i>packets</i> packets cos {<i>cos value</i> { <i>maximum threshold value</i> percent <i>percentage</i> } } values {<i>cos value</i> percent <i>percentage</i> } } dscp {<i>dscp value</i> { <i>maximum threshold value</i> percent <i>percentage</i> } match packet { <i>maximum threshold value</i> percent <i>percentage</i> } default { <i>maximum threshold value</i> percent <i>percentage</i> } ef { <i>maximum threshold value</i> percent <i>percentage</i> } dscp values <i>dscp value</i> } percent <i>percentage</i> } }</p> <p>Example:</p> <pre>Device(config-pmap-c) # queue-limit dscp 3 percent 20 Device(config-pmap-c) # queue-limit dscp 4 percent 30 Device(config-pmap-c) # queue-limit dscp 5 percent</pre>	<p>Sets the queue limit threshold percentage values.</p> <p>With every queue, there are three thresholds (0,1,2), and there are default values for each of these thresholds. Use this command to change the default or any other queue limit threshold setting. For example, if DSCP 3, 4, and 5 packets are being sent into a specific queue in a configuration, then you can use this command to set the threshold percentages for these three DSCP values. For additional information about queue limit threshold values, see Weighted Tail Drop, on page 877.</p> <p>Note The does not support absolute queue-limit percentages. The only supports DSCP or CoS queue-limit percentages.</p>

	Command or Action	Purpose
	40	
Step 6	end Example: <pre>Device(config-pmap-c) # end Device#</pre>	Saves configuration changes.
Step 7	show policy-map Example: <pre>Device# show policy-map</pre>	(Optional) Displays policy configuration information for all classes configured for all service policies.

What to do next

Proceed to configure any additional policy maps for QoS for your network. After creating your policy maps, proceed to attach the traffic policy or polices to an interface using the **service-policy** command.

Configuring Shaping (CLI)

You use the **shape** command to configure shaping (maximum bandwidth) for a particular class. The queue's bandwidth is restricted to this value even though the port has additional bandwidth left. You can configure shaping as an average percent, as well as a shape average value in bits per second.

Before you begin

You should have created a class map for shaping before beginning this procedure.

SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **shape average** {*target bit rate* | **percent** *percentage*}
5. **end**
6. **show policy-map**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters the global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 2	<p><code>policy-map policy name</code></p> <p>Example:</p> <pre>Device(config)# policy-map policy_shaping01 Device(config-pmap)#</pre>	<p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>
Step 3	<p><code>class class name</code></p> <p>Example:</p> <pre>Device(config-pmap)# class class_shaping01 Device(config-pmap-c)#</pre>	<p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> • <i>word</i>—Class map name. • class-default—System default class matching any otherwise unclassified packets.
Step 4	<p><code>shape average {target bit rate percent percentage}</code></p> <p>Example:</p> <pre>Device(config-pmap-c)# shape average percent 50 Device(config-pmap-c)#</pre>	<p>Configures the average shape rate. You can configure the average shape rate by target bit rates (bits per second) or by percentage of interface bandwidth for the Committed Information Rate (CIR).</p> <p>Note For the egress class-default SSID policy, you must configure the queue buffer ratio as 0 after you configure the average shape rate.</p>
Step 5	<p><code>end</code></p> <p>Example:</p> <pre>Device(config-pmap-c)# end Device#</pre>	<p>Saves configuration changes.</p>
Step 6	<p><code>show policy-map</code></p> <p>Example:</p> <pre>Device# show policy-map</pre>	<p>(Optional) Displays policy configuration information for all classes configured for all service policies.</p>

What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

Configuring Precious Metal Policies (CLI)

You can configure precious metal QoS policies on a per-WLAN basis.

SUMMARY STEPS

1. **configure terminal**
2. **wlan *wlan-name***
3. **service-policy {input | output} *policy-name***
4. **end**
5. **show wlan {*wlan-id* | *wlan-name*}**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global command mode.
Step 2	wlan <i>wlan-name</i> Example: Device# wlan test4	Enters the WLAN configuration submode.
Step 3	service-policy {input output} <i>policy-name</i> Example: Device(config-wlan)# service-policy output platinum Example: Device(config-wlan)# service-policy input platinum-up	Configures the WLAN with the QoS policy. To configure the WLAN with precious metal policies, you must enter one of the following keywords: platinum , gold , silver , or bronze . The upstream policy is specified with the keyword platinum-up as shown in the example. Note Upstream policies differ from downstream policies. The upstream policies have a suffix of -up .
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit the global configuration mode.
Step 5	show wlan {<i>wlan-id</i> <i>wlan-name</i>} Example: Device# show wlan name qos-wlan	Verifies the configured QoS policy on the WLAN. Device# show wlan name qos-wlan QoS Service Policy - Input Policy Name : platinum-up Policy State : Validated QoS Service Policy - Output

	Command or Action	Purpose
		Policy Name : platinum Policy State : Validated

Configuring QoS Policies for Multicast Traffic (CLI)

Before you begin

The following are the prerequisites for configuring a QoS policy for multicast traffic:

- You must have a multicast service policy configured.
- You must enable multicast-multicast mode before applying the policy.

SUMMARY STEPS

1. **configure terminal**
2. **ap capwap multicast service-policy output** *service-policy-name*
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap capwap multicast service-policy output <i>service-policy-name</i> Example: Device(config)# ap capwap multicast service-policy output service-policy-mcast	Applies the configured multicast policy.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Port Policies (GUI)

- Step 1** Choose **Configuration > Wireless**
- Step 2** Expand the **QoS** node by clicking on left pane and choose **QOS-Policy**.
The **QOS-Policy** page is displayed.
- Step 3** Click **Add New** to create a new QoS policy.
The **Create QoS Policy** page is displayed.
- Step 4** Select **Port** from the **Policy Type** drop-down menu.
- Step 5** Enter the policy name in the **Policy Name** text field.
- Step 6** Specify a description for the policy you want to create in the **Description** field.
- Step 7** Configure the voice or video priorities for the port policies by enabling the **Enable Voice** and **Enable Video** parameters.
- Note** You must attach the port policy to an interface. Default values are recommended.
- Step 8** Click **Add** to add the policy.
-

What to do next

Proceed to assign the port policy on an interface.

Applying a QoS Policy on a WLAN (GUI)

- Step 1** Choose **Configuration > Wireless**.
- Step 2** Expand the **WLAN** node by clicking on the left pane and choose **WLANs**.
The **WLANs** page is displayed.
- Step 3** Select the WLAN for which you want to configure the QoS policies by clicking on the WLAN **Profile**.
- Step 4** Click the QoS tab to configure the QoS policies on the WLAN.
You can also configure precious metal policies for the WLAN.
The following options are available:

Parameter	Description
QoS SSID Policy	
Egress Policy	QoS downstream policy configuration. The Existing Policy column displays the current applied policy. To change the existing policy, select the policy from the drop-down list in the Assign Policy column. If a policy is not selected, NONE is displayed.
Ingress Policy	QoS upstream policy configuration. The Existing Policy column displays the current applied policy. To change the existing policy, select the policy from the drop-down list in the Assign Policy column. If a policy is not selected, NONE is displayed.
QoS Client Policy	
Egress Policy	QoS downstream policy configuration. The Existing Policy column displays the current applied policy. To change the existing policy, select the policy from the drop-down list in the Assign Policy column. If a policy is not selected, NONE is displayed.
Ingress Policy	QoS upstream policy configuration. The Existing Policy column displays the current applied policy. To change the existing policy, select the policy from the drop-down list in the Assign Policy column. If a policy is not selected, NONE is displayed.
WMM	

Parameter	Description
WMM Policy	<p>WMM Policy. This parameter has the following values:</p> <ul style="list-style-type: none"> • Disabled—Disables this WMM policy. • Allowed—Allows the clients to communicate with the WLAN. • Require—Ensures that it is mandatory for the clients to have WMM features enabled on them to communicate with the WLAN.

Step 5 Click **Apply**.

Monitoring QoS

The following commands can be used to monitor QoS on the .

Table 77: Monitoring QoS

Command	Description
<code>show class-map [class_map_name]</code>	Displays a list of all class maps configured.
<code>show class-map type control subscriber {all name }</code> <code>show class-map type control subscriber detail</code>	Displays control class map and statistics. <ul style="list-style-type: none"> • all—Displays information for all class maps. • name—Displays configured class maps.

Command	Description
show policy-map [<i>policy_map_name</i>]	Displays a list of all policy maps configured. Command parameters include: <ul style="list-style-type: none">• policy map name• control plane• interface• session• type

Command	Description
show policy-map interface { Auto-template Capwap GigabitEthernet GroupVI InternalInterface Loopback Lspvif Null Port-channel TenGigabitEthernet Tunnel Vlan brief class input output wireless }	Displays the runtime representation and statistics of all the policies configured on the . Command parameters include: <ul style="list-style-type: none"> • Auto-template—Auto-Template interface • Capwap—CAPWAP tunnel interface • GigabitEthernet—Gigabit Ethernet IEEE.802.3z • GroupVI—Group virtual interface • InternalInterface—Internal interface • Loopback—Loopback interface • Lspvif—LSP virtual interface • Null—Null interface • Port-channel—Ethernet channel of interfaces • TenGigabitEthernet—10-Gigabit Ethernet • Tunnel—Tunnel interface • Vlan—Catalyst VLANs • brief—Brief description of policy maps • class—Statistics for individual class • input—Input policy • output—Output policy • Wireless—wireless
show policy-map interface wireless ap [<i>access point</i>]	Displays the runtime representation and statistics for all the wireless APs on the .
show policy-map interface wireless ssid [<i>ssid</i>]	Displays the runtime representation and statistics for all the SSID targets on the .

Command	Description
show policy-map interface wireless client mac [<i>mac_address</i>]	Displays the runtime representation and statistics for all the client targets on the .
show policy-map session [input output uid <i>UUID</i>]	Displays the session QoS policy. Command parameters include: <ul style="list-style-type: none"> • input—Input policy • output—Output policy • uid—Policy based on SSS unique identification.
show policy-map type control subscriber { all name }	Displays the type QoS policy-map.
show table-map	Displays all the table maps and their configurations.
show platform qos wireless { afd { client ssid } stats { bssid <i>bssid-value</i> client <i>client name</i> ssid { <i>ssid-value</i> all } client all } }	Displays wireless targets. The following command parameters are supported: <ul style="list-style-type: none"> • afd—AFD information • stats—Statistics information
show policy-map interface wireless ssid name <i>ssid-name</i> [radio type { 24ghz 5ghz } ap name <i>ap-name</i> ap name <i>ap-name</i>]	Displays SSID policy configuration on an access point.
show wireless client mac-address <i>mac_address</i> service-policy { input output }	Displays details of the client policy.
show wlan qos service-policies	Displays the SSID policies configured on all WLANs.
show ap name <i>ap_name</i> service-policy	Displays all the policies configured on the AP.

Monitoring SSID and Client Policies Statistics (GUI)

Statistics are supported only for ingress policies with a maximum of five classes on wireless targets. For very large policies, statistics for ingress policies are not visible at the . The frequency of the statistics depends on the number of clients associated with the access point.

Type of Statistics	Method	Details
SSID Policies	Choose Monitor > Controller > Statistics > QoS .	The QoS page is displayed with a list of SSID policies, Radio Type, and AP. Choose an SSID policy, radio, and access point from the drop-down lists and click Apply to view the statistics of the chosen SSID policy. You can view details such as match criteria, confirmed bytes, conformed rate, and exceeded rate.
Client Policies	Choose Monitor > Clients > Client Details .	The Clients page is displayed with a list of client MAC addresses, AP, and other details. Click the MAC address of a client and click the QoS Statistics tab. You can view details such as match criteria, confirmed bytes, conformed rate, and exceeded rate.

Configuration Examples for QoS

Examples: Classification by Access Control Lists

This example shows how to classify packets for QoS by using access control lists (ACLs):

```
Device# configure terminal
Device(config)# access-list 101 permit ip host 12.4.1.1 host 15.2.1.1
Device(config)# class-map acl-101
Device(config-cmap)# description match on access-list 101
Device(config-cmap)# match access-group 101
Device(config-cmap)#
```

After creating a class map by using an ACL, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Related Topics

[Creating a Traffic Class \(CLI\)](#), on page 895

[Class Maps](#), on page 867

Examples: Class of Service Layer 2 Classification

This example shows how to classify packets for QoS using a class of service Layer 2 classification:

```

Device# configure terminal
Device(config)# class-map cos
Device(config-cmap)# match cos ?
    <0-7> Enter up to 4 class-of-service values separated by white-spaces
Device(config-cmap)# match cos 3 4 5
Device(config-cmap)#

```

After creating a class map by using a CoS Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Class of Service DSCP Classification

This example shows how to classify packets for QoS using a class of service DSCP classification:

```

Device# configure terminal
Device(config)# class-map dscp
Device(config-cmap)# match dscp af21 af22 af23
Device(config-cmap)#

```

After creating a class map by using a DSCP classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: VLAN ID Layer 2 Classification

This example shows how to classify for QoS using a VLAN ID Layer 2 classification:

```

Device# configure terminal
Device(config)# class-map vlan-120
Device(config-cmap)# match vlan ?
    <1-4095> VLAN id
Device(config-cmap)# match vlan 120
Device(config-cmap)#

```

After creating a class map by using a VLAN Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Classification by DSCP or Precedence Values

This example shows how to classify packets by using DSCP or precedence values:

```

Device# configure terminal
Device(config)# class-map prec2
Device(config-cmap)# description matching precedence 2 packets
Device(config-cmap)# match ip precedence 2
Device(config-cmap)# exit
Device(config)# class-map ef
Device(config-cmap)# description EF traffic
Device(config-cmap)# match ip dscp ef
Device(config-cmap)#

```

After creating a class map by using a DSCP or precedence values, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Hierarchical Classification

The following is an example of a hierarchical classification, where a class named parent is created, which matches another class named child. The class named child matches based on the IP precedence being set to 2.

```
Device# configure terminal
Device(config)# class-map child
Device(config-cmap)# match ip precedence 2
Device(config-cmap)# exit
Device(config)# class-map parent
Device(config-cmap)# match class child
Device(config-cmap)#
```

After creating the parent class map, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Related Topics

[Hierarchical QoS](#), on page 859

Examples: Hierarchical Policy Configuration

The following is an example of a configuration using hierarchical policies:

```
Device# configure terminal
Device(config)# class-map c1
Device(config-cmap)# match dscp 30
Device(config-cmap)# exit

Device(config)# class-map c2
Device(config-cmap)# match precedence 4
Device(config-cmap)# exit

Device(config)# class-map c3
Device(config-cmap)# exit

Device(config)# policy-map child
Device(config-pmap)# class c1
Device(config-pmap-c)# priority level 1
Device(config-pmap-c)# police rate percent 20 conform-action transmit exceed action drop
Device(config-pmap-c-police)# exit
Device(config-pmap-c)# exit

Device(config-pmap)# class c2
Device(config-pmap-c)# bandwidth 20000
Device(config-pmap-c)# exit
Device(config-pmap)# class class-default
Device(config-pmap-c)# bandwidth 20000
Device(config-pmap-c)# exit
Device(config-pmap)# exit

Device(config)# policy-map parent
Device(config-pmap)# class class-default
```

```
Device(config-pmap-c) # shape average 1000000
Device(config-pmap-c) # service-policy child
Device(config-pmap-c) # end
```

The following example shows a hierarchical policy using table maps:

```
Device(config) # table-map dscp2dscp
Device(config-tablemap) # default copy
Device(config) # table-map dscp2up
Device(config-tablemap) # map from 46 to 6
Device(config-tablemap) # map from 34 to 5
Device(config-tablemap) # default copy
Device(config) # policy-map ssid_child_policy
Device(config-pmap) # class voice
Device(config-pmap-c) # priority level 1
Device(config-pmap-c) # police 15000000
Device(config-pmap) # class video
Device(config-pmap-c) # priority level 2
Device(config-pmap-c) # police 10000000
Device(config) # policy-map ssid_policy
Device(config-pmap) # class class-default
Device(config-pmap-c) # shape average 30000000
Device(config-pmap-c) # queue-buffer ratio 0
Device(config-pmap-c) # set dscp dscp table dscp2dscp
Device(config-pmap-c) # service-policy ssid_child_policy
```

Related Topics

[Hierarchical QoS](#), on page 859

Examples: Classification for Voice and Video

This example describes how to classify packet streams for voice and video using device specific information.

In this example, voice and video are coming in from end-point A into GigabitEthernet1/0/1 on the device and have precedence values of 5 and 6, respectively. Additionally, voice and video are also coming from end-point B into GigabitEthernet1/0/2 on the device with DSCP values of EF and AF11, respectively.

Assume that all the packets from the both the interfaces are sent on the uplink interface, and there is a requirement to police voice to 100 Mbps and video to 150 Mbps.

To classify per the above requirements, a class to match voice packets coming in on GigabitEthernet1/0/1 is created, named voice-interface-1, which matches precedence 5. Similarly another class for voice is created, named voice-interface-2, which will match voice packets in GigabitEthernet1/0/2. These classes are associated to two separate policies named input-interface-1, which is attached to GigabitEthernet1/0/1, and input-interface-2, which is attached to GigabitEthernet1/0/2. The action for this class is to mark the qos-group to 10. To match packets with QoS-group 10 on the output interface, a class named voice is created which matches on QoS-group 10. This is then associated to another policy named output-interface, which is associated to the uplink interface. Video is handled in the same way, but matches on QoS-group 20.

The following example shows how classify using the above device specific information:

```
Device(config) #
Device(config) # class-map voice-interface-1
Device(config-cmap) # match ip precedence 5
Device(config-cmap) # exit

Device(config) # class-map video-interface-1
Device(config-cmap) # match ip precedence 6
```

```

Device(config-cmap) # exit

Device(config) # class-map voice-interface-2
Device(config-cmap) # match ip dscp ef
Device(config-cmap) # exit

Device(config) # class-map video-interface-2
Device(config-cmap) # match ip dscp af11
Device(config-cmap) # exit

Device(config) # policy-map input-interface-1
Device(config-pmap) # class voice-interface-1
Device(config-pmap-c) # set qos-group 10
Device(config-pmap-c) # exit

Device(config-pmap) # class video-interface-1
Device(config-pmap-c) # set qos-group 20

Device(config-pmap-c) # policy-map input-interface-2
Device(config-pmap) # class voice-interface-2
Device(config-pmap-c) # set qos-group 10
Device(config-pmap-c) # class video-interface-2
Device(config-pmap-c) # set qos-group 20
Device(config-pmap-c) # exit
Device(config-pmap) # exit

Device(config) # class-map voice
Device(config-cmap) # match qos-group 10
Device(config-cmap) # exit

Device(config) # class-map video
Device(config-cmap) # match qos-group 20

Device(config) # policy-map output-interface
Device(config-pmap) # class voice
Device(config-pmap-c) # police 256000 conform-action transmit exceed-action drop
Device(config-pmap-c-police) # exit
Device(config-pmap-c) # exit

Device(config-pmap) # class video
Device(config-pmap-c) # police 1024000 conform-action transmit exceed-action drop
Device(config-pmap-c-police) # exit
Device(config-pmap-c) # exit

```

Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic

The following example provides a template for creating a port child policy for managing quality of service for voice and video traffic.

```

Policy-map port_child_policy
  Class voice (match dscp ef)
    Priority level 1
    Police Multicast Policer
  Class video (match dscp af41)
    Priority level 2
    Police Multicast Policer
  Class mcast-data (match non-client-nrt)

```

```

    Bandwidth remaining ratio <>
Class class-default (NRT Data)
    Bandwidth remaining ratio <>

```

Note Multicast Policer in the example above is not a keyword. It refers to the policing policy configured.

Two class maps with name voice and video are configured with DSCP assignments of 46 and 34. The voice traffic is assigned the priority of 1 and the video traffic is assigned the priority level 2 and is processed using Q0 and Q1. If your network receives multicast voice and video traffic, you can configure multicast policers. The non-client NRT data and NRT data are processed using the Q2 and Q3 queues.

Examples: Ingress SSID Policies

The following examples show ingress SSID hierarchical policies:

Type of ingress SSID policies	Example
Ingress SSID hierarchical policies	<pre> policy-map ssid-child-policy class voice //match dscp 46 police 3m class video //match dscp 34 police 4m policy-map ssid-in-policy class class-default set dscp wlan user-priority table up2dscp service-policy ssid-child-policy </pre>
	<pre> policy-map ssid_in_policy class dscp-40 set cos 1 police 10m class up-1 set dscp 34 police 12m class dscp-10 set dscp 20 police 15m class class-default set dscp wlan user-priority table up2dscp police 50m </pre>

Examples: Client Policies

Type of Client Policy	Example/Details
Default egress client policy	<p>Any incoming traffic contains the user-priority as 0.</p> <p>Note The default client policy is enabled only on WMM clients that are ACM-enabled.</p> <p>You can verify if ACM is enabled by using the show ap dot11 5ghz network command. To enable ACM, use the ap dot11 5ghz cac voice acm command.</p> <pre>Policy-map client-def-down class class-default set wlan user-priority 0</pre>
Default ingress client policy	<p>Any traffic that is sent to the wired network from wireless network will result in the DSCP value being set to 0.</p> <p>Note The default client policy is enabled only on WMM clients that are ACM-enabled.</p> <pre>Policy-map client-def-up class class-default set dscp 0</pre>
Client policies generated automatically and applied to the WMM client when the client authenticates to a profile in AAA with a configured QoS-level attribute.	<pre>Policy Map platinum-WMM Class voice-plat set wlan user-priority 6 Class video-plat set wlan user-priority 4 Class class-default set wlan user-priority 0 Policy Map gold-WMM Class voice-gold set wlan user-priority 4 Class video-gold set wlan user-priority 4 Class class-default set wlan user-priority 0</pre>
Non-WMM client precious metal policies	<pre>Policy Map platinum set wlan user-priority 6</pre>

Type of Client Policy	Example/Details
Egress client policy where any traffic matching class voice1, the user priority is set to a pre-defined value.	<p>The class can be set to assign a DSCP or ACL.</p> <pre> Policy Map client1-down Class voice1 //match dscp, cos set wlan user-priority <> Class voice2 //match acl set wlan user-priority <> Class voice3 set wlan user-priority <> Class class-default set wlan user-priority 0 </pre>
Client policy based on AAA and TCLAS	<pre> Policy Map client2-down[AAA+ TCLAS pol example] Class voice\\match dscp police <> set <> Class class-default set <> Class voice1 voice2 [match acls] police <> class voice1 set <> class voice2 set <> </pre>
Client policy for voice and video for traffic in the egress direction	<pre> Policy Map client3-down class voice \\match dscp, cos police X class video police Y class class-default police Z </pre>
Client policy for voice and video for traffic in the ingress direction using policing	<pre> Policy Map client1-up class voice \\match dscp, up, cos police X class video police Y class class-default police Z </pre>
Client policy for voice and video based on DSCP	<pre> Policy Map client2-up class voice \\match dscp, up, cos set dscp <> class video set dscp <> class class-default set dscp <> </pre>

Type of Client Policy	Example/Details
Client ingress policy with marking and policing	<pre> policy-map client_in_policy class dscp-48 //match dscp 48 set cos 3 police 2m class up-4 //match wlan user-priority 4 set dscp 10 police 3m class acl //match acl set cos 2 police 5m class class-default set dscp 20 police 15m </pre>
Hierarchical client ingress policy	<pre> policy-map client-child-policy class voice //match dscp 46 set dscp 40 police 5m class video //match dscp 34 set dscp 30 police 7m policy-map client-in-policy class class-default police 15m service-policy client-child-policy </pre>

Examples: Average Rate Shaping Configuration

The following example shows how to configure average rate shaping:

```

Device# configure terminal
Device(config)# class-map prec1
Device(config-cmap)# description matching precedence 1 packets
Device(config-cmap)# match ip precedence 1
Device(config-cmap)# end

```

```

Device# configure terminal
Device(config)# class-map prec2
Device(config-cmap)# description matching precedence 2 packets
Device(config-cmap)# match ip precedence 2
Device(config-cmap)# exit

```

```

Device(config)# policy-map shaper
Device(config-pmap)# class prec1
Device(config-pmap-c)# shape average 512000
Device(config-pmap-c)# exit

```

```

Device(config-pmap) # policy-map shaper
Device(config-pmap) # class prec2
Device(config-pmap-c) # shape average 512000
Device(config-pmap-c) # exit

Device(config-pmap) # class class-default
Device(config-pmap-c) # shape average 1024000

```

After configuring the class maps, policy map, and shape averages for your configuration, proceed to then apply the policy map to the interface for QoS.

Examples: Queue-limit Configuration

The following example shows how to configure a queue-limit policy based upon DSCP values and percentages:

```

Device# configure terminal
Device#(config) # policy-map port-queue
Device#(config-pmap) # class dscp-1-2-3
Device#(config-pmap-c) # bandwidth percent 20
Device#(config-pmap-c) # queue-limit dscp 1 percent 80
Device#(config-pmap-c) # queue-limit dscp 2 percent 90
Device#(config-pmap-c) # queue-limit dscp 3 percent 100
Device#(config-pmap-c) # exit

Device#(config-pmap) # class dscp-4-5-6
Device#(config-pmap-c) # bandwidth percent 20
Device#(config-pmap-c) # queue-limit dscp 4 percent 20
Device#(config-pmap-c) # queue-limit dscp 5 percent 30
Device#(config-pmap-c) # queue-limit dscp 6 percent 20
Device#(config-pmap-c) # exit

Device#(config-pmap) # class dscp-7-8-9
Device#(config-pmap-c) # bandwidth percent 20
Device#(config-pmap-c) # queue-limit dscp 7 percent 20
Device#(config-pmap-c) # queue-limit dscp 8 percent 30
Device#(config-pmap-c) # queue-limit dscp 9 percent 20
Device#(config-pmap-c) # exit

Device#(config-pmap) # class dscp-10-11-12
Device#(config-pmap-c) # bandwidth percent 20
Device#(config-pmap-c) # queue-limit dscp 10 percent 20
Device#(config-pmap-c) # queue-limit dscp 11 percent 30
Device#(config-pmap-c) # queue-limit dscp 12 percent 20
Device#(config-pmap-c) # exit

Device#(config-pmap) # class dscp-13-14-15
Device#(config-pmap-c) # bandwidth percent 10
Device#(config-pmap-c) # queue-limit dscp 13 percent 20
Device#(config-pmap-c) # queue-limit dscp 14 percent 30
Device#(config-pmap-c) # queue-limit dscp 15 percent 20
Device#(config-pmap-c) # end
Device#

```

After finishing with the above policy map queue-limit configuration, you can then proceed to apply the policy map to an interface for QoS.

Examples: Queue Buffers Configuration

The following example shows how configure a queue buffer policy and then apply it to an interface for QoS:

```
Device# configure terminal
Device(config)# policy-map policy1001
Device(config-pmap)# class class1001
Device(config-pmap-c)# bandwidth remaining ratio 10
Device(config-pmap-c)# queue-buffer ratio ?
<0-100> Queue-buffers ratio limit
Device(config-pmap-c)# queue-buffer ratio 20
Device(config-pmap-c)# end

Device# configure terminal
Device(config)# interface gigabitEthernet2/0/3
Device(config-if)# service-policy output policy1001
Device(config-if)# end
```

Related Topics

Examples: Policing Action Configuration

The following example displays the various policing actions that can be associated to the policer. These actions are accomplished using the conforming, exceeding, or violating packet configurations. You have the flexibility to drop, mark and transmit, or transmit packets that have exceeded or violated a traffic profile.

For example, a common deployment scenario is one where the enterprise customer polices traffic exiting the network towards the service provider and marks the conforming, exceeding and violating packets with different DSCP values. The service provider could then choose to drop the packets marked with the exceeded and violated DSCP values under cases of congestion, but may choose to transmit them when bandwidth is available.

Note

The Layer 2 fields can be marked to include the CoS fields, and the Layer 3 fields can be marked to include the precedence and the DSCP fields.

One useful feature is the ability to associate multiple actions with an event. For example, you could set the precedence bit and the CoS for all conforming packets. A submode for an action configuration could then be provided by the policing feature.

This is an example of a policing action configuration:

```
Device# configure terminal
```

```

Device(config)# policy-map police
Device(config-pmap)# class class-default
Device(config-pmap-c)# police cir 1000000 pir 2000000
Device(config-pmap-c-police)# conform-action transmit
Device(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Device(config-pmap-c-police)# violate-action set-dscp-transmit dscp table
violate-markdown-table
Device(config-pmap-c-police)# end

```

In this example, the exceed-markdown-table and violate-mark-down-table are table maps.

Note Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the device.

Examples: Policing Units

The following examples display the various units of policing that are supported for QoS. The policing unit is the basis on which the token bucket works .

The following units of policing are supported:

- CIR and PIR are specified in bits per second. The burst parameters are specified in bytes. This is the default mode; it is the unit that is assumed when no units are specified. The CIR and PIR can also be configured in percent, in which case the burst parameters have to be configured in milliseconds.

- CIR and PIR are specified in packets per second. In this case, the burst parameters are configured in packets as well.

The following is an example of a policer configuration in bits per second:

```
Device(config)# policy-map bps-policer
Device(config-pmap)# class class-default
Device(config-pmap-c)# police rate 256000 bps burst 1000 bytes
conform-action transmit exceed-action drop
```

The following is an example of a policer configuration in packets per second. In this configuration, a dual-rate three-color policer is configured where the units of measurement is packet. The burst and peak burst are all specified in packets.

```
Device(config)# policy-map pps-policer
Device(config-pmap)# class class-default
Device(config-pmap-c)# police rate 5000 pps burst 100 packets
peak-rate 10000 pps peak-burst 200 packets conform-action transmit
exceed-action drop violate-action drop
```

Examples: Dual-Rate Three-Color Policing Configuration

The following example shows how to configure a dual-rate three-color policer:

```
Device# configure terminal
Device(config)# policy-Map dual-rate-3color-policer
Device(config-pmap)# class class-default
Device(config-pmap-c)# police cir 64000 bc 2000 pir 128000 be 2000
Device(config-pmap-c-police)# conform-action transmit
Device(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Device(config-pmap-c-police)# violate-action set-dscp-transmit dscp table
```

```
violate-markdown-table
Device(config-pmap-c-police)# exit
Device(config-pmap-c)#
```

In this example, the exceed-markdown-table and violate-mark-down-table are table maps.

Note Policer based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the device.

Examples: Table Map Marking Configuration

The following steps and examples show how to use table map marking for your QoS configuration:

1. Define the table map.

Define the table-map using the **table-map** command and indicate the mapping of the values. This table does not know of the policies or classes within which it will be used. The default command in the table map indicates the value to be copied into the ‘to’ field when there is no matching ‘from’ field. In the example, a table map named table-map1 is created. The mapping defined is to convert the value from 0 to 1 and from 2 to 3, while setting the default value to 4.

```
Device(config)# table-map table-map1
Device(config-tablemap)# map from 0 to 1
Device(config-tablemap)# map from 2 to 3
Device(config-tablemap)# default 4
Device(config-tablemap)# exit
```

2. Define the policy map where the table map will be used.

In the example, the incoming CoS is mapped to the DSCP based on the mapping specified in the table table-map1. For this example, if the incoming packet has a DSCP of 0, the CoS in the packet is set 1. If no table map name is specified the command assumes a default behavior where the value is copied as is from the ‘from’ field (DSCP in this case) to the ‘to’ field (CoS in this case). Note however, that while the CoS is a 3-bit field, the DSCP is a 6-bit field, which implies that the CoS is copied to the first three bits in the DSCP.

```
Device(config)# policy map policy1
Device(config-pmap)# class class-default
Device(config-pmap-c)# set cos dscp table table-map1
Device(config-pmap-c)# exit
```

3. Associate the policy to an interface.

```
Device(config)# interface GigabitEthernet1/0/1
Device(config-if)# service-policy output policy1
```

```
Device(config-if)# exit
```

[Table Map Marking](#), on page 872

Example: Table Map Configuration to Retain CoS Markings

The following example shows how to use table maps to retain CoS markings on an interface for your QoS configuration.

The `cos-trust-policy` policy (configured in the example) is enabled in the ingress direction to retain the CoS marking coming into the interface. If the policy is not enabled, only the DSCP is trusted by default. If a pure Layer 2 packet arrives at the interface, then the CoS value will be rewritten to 0 when there is no such policy in the ingress port for CoS.

```
Device# configure terminal
Device(config)# table-map cos2cos
Device(config-tablemap)# default copy
Device(config-tablemap)# exit

Device(config)# policy map cos-trust-policy
Device(config-pmap)# class class-default
Device(config-pmap-c)# set cos cos table cos2cos
Device(config-pmap-c)# exit

Device(config)# interface GigabitEthernet1/0/2
Device(config-if)# service-policy input cos-trust-policy
Device(config-if)# exit
```

- Additional References for Auto-QoS, on page 1043
- Feature History and Information for Auto-QoS, on page 1044

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Auto-QoS

The prerequisites for auto-QoS are the same as the prerequisites for standard QoS.

Restrictions for Auto-QoS

The following are restrictions for auto-QoS:

- Auto-qos is not supported on SVI interfaces.

- Auto-QoS is not supported on an Etherchannel interface. When applied on member ports, all port-channel interfaces should share the same Auto-QoS policy.
- The **trust device** *device_type* command available in interface configuration mode is a stand-alone command on the switch. When using this command, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.
- When upgrading your software release from a pre- 3.2.2 software version to a 3.2.2 or later software version, you must follow the auto-QoS upgrade procedure described in this chapter.
- Do not configure the **auto qos voip cisco-phone** option for IP phones that support video. This option causes DSCP markings of video packets to get overwritten, because these packets do not have Expedited Forwarding priority, which results in these packets getting classified in the class-default class.
- Auto-QoS does not generate configuration when it is pushed from the startup-configuration using the **auto qos voip cisco-phone** command to the running-configuration. This is expected behavior and this is to prevent overwriting of user-created customized QoS policies by the default configuration, if any, every time the command **auto qos voip cisco-phone** is pushed from the startup-config.

You can use any of the following workarounds for this limitation:

- Configure the **auto qos voip cisco-phone** command manually on the switch interfaces.
- For new switches, if you push auto-QoS commands through startup-config, the command should include each of the following as part of the standard template
 1. Interface-level:
 - **trust device cisco-phone**
 - **auto qos voip cisco-phone**
 - **service-policy input** AutoQos-4.0-CiscoPhone-Input-Policy
 - **service-policy output** AutoQos-4.0-Output-Policy
 2. Global-level:
 - Class-map
 - Policy-map
 - ACL(ACE)
- If the **auto qos voip cisco-phone** command is already configured on an interface but policies are not being generated, disable the command from all the interfaces and reconfigure the command on each interface manually.

Information About Configuring Auto-QoS

Auto-QoS Overview

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows.

The switch employs the MQC model. This means that instead of using certain global configurations, auto-QoS applied to any interface on a switch configures several global class maps and policy maps.

Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

QoS is needed in both directions, both on inbound and outbound. When inbound, the switch port needs to trust the DSCP in the packet (done by default). When outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

Auto-QoS Compact Overview

When you enter an auto-QoS command, the switch displays all the generated commands as if the commands were entered from the CLI. You can use the auto-QoS compact feature to hide the auto-QoS generated commands from the running configuration. This would make it easier to comprehend the running-configuration and also help to increase efficient usage of memory.

Auto-QoS Global Configuration Templates

In general, an auto-QoS command generates a series of class maps that either match on ACLs or on DSCP and/or CoS values to differentiate traffic into application classes. An input policy is also generated, which matches the generated classes and in some cases, polices the classes to a set bandwidth. Eight egress-queue class maps are generated. The actual egress output policy assigns a queue to each one of these eight egress-queue class maps.

The auto-QoS commands only generate templates as needed. For example, the first time any new auto-QoS command is used, global configurations that define the eight queue egress service-policy are generated. From this point on, auto-QoS commands applied to other interfaces do not generate templates for egress queuing because all auto-QoS commands rely on the same eight queue models, which have already been generated from the first time a new auto-QoS command was used.

Auto-QoS Policy and Class Maps

After entering the appropriate auto-QoS command, the following actions occur:

- Specific class maps are created.
- Specific policy maps (input and output) are created.
- Policy maps are attached to the specified interface.
- Trust level for the interface is configured.

Effects of Auto-QoS on Running Configuration

When auto-QoS is enabled, the **auto qos** interface configuration commands and the generated global configuration are added to the running configuration.

The switch applies the auto-QoS-generated commands as if the commands were entered from the CLI. An existing user configuration can cause the application of the generated commands to fail or to be overridden by the generated commands. These actions may occur without warning. If all the generated commands are successfully applied, any user-entered configuration that was not overridden remains in the running configuration. Any user-entered configuration that was overridden can be retrieved by reloading the switch without saving the current configuration to memory. If the generated commands are not applied, the previous running configuration is restored.

Effects of Auto-QoS Compact on Running Configuration

If auto-QoS compact is enabled:

- Only the auto-QoS commands entered from the CLI are displayed in running-config.
- The generated global and interface configurations are hidden.
- When you save the configuration, only the auto-qos commands you have entered are saved (and not the hidden configuration).
- When you reload the switch, the system detects and re-executes the saved auto-QoS commands and the AutoQoS SRND4.0 compliant config-set is generated .

Note Do not make changes to the auto-QoS-generated commands when auto-QoS compact is enabled, because user-modifications are overridden when the switch reloads.

When auto-qos global compact is enabled:

- **show derived-config** command can be used to view hidden AQC derived commands.
- AQC commands will not be stored to memory. They will be regenerated every time the switch is reloaded.
- When compaction is enabled, auto-qos generated commands should not be modified .

- If the interface is configured with auto-QoS and if AQC needs to be disabled, auto-qos should be disabled at interface level first.

How to Configure Auto-QoS

Configuring Auto-QoS (CLI)

For optimum QoS performance, configure auto-QoS on all the devices in your network.

SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. Depending on your auto-QoS configuration, use one of the following commands:
 - **auto qos voip** {*cisco-phone* | *cisco-softphone* | *trust*}
 - **auto qos video** {*cts* | *ip-camera* | *media-player*}
 - **auto qos classify** [*police*]
 - **auto qos trust** {*cos* | *dscp*}
4. **end**
5. **show auto qos interface** *interface-id*

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 3/0/1	Specifies the port that is connected to a VoIP port, video device, or the uplink port that is connected to another trusted switch or router in the network interior, and enters the interface configuration mode.
Step 3	Depending on your auto-QoS configuration, use one of the following commands: <ul style="list-style-type: none"> • auto qos voip {<i>cisco-phone</i> <i>cisco-softphone</i> <i>trust</i>} 	The following commands enable auto-QoS for VoIP: <ul style="list-style-type: none"> • auto qos voip cisco-phone—If the port is connected to a Cisco IP Phone, the QoS labels of incoming packets are only trusted (conditional trust through CDP) when the telephone is detected.

Command or Action	Purpose
<ul style="list-style-type: none"> • auto qos video {cts ip-camera media-player} • auto qos classify [police] • auto qos trust {cos dscp} <p>Example:</p> <pre>Device(config-if)# auto qos trust dscp</pre>	<p>Note Do not configure the auto qos voip cisco-phone option for IP phones that support video. This option causes DSCP markings of video packets to get overwritten, because these packets do not have Expedited Forwarding priority, which results in these packets getting classified in the class-default class.</p> <ul style="list-style-type: none"> • auto qos voip cisco-softphone—The port is connected to device running the Cisco SoftPhone feature. This command generates a QoS configuration for interfaces connected to PCs running the Cisco IP SoftPhone application and mark, as well as police traffic coming from such interfaces. Ports configured with this command are considered untrusted. • auto qos voip trust—The uplink port is connected to a trusted switch or router, and the VoIP traffic classification in the ingress packet is trusted. <p>The following commands enable auto-QoS for the specified video device (system, camera, or media player):</p> <ul style="list-style-type: none"> • auto qos video cts—A port connected to a Cisco Telepresence system. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco TelePresence is detected. • auto qos video ip-camera—A port connected to a Cisco video surveillance camera. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco camera is detected. • auto qos video media-player—A port connected to a CDP-capable Cisco digital media player. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a digital media player is detected. <p>The following command enables auto-QoS for classification:</p> <ul style="list-style-type: none"> • auto qos classify police— This command generates a QoS configuration for untrusted interfaces. The configuration places a service-policy on the interface to classify traffic coming from untrusted desktops/devices and mark them accordingly. The service-policies generated do police. <p>The following commands enable auto-QoS for trusted interfaces:</p> <ul style="list-style-type: none"> • auto qos trust cos—Class of service.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • auto qos trust dscp—Differentiated Services Code Point.
Step 4	end Example: Device(config-if) # end	Returns to privileged EXEC mode.
Step 5	show auto qos interface <i>interface-id</i> Example: Device# show auto qos interface gigabitethernet 3/0/1	(Optional) Displays the auto-QoS command on the interface on which auto-QoS was enabled. Use the show running-config command to display the auto-QoS configuration and user modifications.

Upgrading Auto-QoS (CLI)

This procedure should only be followed when upgrading your software release from a pre- 3.2.2 software version to a 3.2.2 or later software version.

Before you begin

Prior to upgrading, you need to remove all auto-QoS configurations currently on the switch. This sample procedure describes that process.

After following this sample procedure, you must then reboot the switch with the new or upgraded software image and reconfigure auto-QoS.

SUMMARY STEPS

1. **show auto qos**
2. **no auto qos**
3. **show running-config | i autoQos**
4. **no policy-map** *policy-map_name*

5. **show running-config | i AutoQoS**
6. **show auto qos**
7. **write memory**

DETAILED STEPS

Step 1 show auto qos

Example:

```
Device# show auto qos

GigabitEthernet2/0/3
auto qos voip cisco-phone

GigabitEthernet2/0/27
auto qos voip cisco-softphone
```

In privileged EXEC mode, record all current auto QoS configurations by entering this command.

Step 2 no auto qos

Example:

```
Device(config-if)#no auto qos
```

In interface configuration mode, run the appropriate **no auto qos** command on each interface that has an auto QoS configuration.

Step 3 show running-config | i autoQoS

Example:

```
Device# show running-config | i autoQoS
```

Return to privileged EXEC mode, and record any remaining auto QoS maps class maps, policy maps, access lists, table maps, or other configurations by entering this command.

Step 4 no policy-map *policy-map_name*

Example:

```
Device) config# no policy-map pmap_101
Device) config# no class-map cmap_101
Device) config# no ip access-list extended AutoQoS-101
Device) config# no table-map 101
Device) config# no table-map policed-dscp
```

In global configuration mode, remove the QoS class maps, policy maps, access-lists, table maps, and any other auto QoS configurations by entering these commands:

- **no policy-map *policy-map-name***
- **no class-map *class-map-name***

- **no ip access-list extended** *Auto-QoS-x*
- **no table-map** *table-map-name*
- **no table-map policed-dscp**

Step 5 `show running-config | i AutoQoS`**Example:**

```
Device# show running-config | i AutoQoS
```

Return to privileged EXEC mode, run this command again to ensure that no auto-QoS configuration or remaining parts of the auto-QoS configuration exists

Step 6 `show auto qos`**Example:**

```
Device# show auto qos
```

Run this command to ensure that no auto-QoS configuration or remaining parts of the configuration exists.

Step 7 `write memory`**Example:**

```
Device# write memory
```

Write the changes to the auto QoS configuration to NV memory by entering the **write memory** command.

What to do next

Reboot the switch with the new or upgraded software image.

After rebooting with the new or upgraded software image, re-configure auto-QoS for the appropriate switch interfaces as determined by running the **show auto qos** command described in step 1.

Note There is only one table-map for exceed and another table-map for violate markdown per switch or stack. If the switch already has a table-map under the exceed action, then the auto-qos policy cannot be applied.

[Restrictions for Auto-QoS](#), on page 979

Enabling Auto-Qos Compact

To enable auto-Qos compact, enter this command:

SUMMARY STEPS

1. **configure terminal**
2. **auto qos global compact**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 2	auto qos global compact Example: Device(config)# <code>auto qos global compact</code>	<p>Enables auto-Qos compact and generates (hidden) the global configurations for auto-QoS.</p> <p>You can then enter the auto-QoS command you want to configure in the interface configuration mode and the interface commands that the system generates are also hidden.</p> <p>To display the auto-QoS configuration that has been applied, use these the privileged EXEC commands:</p> <ul style="list-style-type: none"> • show derived-config • show policy-map • show access-list • show class-map • show table-map • show auto-qos • show policy-map interface • show ip access-lists <p>These commands will have keyword "AutoQos-".</p>

What to do next

To disable auto-QoS compact, remove auto-Qos instances from all interfaces by entering the **no** form of the corresponding auto-QoS commands and then enter the **no auto qos global compact** global configuration command.

Monitoring Auto-QoS

Table 78: Commands for Monitoring Auto-QoS

Command	Description
<code>show auto qos [interface [interface-id]]</code>	Displays the initial auto-QoS configuration. You can compare the show auto qos and the show running-config command output to identify the user-defined QoS settings.
<code>show running-config</code>	Displays information about the QoS configuration that might be affected by auto-QoS. You can compare the show auto qos and the show running-config command output to identify the user-defined QoS settings.
<code>show derived-config</code>	Displays the hidden mls qos command which get configured along with the running configs because of auto-qos template.

Troubleshooting Auto-QoS

To troubleshoot auto-QoS, use the **debug auto qos** privileged EXEC command. For more information, see the **debug auto qos** command in the command reference for this release.

To disable auto-QoS on a port, use the **no** form of the **auto qos** command interface configuration command, such as **no auto qos voip**. Only the auto-QoS-generated interface configuration commands for this port are removed. If this is the last port on which auto-QoS is enabled and you enter the **no auto qos voip** command, auto-QoS is considered disabled even though the auto-QoS-generated global configuration commands remain (to avoid disrupting traffic on other ports affected by the global configuration).

Configuration Examples for Auto-QoS

Example: auto qos trust cos

The following is an example of the **auto qos trust cos** command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-Trust-Cos-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- class-default (match-any)

- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Radio Resource Management

The device should be configured as a mobility controller and not a mobility anchor to configure Radio Resource Management. It may require dynamic channel assignment functionality for the home APs to be supported.

The new mobility architecture that involves mobility controller and mobility agent must be configured on the switch or controllers for RRM to work.

Note Refer Mobility Configuration Guide for configuring mobility controller and mobility agent.

Restrictions for Radio Resource Management

The number of APs in a RF-group is limited to 2000.

The number of APs in a RF-group is limited to 500.

If an AP tries to join the RF-group that already holds the maximum number of APs it can support, the device rejects the application and throws an error.

To enable Airtime Fairness mode for APs, you should disable enforce-policy mode and reapply it again. This will change the airtime fairness configuration for all the APs. You can also use the **ap name <ap-name> dot11 24ghz airtime-fairness mode enforce-policy** command to change airtime fairness mode for individual APs.

Information About Radio Resource Management

The Radio Resource Management (RRM) software embedded in the device acts as a built-in RF engineer to consistently provide real-time RF management of your wireless network. RRM enables devices to continually monitor their associated lightweight access points for the following information:

- Traffic load—The total bandwidth used for transmitting and receiving traffic. It enables wireless LAN managers to track and plan network growth ahead of client demand.
- Interference—The amount of traffic coming from other 802.11 sources.
- Noise—The amount of non-802.11 traffic that is interfering with the currently assigned channel.
- Coverage—The Received Signal Strength (RSSI) and signal-to-noise ratio (SNR) for all connected clients.
- Other —The number of nearby access points.

RRM performs these functions:

- Radio resource monitoring
- Transmit power control
- Dynamic channel assignment
- Coverage hole detection and correction
- RF grouping

Note

RRM grouping will not happen, since AP operates in a static channel which is not in the DCA channel list. NDP is sent only on DCA channels and when radio operates on a non-DCA channel it will not receive NDA on-channel.

Radio Resource Monitoring

RRM automatically detects and configures new devices and lightweight access points as they are added to the network. It then automatically adjusts associated and nearby lightweight access points to optimize coverage and capacity.

Lightweight access points can scan all valid 2.4 GHz and 5 GHz channels for the country of operation as well as for channels available in other locations. The access points in local mode go “off-channel” for a period not greater than 60 ms to monitor these channels for noise and interference. Packets collected during this time are analyzed to detect rogue access points, rogue clients, ad-hoc clients, and interfering access points.

Note In the presence of voice traffic or other critical traffic (in the last 100 ms), the access points can defer off-channel measurements. It also defers based on WLAN scan defer priority configurations.

Each access point spends only 0.2 percent of its time off-channel. This activity is distributed across all access points so that adjacent access points are not scanning at the same time, which could adversely affect wireless LAN performance.

RRM supports new mobility architecture for RF grouping that involves Mobility Controller (MC) and Mobility Agent (MA).

- Mobility Controller (MC)—The Cisco WLC 5700 Series Controllers, Cisco Catalyst 3850 Switch, or Cisco Unified Wireless Networking Solution controller can act as MC. The MC has MC functionality and MA functionality that is running internally into it.
- Mobility Agent (MA)—The Mobility Agent is the component that maintains client mobility state machine for a mobile client.

Information About RF Groups

An RF group is a logical collection of Cisco WLCs that coordinate to perform RRM in a globally optimized manner to perform network calculations on a per-radio basis. An RF group exists for each 802.11 network type. Clustering Cisco WLCs into a single RF group enable the RRM algorithms to scale beyond the capabilities of a single Cisco WLC.

RF group is created based on following parameters:

- User-configured RF network name.
- Neighbor discovery performed at the radio level.
- Country list configured on MC.

RF grouping runs between MCs.

Lightweight access points periodically send out neighbor messages over the air. Access points using the same RF group name validate messages from each other.

When access points on different Cisco WLCs hear validated neighbor messages at a signal strength of –80 dBm or stronger, the Cisco WLCs dynamically form an RF neighborhood in auto mode. In static mode, the leader is manually selected and the members are added to the RF Group. To know more about RF Group modes, [RF Group Leader](#).

Note RF groups and mobility groups are similar in that they both define clusters of Cisco WLCs, but they are different in terms of their use. An RF group facilitates scalable, system-wide dynamic RF management while a mobility group facilitates scalable, system-wide mobility and Cisco WLC redundancy.

RF Group Leader

Starting in the 7.0.116.0 release, the RF Group Leader can be configured in two ways as follows:

- **Auto Mode**—In this mode, the members of an RF group elect an RF group leader to maintain a “master” power and channel scheme for the group. The RF grouping algorithm dynamically chooses the RF group leader and ensures that an RF group leader is always present. Group leader assignments can and do change (for instance, if the current RF group leader becomes inoperable or if RF group members experience major changes).
- **Static Mode**—In this mode, the user selects a Cisco WLC as an RF group leader manually. In this mode, the leader and the members are manually configured and are therefore fixed. If the members are unable to join the RF group, the reason is indicated. The leader tries to establish a connection with a member every 1 minute if the member has not joined in the previous attempt.

The RF group leader analyzes real-time radio data collected by the system, calculates the power and channel assignments, and sends them to each of the Cisco WLCs in the RF group. The RRM algorithms ensure system-wide stability and restrain channel and power scheme changes to the appropriate local RF neighborhoods.

In Cisco WLC software releases prior to 6.0, the dynamic channel assignment (DCA) search algorithm attempts to find a good channel plan for the radios associated to Cisco WLCs in the RF group, but it does not adopt a new channel plan unless it is considerably better than the current plan. The channel metric of the worst radio in both plans determines which plan is adopted. Using the worst-performing radio as the single criterion for adopting a new channel plan can result in pinning or cascading problems.

Pinning occurs when the algorithm could find a better channel plan for some of the radios in an RF group but is prevented from pursuing such a channel plan change because the worst radio in the network does not have any better channel options. The worst radio in the RF group could potentially prevent other radios in the group from seeking better channel plans. The larger the network, the more likely pinning becomes.

Cascading occurs when one radio’s channel change results in successive channel changes to optimize the remaining radios in the RF neighborhood. Optimizing these radios could lead to their neighbors and their neighbors’ neighbors having a suboptimal channel plan and triggering their channel optimization. This effect could propagate across multiple floors or even multiple buildings, if all the access point radios belong to the same RF group. This change results in considerable client confusion and network instability.

The main cause of both pinning and cascading is the way in which the search for a new channel plan is performed and that any potential channel plan changes are controlled by the RF circumstances of a single radio. In Cisco WLC software release 6.0, the DCA algorithm has been redesigned to prevent both pinning and cascading. The following changes have been implemented:

- **Multiple local searches**—The DCA search algorithm performs multiple local searches initiated by different radios within the same DCA run rather than performing a single global search driven by a single radio. This change addresses both pinning and cascading while maintaining the desired flexibility and adaptability of DCA and without jeopardizing stability.

- Multiple channel plan change initiators (CPCIs)—Previously, the single worst radio was the sole initiator of a channel plan change. Now each radio within the RF group is evaluated and prioritized as a potential initiator. Intelligent randomization of the resulting list ensures that every radio is eventually evaluated, which eliminates the potential for pinning.
- Limiting the propagation of channel plan changes (Localization)—For each CPCI radio, the DCA algorithm performs a local search for a better channel plan, but only the CPCI radio itself and its one-hop neighboring access points are actually allowed to change their current transmit channels. The impact of an access point triggering a channel plan change is felt only to within two RF hops from that access point, and the actual channel plan changes are confined to within a one-hop RF neighborhood. Because this limitation applies across all CPCI radios, cascading cannot occur.
- Non-RSSI-based cumulative cost metric—A cumulative cost metric measures how well an entire region, neighborhood, or network performs with respect to a given channel plan. The individual cost metrics of all access points in that area are considered in order to provide an overall understanding of the channel plan's quality. These metrics ensure that the improvement or deterioration of each single radio is factored into any channel plan change. The objective is to prevent channel plan changes in which a single radio improves but at the expense of multiple other radios experiencing a considerable performance decline.

The RRM algorithms run at a specified updated interval, which is 600 seconds by default. Between update intervals, the RF group leader sends keepalive messages to each of the RF group members and collects real-time RF data.

Note Several monitoring intervals are also available. See the Configuring RRM section for details.

RF Group Name

A Cisco WLC is configured with an RF group name, which is sent to all access points joined to the Cisco WLC and used by the access points as the shared secret for generating the hashed MIC in the neighbor messages. To create an RF group, you configure all of the Cisco WLCs to be included in the group with the same RF group name.

If there is any possibility that an access point joined to a Cisco WLC may hear RF transmissions from an access point on a different Cisco WLC, you should configure the Cisco WLCs with the same RF group name. If RF transmissions between access points can be heard, then system-wide RRM is recommended to avoid 802.11 interference and contention as much as possible.

Mobility Controller

An MC can either be a group leader or a group member. One of the MCs can act as a RF group leader based on RF grouping and RF group election with other MCs. The order of priority to elect the RF leader is based on the maximum number of APs the controller or switch can support. The highest priority being 1 and the least being 5.

1. WiSM 2 Controllers
2. Cisco WLC 5700 Series Controllers
3. WiSM 1 Controllers
4. Catalyst 3850 Series Switches
5. Catalyst 3650 Series Switches

When one of the MCs becomes the RRM group leader, the remaining MCs become RRM group members. RRM group members send their RF information to the Group Leader. The group leader determines a channel and Tx power plan for the network and passes the information back to the RF group members. The MCs push the power plan to MA for the radios that belong to MA. These channel and power plans are ultimately pushed down to individual radios.

Note MC has MA functionality within it.

Mobility Agent

The MA communicates with the MC. The MC includes MAC or IP address of the switch/controller while communicating with the MA.

The MA provides the following information when polled by the MC:

- Interference or noise data.
- Neighbor data.
- Radio capabilities (supported channels, power levels).
- Radio configuration (power, channel, channel width).
- Radar data.

The MC exchanges the following information with the switch/controller (MA). The message includes:

- Configurations (channel/power/channel width) for individual radios.
- Polling requests for current configurations and RF measurements for individual radios
- Group Leader Update

In turn, the MA communicates the following messages with the MC:

- RF measurements from radios (e.g. load, noise and neighbor information)
- RF capabilities and configurations of individual radios

The MA sets channel, power, and channel width on the radios when directed by the MC. The DFS, coverage hole detection/mitigation, static channel/power configurations are performed by the MA.

Information About Rogue Access Point Detection in RF Groups

After you have created an RF group of Cisco WLCs, you need to configure the access points connected to the Cisco WLCs to detect rogue access points. The access points will then select the beacon/probe-response frames in neighboring access point messages to see if they contain an authentication information element (IE) that matches that of the RF group. If the select is successful, the frames are authenticated. Otherwise, the authorized access point reports the neighboring access point as a rogue, records its BSSID in a rogue table, and sends the table to the Cisco WLC.

The AP has a RRM CAPWAP subsystem that exchanges messages with the mobility agent.

RRM components on the AP perform the following functions:

- AP measurements such as interference (Wi-Fi), noise, coverage, and load, and client measurements.
- Radio neighbor discovery.
- Radar detection.
- Set various RF parameters (channel, channel width, transmit power control, etc)

Transmit Power Control

The device dynamically controls access point transmit power based on real-time wireless LAN conditions.

The Transmit Power Control (TPC) algorithm both increases and decreases an access point's power in response to changes in the RF environment. In most instances, TPC seeks to lower an access point's power to reduce interference, but in the case of a sudden change in the RF coverage—for example, if an access point fails or becomes disabled—TPC can also increase power on surrounding access points. This feature is different from coverage hole detection, which is primarily concerned with clients. TPC provides enough RF power to achieve desired coverage levels while avoiding channel interference between access points.

Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings

The TPC algorithm balances RF power in many diverse RF environments. However, it is possible that automatic power control will not be able to resolve some scenarios in which an adequate RF design was not possible to implement due to architectural restrictions or site restrictions—for example, when all access points must be mounted in a central hallway, placing the access points close together, but requiring coverage out to the edge of the building.

In these scenarios, you can configure maximum and minimum transmit power limits to override TPC recommendations. The maximum and minimum TPC power settings apply to all access points through RF profiles in a RF network.

To set the Maximum Power Level Assignment and Minimum Power Level Assignment, enter the maximum and minimum transmit power used by RRM in the text boxes in the Tx Power Control page. The range for these parameters is -10 to 30 dBm. The minimum value cannot be greater than the maximum value; the maximum value cannot be less than the minimum value.

If you configure a maximum transmit power, RRM does not allow any access point attached to the device to exceed this transmit power level (whether the power is set by RRM TPC or by coverage hole detection). For example, if you configure a maximum transmit power of 11 dBm, then no access point would transmit above 11 dBm, unless the access point is configured manually.

Dynamic Channel Assignment

Two adjacent access points on the same channel can cause either signal contention or signal collision. In a collision, data is not received by the access point. This functionality can become a problem, for example, when someone reading e-mail in a café affects the performance of the access point in a neighboring business. Even though these are completely separate networks, someone sending traffic to the café on channel 1 can disrupt communication in an enterprise using the same channel. Devices can dynamically allocate access point channel assignments to avoid conflict and to increase capacity and performance. Channels are “reused” to

avoid wasting scarce RF resources. In other words, channel 1 is allocated to a different access point far from the café, which is more effective than not using channel 1 altogether.

The device's Dynamic Channel Assignment (DCA) capabilities are also useful in minimizing adjacent channel interference between access points. For example, two overlapping channels in the 802.11b/g band, such as 1 and 2, cannot both simultaneously use 11/54 Mbps. By effectively reassigning channels, the device keeps adjacent channels separated.

Note We recommend that you use only non-overlapping channels (1, 6, 11, and so on).

The device examines a variety of real-time RF characteristics to efficiently handle channel assignments as follows:

- Access point received energy—The received signal strength measured between each access point and its nearby neighboring access points. Channels are optimized for the highest network capacity.
- Noise—Noise can limit signal quality at the client and access point. An increase in noise reduces the effective cell size and degrades user experience. By optimizing channels to avoid noise sources, the device can optimize coverage while maintaining system capacity. If a channel is unusable due to excessive noise, that channel can be avoided.
- 802.11 Interference—Interference is any 802.11 traffic that is not part of your wireless LAN, including rogue access points and neighboring wireless networks. Lightweight access points constantly scan all channels looking for sources of interference. If the amount of 802.11 interference exceeds a predefined configurable threshold (the default is 10 percent), the access point sends an alert to the device. Using the RRM algorithms, the device may then dynamically rearrange channel assignments to increase system performance in the presence of the interference. Such an adjustment could result in adjacent lightweight access points being on the same channel, but this setup is preferable to having the access points remain on a channel that is unusable due to an interfering foreign access point.

In addition, if other wireless networks are present, the device shifts the usage of channels to complement the other networks. For example, if one network is on channel 6, an adjacent wireless LAN is assigned to channel 1 or 11. This arrangement increases the capacity of the network by limiting the sharing of frequencies. If a channel has virtually no capacity remaining, the device may choose to avoid this channel. In very dense deployments in which all nonoverlapping channels are occupied, the device does its best, but you must consider RF density when setting expectations.

- Load and utilization—When utilization monitoring is enabled, capacity calculations can consider that some access points are deployed in ways that carry more traffic than other access points (for example, a lobby versus an engineering area). The device can then assign channels to improve the access point with the worst performance reported. The load is taken into account when changing the channel structure to minimize the impact on clients currently in the wireless LAN. This metric keeps track of every access point's transmitted and received packet counts to determine how busy the access points are. New clients avoid an overloaded access point and associate to a new access point. This parameter is disabled by default.

The device combines this RF characteristic information with RRM algorithms to make system-wide decisions. Conflicting demands are resolved using soft-decision metrics that guarantee the best choice for minimizing network interference. The end result is optimal channel configuration in a three-dimensional space, where access points on the floor above and below play a major factor in an overall wireless LAN configuration.

Note Radios using 40-MHz channels in the 2.4-GHz band or 80MHz channels are not supported by DCA.

The RRM startup mode is invoked in the following conditions:

- In a single-device environment, the RRM startup mode is invoked after the device is upgraded and rebooted.
- In a multiple-device environment, the RRM startup mode is invoked after an RF Group leader is elected.

You can trigger RRM startup mode from CLI.

RRM startup mode runs for 100 minutes (10 iterations at 10-minute intervals). The duration of the RRM startup mode is independent of the DCA interval, sensitivity, and network size. The startup mode consists of 10 DCA runs with high sensitivity (making channel changes easy and sensitive to the environment) to converge to a steady state channel plan. After the startup mode is finished, DCA continues to run at the specified interval and sensitivity.

Note DCA algorithm interval is set to one hour, but DCA algorithm always runs in default interval of 10min, channel allocation happens for every 10min interval for the first 10 cycles, and channel changes as per DCA algorithm for every 10min. After that it goes back to the configured time interval. This is common for both DCA interval and Anchor time since it follows the steady state.

Note If DCA/TPC is turned off on the RF-group member, and auto is set on RF-group leader, the channel/TX power on member gets changed as per the algorithm run on the RF-group leader.

Coverage Hole Detection and Correction

The RRM coverage hole detection algorithm can detect areas of radio coverage in a wireless LAN that are below the level needed for robust radio performance. This feature can alert you to the need for an additional (or relocated) lightweight access point.

If clients on a lightweight access point are detected at threshold levels (RSSI, failed client count, percentage of failed packets, and number of failed packets) lower than those specified in the RRM configuration, the access point sends a “coverage hole” alert to the device. The alert indicates the existence of an area where clients are continually experiencing poor signal coverage, without having a viable access point to which to roam. The device discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the device mitigates the coverage hole by increasing the transmit power level for that specific access point. The device does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level because increasing their downstream transmit power might increase interference in the network.

How to Configure RRM

Configuring Advanced RRM CCX Parameters (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm ccx location-measurement interval`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>configure terminal</code> Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ap dot11 24ghz 5ghz rrm ccx location-measurement <i>interval</i></code> Example: Device(config)# <code>ap dot11 24ghz rrm ccx location-measurement 15</code>	Configures the interval for 802.11 CCX client location measurements. The range is from 10 to 32400 seconds.
Step 3	<code>end</code> Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Neighbor Discovery Type (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm ndp-type {protected | transparent}`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>configure terminal</code> Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	<p>ap dot11 24ghz 5ghz rrm ndp-type {protected transparent}</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm ndp-type protected</pre> <pre>Device(config)#ap dot11 24ghz rrm ndp-type transparent</pre>	<p>Configures the neighbor discovery type. By default, the mode is set to “transparent”.</p> <ul style="list-style-type: none"> • protected—Sets the neighbor discover type to protected. Packets are encrypted. • transparent—Sets the neighbor discover type to transparent. Packets are sent as is.
Step 3	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</p>

Configuring RRM Profile Thresholds, Monitoring Channels, and Monitoring Intervals (GUI)

Step 1 Choose **Configuration > Wireless > 802.11a/n/ac > RRM > General** or **Configuration > Wireless > 802.11b/g/n > RRM > General** to open RRM General page.

Step 2 Configure profile thresholds used for alarming as follows:

Note The profile thresholds have no bearing on the functionality of the RRM algorithms. Devices send an SNMP trap (or an alert) to the Cisco Prime Infrastructure or another trap receiver when individual APs values set for these threshold parameters are exceeded.

- In the **Interference** text box, enter the percentage of interference (802.11 traffic from sources outside of your wireless network) on a single access point. The valid range is 0 to 100%, and the default value is 10%.
- In the **Clients** text box, enter the number of clients on a single access point. The valid range is 1 to 75, and the default value is 12.
- In the **Noise** text box, enter the level of noise (non-802.11 traffic) on a single access point. The valid range is –127 to 0 dBm, and the default value is –70 dBm.
- In the **Utilization** text box, enter the percentage of RF bandwidth being used by a single access point. The valid range is 0 to 100%, and the default value is 80%.
- In the **Throughput** text box, enter the level of Throughput being used by a single access point. The valid range is 1000 to 10000000, and the default value is 1000000.

Step 3 From the **Channel List** drop-down list, choose one of the following options to specify the set of channels that the access point uses for RRM scanning:

- **All Channels**—RRM channel scanning occurs on all channels supported by the selected radio, which includes channels not allowed in the country of operation.
- **Country Channels**—RRM channel scanning occurs only on the data channels in the country of operation. This is the default value.
- **DCA Channels**—RRM channel scanning occurs only on the channel set used by the DCA algorithm, which by default includes all of the non-overlapping channels allowed in the country of operation. However, you can specify the channel set to be used by DCA if desired. To do so, follow instructions in the [Dynamic Channel Assignment](#).

Step 4 Configure monitor intervals as follows:

- a. In the **Channel Scan Interval** text box, enter (in seconds) the sum of the time between scans for each channel within a radio band. The entire scanning process takes 50 ms per channel, per radio and runs at the interval configured here. The time spent listening on each channel is determined by the non-configurable 50-ms scan time and the number of channels to be scanned. For example, in the U.S. all 11 802.11b/g channels are scanned for 50 ms each within the default 180-second interval. So every 16 seconds, 50 ms is spent listening on each scanned channel ($180/11 = \sim 16$ seconds). The Channel Scan Interval parameter determines the interval at which the scanning occurs. The valid range is 60 to 3600 seconds, and the default value for 802.11a/n/ac and 802.11b/g/n radios is 180 seconds.
- b. In the **Neighbor Packet Frequency** text box, enter (in seconds) how frequently neighbor packets (messages) are sent, which eventually builds the neighbor list. The valid range is 60 to 3600 seconds, and the default value is 60 seconds.

Note If the access point radio does not receive a neighbor packet from an existing neighbor within 60 minutes, the Cisco WLC deletes that neighbor from the neighbor list.

Step 5 Click **Apply**.

Step 6 Click **Save Configuration**.

Note Click **Set to Factory Default** if you want to return all of the Cisco WLC's RRM parameters to their factory-default values.

Configuring RF Groups

This section describes how to configure RF groups through either the GUI or the CLI.

Note The RF group name is generally set at deployment time through the Startup Wizard. However, you can change it as necessary.

Note When the multiple-country feature is being used, all Cisco WLCs intended to join the same RF group must be configured with the same set of countries, configured in the same order.

Note You can also configure RF groups using the Cisco Prime Infrastructure.

Configuring the RF Group Mode (GUI)

Step 1 Choose **Configuration > Wireless > 802.11a/n/ac > RRM > RF Grouping** or **Configuration > Wireless > 802.11b/g/n > RRM > RF Grouping** to open the RF Grouping page.

Step 2 From the **Group Mode** drop-down list, choose the mode that you want to configure for this Cisco WLC.

You can configure RF grouping in the following modes:

- **auto**—Sets the RF group selection to automatic update mode.
 - Note** A configured static leader cannot become a member of another RF group until its mode is set to “auto”.
- **leader**—Sets the RF group selection to static mode, and sets this Cisco WLC as the group leader.
- **off**—Sets the RF group selection off. Every Cisco WLC optimizes its own access point parameters.
 - Note** A Cisco WLC with a lower priority cannot assume the role of a group leader if a Cisco WLC with a higher priority is available. Here, priority is related to the processing power of the Cisco WLC.
 - Note** We recommend that Cisco WLCs participate in automatic RF grouping. You can override RRM settings without disabling automatic RF group participation.

Step 3 Click **Apply** to save the configuration and click **Restart** to restart the RRM RF Grouping algorithm.

Step 4 If you configured RF Grouping mode for this Cisco WLC as a static leader, you can add group members from the Group Members section as follows:

- a. In the device Name text box, enter the Cisco WLC that you want to add as a member to this group.
- b. In the IP Address text box, enter the IP address of the Cisco WLC.
- c. Click **Add** to add the member to this group.

Note If the member has not joined the static leader, the reason of the failure is shown in parentheses.

Step 5 Click **Apply**.

Step 6 Click **Save Configuration**.

Configuring RF Group Selection Mode (CLI)

SUMMARY STEPS

1. **configure terminal**
2. **ap dot11 24ghz | 5ghz rrm group-mode {auto | leader | off}**
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 24ghz 5ghz rrm group-mode {auto leader off} Example:	Configures RF group selection mode for 802.11 bands. • auto —Sets the 802.11 RF group selection to automatic update mode.

	Command or Action	Purpose
	Device (config) # <code>ap dot11 24ghz rrm group-mode leader</code>	<ul style="list-style-type: none"> • leader—Sets the 802.11 RF group selection to leader mode. • off—Disables the 802.11 RF group selection.
Step 3	end Example: Device (config) # <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring an RF Group Name (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `wireless rf-network name`
3. `end`
4. `show network profile profile_number`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless rf-network name Example: Device (config) # <code>wireless rf-network test1</code>	Creates an RF group. The group name should be ASCII String up to 19 characters and is case sensitive. Note Repeat this procedure for each controller that you want to include in the RF group.
Step 3	end Example: Device (config) # <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 4	show network profile profile_number	Displays the RF group. Note You can view the network profile number from 1 to 4294967295.

Configuring an RF Group Name (GUI)

- Step 1** Choose **Configuration > Controller > General** to open the General page.
- Step 2** Enter a name for the RF group in the RF Group Name text box. The name can contain up to 19 ASCII characters and is case sensitive.

- Step 3** Click **Apply** to commit your changes.
- Step 4** Click **Save Configuration** to save your changes.
- Step 5** Repeat this procedure for each controller that you want to include in the RF group.

Configuring Members in a 802.11 Static RF Group (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm group-member group_name ip_addr`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 24ghz 5ghz rrm group-member group_name ip_addr Example: Device(config)# <code>ap dot11 24ghz rrm group-member Grpmem01 10.1.1.1</code>	Configures members in a 802.11 static RF group. The group mode should be set as leader for the group member to be active.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Transmit Power Control

Configuring the Tx-Power Control Threshold (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm tpc-threshold threshold_value`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 24ghz 5ghz rrm tpc-threshold <i>threshold_value</i> Example: Device(config)# <code>ap dot11 24ghz rrm tpc-threshold -60</code>	Configures the Tx-power control threshold used by RRM for auto power assignment. The range is from –80 to –50.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring the Tx-Power Level (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm txpower{trans_power_level | auto | max | min | once}`
3. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 24ghz 5ghz rrm txpower{<i>trans_power_level</i> auto max min once} Example: Device(config)# <code>ap dot11 24ghz rrm txpower auto</code>	Configures the 802.11 tx-power level <ul style="list-style-type: none"> • trans_power_level—Sets the transmit power level. • auto—Enables auto-RF. • max—Configures the maximum auto-RF tx-power. • min—Configures the minimum auto-RF tx-power. • once—Enables one-time auto-RF.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Transmit Power Control (GUI)

- Step 1** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > TPC** or **Configuration > Wireless > 802.11b > RRM > TPC** to open RRM Tx Power Control (TPC) page.
- Step 2** Choose the Transmit Power Control.
- Coverage Optimal Mode (TPCv1)— Offers strong signal coverage and stability. In this mode, power can be kept low to gain extra capacity and reduce interference.
- Step 3** Choose one of the following options from the Power Level Assignment Method list to specify the Cisco WLC's dynamic power assignment mode:
- **Automatic**—Causes the Cisco WLC to periodically evaluate and, if necessary, update the transmit power for all joined access points. This is the default value.
 - **On Demand**—Causes the Cisco WLC to periodically evaluate the transmit power for all joined access points. However, the Cisco WLC updates the power, if necessary, only when you click **Apply** after choosing **On Demand**.
- Note** The Cisco WLC does not evaluate and update the transmit power immediately when you click **Apply** after choosing **On Demand**. It waits for the next 600-second interval. This value is not configurable.
- **Fixed**—Prevents the Cisco WLC from evaluating and, if necessary, updating the transmit power for joined access points. The power level is set to the fixed value chosen from the drop-down list. The corresponding option for **Fixed** when you try to configure from CLI is **once**.
- Note** The transmit power level is assigned an integer value instead of a value in mW or dBm. The integer corresponds to a power level that varies depending on the regulatory domain, channel, and antennas in which the access points are deployed.
- Note** For optimal performance, we recommend that you use the Automatic setting.
- Step 4** Enter the maximum and minimum power level assignment values in the Maximum Power Level Assignment and Minimum Power Level Assignment text boxes.
- The range for the Maximum Power Level Assignment is –10 to 30 dBm.
- The range for the Minimum Power Level Assignment is –10 to 30 dBm.
- Step 5** In the Power Threshold text box, enter the cutoff signal level used by RRM when determining whether to reduce an access point's power. The default value for this parameter is –70 dBm for TPCv1, but can be changed when access points are transmitting at higher (or lower) than desired power levels.
- The range for this parameter is –80 to –50 dBm. Increasing this value (between –65 and –50 dBm) causes the access points to operate at a higher transmit power. Decreasing the value has the opposite effect.
- In applications with a dense population of access points, it may be useful to decrease the threshold to –80 or –75 dBm to reduce the number of BSSIDs (access points) and beacons seen by the wireless clients. Some wireless clients might have difficulty processing a large number of BSSIDs or a high beacon rate and might exhibit problematic behavior with the default threshold.
- This page also shows the following nonconfigurable transmit power level parameter settings:
- **Power Neighbor Count**—The minimum number of neighbors an access point must have for the transmit power control algorithm to run.

- Power Assignment Leader—The MAC address of the RF group leader, which is responsible for power level assignment.
- Last Power Level Assignment—The last time RRM evaluated the current transmit power level assignments.

Step 6 Click Apply.

Step 7 Click Save Configuration.

Configuring 802.11 RRM Parameters

Configuring Advanced 802.11 Channel Assignment Parameters (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 {24ghz | 5ghz} rrm channel cleanair-event sensitivity {high | low | medium}`
3. `ap dot11 {24ghz | 5ghz} rrm channel dca {channel number | anchor-time | global {auto | once} | interval | min-metric | sensitivity {high | low | medium}}`
4. `ap dot11 5ghz rrm channel dca chan-width {20 | 40 | 80}`
5. `ap dot11 {24ghz | 5ghz} rrm channel dca {{add | remove} channel number | anchor-time | global {auto | once} | interval | min-metric | sensitivity {high | low | medium}}`
6. `ap dot11 {24ghz | 5ghz} rrm channel device`
7. `ap dot11 {24ghz | 5ghz} rrm channel foreign`
8. `ap dot11 {24ghz | 5ghz} rrm channel load`
9. `ap dot11 {24ghz | 5ghz} rrm channel noise`
10. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>configure terminal</code> Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ap dot11 {24ghz 5ghz} rrm channel cleanair-event sensitivity {high low medium}</code> Example: Device(config)# <code>ap dot11 24ghz rrm channel cleanair-event sensitivity high</code>	Configures CleanAir event-driven RRM parameters. <ul style="list-style-type: none"> • High—Specifies the most sensitivity to non-Wi-Fi interference as indicated by the air quality (AQ) value. • Low—Specifies the least sensitivity to non-Wi-Fi interference as indicated by the AQ value. • Medium—Specifies medium sensitivity to non-Wi-Fi interference as indicated by the AQ value.

	Command or Action	Purpose
Step 3	<p>ap dot11 {24ghz 5ghz} rrm channel dca {channel number anchor-time global {auto once} interval min-metric sensitivity {high low medium}}</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm channel dca interval 2</pre>	<p>Configures Dynamic Channel Assignment (DCA) algorithm parameters for the 802.11 band.</p> <ul style="list-style-type: none"> • <I-14>—Enter a channel number to be added to the DCA list. • anchor-time—Configures the anchor time for the DCA. The range is between 0 and 23 hours. • global—Configures the DCA mode for all 802.11 Cisco APs. <ul style="list-style-type: none"> • auto—Enables auto-RF. • once—Enables auto-RF only once. • interval—Configures the DCA interval value. The values are 1, 2, 3, 4, 6, 8, 12 and 24 hours and the default value 0 denotes 10 minutes. • min-metric—Configures the DCA minimum RSSI energy metric. The range is between -100 and -60. • sensitivity—Configures the DCA sensitivity level to changes in the environment. <ul style="list-style-type: none"> • high—Specifies the most sensitivity. • low—Specifies the least sensitivity. • medium—Specifies medium sensitivity.
Step 4	<p>ap dot11 5ghz rrm channel dca chan-width {20 40 80}</p>	<p>Configures the DCA channel width for all 802.11 radios in the 5-GHz band. Sets the channel width to 20 MHz, 40 MHz, or 80 MHz, ; 20 MHz is the default value.</p>
Step 5	<p>ap dot11 {24ghz 5ghz} rrm channel dca {{add remove} channel number anchor-time global {auto once} interval min-metric sensitivity {high low medium}}</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm channel dca interval 2</pre>	<p>Configures dynamic channel assignment (DCA) algorithm parameters for the 802.11 band.</p> <ul style="list-style-type: none"> • <I-14>—Enter a channel number to be added to the DCA list. • anchor-time—Configures the anchor time for the DCA. The range is between 0 and 23 hours. • global—Configures the DCA mode for all 802.11 Cisco APs. <ul style="list-style-type: none"> • auto—Runs auto-RF. • once—Runs auto-RF only once. • interval— Configures the DCA interval value. The values are 1, 2, 3, 4, 6, 8, 12 and 24 hours and the default value 0 denotes 10 minutes.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • min-metric—Configures the DCA minimum RSSI energy metric. The range is between -100 and -60. • sensitivity—Configures the DCA sensitivity level to changes in the environment. <ul style="list-style-type: none"> • high—Specifies the most sensitivity. • low—Specifies the least sensitivity. • medium—Specifies medium sensitivity.
Step 6	ap dot11 {24ghz 5ghz} rrm channel device Example: <pre>Device(config)#ap dot11 24ghz rrm channel device</pre>	Configures the persistent non-Wi-Fi device avoidance in the 802.11 channel assignment.
Step 7	ap dot11 {24ghz 5ghz} rrm channel foreign Example: <pre>Device(config)#ap dot11 24ghz rrm channel foreign</pre>	Configures the foreign AP 802.11 interference avoidance in the channel assignment.
Step 8	ap dot11 {24ghz 5ghz} rrm channel load Example: <pre>Device(config)#ap dot11 24ghz rrm channel load</pre>	Configures the Cisco AP 802.11 load avoidance in the channel assignment.
Step 9	ap dot11 {24ghz 5ghz} rrm channel noise Example: <pre>Device(config)#ap dot11 24ghz rrm channel noise</pre>	Configures the 802.11 noise avoidance in the channel assignment.
Step 10	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Dynamic Channel Assignment (GUI)

You can specify the channels that the Dynamic Channel Assignment (DCA) algorithm considers when selecting the channels to be used for RRM scanning by using the Cisco WLC GUI.

Note This functionality is helpful when you know that the clients do not support certain channels because they are legacy devices or they have certain regulatory restrictions.

-
- Step 1** Disable the 802.11a/n/ac or 802.11b/g/n network as follows:
- Choose **Configuration > Wireless > 802.11a/n/ac > Network** or **Configuration > Wireless > 802.11b/g/n > Network** to open the Global Parameters page.
 - Unselect the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.
 - Click **Apply**.
- Step 2** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > DCA** or **Configuration > Wireless > 802.11b/g/n > RRM > DCA** to open the Dynamic Channel Assignment (DCA) page.
- Step 3** Choose one of the following options from the **Channel Assignment Method** drop-down list to specify the Cisco WLC's DCA mode:
- **Automatic**—Causes the Cisco WLC to periodically evaluate and, if necessary, update the channel assignment for all joined access points. This is the default value.
 - **Freeze**—Causes the Cisco WLC to evaluate and update the channel assignment for all joined access points, if necessary, only when you click **Apply** after selecting the **Freeze** option.
Note The Cisco WLC does not evaluate and update the channel assignment immediately when you click **Apply** after selecting the **Freeze** option. It waits for the next interval to elapse.
 - **OFF**—Turns off DCA and sets all access point radios to the first channel of the band. If you choose this option, you must manually assign channels on all radios.
Note For optimal performance, we recommend that you use the Automatic setting.
- Step 4** From the Interval drop-down list, choose one of the following options to specify how often the DCA algorithm is allowed to run: **10 minutes**, **1 hour**, **2 hours**, **3 hours**, **4 hours**, **6 hours**, **8 hours**, **12 hours**, or **24 hours**. The default value is 10 minutes.
- Step 5** From the AnchorTime drop-down list, choose a number to specify the time of day when the DCA algorithm is to start. The options are numbers between 0 and 23 (inclusive) representing the hour of the day from 12:00 a.m. to 11:00 p.m.
- Step 6** Check the **Avoid Foreign AP Interference** check box to cause the Cisco WLC's RRM algorithms to consider 802.11 traffic from foreign access points (those not included in your wireless network) when assigning channels to lightweight access points, or unselect it to disable this feature. For example, RRM may adjust the channel assignment to have access points avoid channels close to foreign access points. The default value is selected.
- Step 7** Select the **Avoid Cisco AP Load** check box to cause the Cisco WLC's RRM algorithms to consider 802.11 traffic from Cisco lightweight access points in your wireless network when assigning channels, or unselect it to disable this feature. For example, RRM can assign better reuse patterns to access points that carry a heavier traffic load. The default value is unselected.
- Step 8** Select the **Avoid Non-802.11a (802.11b) Noise** check box to cause the Cisco WLC's RRM algorithms to consider noise (non-802.11 traffic) in the channel when assigning channels to lightweight access points, or unselect it to disable this feature. For example, RRM may have access points avoid channels with significant interference from nonaccess point sources, such as microwave ovens. The default value is selected.
- Step 9** Select the **Avoid Persistent Non-WiFi Interference** check box to enable the Cisco WLC to ignore persistent non-Wi-Fi interference.
- Step 10** From the **DCA Channel Sensitivity** drop-down list, choose one of the following options to specify how sensitive the DCA algorithm is to environmental changes such as signal, load, noise, and interference when determining whether to change channels:
- **Low**—The DCA algorithm is not particularly sensitive to environmental changes.

- **Medium**—The DCA algorithm is moderately sensitive to environmental changes.
- **High**—The DCA algorithm is highly sensitive to environmental changes.

The default value is Medium. The DCA sensitivity thresholds vary by radio band, as noted in the following table:

Table 79: DCA Sensitivity Thresholds

Option	2.4-GHz DCA Sensitivity Threshold	5-GHz DCA Sensitivity Threshold
High	5 dB	5 dB
Medium	10 dB	15 dB
Low	20 dB	20 dB

Step 11

For 802.11a/n/ac networks only, choose one of the following channel width options to specify the channel bandwidth supported for all 802.11n radios in the 5-GHz band:

- **20 MHz**—The 20-MHz channel bandwidth (default)
- **40 MHz**—The 40-MHz channel bandwidth

Note If you choose 40 MHz, be sure to choose at least two adjacent channels from the DCA Channel List in *Step 13* (for example, a primary channel of 36 and an extension channel of 40). If you choose only one channel, that channel is not used for 40-MHz channel width.

Note If you choose 40 MHz, you can also configure the primary and extension channels used by individual access points.

Note To override the globally configured DCA channel width setting, you can statically configure an access point's radio for 20- or 40-MHz mode in the 802.11a/n Cisco APs > Configure page. If you then change the static RF channel assignment method to WLC Controlled on the access point radio, the global DCA configuration overrides the channel width configuration that the access point was previously using. It can take up to 30 minutes (depending on how often DCA is configured to run) for the change to take effect.

Note If you choose 40 MHz on the A radio, you cannot pair channels 116, 140, and 165 with any other channels.

This page also shows the following nonconfigurable channel parameter settings:

- **Channel Assignment Leader**—The MAC address of the RF group leader, which is responsible for channel assignment.
- **Last Auto Channel Assignment**—The last time RRM evaluated the current channel assignments. This is used only for RF leader and not for the RF member.

Step 12

In the DCA Channel List area, the DCA Channels text box shows the channels that are currently selected. To choose a channel, select its check box in the Select column. To exclude a channel, unselect its check box.

The ranges are as follows:

- 802.11a—36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 132, 136, 140, 149, 153, 157, 161, 165 (depending on countries).

- 802.11b/g—1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 (depending on countries).

The defaults are as follows:

- 802.11a—36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 132, 136, 140, 149, 153, 157, 161
- 802.11b/g—1, 6, 11

Step 13 Click **Apply**.

Step 14 Reenable the 802.11 networks as follows:

- Choose **Configuration > Wireless > 802.11a/n/ac > Network** or **Configuration > Wireless > 802.11b/g/n > Network** to open the Global Parameters page.
- Select the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.
- Click **Apply**.

Step 15 Click **Save Configuration**.

Configuring 802.11 Coverage Hole Detection (CLI)

SUMMARY STEPS

1. **configure terminal**
2. **ap dot11 24ghz | 5ghz rrm coverage data {fail-percentage | packet-count | rssi-threshold}**
3. **ap dot11 24ghz | 5ghz rrm coverage exception global *exception level***
4. **ap dot11 24ghz | 5ghz rrm coverage level global *cli_min exception level***
5. **ap dot11 24ghz | 5ghz rrm coverage voice {fail-percentage | packet-count | rssi-threshold}**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 24ghz 5ghz rrm coverage data {fail-percentage packet-count rssi-threshold} Example: Device(config)# ap dot11 24ghz rrm coverage data fail-percentage 60	Configures the 802.11 coverage hole detection for data packets. <ul style="list-style-type: none"> • fail-percentage—Configures the 802.11 coverage failure-rate threshold for uplink data packets as a percentage that ranges from 1 to 100%. • packet-count—Configures the 802.11 coverage minimum failure count threshold for uplink data packets that ranges from 1 to 255.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • rsi-threshold—Configures the 802.11 minimum receive coverage level for data packets that range from –90 to –60 dBm.
Step 3	ap dot11 24ghz 5ghz rrm coverage exception global exception level Example: <pre>Device(config)#ap dot11 24ghz rrm coverage exception global 50</pre>	Configures the 802.11 Cisco AP coverage exception level as a percentage that ranges from 0 to 100%.
Step 4	ap dot11 24ghz 5ghz rrm coverage level global cli_min exception level Example: <pre>Device(config)#ap dot11 24ghz rrm coverage level global 10</pre>	Configures the 802.11 Cisco AP client minimum exception level that ranges from 1 to 75 clients.
Step 5	ap dot11 24ghz 5ghz rrm coverage voice {fail-percentage packet-count rssi-threshold} Example: <pre>Device(config)#ap dot11 24ghz rrm coverage voice packet-count 10</pre>	Configures the 802.11 coverage hole detection for voice packets. <ul style="list-style-type: none"> • fail-percentage—Configures the 802.11 coverage failure-rate threshold for uplink voice packets as a percentage that ranges from 1 to 100%. • packet-count—Configures the 802.11 coverage minimum failure count threshold for uplink voice packets that ranges from 1 to 255. • rssi-threshold—Configures the 802.11 minimum receive coverage level for voice packets that range from –90 to –60 dBm.
Step 6	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Coverage Hole Detection (GUI)

- Step 1** Disable the 802.11 network as follows:
- Choose **Configuration > Wireless > 802.11a/n/ac** or **Configuration > Wireless > 802.11b/g/n** to open the 802.11a/n/ac (or 802.11b/g/n) Global Parameters page.
 - Unselect the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.
 - Click **Apply**.
- Step 2** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > Coverage Thresholds** or **Configuration > Wireless > 802.11b/g/n > RRM > Coverage Thresholds** to open coverage page.

- Step 3** Select the **Enable Coverage Hole Detection** check box to enable coverage hole detection, or unselect it to disable this feature. If you enable coverage hole detection, the Cisco WLC automatically determines, based on data received from the access points, if any access points have clients that are potentially located in areas with poor coverage. The default value is selected.
- Step 4** In the **Data RSSI** text box, enter the minimum Receive Signal Strength Indication (RSSI) value for data packets received by the access point. The value that you enter is used to identify coverage holes (or areas of poor coverage) within your network. If the access point receives a packet in the data queue with an RSSI value below the value that you enter here, a potential coverage hole has been detected. The valid range is –90 to –60 dBm, and the default value is –80 dBm. The access point takes data RSSI measurements every 5 seconds and reports them to the Cisco WLC in 90-second intervals.
